

16-BIT, HIGH-SPEED, 2.7-V TO 5-V, MICROPOWER SAMPLING ANALOG-TO-DIGITAL CONVERTER

Check for Samples: ADS8320-HT

FEATURES

- 100-kHz Sampling Rate
- Micropower:
 - 3.8 mW at 100 kHz and 2.7 V
 - 0.3 mW at 10 kHz and 2.7 V
- Power Down: 6 µA max
- 8-Pin Ceramic Package
- Pin Compatible to ADS7816 and ADS7822
- Serial (SPI™/SSI) Interface

APPLICATIONS

- **Down-Hole Drilling**
- **High Temperature Environments**
- Vibration/Modal Analysis
- **Multi-Channel Data Acquisition**
- **Acoustics/Dynamic Strain Gauges**
- **Pressure Sensors**

SUPPORTS EXTREME TEMPERATURE APPLICATIONS

DESCRIPTION

The ADS8320 is a 16-bit, sampling analog-to-digital (A/D) converter with ensured specifications over a 2.7-V to 5.25-V supply range. It requires very little power even when operating at the full 100-kHz data rate. At lower data rates, the high speed of the device enables it to spend most of its time in the power-down mode—the average power dissipation is less than 100 mW at 10-kHz data rate.

The ADS8320 also features operation from 2 V to 5.25 V, a synchronous serial (SPI/SSI compatible) interface, and a differential input. The reference voltage can be set to any level within the range of 500 mV to V_{CC}.

Ultra-low power and small size make the ADS8320 ideal for portable and battery-operated systems. It is also a perfect fit for remote data acquisition modules, simultaneous multi-channel systems, and isolated data acquisition. The ADS8320 is available in 8-pin ceramic surface-mount packages, specified for the -55°C to 210°C temperature range.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet. SPI is a trademark of Motorola, Inc.,

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

THEORY OF OPERATION

The ADS8320 is a classic successive approximation register (SAR) analog-to-digital (A/D) converter. The architecture is based on capacitive redistribution, which inherently includes a sample/hold function. The converter is fabricated on a 0.6µ CMOS process. The architecture and process allow the ADS8320 to acquire and convert an analog signal at up to 100,000 conversions per second while consuming less than 4.5 mW from+V_{CC}.

The ADS8320 requires an external reference, an external clock, and a single power source (V_{CC}). The external reference can be any voltage between 500 mV and V_{CC} . The value of the reference voltage directly sets the range of the analog input. The reference input current depends on the conversion rate of the ADS8320.

The external clock can vary between 24 kHz (1-kHz throughput) and 2.4 MHz (100-kHz throughput). The duty cycle of the clock is essentially unimportant, as long as the minimum high and low times are at least 200 ns ($V_{CC} = 2.7 \text{ V}$ or greater). The minimum clock frequency is set by the leakage on the capacitors internal to the ADS8320.

The analog input is provided to two input pins: +IN and -IN. When a conversion is initiated, the differential input on these pins is sampled on the internal capacitor array. While a conversion is in progress, both inputs are disconnected from any internal function.

The digital result of the conversion is clocked out by the DCLOCK input and is provided serially, most significant bit first, on the D_{OUT} pin. The digital data that is provided on the DOUT pin is for the conversion currently in progress—there is no pipeline delay. It is possible to continue to clock the ADS8320 after the conversion is complete and to obtain the serial data least significant bit first. See the digital timing section for more information.

ANALOG INPUT

The +IN and -IN input pins allow for a differential input signal. Unlike some converters of this type, the -IN input is not re-sampled later in the conversion cycle. When the converter goes into the hold mode, the voltage difference between +IN and -IN is captured on the internal capacitor array.

The range of the -IN input is limited to -0.1 V to 1 V (-0.1 V to 0.5 V when using a 2.7-V supply). Because of this, the differential input can be used to reject only small signals that are common to both inputs. Thus, the -IN input is best used to sense a remote signal ground that may move slightly with respect to the local ground potential.

The input current on the analog inputs depends on a number of factors: sample rate, input voltage, source impedance, and power-down mode. Essentially, the current into the ADS8320 charges the internal capacitor array during the sample period. After this capacitance has been fully charged, there is no further input current. The source of the analog input voltage must be able to charge the input capacitance (45 pF) to a 16-bit settling level within 4.5 clock cycles. When the converter goes into the hold mode or while it is in the powerdown mode, the input impedance is greater than 1 Ω .

Care must be taken regarding the absolute analog input voltage. To maintain the linearity of the converter, the -IN input should not drop below GND-100 mV or exceed GND+1 V. The +IN input should always remain within the range of GND-100 mV to $V_{CC}+100$ mV. Outside of these ranges, the converter linearity may not meet specifications. To minimize noise, low bandwidth input signals with lowpass filters should be used.

REFERENCE INPUT

The external reference sets the analog input range. The ADS8320 operates with a reference in the range of 500 mV to V_{CC} . There are several important implications of this.

As the reference voltage is reduced, the analog voltage weight of each digital output code is reduced. This is often referred to as the Least Significant Bit (LSB) size and is equal to the reference voltage divided by 65,536. This means that any offset or gain error inherent in the A/D converter will appear to increase, in terms of LSB size, as the reference voltage is reduced.

The noise inherent in the converter also appears to increase with lower LSB size. With a 5-V reference, the internal noise of the converter typically contributes only 1.5 LSB peak-to-peak of potential error to the output code. When the external reference is 500 mV, the potential error contribution from the internal noise will be 10 times larger—15 LSBs. The errors due to the internal noise are gaussian in nature and can be reduced by averaging consecutive conversion results.

Copyright © 2010–2012, Texas Instruments Incorporated

For more information regarding noise, consult the typical performance curve "Peak-to-Peak Noise vs Reference Voltage." Note that the Effective Number of Bits (ENOB) figure is calculated based on the converter's signal-to-(noise + distortion) ratio with a 1-kHz, 0-dB input signal. SINAD is related to ENOB as follows:

$$SINAD = 6.02 \bullet ENOB + 1.76 \tag{1}$$

With lower reference voltages, extra care should be taken to provide a clean layout including adequate bypassing, a clean power supply, a low-noise reference, and a low-noise input signal. Because the LSB size is lower, the converter is also more sensitive to external sources of error such as nearby digital signals and electromagnetic interference.

NOISE

The noise floor of the ADS8320 itself is extremely low, as can be seen in Figure 19 and Figure 20, and is much lower than competing A/D converters. It was tested by applying a lownoise DC input and a 5-V reference to the ADS8320 and initiating 5000 conversions. The digital output of the A/D converter varies in output code due to the internal noise of the ADS8320. This is true for all 16-bit SAR-type A/D converters. Using a histogram to plot the output codes, the distribution should appear bell-shaped with the peak of the bell curve representing the nominal code for the input value. The $\pm 1\sigma$, $\pm 2\sigma$ and $\pm 3\sigma$ distributions represents the 68.3%, 95.5%, and 99.7%, respectively, of all codes. The transition noise can be calculated by dividing the number of codes measured by 6 and this yields the $\pm 3\sigma$ distribution or 99.7% of all codes. Statistically, up to 3 codes could fall outside the distribution when executing 1000 conversions. The ADS8320, with < 3 output codes for $\pm 3\sigma$ distribution, yields a < ± 0.5 LSB transition noise. Remember, to achieve this low noise performance, the peak-to-peak noise of the input signal and reference must be < $50 \, \mu V$.

DIGITAL INTERFACE

SIGNAL LEVELS

The digital inputs of the ADS8320 can accommodate logic levels up to 5.5 V regardless of the value of V_{CC} . Thus, the ADS8320 can be powered at 3 V and still accept inputs from logic powered at 5 V.

The CMOS digital output (D_{OUT}) swings 0 V to V_{CC} . If V_{CC} is 3 V and this output is connected to a 5-V CMOS logic input, then that IC may require more supply current than normal and may have a slightly longer propagation delay.

SERIAL INTERFACE

The ADS8320 communicates with microprocessors and other digital systems via a synchronous 3-wire serial interface, as shown in Figure 21 and Table 2. The DCLOCK signal synchronizes the data transfer with each bit being transmitted on the falling edge of DCLOCK. Most receiving systems will capture the bitstream on the rising edge of DCLOCK. However, if the minimum hold time for D_{OUT} is acceptable, the system can use the falling edge of DCLOCK to capture each bit.

A falling $\overline{\text{CS}}$ signal initiates the conversion and data transfer. The first 4.5 to 5.0 clock periods of the conversion cycle are used to sample the input signal. After the fifth falling DCLOCK edge, D_{OUT} is enabled and outputs a LOW value for one clock period. For the next 16 DCLOCK periods, D_{OUT} outputs the conversion result, most significant bit first. After the least significant bit (B0) has been output, subsequent clocks repeat the output data but in a least significant bit first format.

After the most significant bit (B15) has been repeated, D_{OUT} will tri-state. Subsequent clocks will have no effect on the converter. A new conversion is initiated only when CS has been taken HIGH and returned LOW.

POWER DISSIPATION

The architecture of the converter, the semiconductor fabrication process, and a careful design allow the ADS8320 to convert at up to a 100-kHz rate while requiring very little power. Still, for the absolute lowest power dissipation, there are several things to keep in mind.

The power dissipation of the ADS8320 scales directly with conversion rate. Therefore, the first step to achieving the lowest power dissipation is to find the lowest conversion rate that satisfies the requirements of the system.

In addition, the ADS8320 is in power-down mode under two conditions: when the conversion is complete and whenever $\overline{\text{CS}}$ is HIGH (as shown in Figure 21). Ideally, each conversion should occur as quickly as possible, preferably at a 2.4-MHz clock rate. This way, the converter spends the longest possible time in the power-down mode. This is very important as the converter not only uses power on each DCLOCK transition (as is typical for digital CMOS components), but also uses some current for the analog circuitry, such as the comparator. The analog section dissipates power continuously, until the power-down mode is entered.

If $\overline{\text{CS}}$ remains LOW at the end of conversion, a new datastream with LSB-first is shifted out again.

NOTES: (1) Waveform 1 is for an output with internal conditions such that the output is HIGH unless disabled by the output control. (2) Waveform 2 is for an output with internal conditions such that the output is LOW unless disabled by the output control.

Figure 22. Timing Diagrams and Test Circuits for the Parameters in Table 2

Figure 23 shows the current consumption of the ADS8320 versus sample rate. For this graph, the converter is clocked at 2.4 MHz regardless of the sample rate—CS is HIGH for the remaining sample period. Figure 24 also shows current consumption versus sample rate. However, in this case, the DCLOCK period is 1/24th of the sample period—CS is HIGH for one DCLOCK cycle out of every 16.

There is an important distinction between the power-down mode that <u>is entered</u> after a conversion is complete and the full power-down mode which is enabled when \overline{CS} is <u>HIGH</u>. \overline{CS} LOW will shut down only the analog section. The digital section is completely shut down only when \overline{CS} is HIGH. Thus, if \overline{CS} is left LOW at the <u>end</u> of a conversion and the converter is continually clocked, the power consumption will not be as low as when \overline{CS} is HIGH. Figure 25 shows more information.

Power dissipation can also be reduced by lowering the power-supply voltage and the reference voltage. The ADS8320 operates over a V_{CC} range of 2.0 V to 5.25 V. However, at voltages below 2.7 V, the converter will not run at a 100-kHz sample rate. See the typical performance curves for more information regarding power supply voltage and maximum sample rate.

SHORT CYCLING

Another way of saving power is to utilize the $\overline{\text{CS}}$ signal to short cycle the conversion. Because the ADS8320 places the latest data bit on the D_{OUT} line as it is generated, the converter can easily be short cycled. This term means that the conversion can be terminated at any time. For example, if only 14 bits of the conversion result are needed, then the conversion can be terminated (by pulling $\overline{\text{CS}}$ HIGH) after the 14th bit has been clocked out.

This technique can be used to lower the power dissipation (or to increase the conversion rate) in those applications where an analog signal is being monitored until some condition becomes true. For example, if the signal is outside a predetermined range, the full 16-bit conversion result may not be needed. If so, the conversion can be terminated after the first n bits, where n might be as low as 3 or 4. This results in lower power dissipation in both the converter and the rest of the system, as they spend more time in the power-down mode.

LAYOUT (1)

For optimum performance, care should be taken with the physical layout of the ADS8320 circuitry. This is particularly true if the reference voltage is low and/or the conversion rate is high. At a 100-kHz conversion rate, the ADS8320 makes a bit decision every 416 ns. That is, for each subsequent bit decision, the digital output must be updated with the results of the last bit decision, the capacitor array appropriately switched and charged, and the input to the comparator settled to a 16-bit level all within one clock cycle.

The basic SAR architecture is sensitive to spikes on the power supply, reference, and ground connections that occur just prior to latching the comparator output. Thus, during any single conversion for an n-bit SAR converter, there are n "windows" in which large external transient voltages can easily affect the conversion result. Such spikes might originate from switching power supplies, digital logic, and high power devices, to name a few. This particular source of error can be very difficult to track down if the glitch is almost synchronous to the converter DCLOCK signal—as the phase difference between the two changes with time and temperature, causing sporadic misoperation.

With this in mind, power to the ADS8320 should be clean and well bypassed. A 0.1- μ F ceramic bypass capacitor should be placed as close to the ADS8320 package as possible. In addition, a 1- μ F to 10- μ F capacitor and a 5- Ω or 10- Ω series resistor may be used to low-pass filter a noisy supply.

The reference should be similarly bypassed with a 0.1-µF capacitor. Again, a series resistor and large capacitor can be used to low-pass filter the reference voltage. If the reference voltage originates from an op amp, be careful that the op amp can drive the bypass capacitor without oscillation (the series resistor can help in this case). Keep in mind that while the ADS8320 draws very little current from the reference on average, there are still instantaneous current demands placed on the external input and reference circuitry.

Texas Instruments' OPA627 op amp provides optimum performance for buffering both the signal and reference inputs. For low-cost, low-voltage, single-supply applications, the OPA2350 or OPA2340 dual op amps are recommended.

Also, keep in mind that the ADS8320 offers no inherent rejection of noise or voltage variation in regards to the reference input. This is of particular concern when the reference input is tied to the power supply. Any noise and ripple from the supply will appear directly in the digital results. While high-frequency noise can be filtered out as described in the previous paragraph, voltage variation due to the line frequency (50 Hz or 60 Hz), can be difficult to remove.

The GND pin on the ADS8320 should be placed on a clean ground point. In many cases, this will be the "analog" ground. Avoid connecting the GND pin too close to the grounding point for a microprocessor, microcontroller, or digital signal processor. If needed, run a ground trace directly from the converter to the power-supply connection point. The ideal layout includes an analog ground plane for the converter and associated analog circuitry.

APPLICATION CIRCUITS

Figure 26 shows a basic data acquisition system. The ADS8320 input range is 0 V to V_{CC} , as the reference input is connected directly to the power supply. The $5-\Omega$ resistor and $1-\mu F$ to $10-\mu F$ capacitor filter the microcontroller "noise" on the supply, as well as any high-frequency noise from the supply itself. The exact values should be picked such that the filter provides adequate rejection of the noise.
