

DRV5057 Linear Hall Effect Sensor With PWM Output

1 Features

- PWM-output linear Hall effect magnetic sensor
- Operates from 3.3-V and 5-V power supplies
- 2-kHz clock output with 50% quiescent duty cycle
- Magnetic sensitivity options (at $V_{CC} = 5\text{ V}$):
 - A1/Z1: 2%D/mT, $\pm 21\text{-mT}$ range
 - A2/Z2: 1%D/mT, $\pm 42\text{-mT}$ range
 - A3/Z3: 0.5%D/mT, $\pm 84\text{-mT}$ range
 - A4/Z4: 0.25%D/mT, $\pm 168\text{-mT}$ range
- Open-drain output with 20-mA sink capability
- Compensation for magnet temperature drift for A1/A2/A3/A4 Versions and None for Z1/Z2/Z3/Z4 Versions
- Industry standard package:
 - Surface-mount SOT-23
 - Through-hole TO-92

2 Applications

- Precise position sensing
- Industrial automation and robotics
- Home appliances
- Gamepads, pedals, keyboards, triggers
- Height leveling, tilt and weight measurement
- Fluid flow rate measurement
- Medical devices
- Absolute angle encoding
- Current sensing

3 Description

The DRV5057 is a linear Hall effect sensor that responds proportionally to magnetic flux density. The device can be used for accurate position sensing in a wide range of applications.

The device operates from 3.3-V or 5-V power supplies. When no magnetic field is present, the output produces a clock with a 50% duty cycle. The output duty cycle changes linearly with the applied magnetic flux density, and four sensitivity options maximize the output dynamic range based on the required sensing range. North and south magnetic poles produce unique outputs. The typical pulse-width modulation (PWM) carrier frequency is 2 kHz.

Magnetic flux perpendicular to the top of the package is sensed, and the two package options provide different sensing directions.

Because the PWM signal is based on edge-to-edge timing, signal integrity is maintained in the presence of voltage noise or ground potential mismatch. This signal is suitable for distance transmission in noisy environments, and the always-present clock allows the system controller to confirm there are good interconnects. Additionally, the device features magnet temperature compensation to counteract how magnets drift for linear performance across a wide – 40°C to +125°C temperature range. Device options for no temperature compensation of magnet drift are also available.

Device Information

PART NUMBER	PACKAGE ⁽¹⁾	BODY SIZE (NOM)
DRV5057	SOT-23 (3)	2.92 mm × 1.30 mm
	TO-92 (3)	4.00 mm × 3.15 mm

- (1) For all available packages, see the package option addendum at the end of the data sheet.

4 Revision History

Changes from Revision * (November 2018) to Revision A (August 2020)	Page
• Updated the numbering format for tables, figures, and cross-references throughout the document.....	1
• Added Zero TC sensitivity options	1
• Added Zero TC information to Section 6.6	4
• Fixed labels for some of the plots for graphs for DRV5057 A1/A2/A3/A4 devices and added Zero TC characteristics plots for DRV5057 Z1/Z2/Z3/Z4 devices in Section 6.7	6
• Updated Section 7.3.4 section for Zero TC options.....	12

Pin Functions

NAME	PIN		TYPE	DESCRIPTION
	SOT-23	TO-92		
GND	3	2	Ground	Ground reference
OUT	2	3	Output	Analog output
V _{CC}	1	1	Power	Power supply. Connect this pin to a ceramic capacitor to ground with a value of at least 0.01 μ F.

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

				MIN	MAX	UNIT
V _{CC}	Power supply voltage	V _{CC}		–0.3	7	V
	Output voltage	OUT		–0.3	6	V
	Output current	OUT			30	mA
B	Magnetic flux density			Unlimited		T
T _J	Operating junction temperature			–40	150	°C
T _{stg}	Storage temperature			–65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±3000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±750	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	MAX	UNIT
V_{CC}	Power-supply voltage ⁽¹⁾	3	3.63	V
		4.5	5.5	
V_O	Output pullup voltage	0	5.5	V
I_O	Output continuous current	0	20	mA
T_A	Operating ambient temperature ⁽²⁾	−40	125	°C

(1) There are two isolated operating V_{CC} ranges. For more information see the [Section 7.3.3](#) section.

(2) Power dissipation and thermal limits must be observed.

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		DRV5057		UNIT
		SOT-23 (DBZ)	TO-92 (LPG)	
		3 PINS	3 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	170	121	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	66	67	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	49	97	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	1.7	7.6	°C/W
Ψ_{JB}	Junction-to-board characterization parameter	48	97	°C/W

(1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics application report](#).

6.5 Electrical Characteristics

for $V_{CC} = 3\text{ V}$ to 3.63 V and 4.5 V to 5.5 V , over operating free-air temperature range (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I_{CC}	Operating supply current			6	10	mA
t_{ON}	Power-on time (see Figure 7-4) ⁽²⁾	$B^{(1)} = 0\text{ mT}$, no load on OUT		0.6	0.9	ms
f_{PWM}	PWM carrier frequency		1.8	2.0	2.2	kHz
D_J	Duty cycle peak-to-peak jitter	From change in B to change in OUT		±0.1		%D ⁽¹⁾
I_{OZ}	High-impedance output leakage current	$V_{CC} = 5\text{ V}$			100	nA
V_{OL}	Low-level output voltage	$I_{OUT} = 20\text{ mA}$		0.15	0.4	V

(1) This unit is a percentage of duty cycle.

(2) t_{ON} is the time from when V_{CC} goes above 3 V until the first rising edge of the first valid pulse.

6.6 Magnetic Characteristics

for $V_{CC} = 3\text{ V}$ to 3.63 V and 4.5 V to 5.5 V , over operating free-air temperature range (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
D_L	Linear duty cycle range		8		92	%D ⁽¹⁾

for $V_{CC} = 3\text{ V}$ to 3.63 V and 4.5 V to 5.5 V , over operating free-air temperature range (unless otherwise noted)

PARAMETER		TEST CONDITIONS		MIN	TYP	MAX	UNIT
D _{CL}	Clamped-low duty cycle	B ⁽¹⁾ < −250 mT		5.3	6	6.7	%D
D _{CH}	Clamped-high duty cycle	B > 250 mT		93.3	94	94.7	
D _Q	Quiescent duty cycle ⁽²⁾	B = 0 mT, T _A = 25°C, V _{CC} = 3.3 V or 5 V		46	50	54	%D

7 Detailed Description

7.1 Overview

The DRV5057 is a 3-pin pulse-width modulation (PWM) output Hall effect sensor with fully integrated signal conditioning, temperature compensation circuits, mechanical stress cancellation, and amplifiers. The device operates from 3.3-V and 5-V ($\pm 10\%$) power supplies, measures magnetic flux density, and outputs a pulse-width modulated, 2-kHz digital signal.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Magnetic Flux Direction

As shown in Figure 7-1, the DRV5057 is sensitive to the magnetic field component that is perpendicular to the top of the package.

Figure 7-1. Direction of Sensitivity

Magnetic flux that travels from the bottom to the top of the package is considered positive in this document. This condition exists when a south magnetic pole is near the top (marked-side) of the package. Magnetic flux that travels from the top to the bottom of the package results in negative millitesla values. Figure 7-2 shows flux direction.

Figure 7-2. Flux Direction for Positive B

7.3.2 Sensitivity Linearity

The device produces a pulse-width modulated digital signal output. As shown in Figure 7-3, the duty-cycle of the PWM output signal is proportional to the magnetic field detected by the Hall element of the device. If there is no magnetic field present, the duty cycle is 50%. The DRV5057 can detect both magnetic north and south poles. The output duty cycle maintains a linear relationship with the input magnetic field from 8% to 92%.

Figure 7-3. Magnetic Response

7.3.3 Operating V_{CC} Ranges

The DRV5057 has two recommended operating V_{CC} ranges: 3 V to 3.63 V and 4.5 V to 5.5 V. When V_{CC} is in the middle region between 3.63 V to 4.5 V, the device continues to function but sensitivity is less known because there is a crossover threshold near 4 V that adjusts device characteristics.

7.3.4 Sensitivity Temperature Compensation for Magnets

Magnets generally produce weaker fields as temperature increases. The DRV5057A1 - DRV5057A4 device options have a temperature compensation feature that is designed to directly compensate the average drift of neodymium (NdFeB) magnets and partially compensate ferrite magnets. The residual induction (B_r) of a magnet typically reduces by 0.12%/°C for NdFeB, and 0.20%/°C for ferrite. When the operating temperature of a system is reduced, temperature drift errors are also reduced. The DRV5057Z1 - DRV5057Z4 devices options do not compensate for the drift external magnets

7.3.5 Power-On Time

After the V_{CC} voltage is applied, the DRV5057 requires a short initialization time before the output is set. The parameter t_{ON} describes the time from when V_{CC} crosses 3 V until OUT is within 5% of V_Q , with 0 mT applied and no load attached to OUT. Figure 7-4 shows this timing diagram.

Figure 7-4. t_{ON} Definition

7.3.6 Hall Element Location

Figure 7-5 shows the location of the sensing element inside each package option.

Figure 7-5. Hall Element Location

7.4 Device Functional Modes

The DRV5057 has one mode of operation that applies when the *Recommended Operating Conditions* are met.

8 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

8.1.1 Selecting the Sensitivity Option

Select the highest DRV5057 sensitivity option that can measure the required range of magnetic flux density so that the output voltage swing is maximized.

Larger-sized magnets and farther sensing distances can generally enable better positional accuracy than very small magnets at close distances, because magnetic flux density increases exponentially with the proximity to a magnet. TI created an online tool to help with simple magnet calculations on the DRV5057 [product folder](#).

8.1.2 Decoding a PWM

A PWM output helps system designers drive signals for long distances in noisy environments, with the ability to retrieve the signal accurately. A decoder is employed at the load to retrieve the analog magnetic signal. Two different methods of decoding are discussed in this section.

8.1.2.1 Decoding a PWM (Digital)

8.1.2.1.1 Capture and Compare Timer Interrupt

Many microcontrollers have a capture and compare timer mode that can simplify the PWM decoding process. Use the timer in capture and compare mode with an interrupt that triggers on both the rising and falling edges of the signal to obtain both the relative high (on) and low (off) time of the PWM. Make sure that the timer period is significantly faster than the period of the PWM, based on the desired resolution. Calculate the percent duty cycle (%D) of the PWM with [Equation 1](#) by using the relative on and off time of the signal.

$$\%D = \frac{\text{OnTime}}{\text{OnTime} + \text{OffTime}} \times 100 \quad (1)$$

8.1.2.1.2 Oversampling and Counting With a Timer Interrupt

If a capture and compare timer is not available, a standard timer interrupt and a counter can be used. Configure the timer interrupt to be significantly faster than the period of the PWM, based on the desired resolution. Count how many times the timer interrupts while the signal is high (OnTime), then count how many times the timer interrupts while the signal is low (OffTime). Then use [Equation 1](#) to calculate the duty cycle.

8.1.2.1.3 Accuracy and Resolution

The accuracy and resolution for the methods described in the [Section 8.1.2.1.1](#) and [Section 8.1.2.1.2](#) sections depends significantly on the timer sampling frequency. [Equation 2](#) calculates the least significant bit of the duty cycle (%D_{LSB}) based on the chosen timer sampling frequency.

$$\%D_{\text{LSB}} = \frac{\text{PWM}_{\text{frequency}}}{\text{TIMER}_{\text{frequency}}} \times 100 \quad (2)$$

For example, with a 2-kHz PWM and a 400-kHz sampling frequency, the %D_{LSB} is:

$$(2 \text{ kHz} / 400 \text{ kHz}) \times 100 = 0.5\%D_{\text{LSB}}$$

If the sampling frequency is increased to 2-MHz, the %D_{LSB} is improved to be:

$$(2 \text{ MHz} / 400 \text{ kHz}) \times 100 = 0.1\%D_{\text{LSB}}$$

However, accuracy and resolution are still subject to noise and sensitivity.

8.1.2.2 Decoding a PWM (Analog)

If an analog signal is needed at the end of a large travel distance, first use a microcontroller to digitally decode the PWM, then use a DAC to produce the analog signal. If an analog signal is needed after a short signal travel distance, use an analog output device, such as the [DRV5055](#).

If an analog signal is needed at the end of a large travel distance and a microcontroller is unavailable, use a low-pass filter to convert the PWM signal into an analog voltage, as shown in [Figure 8-1](#). When using this method, note the following:

- A ripple appears at the analog voltage output, causing a decrease in accuracy. The ripple intensity and frequency depend on the values chosen for R and C in the filter.
- The minimum and maximum voltages of the PWM must be known to calculate the magnetic field strength from the analog voltage. Thus, if the signal is traveling a large distance, then the minimum and maximum values must be either measured or buffered back to a known value.

Figure 8-1. Low-Pass RC Filter

8.2 Typical Applications

The DRV557-Q1 is a very robust linear position sensor for applications such as throttle positions, brakes, and clutch pedals. In linear position applications, depending on the mechanical placement and design limitations, two common types of magnet orientations are selected: full-swing and half-swing.

8.2.1 Full-Swing Orientation Example

In the full-swing orientation, a magnet travels in parallel to the DRV5057-Q1 surface. In this case, the magnetic range extends from south polarity to north polarity, and allows the DRV5057-Q1 to use the full linear magnetic flux density sensing range.

Figure 8-2. Full-Swing Orientation Example

8.2.1.1 Design Requirements

Use the parameters listed in [Table 8-1](#) for this design example.

Table 8-1. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
Device	DRV5057
V _{CC}	5 V
Magnet	Cylinder: 4.7625-mm diameter, 12.7-mm thick, neodymium N52, Br = 1480 mT
Travel distance	10 mm
Desired accuracy	< 0.1 mm

8.2.1.2 Detailed Design Procedure

Linear Hall effect sensors provide flexibility in mechanical design because many possible magnet orientations and movements produce a usable response from the sensor. [Figure 8-2](#) illustrates one of the most common orientations that uses the full north to south range of the sensor and causes a close-to-linear change in magnetic flux density as the magnet moves across the sensor. [Figure 8-3](#) illustrates the close-to-linear change in magnetic field present at the sensor as the magnet moves a given distance across the sensor. The usable linear region is close to but less than the length (thickness) of the magnet.

When designing a linear magnetic sensing system, always consider these three variables: the magnet, sensing distance, and the range of the sensor. Select the DRV5057 with the highest sensitivity possible based on the system distance requirements without railing the sensor PWM output. To determine the magnetic flux density the sensor receives at the various positions of the magnet, use a magnetic field calculator or simulation software, referring to magnet specifications, and testing.

Determine if the desired accuracy is met by comparing the maximum allowed duty cycle least significant bit (%D_{LSBmax}) with the noise level (PWM jitter) of the device. [Equation 3](#) calculates the %D_{LSBmax} by taking into account the used length of the linear region (travel distance), the desired resolution, and the output PWM swing (within the linear duty cycle range).

$$\%D_{LSBmax} = \frac{\%D_{swing}}{\text{Travel Distance}} \times \text{Resolution} \quad (3)$$

Thus, with this example (and a linear duty cycle range of 8%D to 92%D), using Equation 3 gives $(92 - 8) / (10) \times 0.1 = 0.84\%D_{LSB_{max}}$. This value is larger than the 0.1%D jitter, and therefore the desired accuracy can be achieved by using Equation 2 to select a $\%D_{LSB}$ that is equal to or less than 0.84. Then, simply calibrate the magnet position to align the sensor output along the movement path.

8.2.1.3 Application Curve

Figure 8-3 shows the magnetic field present at the sensor as the magnet passes by as described in Figure 8-2. The change in distance from the trough to the peak is approximately the length (thickness) of the magnet. B changes based on the strength of the magnet and how close the magnet is to the sensor.

Figure 8-3. Magnetic Field vs Distance

8.2.2 Half-Swing Orientation Example

In the half-swing orientation, a magnet travels perpendicular to the DRV5057-Q1 surface. In this case, the magnetic range extends only to either the south or north pole, using only half of the DRV5057-Q1 linear magnetic flux density sensing range.

Figure 8-4. Half-Swing Orientation Example

8.2.2.1 Design Requirements

Use the parameters listed in Table 8-2 for this design example.

Table 8-2. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
Device	DRV5057
V_{CC}	5 V
Magnet	Cylinder: 4.7625 mm diameter, 12.7 mm thick, Neodymium N52, $B_r = 1480$ mT
Travel distance	5 mm
Desired accuracy	< 0.1 mm

8.2.2.2 Detailed Design Procedure

As illustrated in Figure 8-4, this design example consists of a mechanical component that moves back and forth, an embedded magnet with the south pole facing the printed-circuit board, and a DRV5057. The DRV5057 outputs a PWM that describes the precise position of the component. The component must not contain ferromagnetic materials such as iron, nickel, and cobalt because these materials change the magnetic flux density at the sensor.

When designing a linear magnetic sensing system, always consider these three variables: the magnet, sensing distance, and the range of the sensor. Select the DRV5057 with the highest sensitivity possible based on the system distance requirements without railing the sensor PWM output. To determine the magnetic flux density the sensor receives at the various positions of the magnet, use a magnetic field calculator or simulation software, referring to magnet specifications, and testing.

Magnets are made from various ferromagnetic materials that have tradeoffs in cost, drift with temperature, absolute maximum temperature ratings, remanence or residual induction (B_r), and coercivity (H_c). The B_r and the dimensions of a magnet determine the magnetic flux density (B) produced in 3-dimensional space. For simple

magnet shapes, such as rectangular blocks and cylinders, there are simple equations that solve B at a given distance centered with the magnet. Figure 8-5 shows diagrams for Equation 4 and Equation 5.

Figure 8-5. Rectangular Block and Cylinder Magnets

Use Equation 4 for the rectangular block shown in Figure 8-5:

$$\vec{B} = \frac{B_r}{\pi} \left(\arctan\left(\frac{WL}{2D\sqrt{4D^2 + W^2 + L^2}}\right) - \arctan\left(\frac{WL}{2(D+T)\sqrt{4(D+T)^2 + W^2 + L^2}}\right) \right) \quad (4)$$

Use Equation 5 for the cylinder illustrated in Figure 8-5:

$$\vec{B} = \frac{B_r}{2} \left(\frac{D+T}{\sqrt{(0.5C)^2 + (D+T)^2}} - \frac{D}{\sqrt{(0.5C)^2 + D^2}} \right) \quad (5)$$

where:

- W is width
- L is length
- T is thickness (the direction of magnetization)
- D is distance
- C is diameter

This example uses a cylinder magnet; therefore, Equation 5 can be used to create a lookup table for the distances from a specific magnet based on a magnetic field strength. Figure 8-6 shows a magnetic field from 0 mm to 16 mm with the magnet defined in Table 8-2 as C = 4.7625 mm, T = 12.7 mm, and B_r = 1480 mT.

Figure 8-6. Magnetic Field vs Distance

In this setup, each gain version of the sensor produces the corresponding duty cycle shown in Figure 8-7 for 0 mm to 16 mm.

Figure 8-7. %D vs South Pole Distance (All Gains)

With a desired 5-mm movement swing, select the DRV5057 with the largest possible sensitivity that fits the system requirements for the magnet distance to the sensor. Assume that for this example, because of mechanical restrictions, the magnet at the nearest point to the sensor must be selected to be within 5 mm to 8 mm. The largest sensitivity option (A1) does not work in this situation because the device output is railed at the farthest allowed distance of 8 mm. The A2 version is not railed at this point, and is therefore the sensor selected for this example. Choose the closest point of the magnet to the sensor to be a distance that allows the magnet to get as close to the sensor as possible without railing but stays within the selectable 5-mm to 8-mm allowed range. Because the A2 version rails at approximately 6 mm, choose a closest distance of 6.5 mm to allow for a little bit of margin. With this choice, Figure 8-8 shows the %D response at the sensor across the full movement range.

Figure 8-8. %D vs South Pole Distance (Gain A2)

The magnetic field strength is calculated using [Equation 6](#), where a negative number represents the opposite pole (in this example a south pole is over the sensor, causing the results to be a positive number).

$$B = \frac{(\%D - 50)}{\text{Gain}} \quad (6)$$

For example, if the A2 version of the DRV5057 measured a duty cycle of $\%D = 74.6\%$ using [Equation 1](#), then the magnetic field strength present at the sensor is $(74.6 - 50) / 1 = 24.6 \text{ mT}$.

Using the lookup table that was used to create the plot in [Figure 8-6](#), the distance from the magnet at 24.6 mT is $D \approx 8.2 \text{ mm}$.

For more accurate results, the lookup table can be calibrated along the movement path of the magnet. Additionally, instead of using the calibrated lookup table for each measurement, consider using a best-fit polynomial equation from the curve for the desired movement range to calculate D in terms of B.

The curve in [Figure 8-8](#) is not linear; therefore, the achievable accuracy varies for each position along the movement path. The location with the worst accuracy is where there is the smallest change in output for a given amount of movement, which in this example is where the magnet is farthest from the sensor (at 11.5 mm). Determine if the desired accuracy is met by checking if the needed $\%D_{\text{LSB}}$ at this location for the specified accuracy is greater than the noise level (PWM jitter) of 0.1%D. Thus, with a desired accuracy of 0.1 mm, the needed $\%D_{\text{LSB}}$ is the change in %D between 11.4 mm and 11.5 mm. Using the lookup table to find B and then solving for %D in [Equation 6](#), at 11.5 mm, $B = 11.815 \text{ mT}$ (which equates to 61.815%D), and at 11.4 mm $B = 12.048 \text{ mT}$ (which equates to 62.048%D). The difference in %D between these two points is $62.048 - 61.815 = 0.223\%D_{\text{LSB}}$. This value is larger than the 0.1%D jitter, so the desired accuracy can be met as long as a $\%D_{\text{LSB}}$ is selected that is equal to or less than 0.223 using [Equation 2](#).

8.3 What to Do and What Not to Do

The Hall element is sensitive to magnetic fields that are perpendicular to the top of the package. Therefore, to correctly detect the magnetic field, make sure to use the correct magnet orientation for the sensor. [Figure 8-9](#) shows correct and incorrect orientation.

Figure 8-9. Correct and Incorrect Magnet Orientation

9 Power Supply Recommendations

Use a decoupling capacitor placed close to the device to provide local energy with minimal inductance. Use a ceramic capacitor with a value of at least 0.01 μF .

10 Layout

10.1 Layout Guidelines

Magnetic fields pass through most nonferromagnetic materials with no significant disturbance. Embedding Hall effect sensors within plastic or aluminum enclosures and sensing magnets on the outside is common practice. Magnetic fields also easily pass through most printed-circuit boards, which makes placing the magnet on the opposite side possible.

10.2 Layout Examples

Figure 10-1. Layout Examples

11 Device and Documentation Support

11.1 Documentation Support

11.1.1 Related Documentation

For related documentation see the following:

- Texas Instruments, [Using Linear Hall Effect Sensors to Measure Angle tech note](#)
- Texas Instruments, [Incremental Rotary Encoder Design Considerations tech note](#)
- Texas Instruments, [DRV5055 Ratiometric Linear Hall Effect Sensor data sheet](#)

11.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. Click on *Subscribe to updates* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

11.3 Support Resources

TI E2E™ [support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

11.4 Trademarks

TI E2E™ is a trademark of Texas Instruments.

All other trademarks are the property of their respective owners.

11.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

11.6 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

12 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
