

INA500 Cost and Size Optimized, Low Power, 1.7V to 5.5V Difference Amplifier with >1MΩ Input Impedance

1 Features

- Optimized for small-size, low-power, and low-cost
- >1MΩ Ultra-high input impedance
- Three gain options ($G = 1, 0.50$, and 0.25)
- Good precision for 8-bit to 12-bit systems
 - CMRR: 87dB (typical)
 - Gain error: $\pm 0.01\%$ (typical)
 - Offset voltage: $\pm 0.70\text{mV}$ (typical)
- Space saving 0.8mm^2 X2SON package
- Bandwidth: 125kHz (typical)
- Drives 200pF with $<20\%$ overshoot (typical)
- Low quiescent current: $13.5\mu\text{A}$ (typical)
- Supply range: 1.7V ($\pm 0.85\text{V}$) to 5.5V ($\pm 2.75\text{V}$)
- Specified temperature range: -40°C to 125°C

2 Applications

- Battery cell formation and test equipment
- String inverter
- EV charging station power module
- Battery energy storage system
- Power tools
- Industrial AC-DC
- Wearable fitness and activity monitor

NOTE: The input resistors (R_{IN}) values are $1.08\text{M}\Omega$ for INA500A, $1.44\text{M}\Omega$ for INA500B, and $1.68\text{M}\Omega$ for INA500C.

INA500 Simplified Internal Schematic

3 Description

The INA500 is a difference amplifier with integrated op-amp and matched resistors that offers three gain options. The INA500A version offers gain option of 1, while the INA500B and INA500C versions offer gain options of 0.50 and 0.25 respectively.

These are voltage sensing INAs in difference amplifier configuration with high input impedance of $>1\text{M}\Omega$ and low quiescent current of $13.5\mu\text{A}$. The device achieves 75dB of minimum CMRR and an accurate $\pm 0.05\%$ of maximum gain error, along with 3.5mV of maximum offset (referred to output) in $G = 1$ configuration. The device can handle up to 27.5V ($\pm 13.75\text{V}$) of input common-mode voltage in $G = 0.25$ with 5.5V ($\pm 2.75\text{V}$) of supply voltage. The combination of specifications noted above are designed for a variety of level translation and battery monitoring applications.

The precision matched integrated resistors of the INA500 saves BOM costs and board space by removing the need for precise and low tolerance external resistors. The INA500 can interface directly to low-speed, 8-bit to 12-bit, analog-to-digital converters (ADC) and is an excellent choice for replacing discrete implementation of difference amplifiers built with commodity amplifiers and discrete resistors. The INA500 is offered in standard 6-pin packages such as SOT-23 and SC70 as well as the space saving, X2SON package.

Package Information

PART NUMBER ⁽¹⁾	VERSION	PACKAGE ⁽²⁾	PACKAGE SIZE ⁽⁴⁾
INA500	A	DCK (SC70, 6)	$2.1\text{mm} \times 1.25\text{mm}$
		DBV (SOT-23, 6)	$2.9\text{mm} \times 2.8\text{mm}$

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Supply voltage, $V_S = (V+) - (V-)$	Single Supply		6	V
	Dual Supply		±3	V
Signal input pins	Current	–10	10	mA
Output short-circuit ⁽²⁾		Continuous		
Operating Temperature, T_A		–55	150	°C
Junction Temperature, T_J			150	
Storage Temperature, T_{stg}		–65	150	

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) Short-circuit to $V_S / 2$.

6.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2500	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±1500	

- (1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	MAX	UNIT
Supply voltage $V_S = (V+) - (V-)$	Single-supply	1.7	5.5	V
	Dual-supply	±0.85	±2.75	
C_{BYP}	Bypass capacitor on the power supply pins ⁽¹⁾	0.1		μF
Specified temperature	Specified temperature	–40	125	°C

- (1) For C_{BYP} , use low-ESR ceramic capacitors between each supply pin and ground. Only one C_{BYP} is sufficient for single supply operation. Ensure that C_{BYP} is placed as close to the device as possible and the supply trace routes through C_{BYP} before reaching the supply pin.

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		INA500			UNIT
		DCK (SC70)	DBV (SOT-23)	DTQ (X2SON)	
		6 PINS	6 PINS	6 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	200.2	195.9	TBD	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	127.6	115.5	TBD	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	59.6	77.1	TBD	°C/W
ψ_{JT}	Junction-to-top characterization parameter	42.6	52.2	TBD	°C/W
ψ_{JB}	Junction-to-board characterization parameter	59.4	76.8	TBD	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	n/a	n/a	TBD	°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application note.

6.5 Electrical Characteristics - INA500A

For $V_S = (V_+) - (V_-) = 1.7V$ to $5.5V$ ($\pm 0.85V$ to $\pm 2.75V$) at $T_A = 25^\circ C$, $V_{REF} = V_S / 2$, $G = 1$, $R_L = 100k\Omega$ connected to $V_S / 2$, $V_{CM} = (V_{IN+} + V_{IN-}) / 2 = V_S / 2$, $V_{IN} = (V_{IN+} - V_{IN-}) = 0V$ and $V_{OUT} = V_S / 2$ (unless otherwise noted)

7 Detailed Description

7.1 Overview

The INA500 is a cost-effective, integrated difference amplifier designed to provide better performance, and smaller solution size for applications employing discrete implementation of difference amplifiers using commodity amplifiers and discrete resistors. The device incorporates one low power operational amplifier and four precision matched integrated resistors. INA500 can be used in 8-bit system without any calibration. Further calibration of offset and gain error at a system level can improve system resolution and accuracy, enabling use in 10-bit and 12-bit systems.

The INA500 is offered in three gain options across three variants. The INA500A version offers gain option of 1, while the INA500B and INA500C versions offer gain options of 0.50 and 0.25 respectively. Optimized for voltage sensing applications, the INA500 offers 75dB of minimum common-mode rejection ratio (CMRR) and $\pm 0.05\%$ of maximum gain error. A high input impedance of $>1\text{M}\Omega$ along with just $13.5\mu\text{A}$ of quiescent current is one of the key features of the INA500, which is very useful in single cell battery monitoring applications. All of the errors including offset, offset drift, CMRR and so forth are referred to the output so as to enable easy calculation of signal-to-noise ratio (SNR) and effective number of bits (ENOB) close to the analog-to-digital converter (ADC).

The INA500 gain options are designed for level translation applications that interface with a wide variety of differential ($\pm 12\text{V}$, $\pm 10\text{V}$, $\pm 5\text{V}$, and so forth) and single-ended (0V to 12V, 0V to 10V, 0V to 5V, and so forth) high voltage signals into low voltage (0V to 5V, 0V to 3V, 0V to 2.5V, and so forth) ADCs. This would be useful in a variety of end equipments such as Battery testers, Solar string inverters, Power tools, Analog input modules, Battery energy storage systems and so forth where multiple high voltage signals and supply domains are required to be monitored. When routing signals differentially for common-mode noise immunity, the INA500 in $G = 1$ would be useful in converting the differential signal back to single-ended signal for easy interface to single-ended ADCs while rejecting the common-mode noise. The device also has enough bandwidth of 125kHz to directly drive low-speed ($\leq 10\text{ksps}$) ADCs.

The INA500 is an excellent choice for use in space-constrained applications such as wearable fitness and activity monitors, cell phones, and so forth as it is offered in ultra-small, 0.8mm^2 X2SON package. For easy use in industrial applications, it is also available in industry standard packages including SOT-23 and SC70.

7.2 Functional Block Diagram

Note: Input resistors (R_{IN}) values are $1.08\text{M}\Omega$ for INA500A, $1.44\text{M}\Omega$ for INA500B, and $1.68\text{M}\Omega$ for INA500C

Figure 7-1. INA500A Simplified Internal Schematic

7.3 Feature Description

7.3.1 Gain Options and Resistors

The gain value of the INA500 is given by the ratio of feedback resistor and input resistor. The gain options are offered across different device variants as provided in [Table 7-1](#). While the typical value of input and feedback resistors are shown in the following table, it is important to note that these values can vary together by about $\pm 15\%$ while maintaining tighter gain error (tolerance) numbers as specified in the [Electrical Characteristics](#) table.

Table 7-1. Gain Selection Table

DEVICE	INPUT RESISTOR	FEEDBACK RESISTOR	GAIN
INA500A	1.08M Ω	1.08M Ω	1
INA500B	1.44M Ω	0.72M Ω	0.50
INA500C	1.68M Ω	0.42M Ω	0.25

7.3.1.1 Gain Error and Drift

Gain error in the INA500 is limited by the mismatch of the integrated precision resistors and is specified based on characterization results. Maximum gain error of $\pm 0.05\%$ can be expected for all gains of 1, 0.50, and 0.25. Gain drift in the INA500 is limited by the slight mismatch of the temperature coefficient of the integrated resistors. Since these integrated resistors are precision matched with low temperature coefficient resistors to begin with, the overall gain drift is much better in comparison to discrete implementation of the difference amplifiers built using external resistors. Maximum gain error of $\pm 0.02\%$ can be expected for inputs from the reference pin that sets output common-mode voltage.

7.3.2 Input Common-Mode Voltage Range

The INA500 difference-amplifier rejects the input common mode. The rejection capability is based on the matching of the internal resistors. The input voltage range of the INA500 is primarily dictated by the signal swing at the op-amp inputs. The INA500 input common-mode voltage range can extend well beyond the supply rails and is a major function of the gain configuration. To maximize performance, it is critical to keep the op-amp inside the INA500 within the linear range for a given combination of gain, reference voltage, and input common-mode voltage for a particular input differential voltage and output swing.

Input common-mode voltage (V_{CM}) vs output voltage graphs (V_{OUT}) in this section outlines the linear performance region of the INA500 for a particular combination of gain and reference voltage values. A good common-mode rejection can be expected when operating within the limits of the V_{CM} versus V_{OUT} graph. The common-mode range for the INA500 in equation form is outlined in the [Electrical Characteristics](#) for each gain. The most common operating conditions are outlined graphically in the [Typical Characteristics](#) section. [Figure 7-2](#) shows the region of operation where a minimum of 75dB CMRR can be achieved. This is referred to as the high CMRR region. [Figure 7-3](#) has a much wider region of operation with a lower CMRR of 62dB minimum. This is because the input signal crosses over the transition region of the input pairs to achieve rail-to-rail operation.

Figure 7-2. Input Common-Mode Voltage vs Output Voltage (High CMRR Region)

Figure 7-3. Input Common-Mode Voltage vs Output Voltage

7.3.3 EMI Rejection

The INA500 uses integrated electromagnetic interference (EMI) filtering to reduce the effects of EMI from sources such as wireless communications and densely-populated boards with a mix of analog signal chain and digital components. EMI immunity can be improved with circuit design techniques; the INA500 benefits from these design improvements. Texas Instruments has the ability to accurately measure and quantify the immunity of an operational amplifier over a broad frequency spectrum extending from 10MHz to 6GHz. Figure 7-4 shows the results of this testing on the INA500 for differential EMI interference and Figure 7-5 shows the results of this testing on the INA500 for common-mode EMI interference. Table 7-2 provides the EMIRR IN+ values for the INA500 at particular frequencies commonly encountered in real-world applications. The [EMI Rejection Ratio of Operational Amplifiers](#) application report contains detailed information on the topic of EMIRR performance relating to op amps and is available for download from www.ti.com.

Figure 7-4. Electromagnetic Interference Rejection Ratio Referred to Output vs Frequency (Differential Input)

Figure 7-5. Electromagnetic Interference Rejection Ratio Referred to Output vs Frequency (Common-Mode Input)

Table 7-2. INA500 EMIRR for Frequencies of Interest

FREQUENCY	APPLICATION OR ALLOCATION	EMIRR DIFFERENTIAL	EMIRR COMMON-MODE
400MHz	Mobile radio, mobile satellite, space operation, weather, radar, ultra-high frequency (UHF) applications	91dB	83dB
900MHz	Global system for mobile communications (GSM) applications, radio communication, navigation, GPS (to 1.6GHz), GSM, aeronautical mobile, UHF applications	98dB	82dB
1.8GHz	GSM applications, mobile personal communications, broadband, satellite, L-band (1GHz to 2GHz)	101dB	80dB
2.4GHz	802.11b, 802.11g, 802.11n, Bluetooth®, mobile personal communications, industrial, scientific and medical (ISM) radio band, amateur radio and satellite, S-band (2GHz to 4GHz)	95dB	78dB
3.6GHz	Radiolocation, aero communication and navigation, satellite, mobile, S-band	88dB	79dB
5GHz	802.11a, 802.11n, aero communication and navigation, mobile communication, space and satellite operation, C-band (4GHz to 8GHz)	94dB	80dB

7.3.4 Typical Specifications and Distributions

Designers often have questions about a typical specification of an amplifier to design a more robust circuit. Due to natural variation in process technology and manufacturing procedures, every specification of an amplifier exhibits some amount of deviation from the ideal value, like an amplifier's offset voltage. These deviations often follow *Gaussian (bell curve)*, or *normal* distributions, and circuit designers can leverage this information to guard band their system, even when there is not a minimum or maximum specification in the [Electrical Characteristics](#) table.

Figure 7-6. Ideal Gaussian Distribution

Figure 7-6 shows an example distribution, where μ , or μ , is the mean of the distribution, and where σ , or σ , is the standard deviation of a system. For a specification that exhibits this kind of distribution, approximately two-thirds (68.26%) of all units can be expected to have a value within one standard deviation, or one sigma, of the mean (from $\mu - \sigma$ to $\mu + \sigma$).

Depending on the specification, values listed in the *typical* column of the [Electrical Characteristics](#) table are represented in different ways. As a general rule, if a specification naturally has a nonzero mean (for example, like gain bandwidth), then the typical value is equal to the mean (μ). However, if a specification naturally has a mean near zero (like offset voltage), then the typical value is equal to the mean plus one standard deviation ($\mu + \sigma$) to most accurately represent the typical value.

This chart can be used to calculate approximate probability of a specification in a unit; for example, the INA500A typical offset voltage is 700 μ V, so 68.2% of all INA500A devices are expected to have an offset from -700μ V to $+700\mu$ V. At 4 σ ($\pm 2800\mu$ V), 99.9937% of the distribution has an offset voltage less than $\pm 2800\mu$ V, which means 0.0063% of the population is outside of these limits, which corresponds to about 1 in 15,873 units.

Specifications with a value in the minimum or maximum column are verified by TI, and units outside these limits are removed from production material. For example, the INA500A family has a maximum offset voltage of ± 3.5 mV at 25°C, and even though this corresponds to 5 σ (equals approximately 1 in 3.5 million units), which is extremely unlikely, TI verifies that any unit with larger offset than ± 3.5 mV are removed from production material.

For specifications with no value in the minimum or maximum column, consider selecting a sigma value of sufficient guard band for the application, and design worst-case conditions using this value. A 6 σ value corresponds to about 1 in 500 million units, which is an extremely unlikely chance, and can be an option as a wide guard band to design a system around. Histograms for some of the important specifications like offset, offset drift, CMRR, gain error are shown in the [Typical Characteristics](#) section.

In the case of gain error, the INA500 family does not specify a maximum value based on final test but based on characterization as mentioned in the [Electrical Characteristics](#) table. The corresponding distribution mentioned in [Figure 6-10](#) has a mean of 0.01% and sigma of 0.003%. Hence, the mean plus 6 σ value for gain error can be calculated to be approximately 0.03%. When designing for system conditions with 6 σ guardband, this method and value can be used to estimate the worst possible gain error.

However, process variation and adjustments over time can shift typical means and standard deviations, and unless there is a value in the minimum or maximum specification column that is specified based on final test, TI cannot verify the performance of a device. Hence, the maximum gain error spec in the [Electrical Characteristics](#) table is relaxed beyond 6σ guardband to be $\pm 0.05\%$.

7.3.5 Electrical Overstress

Designers often ask questions about the capability of an operational amplifier to withstand electrical overstress. These questions tend to focus on the device inputs, but can involve the supply voltage pins or even the output pin. Each of these different pin functions have electrical stress limits determined by the voltage breakdown characteristics of the particular semiconductor fabrication process and specific circuits connected to the pin. Additionally, internal electrostatic discharge (ESD) protection is built into these circuits to protect them from accidental ESD events both before and during product assembly.

Having a good understanding of this basic ESD circuitry and the relevance to an electrical overstress event is helpful. [Figure 7-7](#) shows the ESD circuits contained in the INA500 devices. On the input pins, the ESD protection circuitry involves local high impedance diode structures and do not route the ESD current to power supply ESD cell. On the output pin, there are reverse biased diodes to both the power supply rails. These diode structures route the ESD current back to the internal power supply lines, where there is an absorption power supply ESD cell internal to the difference amplifier. On the reference pin, the ESD protection is local and does not route current to the power supply ESD cell.

All of the ESD protection circuitry is intended to remain inactive during normal circuit operation.

Figure 7-7. Equivalent Internal ESD Circuitry

7.4 Device Functional Modes

The INA500 has only one functional mode. The device powers on, starts drawing quiescent current and is functional as long as the power supply voltages are in the recommended operating voltage range of 1.7V ($\pm 0.85V$) to 5.5V ($\pm 2.75V$). Operational temperature range of INA500 is from -40°C to 125°C .

8 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

8.1 Application Information

8.1.1 Reference Pin

The output voltage of the INA500 is developed with respect to the voltage on the reference pin (REF). Often in dual-supply operation, REF pin connects to the system ground. However, in single-supply operation, offsetting the output signal to a precise mid-supply level is useful and required (for example, 2.5V in a 5.0V supply environment). To accomplish this level shift, a voltage source must be connected to the REF pin to level-shift the output so that the INA can drive a single-supply ADC. This is accomplished using an external reference buffer configured in unity gain, voltage follower configuration as shown in [Figure 8-1](#).

Figure 8-1. INA500 with External Reference Buffer

8.2 Typical Applications

8.2.1 Battery Monitoring using Difference Amplifier

The INA500 is an integrated difference amplifier that processes large differential voltages while simultaneously rejecting larger common-mode voltages. The device offers a low power consumption of 13.5 μ A (typical) and has a smaller form factor.

With the specifications above, the device is a good fit for portable applications that are powered with single cell or coin-cell batteries. Often, these systems do not need sophisticated battery management technology but a solution that is rather simple and small-size. In a few other systems, battery monitoring ICs are preferred to perform sophisticated functions including cell balancing, protection, voltage and current sensing and so forth but these systems still need a secondary level of protection or redundancy with a simpler and reliable solution for system integrity. It is in these scenarios, the amplifier based battery monitoring application shown below could be quite useful.

Figure 8-2 shows an example circuit that monitors a 12V battery voltage and interfaces it to an ADC that is powered using a 3V power supply. The main advantage for using difference amplifiers in this application is the elimination of ground bounce, which is a common-mode signal, when measuring the battery voltage. These ground bounce signals, when not rejected, are capable of causing errors in the range of few milli-volts to tens or hundreds of milli-volts.

Figure 8-2. Battery Monitoring Circuitry

8.2.1.1 Design Requirements

For this application, the design requirements are as provided in [Table 8-1](#).

Table 8-1. Design Requirements

DESCRIPTION	VALUE
Battery voltage	$V_{BAT} = 12V$
Supply voltage	$V_S = 3V$
Full-scale range of ADC	$V_{ADC(fs)} = V_{OUT} = 3V$
Quiescent current	$30\mu A$
Accuracy	8 bits
Common-mode rejection ratio	60dB or a factor of 1000

8.2.1.2 Detailed Design Procedure

This section provides basic calculations for the INA500C difference amplifier with respect to the given design requirements.

Firstly, the 12V battery voltage needs to be attenuated and interfaced to ADC reference voltage of 3V. This requires a $G = \frac{1}{4}$ or 0.25V/V and hence INA500C is chosen for the application.

$$\text{Gain} = \frac{V_{BAT}}{V_{ADC}} = \frac{12}{3} = \frac{1}{4} = 0.25 \quad (1)$$

The maximum common-mode range of INA500 in a gain of 0.25 is given by,

$$V_{CM_MAX} = 5*(V+) - 4*V_{REF} = 5*3 - 4*0 = 15V \quad (2)$$

This is well within the requirements for sensing 12V battery voltage and the common-mode rejection ratio (CMRR) referred to output is a minimum of 62dB as per [Electrical Characteristics](#) table. This corresponds to an attenuation factor of $\frac{1}{1250}$. This helps attenuate the 100mV common-mode error shown in the [Figure 8-2](#) to just 80μV.

$$CM_{Err_RTO} = \frac{100mV}{1250} = 80\mu V, \text{ when referred to INA500C's output.} \quad (3)$$

Next, INA500C has input impedance of 1.68MΩ as per the [Electrical Characteristics](#) table. Assuming a full battery voltage of 12V, the input current through the resistor is calculated as,

$$I_{RIN} = \frac{V_{BAT}}{R_{IN}} = \frac{12}{1.68M} = 7.2\mu A \quad (4)$$

This input current through the resistor adds to the amplifier quiescent current of 13.5μA resulting in a total current consumption of 20.7μA, which meets the design requirement of 30μA.

$$I_{total} = I_{RIN} + I_Q \quad (5)$$

The next step is to calculate the other error sources in the application. Maximum gain error and offset error as per [Electrical Characteristics](#) table are 0.05% and 2.5mV for the Gain = 0.25V/V.

$$\text{Total Error} = \sqrt{(0.0005*12)^2 + 0.0025^2} = 6.5mV \quad (6)$$

For an 8 bit, 3V ADC, V_{LSB} is calculated as,

$$V_{LSB} = \frac{3}{2^8} = 11.7mV \quad (7)$$

The total error of 6.5mV that was calculated is approximately 0.5LSB of ADC full scale voltage of 3V and hence meets the 8-bit accuracy requirement.

Note, that the errors across temperature are not calculated here but can be easily included in the error analysis based on the drift specifications provided in the [Electrical Characteristics](#) table as per the application's temperature requirements. These drift errors and noise often do not heavily affect the performance at 8 bit accuracy levels. Finally, calibration of offset and gain error can improve the accuracy beyond 10 to 12 bits as these factors can be the major sources of error in the application.

8.2.1.3 Application Curves

The following typical characteristic curve is for the circuit in [Figure 8-2](#).

Figure 8-3. Battery Input Voltage vs INA500C Output Voltage

8.3 Power Supply Recommendations

The nominal performance of the INA500 is specified with a supply voltage of $\pm 2.75V$ and midsupply reference voltage. The device also operates using power supplies from $\pm 0.85V$ (1.7V) to $\pm 2.75V$ (5.5V) and non-midsupply reference voltages with good performance. Many specifications apply from $-40^{\circ}C$ to $125^{\circ}C$. [Electrical Characteristics](#) presents parameters that can exhibit significant variance due to operating voltage or temperature.

TI highly recommends to add low-ESR ceramic bypass capacitors (C_{BYP}) between each supply pin and ground. Only one C_{BYP} is sufficient for single supply operation. Place the C_{BYP} as close to the device as possible to reduce coupling errors from noisy or high-impedance power supplies. Please ensure the power supply trace routes through C_{BYP} before reaching the amplifier power supply terminals. For more information, see [Layout Guidelines](#).

Parameters can vary with operating voltage and reference voltage. [Typical Characteristics](#) section can be used to estimate the performance outside of the [Electrical Characteristics](#) section.

8.4 Layout

8.4.1 Layout Guidelines

Attention to good layout practices is always recommended. For best operational performance of the device, use the following PCB layout practices:

- Ensure that both input paths are well-matched for source impedance and capacitance to avoid converting common-mode signals into differential signals.
- Use bypass capacitors to reduce the coupled noise by providing low-impedance power sources local to the analog circuitry.
 - Connect low-ESR, 0.1 μ F ceramic bypass capacitors between each supply pin and ground, placed as close to the device as possible. A single bypass capacitor from V+ to ground is applicable for single-supply applications.
- Route the input traces as far away from the supply or output traces as possible to reduce parasitic coupling. If these traces cannot be kept separate, crossing the sensitive trace perpendicular is much better than crossing in parallel with the noisy trace.
- Place the external components as close to the device as possible.
- Keep the traces as short as possible.

8.4.2 Layout Example

Figure 8-4. Example Schematic and Associated PCB Layout

9 Device and Documentation Support

9.1 Device Support

9.1.1 Development Support

- [SPICE-based analog simulation program — TINA-TI software folder](#)
- [Analog Engineers Calculator](#)

9.1.1.1 PSpice® for TI

PSpice® for TI is a design and simulation environment that helps evaluate performance of analog circuits. Create subsystem designs and prototype solutions before committing to layout and fabrication, reducing development cost and time to market.

9.2 Documentation Support

9.2.1 Related Documentation

For related documentation see the following:

- Texas Instruments, [EMI Rejection Ratio of Operational Amplifiers application note](#)

9.3 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on [ti.com](https://www.ti.com). Click on *Notifications* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

9.4 Support Resources

TI E2E™ support forums are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

9.5 Trademarks

TI E2E™ is a trademark of Texas Instruments.

Bluetooth® is a registered trademark of Bluetooth SIG, Inc.

PSpice® is a registered trademark of Cadence Design Systems, Inc.

All trademarks are the property of their respective owners.

9.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

9.7 Glossary

TI Glossary

This glossary lists and explains terms, acronyms, and definitions.

10 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision A (January 2024) to Revision B (March 2024)	Page
• Changed the status of DBV, DCK packages of INA500B and INA500C from: <i>preview</i> to: <i>active</i>	2
• Added <i>Electrical Characteristics</i> table for gain options of 0.5 and 0.25.....	4

-
- Added *Typical Characteristics* graphs for the 0.5 and 0.25 gain options..... [11](#)
-

Changes from Revision * (December 2023) to Revision A (January 2024)	Page
--	------

- | | |
|---|-------------------|
| • Added footnote for Reference gain error in Electrical Characteristics table,..... | 5 |

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "-" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
