About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

Related Documentation From Texas Instruments

1 Introduction

This chapter introduces the features, subsystems, and architecture of the J784S4 Processor Platform high-performance System-on-Chip (SoC).

Note

This document describes the Superset architecture, processors and peripherals of the J784S4 Family of SoCs, which are part of the K3 Multicore SoC architecture platform. The J742S2 Processor Family is a subset of the J784S4 Processor Family. Not all features are available on each family of devices. The superset J784S4 and J742S2 devices are available for preproduction software development. Software should constrain the features used to match the intended production device. For more information on the specific features, processors and peripherals available on a particular device, refer to the Device Comparison table in the corresponding device-specific Data sheet.

The J784S4 Processor Platforms are hereinafter commonly referred to as J784S4 *platform*, *device*, or *SoC*.

TI limits support for this family of SoCs to features that are supported via Software Development Kits (SDK). The SDK “build sheet” is available for download as part of each SDK and should be referenced to understand the subset of SoC hardware functionality that is available in software:

<https://www.ti.com/tool/PROCESSOR-SDK-J784S4>

<https://www.ti.com/tool/PROCESSOR-SDK-J742S2>

<https://www.ti.com/tool/PROCESSOR-SDK-AM69A>

<https://www.ti.com/toll/PROCESSOR-SDK-AM69>

This document describes the Superset features of the Modules integrated into this Device. See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

1.1 Device Overview

1.1.1 Device Overview Feature List

The TDA4VH and TDA4AH SoCs are targeted for automotive applications and aim to meet the complex processing needs of modern embedded products. They are designed as a high performance and highly integrated device architecture, providing significant levels of processing power, graphics capability, video and imaging processing, virtualization, and coherent memory support.

Key distinguishing device features:

- 64-bit architecture with virtualization and coherent memory support, which leverages full processing capability of 64-bit Arm® Cortex® -A72
- Integration of vision hardware processing accelerators to facilitate extensive processing requirements in low power budget for automotive ADAS , autonomous mobile robot, and edge AI applications
- Integration of multiple general-purpose microcontroller unit (MCU) clusters with a dual Arm® Cortex®-R5F MCU subsystem available for general purpose use as either two separate cores operating in lockstep, intended to help customers achieve functional safety goals for their end products
- Integration of multiple fixed and floating-point C71x Digital Signal Processors (DSP) that significantly boost power over a broad range of general signal processing tasks for both general applications and automotive functions which also incorporate advanced techniques to improve control code efficiency and ease of programming such as branch prediction, protected pipeline, precise exception and virtual memory management
- Multiple tightly coupled Matrix Multiplication Accelerators (MMA) that extend the C71x DSP architecture's scalar and vector facilities enabling deep learning and enhance vision, analytics and wide range of general applications. The achieved total TOPS (Tera Operations Per Second) performance significantly differentiates the device for single board computer in machine vision and deep learning applications
- Multi-display support, including flexibility to interface with different panel types (eDP, DSI, DPI) with multi-layer hardware composition
- Integration of hardware features that help applications to achieve functional safety mechanisms
- Robust security architecture with sandboxed Security Controller managing all secure configurations with high performance client-server messaging scheme between secure Security Controller and all cores
- Simplified solution for power supply management, enabling lower cost system solution (on-die bias LDOs and power good comparators for minimal power sequencing requirements consistent with low cost supply design)

Processor cores:

- Up to Four C7x floating point, vector DSP, up to 1.0 GHz, 320 GFLOPS, 1024 GOPS
- Up to Four Deep-learning matrix multiply accelerator (MMA), up to 32 TOPS (8b) at 1.0 GHz
- TwoVision Processing Accelerators (VPAC) with Image Signal Processor (ISP) and multiple vision assist accelerators
- Depth and Motion Processing Accelerators (DMPAC)
- Eight Arm® Cortex®-A72 microprocessor subsystem at up to 2.0 GHz
 - 2MB shared L2 cache per quad-core Cortex®-A72 cluster
 - 32KB L1 DCache and 48KB L1 ICache per Cortex®-A72 core
- Eight Arm® Cortex®-R5F MCUs at up to 1.0 GHz
 - 16K I-Cache, 16K D-Cache, 64K L2 TCM
 - Two Arm® Cortex®-R5F MCUs in isolated MCU subsystem
 - Six Arm® Cortex®-R5F MCUs in general compute partition
- GPU IMG BXS-64-4, 256kB Cache, up to 800 MHz, 50 GFLOPS, 4 GTexels/s
- Custom-designed interconnect fabric supporting near max processing entitlement

Memory subsystem:

- Up to 8MB of on-chip L3 RAM with ECC and coherency
 - ECC error protection
 - Shared coherent cache
 - Supports internal DMA engine
- Up to Four External Memory Interface (EMIF) module with ECC

- Supports LPDDR4 memory types
- Supports speeds up to 4266 MT/s
- Up to 4x32-b bus with inline ECC up to 68 GB/s

Functional Safety:

- **Functional Safety-Compliant** targeted (on select part numbers)
 - Developed for functional safety applications
 - Documentation available to aid ISO 26262 functional safety system design up to ASIL-D/SIL-3 targeted
 - Systematic capability up to ASIL-D/SIL-3 targeted
 - Hardware integrity up to ASIL-D/SIL-3 targeted for MCU Domain
 - Hardware integrity up to ASIL-B/SIL-2 targeted for Main Domain
 - Safety-related certification
 - ISO 26262 planned
- AEC-Q100 qualified on part number variants ending in Q1

Device security (on select part numbers):

- Secure boot with secure runtime support
- Customer programmable root key, up to RSA-4K or ECC-512
- Embedded hardware security module
- Crypto hardware accelerators – PKA with ECC, AES, SHA, RNG, DES and 3DES

High speed serial interfaces:

- Integrated ethernet switch supporting up to 8 (TDA4xH) or 4 (TDA4xP) external ports
 - Two ports support 5Gb, 10Gb USXGMII or 5Gb XFI
 - All ports support 1Gb, 2.5Gb SGMII
 - All ports can support QSGMII. A maximum of 2 (TDA4xH) or 1 (TDA4xP) QSGMII can be enabled and uses all 8 or 4 internal lanes
- Up to 4x2-L/2x4L (TDA4xH) or 2x2L/1x4L (TDA4xP) PCI-Express® (PCIe) Gen3 controllers
 - Gen1 (2.5GT/s), Gen2 (5.0GT/s), and Gen3 (8.0GT/s) operation with auto-negotiation
- One USB 3.0 dual-role device (DRD) subsystem
 - Enhanced SuperSpeed Gen1 Port
 - Supports Type-C switching
 - Independently configurable as USB host, USB peripheral, or USB DRD
- Three CSI2.0 4L RX plus Two CSI2.0 4L TX

Ethernet

- Two RGMII/RMII interfaces

Automotive interfaces:

- Twenty Modular Controller Area Network (MCAN) modules with full CAN-FD support

Display subsystem:

- Two DSI 4L TX (up to 2.5k)
- One eDP/DP interface with Multi-Display Support (MST)
- One DPI

Audio interfaces:

- Five Multichannel Audio Serial Port (MCASP) modules

Video acceleration:

- H.264/H.265 Encode/Decode, up to 960MP/s (TDA4xH) or 480MP/s (TDA4xP)

Flash memory interfaces:

- Embedded MultiMediaCard Interface (eMMC™ 5.1)
- One Secure Digital® 3.0/Secure Digital Input Output 3.0 interfaces (SD3.0/SDIO3.0)
- Universal Flash Storage (UFS 2.1) interface with two lanes
- Two simultaneous flash interfaces configured as
 - One OSPI or HyperBus™ or QSPI flash interfaces, and
 - One QSPI flash interface

Note

The supported set of features and peripherals is device part number dependent. For more information, see the device-specific Datasheet.

1.2 Module Descriptions**1.2.1 Arm Cortex-A72 Subsystem**

Each core of the quad-core Arm Cortex-A72 Microprocessor Units (MPU) has the following main features:

- Full Armv8-A architecture compliancy
- Advanced Single Instruction Multiple Data (SIMD) and floating point extension (Arm Neon™)
- Armv8 cryptography extensions
- Superscalar, variable length, out-of-order pipeline
- 48KB program and 32KB data Level 1 (L1) Cache
- 2MB shared Level 2 (L2) Cache
- ECC protection for L1 data cache and L2 Cache
- Parity protection for L1 Instruction Cache
- Dynamic branch prediction with Branch Target Buffer (BTB) and Global History Buffer (GHB) RAMs, return stack, and indirect predictor
- Arm General Interrupt Controller (GICv3) architecture
- Support timers for each Cortex-A72 core
- 512-bit wide, synchronous or asynchronous VBUSM.C master interface
- Arm CoreSight™ Debug and Trace Architecture
- Advanced power management for low power optimization
- SoC level dedicated RTI windowed watchdog timer per core

1.2.2 Arm Cortex-R5F Processor

Each instance of the dual-core Arm Cortex-R5F processor supports the following main features:

- Armv7-R architecture
- Two modes of operation, boot-time configurable:
 - Split mode: two independently operating cores (asymmetric multi processing, no coherence)
 - Lock (lockstep) mode: one main operating core with the other operating in lockstep
 - Boot-time configurable to be in split or lock mode
- 32KB instruction and 32KB data SECDED ECC protected L1 cache per core
- 64KB of Tightly Coupled Memory (TCM) per core in a split mode
- 128KB of TCM for CPU0 in lock mode

- Full-Precision Floating Point (VFPv3)
- 8 breakpoints, 8 watch points
- 16-region Memory Protection Unit (MPU)
- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface
- Performance Monitoring Unit (PMU)
- 32-bit to 48-bit Region-based Address Translation (RAT) on memory access masters
- Integrated Vectored Interrupt Manager (VIM)
- Interfaces:
 - 64-bit VBUSM master pair (1 read, 1 write) for L3 memory accesses (per core)
 - 64-bit VBUSM slave for TCM access (per core)
 - 32-bit VBUSM master pair (1 read, 1 write) for peripheral access
 - 32-bit VBUSP master for peripheral access (per core)
 - 32-bit VBUSP slave configuration port (per core)
 - 32-bit VBUSP slave debug port

1.2.3 C71x DSP Subsystem

Each instance of the C71x DSP supports the following main features:

- True 64-bit C7120 CPU core with:
 - Instruction fetch unit
 - Instruction dispatch unit
 - Instruction decode unit
 - CPU dual data path with one 64-bit scalar side (side A) and one 512-bit vector side (side B)
 - CPU control logic
 - Test, debug, and interrupt logic
 - Enhanced Instruction Set Architecture (ISA)
 - OpenCL features
- Matrix Multiply Accelerator (MMA) as a special functional unit in C71x CorePac CPUs
- L1 Program Memory Controller (PMC) with 32KB L1P memory, all cache
- L1 Data Memory Controller (DMC) with 48KB L1D memory, configurable as cache and/or SRAM
- L2 Unified Memory Controller (UMC) with 512KB L2 memory, configurable as cache and/or SRAM
- Multi-dimensional Streaming Engine (SE) - flexible, high bandwidth mechanism for reading large quantities of data into C71x DSP
- CorePac Memory Management Unit (CMMU)
- Power-down controller
- Debug capabilities

1.2.4 Graphics Processing Unit

The Graphics Processing Unit (GPU) which accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics and compute applications. It supports the following main features:

- Architecture based on IMG BXS-64-4 with 256KB cache
- OpenGL 3.x and Vulkan API support
- Up to 50 GFLOPS
- Support for GPU virtualization
- Support for HyperLane Technology, with 8 HyperLanes available

1.2.5 Video Accelerator

The Video Accelerator (CODEC) has the following main features, among others:

- Encode/Decode:
 - H.265/HEVC – Main and Main Still Picture Profile @L5.1 High-tier
 - H.264/AVC – Baseline/Constrained Baseline/Main/High Profiles Level @L5.2
 - Max resolution: 8192x8192
 - YUV420 video format
 - YUV422 video format (only encoder)

- 8-bit depth
- Encode, Decode or combination up to 4k60 total rate
- Up to 8x separate concurrent video encode, decode or combination (8x1080p30)

1.2.6 Vision Pre-processing Accelerator

The Vision Pre-processing Accelerator (VPAC) provides a set of common vision primitive functions, performing various pixel data processing tasks, such as: color processing and enhancement, noise filtering, wide dynamic range (WDR) processing, lens distortion correction, pixel remap for de-warping, on-the-fly scale generation, on-the-fly pyramid generation, and offloads these common tasks from the main SoC processors (ARM, DSP, etc.). The VPAC includes the following processing and infrastructure sub-modules:

- Vision Imaging Sub-System (VISS) which provides raw data image processing such as:
 - Wide Dynamic Range (WDR) merge
 - Defect Pixel Correction (DPC)
 - Lens Shading Correction (LSC)
 - Global/Local Brightness and Contrast Enhancement (GLBCE)
 - Advanced Spatial Noise Filter (NSF4V)
 - Edge Enhancement (EE)
 - Demosaicing
 - Color conversion
- Lens Distortion Correction (LDC) block, which provides data reading from memory (DDR or on-chip) and applies perspective transformation as well as correction of lens distortion (including fisheye lenses).
- Multi-Scalar (MSC) block reads data from memory (DDR or on-chip) to internal shared level 2 (SL2) memory and generates up to 10 scaled outputs from one or two inputs, with various scaling ratios.
- Noise Filter (NF) block reads data from memory (DDR or on-chip) to internal SL2 memory and does Bilateral filtering to remove noise.
- Hardware Thread Scheduler (HTS) provides inter-processor communication among various VPAC sub-modules (VISS, LDC, MSC and NF) as well as with the local DMA Engine (UTC).
- Internal Shared Level 2 (SL2) memory for data exchange across VPAC sub-modules (VISS, LDC, MSC and NF) and from DDR/MSMC, using the K3 Data Movement Architecture (DMA) mechanism
- Load/Store Engine (LSE) which performs data load and store tasks on a the SL2 memory for the hardware accelerator algorithm cores
- VISS to LDC direct OTF (On-the-Fly) for multi-camera
- YUV422 10 and 12 bit format support on all units except NF (e.g. LDC/MSC)
- Simultaneous visual (HV) and analytics (MV) output to system memory including L3 flex connect, saving need for additional read from system memory for HV+MV processing.
- Chromatic Aberration Correction (CAC) to support lower cost lens
- RGBIR support

1.2.7 Depth and Motion Perception Accelerator

The Depth and Motion Perception Accelerator (DMPAC) computes dense stereo depth maps (*depth*) and dense optical flow vectors (*motion*) from camera inputs. The stereo and optical flow processing is partitioned into two top level sub-blocks: the Dense Optical Flow (DOF) engine and the Stereo Disparity Engine (SDE). The DOF and SDE blocks share a common local memory, DMA, external messaging and control infrastructure. The DMPAC provides the following main features, among others:

- Image resolution up to 2MPix (maximum horizontal resolution up to 2048 pixels; maximum vertical resolution up to 1024 pixels)
- Maximum throughput up to 220MPix/sec for DOF, and up to 84-100MPix/sec for SDE
- Simultaneous operation of Stereo (1MPix@30fps) and Optical flow (1MP@30fps)
- 12-bit fully packed luminance data input pixel data format (other formats supported through conversion)
- Packed 16-bit (disparity) or 32-bit (flow vector) output data formats
- Shared Level 2 (SL2) memory sub-system, which serves the data transfer of the DOF and SDE blocks
- Unified Transfer Controller (UTC), which serves as a DMA engine
- Hardware Thread Scheduler (HTS) block for messaging and control mechanism
- Counter, Timer and System Event Trace (CTSET) module, which provides event tracing capability for the Stereo and Optical Flow hardware threads

1.2.8 Navigator Subsystem

The Navigator subsystem (NAVSS) can be used for efficient transfer of data support between software, firmware and hardware in all combinations. It consists of the following main modules:

- Unified DMA Controller with the following main modes and features:
 - K3 DMA Architecture compliant Tx/Rx port implementation
 - K3 DMA Architecture compliant Packet-Oriented DMA Functionality (UDMA-P)
 - K3 DMA Architecture compliant Third Party Channel Controller
 - K3 DMA Architecture compliant Unified Transfer Controller
 - K3 DMA Architecture compliant Unified DMA channels which all share the execution hardware using time division multiplexing
- Ring Accelerator provides hardware acceleration to enable straightforward passing of work between a producer and a consumer and has the following main features:
 - Supports 1024 independent memory-mapped ring structures
 - Supports various modes for each ring based on usage and compatibility
 - Provides 2-words deep shared incoming Transfer Response FIFO
 - Provides bit-wide source VBUSM read/write slave interface for accesses from DMA controller entities
- Proxy module with the following main features:
 - Provides proxy buffers to store large data bursts that a host can only access in smaller amounts
 - Keeps the large data coherent until the complete data has been accessed
 - Allows interleaved access between multiple hosts using multiple proxies
 - Supports a pre-configured number of target resources to proxy with pre-configured number of channels, size of each channel, and address offset per each target
- Secure proxy module is a modified version of the proxy module and in addition has the following main features:
 - Supports a number of threads, where each has their own independent proxy function
 - Supports a programmable fixed queue for each proxy thread
 - Supports multiple producers all writing to the same queue
 - Supports programmable thresholds for when to generate events
 - Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
- Interrupt Aggregator modules provide a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Main features are as follows:
 - 64-bit VBUSP slave using 64-bit registers
 - Provide a set of TI Interrupt Architecture compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks.
 - Provide a set of Global Event Input (GEVI) counters which can count events delivered via an ingress Event Transport Lane (ETL)
 - Provides a set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
 - Provides a set of GEVI 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces
- Peripheral Virtualization Unit (PVU) module which provides TLBs (Translation Look-aside Buffers) for static virtual address translation on a CBA VBUSM bus with the following main features:
 - Implements a channelized TLB for virtual address translation
 - Supports a pre-configured number of entries per TLB channel
 - Supports TLB chaining to extend the search but at a latency penalty
 - Supports a 48-bit address size
 - Supports page sizes of 4KB, 16KB, 64KB, 2MB, 32MB, 512MB, 1GB, and 16GB
 - Support TLBs in software mode, where they are maintained by software only
 - Produces a fault interrupt when the TLB misses or upon a permission error
- Mailbox module to facilitate the communication between the various on-chip processors of the device by providing a queued mailbox-interrupt mechanism with the following main features:
 - 12 clusters

- 32-bit message width
- Message reception and queue-not-full notification using interrupts
- Non-intrusive emulation
- Spinlock module (256 hardware semaphores) for synchronizing the processes running on multiple processors in the device.
- Timer Manager modules to support timing operations for the processes running on multiple processors, with the following main features:
 - 1024 × 32-bit RAM-based independent timers (2048 in total)
 - Event interface to an interrupt aggregation module in the NAVSS subsystem with events triggering when a timer expires or when an expired timer is reset or deactivated
 - Host access to determine which timer(s) expired
 - 32 registers with individual timeout status (one bit per timer)
 - Groups of 16 timers separated into pages of 4-K address space
 - Timer bits within each page to read expiration status for each timer when software only has access to that page
 - 10 µs time to cycle through all of the timers
 - Host access to reset individual timers
 - Periodic hardware timers – a timer may be set to automatically reprogram itself upon expiration without software intervention.
- Time Sync modules to facilitate host control of time sync operations, each with the following main features:
 - Supports a selection of multiple external clock sources
 - Software control of time sync events via interrupt or polling
 - Supports 8 hardware timestamp push inputs
 - Supports timestamp counter compare output
 - Supports timestamp counter bit output
 - Supports 6 timestamp generator function outputs
 - 32-bit and 64-bit timestamp modes
- Memory Cyclic Redundancy Check module used to perform CRC to verify the integrity of a memory system with the following main features:
 - Four channels to perform background signature verification on any memory subsystem
 - Data compression on 8-, 16-, 32-, and 64-bit data size
 - Dedicated CRC value register per channel which contains the pre-determined CRC value
 - Timed base event trigger from timer to initiate DMA data transfer
 - Programmable 20-bit pattern counter per channel to count the number of data patterns for compression
 - Three modes of operation: Auto, Semi-CPU, and Full-CPU
 - Timeout interrupt generation if CRC is not performed within the time limit
 - Per channel DMA request generation to initiate CRC value transfer

1.2.9 Region-based Address Translation Module

The Region-based Address Translation (RAT) module performs a region based address translation of a 32-bit input address into a 48-bit output address. The RAT provides the following main features:

- 16 regions with dedicated registers for attributes configuration:
 - Region base address
 - Region size
 - Translated base address
- Address translation for only enabled regions
- Region boundary crossing transactions error generation

1.2.10 Data Routing Unit

The Data Routing Unit (DRU) is a high bandwidth, flexible routing engine with programmable DMA transfer requests which enables performing of high speed data transfers between memory mapped slave endpoints, processor caches and shared caches. It behaves like a DMA transfer controller, moving data at MPU frequency and has the following main features:

- Programmable configuration registers for direct transfer request submission

- Read and write command queues
- Programmable priority for each queue
- Two dedicated ports (one read and one write) to generate independent read and write commands
- Support for region based and channelized firewall
- Independent 48-bit address fields for source and destinations
- Up to four dimensional data transfers
- Error detection and Correction
- CMMU support for IO virtualization
- Compression for DDR bandwidth reduction in CNN application and video stream data from VPAC

1.2.11 Display Subsystem

The Display Subsystem (DSS) is a flexible composition-enabled display subsystem that supports multiple high resolution display outputs. It consists of the following main modules:

- Display Controller (DISPC), with the following main features:
 - Support of multi-layer blending and transparency for each of display outputs
 - Supports write-back pipeline with scaling to enable memory-to-memory composition and/or to capture a display output for Ethernet video encoding
 - Supports gamma correction and programmable color control in both source and destination pipelines
 - Embedded DMA Controller with the following main features:
 - Support for 1D-only DMA transfers
 - Support for 48b addressable memory space
 - Support for memory fragmentation through external PAT at SoC level
 - Integrated shared buffer management for pipelines within the same DMA controller group
 - Programmable DMA requests management
 - Support for source image flip along X and Y-axis
 - Support for secure access to firewall protected frame buffer in DDR memory
 - Two input display processing Video Pipelines, each supporting:
 - Wide range of input RGB source pixel formats
 - Wide range of input YUV source pixel formats
 - Programmable poly-phase filter (scaler)
 - Programmable color space conversion
 - Programmable Brightness/Contrast/Hue/Saturation
 - Programmable Gamma Correction LUT
 - Luma Key generation
 - 10-bit processing pipeline
 - Two input display processing Video Lite Pipelines, each supporting:
 - Wide range of input RGB source pixel formats
 - Wide range of input YUV source pixel formats
 - YUV420 to YUV422 chroma up-sampling using an average filter
 - YUV422 to YUV444 chroma up-sampling using a 4-tap filter based on Catmull-Rom algorithm
 - Programmable color space conversion
 - Programmable Brightness/Contrast/Hue/Saturation
 - Programmable Gamma Correction LUT
 - Luma Key generation
 - 10-bit processing pipeline
 - One Write-back (WB) pipeline, supporting:
 - Wide range of destination RGB pixel formats
 - Wide range of destination YUV pixel formats
 - Programmable poly-phase filter (scaler)
 - Output capture and Memory-to-memory (M2M) operation modes
 - Four Overlay Managers (OVR), each supporting:
 - Input pixel format: ARGB48-12121212
 - Output pixel format: ARGB48-12121212

- Overlay of the input pipelines
- Up to 5 input layers blending
- Transparency color key
- Alpha blending support: Embedded pixel alpha (ARGB and RGBA), global pixel, and combination of global pixel and pixel alpha
- Z-order programmable (full flexibility)
- Color bar test pattern insertion
- Any overlay output can be selected to drive the Write-back pipeline
- Four Video Port (VP) display outputs, each supporting:
 - 36-bit per pixel on the RGB output interface
 - Independent programmable timing generator, supporting up to 600 MHz pixel clock video formats
 - Independent programmable 10-bit gamma correction
 - Independent programmable multiple cycles output format on 8/9/12/16-bit interface
 - Selection between RGB and YUV422 output pixel
 - Configurable VP output mode
- Internal diagnostic features:
 - Supports up to 4 programmable (position/size) check regions on the DISPC video port display outputs
 - Support for 1 check region on each input video pipeline output
 - MISR (Multiple Input Signature Register) used on each check region to perform data correctness check and/or freeze frame detection
- Local power features:
 - Low power saving modes
 - On-the-fly Dynamic Frequency Scaling (DFS) support
 - Capability to associate all buffers a single pipeline for a display self-refresh
- System interconnect ports:
 - Two 128-bit VBUSM master interfaces for data read/write
 - One 32-bit VBUSP slave interface for configuration
- Fram Buffer Decompression Core (FBDC), that performs a decompression on lossless compressed images on a tile-by-tile basis.
- MIPI Display Serial Interface (DSI) transmitter host controller, with the following main features:
 - Compliance with MIPI DSI 1.3.1 and previous protocol specifications
 - Compliance with Stereoscopic Display Format (SDF) specification
 - Video and command operational modes
 - Both burst and non-burst modes for video mode data transmission
 - Up to 4 virtual channels via command mode
 - Bi-directional communication and escape mode
 - Pixel clock rate range: 25-330 MHz
 - Programmable display resolutions
 - 16/18/24/30/36-bit RGB input data formats for video mode
 - RGB16, RGB18 packed, and RGB24 input data formats for command mode
 - All generic data types defined by MIPI
 - Display Command Set (DCS) transparent to the protocol engine
 - ECC on the APB interface
 - Data splitter for 2-,3-, or 4-data lane configuration
 - Connection to a single MIPI D-PHY complex I/O through an 8-bit Protocol Peripheral Interface (PPI)
 - Tearing effect (TE) input signals for command mode display
 - Bus contention recovery
 - Video mode pattern generator: color bar pattern image and D-PHY BET testing pattern
 - APB slave interface with 32-bit data and address for configuration
- The MIPI DSI Physical Layer (D-PHY) module with the following main features:
 - Compliance with MIPI D-PHY 1.2 physical layer interface specification and features
 - 1, 2 or 4 data lanes, in addition to clock signaling
 - Maximum data rate up to 2.5 Gbps per data lane
 - Protocol Peripheral Interface (PPI)

- HS continuous and burst mode
- Low-Power (LP), Ultra-Lower Power Mode (ULPM), and Shutdown modes
- Forward direction and reverse direction escape modes
- Automatic termination control in both high-speed and low-power modes
- Single 32-bit VBUSP slave interface
- Embedded DisplayPort (eDP) transmitter host controller with the following main features:
 - Compliance with VESA® DisplayPort™ (DP) 1.3 (with 1.4 DSC/FEC support) specification
 - Compliance with VESA Embedded DisplayPort (eDP) 1.4 specification
 - Static configuration of either DP or eDP mode
 - Link rates up to High Bit Rate 3 (HBR3)
 - Pixel clock rate range: 25-600 MHz
 - 8, 10, and 12 bpc (bits per component), in RGB/YCbCr444 colorimetry formats (CEA-861 compliant) and YCbCr422 (via simple decimation)
 - Data splitter for 1-, 2-, or 4-data lane configuration
 - Single Stream Transport (SST)
 - Multiple Stream Transport (MST)
 - High-bandwidth Digital Content Protection (HDCP) data encryption via an embedded HDCP core
 - Display Stream Compression (DSC) encoded stream data transport via an embedded DSC core
 - Forward Error Correction (FEC) encoder with/without DSC enabled in DP mode
 - Single Stream Transport (SST)
 - Audio transport features
 - Metadata transport via Main Stream Attribute (MSA) packet or via SDP
 - APB slave ports for TX/PHY controller configuration
 - SAPB (secure) slave port for secure connection
 - Video source muxing options
 - One 32-bit VBUSP slave interface used for configuration
 - ECC on the critical memories
 - Parity check on the configuration interface
 - Encoder self-check diagnostics support in the DSC core
 - Injection of ECC and parity errors
- eDP (Physical Layer) SERDES and Aux PHY modules with the following main features:
 - DP1.3, HBR3 and eDP1.4a HBR3 throughput
 - 1, 2, or 4 lanes at 1.62Gbps, 2.7Gbps, 5.4Gbps, and 8.1Gbps per lane
 - Additional link rates (2.16, 2.43, 3.24, 4.32Gbps) per lane in eDP mode
 - Reduced differential voltage swing (0.2/0.25/0.30/0.35/0.40/0.45) in eDP mode
 - Hot Plug Detect (HPD) for connection detection and interrupt from sink
 - Integrated Low Jitter, Fixed Bandwidth PLL
 - DisplayPort physical layer functionalities:
 - Scrambler
 - 8/10-bit encoder (within the eDP transmitter)
 - Inter Lane Skew Insertion
 - Training Pattern Generation – TPS1,2,3,4 PRBS7 and 80-bit custom training pattern generation (bypassing the scrambler and encoder)
- 1 Mbps AUX PHY for link training, DPCD register access, HDCP authentication and EDID access

1.2.12 Camera Subsystem

Camera Subsystem unites three camera streaming interfaces – receiver and transmitter, allowing the device to stream video inputs from multiple cameras to the video processing accelerator (VPAC) or to internal memory and to output CSI-2 protocol image data to any device that supports MIPI CSI-2 protocol. Main modules are as follows:

- Camera Streaming Interface Receiver (CSI_RX_IF) with the following main features:
 - Compliant to MIPI CSI-2 v1.3+ and MIPI CSI-2 v2.0
 - Supports up to 16 virtual channels per input
 - Supports one 4MP camera or eight 2MP camera streams

- Supports data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connections to MIPI D-PHY Receiver (DPHY_RX)
- Over 25 different programmable formats including YUV420, YUV422, RGB, Raw, and User Defined
- Supports four independent (simultaneous) output streams:
 - Two VP 32-bit streams to VISS inputs of VPAC image processing accelerator
 - One (up to 4 channels) PPI 16-bit pixel retransmission interface to Camera Streaming Interface Transmitter (CSI_TX_IF)
 - One (up to 32 Channels) DMA interface through a 128-bit Packet Streaming Interface Link (PSI_L) connection to NAVSS for transfers to memory:
- Functional and data path error interrupts
- ECC support
- MIPI D-PHY Receiver (DPHY_RX) with the following main features:
 - Allows the device to input video streams from external sensor cameras and other CSI2 compliant sources
 - Compliant to MIPI D-PHY standard v1.2
 - Supports up to 4 data and 1 clock lanes
 - Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
 - Clock lane Control / Interface logic type: CIL-SCNN for HS and low power receiving
 - Data lane Control / Interface logic type: CIL-SFAN for HS and low power receiving
 - Data lanes can be independently operated in HS or ULP mode
 - Swapping of DP/DN signals within each clock/data pair
- Camera Streaming Interface Transmitter (CSI_TX_IF) with the following main features:
 - Compliant to MIPI CSI-2 v1.3+, MIPI CSI-2 v2.0, and MIPI D-PHY v1.2
 - Data rate up to 2.5 Gbps per lane (wire rate)
 - Supports 1, 2, 3, or 4 Data Lane connections to MIPI D-PHY Transmitter (DPHY_TX)
 - Over 25 different programmable formats including YUV420, YUV422, RGB, Raw, and User Defined
 - Support of 16 virtual channels
 - Support of four configurable input streams

1.2.13 Shared D-PHY Transmitter

The DPHY_TX module provides an option for video output interfacing by implementing a four lane, MIPI D-PHY Transmitter. DPHY_TX module supports the following main features:

- Compliancy to MIPI D-PHY Standard version 1.2
- Supports up to 4 data lanes
- Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
- Supports Escape mode
- Data Lanes can be independently operated in HS or ULP mode
- Includes a CMN block with reference generators / resistor calibration and an integrated PLL
- Fault detection

1.2.14 Central Multicore Shared Memory Controller

Central Multicore Shared Memory Controller (MSMC) provides high-bandwidth resource access both to and from all of the connected processing elements and the rest of the system and supports the following main features:

- 8MB (4 banks x 2MB) SRAM with ECC
- 512-bit processor port bus and 40-bit physical address bus
- Coherent unified bi-directional interfaces to connect to processors or device masters
- One infrastructure master interface
- Single external memory master interface
- Support of distributed virtual system
- Bandwidth management with starvation bound
- Two-level Quality-of-Service (QoS) support for real-time/non-real-time split
- Security firewall for SRAM/cache and external memory
- ECC error protection
- Trace and debug features
- Support of dynamic clock gating on all logic units

1.2.15 Local C7/MMA Multicore Shared Memory Controller

Local C7/MMA Multicore Shared Memory Controller (C7/MMA MSMC) provides high-bandwidth resource access both to and from each C7/MMA instance and the Central MSMC system and supports the following main features:

- 3MB Extended L2 SRAM with ECC
- 512-bit processor port bus and 40-bit physical address bus
- Closely coupled to C1/MMA with one local MSMC per C7/MMA instance
- All local MSMC instances connect to simple 512b MSMC crossbar (with no memory) to connect all C7/MMA instances to one Central MSMC port

1.2.16 DDR Subsystem

The DDR Subsystem (DDRSS) is used as an interface to external SDRAM devices which can be utilized for storing program or data. DDRSS provides the following main features:

- Support of LPDDR4 memory type
- 32-bit memory bus interface with in-line ECC
- Up to 8 GB per DDRSS across 2 ranks (4 GB per rank)
- System bus interface: little endian only with 256-bit data width
- Configuration bus Interface: little endian only with 32-bit data width
- Support of dual rank configuration
- Support of automatic idle power saving mode when no or low activity is detected
- Class of Service (CoS) - three latency classes supported
- Prioritized refresh scheduling
- Statistical counters for performance management

1.2.17 General Purpose Input/Output Interface

The General Purpose Input/Output (GPIO) modules provide dedicated general-purpose pins that can be configured as either inputs or outputs. Modules main features are:

- Support of 9 banks x 16 GPIO pins
- Support of up to 9 banks of interrupt capable GPIOs
- Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO pin
- Set/clear functionality per individual GPIO pin

1.2.18 Inter-Integrated Circuit Interface

The multi-master Inter-Integrated Circuit (I2C) interfaces support the following main features:

- Compliancy to the Philips I2C-bus specification version 2.1
- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- Support of multi-master transmitter/slave receiver and receiver/slave transmitter modes
- Built-in FIFOs with programmable size of 8 to 64 bytes for buffered read or write
- 8-bit-wide data access
- Support of Auto Idle, Idle Request/Idle Acknowledge handshake, and Asynchronous Wakeup mechanisms
- Low power consumption

1.2.19 Improved Inter-Integrated Circuit Interface

The multi-master Improved Inter-Integrated Circuit (I3C) module supports the following main features:

- Supports Single Data Rate (SDR) and High Data Rate – Dual Data Rate (HD-DDR) communication modes
- Support of Common Command Codes (CCC)
- Hot-Join capability
- In Band Interrupts (IBI)
- Support of Dynamic Address Assignment (DAA)
- Support of Static Addressing (SA)
- FIFO Buffers
- Registers to store the parameters for the response to an IBI interrupt from a number of slaves

1.2.20 Multi-channel Serial Peripheral Interface

The Multi-channel Serial Peripheral Interface (MCSPI) module supports the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of MCSPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Support of different master multichannel modes
- Single interrupt line for multiple interrupt source events
- Support of start-bit write command
- Support of start-bit pause and break sequence
- Built-in FIFO available for a single channel

1.2.21 Universal Asynchronous Receiver/Transmitter

The configurable Universal Asynchronous Receiver/Transmitter (UART) interface supports the following main features:

- 16C750-compatible
- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- Baud rates up to 3.6 Mbps with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

1.2.22 Peripheral Component Interconnect Express Subsystem

The Peripheral Component Interconnect express (PCIe) subsystem with shared SerDes lines provides the following main features:

- Compliant to PCI-Express® Base Specification, Revision 4.0 (Version 0.7)
- 4-lane configuration with up to 8.0 Gbps/lane (Gen3). Can support up to 4x2 or 2x4 lanes.
- Gen3 (8 Gbps 128/130-bit encoding), Gen2 (5 Gbps 8/10-bit encoding), and Gen1 (2.5 Gbps 8/10-bit encoding) with auto-negotiation
- Dual mode: Root Port (RP) or End Point (EP) operation modes, selectable via bootstrap pins
- Dynamic PIPE width change when switching between Gen1/2/3 modes
- Constant 32-bit PIPE width for Gen1/2/3 modes
- Maximum payload size of 256 bytes
- Maximum remote read request size of 4KB
- Single-root I/O Virtualization (SR-IOV) with Physical Functions (PF) and Virtual Functions (VF) in End Point mode
- Maximum number of non-posted outstanding transactions: 32
- Resizable Base Address Registers (BAR) capability
- Separate Reference Clock with Independent Spread (SRIS)
- Legacy, MSI and MSI-X Interrupt Support
- 32 outbound address translation regions
- Precision time measurement (PTM)

1.2.23 Universal Serial Bus (USB) Subsystem

The Universal Serial Bus (USB) subsystem with integrated PHY has the following main features:

- Dual-Role Device (DRD) capability
- Compliance with USB 3.1 Gen1 Specification
- Support of Peripheral (aka Device) mode at Super Speed (SS at 5 Gbps), High Speed (HS at 480 Mbps), and Full Speed (FS at 12 Mbps)
- Support of Host mode at SS (5 Gbps), HS (480 Mbps), FS (12 Mbps), and Low Speed (LS at 1.5 Mbps)
- Support of Host Negotiation Protocol (HNP)
- Support of USB3 low power protocol states (U0, U1, U2, and U3)

- USB instance contains a single xHCI compliant with xHCI 1.0 specification with internal DMA controller
- ECC on internal RAMs
- Embedded USB 2.0 PHY

1.2.24 SerDes

The Serializer/Deserializer (SERDES) Multi-protocol Multi-link modules support the following main blocks:

- Quad lane PHY with common module for peripheral and Tx clocking handling
- Physical coding sub-block for data translation from/to the parallel interface, as well as data encoding/decoding and symbol alignment
- MUX module for device interfaces multiplexing into three SERDES lanes (Tx and Rx)
- A wrapper for sending control and reporting status signals from the SerDes and muxes

1.2.25 General Purpose Memory Controller with Error Location Module

The General-Purpose Memory Controller (GPMC) with Error Location Module (ELM) is dedicated for interfacing with external memory devices and has the following main features:

- Support of 8- or 16-bit-wide data path to external memory devices
- Supports up to 4 independent chip-select regions of programmable size and programmable base addresses on 16MB, 32MB, 64MB, or 128MB boundary in a total address space of 1GB
- Support of the following wide range of external memories/devices:
 - Asynchronous or synchronous 8-bit wide memory or device (non-burst device)
 - Asynchronous or synchronous 16-bit wide memory or device
 - 16-bit non-multiplexed NOR flash device
 - 16-bit address and data multiplexed NOR flash device
 - 8-bit and 16-bit NAND flash device
 - 16-bit pseudo-SRAM (pSRAM) device
- Supports various interface protocols when communicating with external memory or external devices:
 - Asynchronous read/write access
 - Asynchronous read page access (4, 8, and 16 Word16)
 - Synchronous read/write access
 - Synchronous read burst access without wrap capability (4, 8, and 16 Word16)
 - Synchronous read burst access with wrap capability (4, 8, and 16 Word16)
- Supports on-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- ELM module which used in a conjunction with the GPMC and provides ECC calculation (up to 16-bit) for NAND support and ability to work in both page-based and continuous modes, has the following main features:
 - 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
 - Eight simultaneous processing contexts
 - Page-based and continuous modes
 - Interrupt generation on error-location process completion

1.2.26 Multimedia Card/Secure Digital Interface

The Multimedia Card/Secure Digital (MMCSD) controller supports the following main features:

- 8-bit or 4-bit wide data bus, depending on instance
- Support of eMMC5.1 Host Specification (JESD84-B51)
- Support of SD Host Controller Standard Specification - SDIO 3.00
- Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3
- eMMC Electrical Standard 5.1 (JESD84-B51)
- Multimedia card features:
 - Backward compatible with earlier eMMC standards
 - Legacy MMC SDR: 1.8 V, 8/4/1-bit bus width, 0-25 MHz, 25/12.5/3.125 MB/s
 - High Speed SDR: 1.8 V, 8/4/1-bit bus width, 0-50 MHz, 50/25/6.25 MB/s
 - High Speed DDR: 1.8 V, 8/4-bit bus width, 0-50 MHz, 100/50 MB/s

- HS200 SDR: 1.8 V, 0-200 MHz, 8/4-bit bus width, 200/100 MB/s
- SD card support: SDIO, SDR12, SDR25, SDR50, DDR50
- System bus interface: CBA 4.0 VBUSM master port with 64-bit data width and 64-bit address, little endian only
- Configuration bus interface: CBA 4.0 VBUSM with 32-bit data width, 32-bit aligned accesses only, linear incrementing addressing mode, little endian only

1.2.27 Universal Flash Storage Interface

Device MAIN domain supports one standard-based serial interface engine - Universal Flash Storage (UFS) interface with an integrated M-PHY. UFS provides the following main features:

- Support of Universal Flash Storage Host (UFS2.1, JESD220C)
- Support of Universal Flash Storage Host Controller Interface (UFSHCI, JESD223C)
- Support of UFS interconnect - MIPI UniPro (v.1.60, 2013) and MIPI M-PHY (v3.1, 2014)
- Supports speeds 1.46 Gbps (Gear 1), 2.91 Gbps (Gear 2) and 5.83 Gbps (Gear 3), 2-lanes
- Support of all UFS mandatory SCSI commands required by JEDEC specification
- Master bus Interface: one 64-bit master interface for data transfers, 48-bit address width, embedded
- DMA within the host controller with support of little-endian mode only
- Configuration Bus Interface: one 32-bit slave interface for configuration access, support of linear incrementing addressing mode and only aligned accesses
- ECC support on internal RAMs
- M-PHY Features: supports reference clocks of 19.2 MHz and 26 MHz

1.2.28 Enhanced Capture Module

The Enhanced Capture (ECAP) module provides accurate timing for different events. When not being used for event capture, its resources can be used to generate a single channel of asymmetrical PWM waveforms (configurable as either one capture input, or as one auxiliary PWM output). The ECAP module supports the following main features:

- 32-bit time base counter
- 4 x 32 bits event time-stamp capture registers
- 4 stage sequencer (Mod4 counter), synchronized to external events
- Independent edge polarity selection for up to four sequenced time-stamp capture events
- Input capture signal pre-scaling (from 1 to 16)
- Interrupt capabilities on any of the four capture events
- Support of different capture modes (single shot capture, continuous mode capture, absolute timestamp capture or delta mode time-stamp capture)

1.2.29 Enhanced Pulse-Width Modulation Module

The Enhanced Pulse-Width Modulation (EPWM) module supports the following main features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two independent PWM outputs that can be used in different configurations (with single-edge operation, with dual-edge symmetric operation or one independent PWM output with dual-edge asymmetric operation)
- Asynchronous override control of PWM signals through software
- Programmable phase-control support for lag or lead operation relative to other EPWM modules
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions
- Events enabling to trigger both CPU interrupts and start of ADC conversions

1.2.30 Enhanced Quadrature Encoder Pulse Module

The 32-bit Enhanced Quadrature Encoder Pulse (EQEP) module for position, speed, and frequency measurements supports the following main features:

- Input synchronization
- Three stage/six stage digital noise filter
- Quadrature decoder unit
- Position counter and control unit for position measurement

- Quadrature edge capture unit for low speed measurement
- Unit time base for speed/frequency measurement
- Watchdog timer for detecting stalls

1.2.31 Controller Area Network

The Controller Area Network (MCAN) interface supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications and has the following main features:

- Conforms with CAN Protocol version 2.0 part A, B and ISO 11898-1:2015
- Full CAN FD (up to 64 data bytes) support
- SAE J1939 support
- AUTOSAR support
- Up to 32 dedicated transmit buffers and 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit event FIFO, up to 32 elements
- Up to 128 filter elements
- Maskable interrupts, two interrupt lines
- Timestamp Counter

1.2.32 Audio Tracking Logic

The Audio Tracking Logic (ATL) module, which is used by HD Radio™ applications to synchronize the digital audio output to the baseband clock, supports the following main features:

- Contains four ATL instances, for HD Radio support and asynchronous sample rate conversion assistance
- Each instance tracks the time error between two syncs (local Audio Word Select [AWS] and Baseband Word Select [BWS])
- Each instance selects between 8 mux choices for BWS and 8 mux choices for AWS
- Each instance generates modulated ATCLK clock signals with software-initiated pulse stealing
- Selection between interface or functional clock to run error counting timers and to derive modulated clock outputs
- Clock and reset management: receives clock and reset signals from the device PSC module
- Hardware reset
- Local software reset

1.2.33 Multi-channel Audio Serial Port

The Multi-channel Audio Serial Ports (MCASP) is a general purpose audio serial port, useful for Time-Division Multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an inter-component Digital audio Interface Transmission (DIT). The MCASP module has the following main features:

- Connection to audio Analog-to-Digital Converters (ADC), Digital-to-Analog Converters (DAC), codec, digital audio interface receiver (DIR), and Sony/Philips Digital Interface (S/PDIF) transmit physical layer components
- Support of Time Division Multiplexed (TDM) interface, Inter-IC Sound (I2S) standard, and similar bit stream formats
- Integrated Digital Audio Interface Transmitter (DIT) with enhanced channel status/user data RAM and support of S/PDIF, IEC60958-1, and AES-3 formats
- Independent serializer for each AXRx channel of each MCASP module
- A single 32-bit buffer per serializer for transmit and receive operations
- Support for two DMA requests (one per direction)
- One transmit and one receive interrupt requests common for all serializers
- Two independent clock generator modules for transmit and receive allowing the MCASP to receive and transmit at different rates
- Support of up to 16 serial data pins

1.2.34 Timers

There are three different types of timer modules:

- The Global Time Counter (GTC) module can be used for time synchronization and debug trace time stamping with the following main features:
 - 64-bit up counter
 - No rollover during the lifetime of the device
 - Compatible with Armv8 system counter requirements
 - Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
 - Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols
- The Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module providing timer functionality for operation systems and benchmarking code with the following main features:
 - Two independent 64 bit counter blocks
 - Four configurable compare registers for generating operating system ticks
 - Free running counter 0 can be incremented by either the internal prescale counter or by an external event
 - Selectable RTI clock input (derived from any of the available clock sources)
 - Fast enabling/disabling of events
- The Timer module with support of the following main features:
 - Free running 32-bit upward counter
 - Generates a 1-ms tick with a 32.768 kHz functional clock
 - Interrupts generated on overflow, compare and capture
 - Supported modes of operation: compare and capture, auto-reload and start-stop
 - Programmable divider clock source (2^n , where $n = [0-8]$)
 - Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
 - On-the-fly read/write register (while counting) for systems operation and benchmarking code

1.2.35 Internal Diagnostics Modules

Internal diagnostics modules provide monitoring and diagnostic functions required to achieve certain safety compliance levels:

- Dual Clock Comparator (DCC) modules, used to determine the accuracy of a clock signal during the time execution of an application, each having the following main features:
 - Two independent counter blocks count clock pulses from each clock source
 - Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
 - Configurable time base for error signal
 - Error signal generation when one of the clocks is out of specification
 - Clock frequency measurement
- Error Signaling Module (ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:
 - Up to 1024 level or pulse error event inputs
 - Selectable low and high priority interrupt error pin prioritization of each error event
 - Error pin to signal severe device failure
 - Configurable time base for error signal
 - Error forcing capability
 - Internal redundant flops on safety critical fields
- ECC aggregator modules supporting ECC mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED). Applied to different memories in many of the subsystems, each of the ECC aggregators has the following main features:
 - Reduces memory software errors via single error correction (SEC) and double error detection (DED)
 - Provides a mechanism to control and monitor the ECC RAMs in a module or subsystem
 - Supports software readable status of ECC errors (single and double-bit) and associated info such as RAM address and data bit or bits that are in error
 - Aggregates level pending status from the ECC RAMs in two interrupts to the device CPU – interrupt for correctable error (SEC) and interrupt for uncorrectable error (DED)

- Supports up to 256 ECC endpoints (either ECC RAM or interconnect ECC component)
- Single bit error detection via parity checking results in a non-correctable error interrupt
- Memory Cyclic Redundancy Check (MCRC) module used to perform CRC to verify the integrity of a memory system – part of the NAVSS

1.2.36 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module contains a single 12-bit ADC which can be multiplexed to any 1 of 8 analog inputs (channels) and supports the following main features:

- 4 MSPS rate with a 60 MHz sample clock
- Single-ended or differential input options
- ADC module can be configured and transformed into digital test inputs
- Programmable 16 steps Finite State Machine (FSM) sequencer

1.2.37 Two-Port Gigabit Ethernet Switch

The 2-port Gigabit Ethernet Switch (CPSW2G) subsystem provides Ethernet packet communication for the device, and has the following main features:

- One Ethernet port (port 1) with selectable RGMII and RMII interfaces and an internal Communications Port Programming Interface (CPPI) port (port 0)
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
- DSCP Priority Mapping (IPv4 and IPv6)
- IPV4/IPV6 UDP/TCP checksum offload
- Energy Efficient Ethernet (EEE) support (802.3az)
- Priority-Based Flow Control (802.1QBB) and Flow Control (802.3x) Support
- Wire rate switching (802.1d)
- Non-Blocking switch fabric
- Time Sensitive Network Support
- Address Lookup Engine (ALE)
- EtherStats and 802.3Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Ethernet Mac transmit to Ethernet Mac receive Loopback mode (digital loopback) supported
- CPSGMII Loopback Modes (transmit to receive)
- Maximum frame size of 2024 bytes
- Management Data Input/Output (MDIO) module for PHY Management with Clause 45 support
- Programmable interrupt control with selected interrupt pacing
- Host port CPPI Streaming Packet Interface (CPPI_GCLK)
- Digital loopback and FIFO loopback modes supported
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only
- RAM Error Detection and Correction (SECDDED)

1.2.38 Nine-Port Gigabit Ethernet Switch

The 9-port Gigabit Ethernet Switch (CPSW9G) subsystem provides Ethernet packet communication for the device, and has the following main features:

- Eight Ethernet ports with selectable SGMII, XFI, QSGMII and USXGMII interfaces and an internal Communications Port Programming Interface (CPPI) port
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
- Ethernet port reset isolation

- DSCP Priority Mapping (IPv4 and IPv6)
- IPV4/IPV6 UDP/TCP checksum offload
- Energy Efficient Ethernet (EEE) support (802.3az)
- Priority-Based Flow Control (802.1QBB) and Flow Control (802.3x) Support
- Wire rate switching (802.1d)
- Non-Blocking switch fabric
- Time Sensitive Network Support
- Address Lookup Engine (ALE)
- EtherStats and 802.3Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- CPSGMII Loopback Modes (transmit to receive)
- Maximum frame size of 2020 bytes
- Host port CPPI Streaming Packet Interface (CPPI_GCLK)
- Digital loopback and FIFO loopback modes supported
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only
- RAM Error Detection and Correction (SECCDED)

1.2.39 Octal Serial Peripheral Interface and HyperBus Memory Controller as a Flash Subsystem

The Flash Subsystem (FSS) provides access to external flash devices via Octal Serial Peripheral Interface (OSPI) and HyperBus interface along with encryption/decryption, authentication, and in-line ECC protection. FSS supports the following main features:

- Provides two OSPIs or one OSPI and one HyperBus flash interfaces
- OSPI0/HyperBus interface supports:
 - Execute in place (XIP) operation
 - 32-byte Block Copy (BC) operation
 - ECC and/or authentication with four configurable authentication regions and authentication on 32-byte blocks
- OSPI supports up to 4 devices
- OSPI supports single, dual, quad, or octal SPI devices
- HyperBus interface supports up to 2 devices
- The OSPI and HyperBus interface have independent power management for low power operations

1.2.40 Security Management Subsystem

The Security Management Subsystem (SMS) which provides control over the device boot sequencing, device management, and security. With the factory-sealed firmware, SMS main functions include:

- Device management (security only)
- Device boot configuration and sequence
- Secure boot setup
- Decryption routines
- Firewall control for isolation and Security
- Runtime Security Management and resource allocation

Arm Cortex-M4F based SMS acts as a system security master and protects critical security assets during run-time. As part of booting a High Security (HS) device, SMS uses on-chip keys to establish root-of-trust and authenticate images to reinforce trust. SMS acts also as main boot processor and as such is the very first subsystem that is brought out of reset after device power-on-reset.

Main components of the SMS are:

- Two independent M4F processor cores with floating point extension (primary and secondary)
- M4F primary core features include:
 - RTI/WDT (only digital watchdog (non-windowed) feature is supported in SMS primary core context)
 - 128KB IMEM and 48KB DMEM, accessible from M4F primary core and system masters via firewall
 - Messaging between M4F core and host processors using Secure Proxy and RA located in MCU_NAVSS and MAIN NAVSS.

- 160KB ROM for boot of M4F core
- M4F secondary core features include:
 - Dedicated RTI/WWDT (with windowed watchdog mode, disabled by default)
 - 192KB IMEM and 64KB DMEM, accessible from M4F secondary core and system masters via firewall
 - Messaging between M4F secondary core and up to five host cores (including primary core and 4 other device level cores) using Secure Proxy and RA
- Common features of both M4F primary and secondary cores:
 - Following resources can be accessed from either primary or secondary core with permissions via firewall:
 - Four 32-bit Timers - same as SOC level timers
 - AES engine with 128, 192 and 256-bit support
 - Security Manager
 - SMS control module - contains various control, configuration and status MMRs including firewall management for the full device
 - Other core features:
 - Ability to execute code from unified memory or external memories
 - Up to 240 input interrupts, level or pulse interrupts, capable of waking up the SMS cores from low power mode
 - Two interrupt outputs (per M4F core) to host SOC; support of both level and pulse interrupts
 - One fault detected interrupt output (per M4F core); support of both level and pulse interrupts
 - DAP based debug interface to the M4F core
 - ITM trace to chip level trace framework
 - Support of double detection and single error correction
 - Support of Little Endian mode only
 - In addition to local SMS RAM, the SMS M4F cores may utilize MSMC memory space as secure RAM via firewall

1.3 Device Identification

The JTAGID and JTAG_USER_ID can be used to identify the J784S4 and J742S2 devices. The register values are summarized in [Table 1-2](#).

Table 1-2. Device Identification Mapping

Register	Address	Bitfield	Value	Description
CTRL_MMR_CFG0_JTAGID	4300 0014h	[31-28] VARIANT	0x0	Silicon Revision 1.0
		[27-12] PARTNO	0xBB80	Boundary Scan identifier for J784S4 and J742S2
		[11-1] MFG	0x17	Manufacturer - TI
		[0] LSB	0x1	Always Reads 1
CTRL_MMR_CFG0_JTAG_USER_ID	4300 0018h	[2-0] PKG	0x5	J784S4 device in ALY 31mm package
			0x7	J742S2 device in AND 27mm package

2.4 Processors View Memory Map

Section 2.1 through Section 2.3 show the processors view memory maps.

Note

The memory locations not shown in Section 2.1 through Section 2.3 are either unallocated or reserved and not used. Accesses to these locations are not recommended and should be avoided.

2.5 Region-based Address Translation

The SoC memory map view shown in this section are used by the processors in COMPUTE_CLUSTER0 but there are processors which support only 32-bit addressing and cannot access higher address ranges. For these processors, RAT modules are integrated to remap the 32-bit addresses to 48-bit addresses allowing higher address range accesses. The "RAT_REGION" regions shown in *RAT Registers* are dedicated to RAT remapping.

3 System Interconnect

The following sections describe the device system interconnect.

3.1 System Interconnect Overview

All modules and subsystems in the device communicate with each other through the system interconnect for any memory map accesses. It is partitioned into the following sections:

- MAIN_CBASS Group - located in VD_CORE and connect most of the device modules in the device MAIN domain.
- INFRA_CBASS0 and INFRA_NS_CBASS0 - located in VD_CORE and contains almost all infrastructure and internal diagnostic components. It also contains peripherals not power managed in the MAIN domain.
- MCU_CBASS0 - located in VD_MCU and connects modules from the MCU domain.
- WKUP_CBASS0 - located in VD_WKUP and connects modules in the WKUP domain.

These interconnects are used for data transfers and configuration. They are composed by switch fabrics enabling fast internal data movement. They also provide low-latency and concurrent data transfers between initiator and target peripherals.

The MAIN_CBASS GROUP is composed of the following interconnects:

- CBASS_IPPHY_S0
- CBASS_IP_PHY0
- CBASS_RC0
- CBASS_RC_CFG_B0
- CBASS_CSI0
- CBASS_DEBUG0
- CBASS_HC2_0
- CBASS_HC_CFG_B0
- CBASS_AC_NS0
- CBASS_AC_CFG_NS0
- CBASS_PULSAR_SLV0
- CBASS_AC_CFG0
- CBASS_PULSAR0_MEM0
- CBASS_PULSAR1_MEM0

Figure 3-1 shows the device system interconnect. All modules and subsystems can be classified into two categories: initiators and targets. The initiators are capable of initiating read and write transfers in the system. The targets on the other hand depend on the initiators to perform transfers to and from them. They cannot generate read/write requests but can respond to these requests generating interrupts or DMA requests.

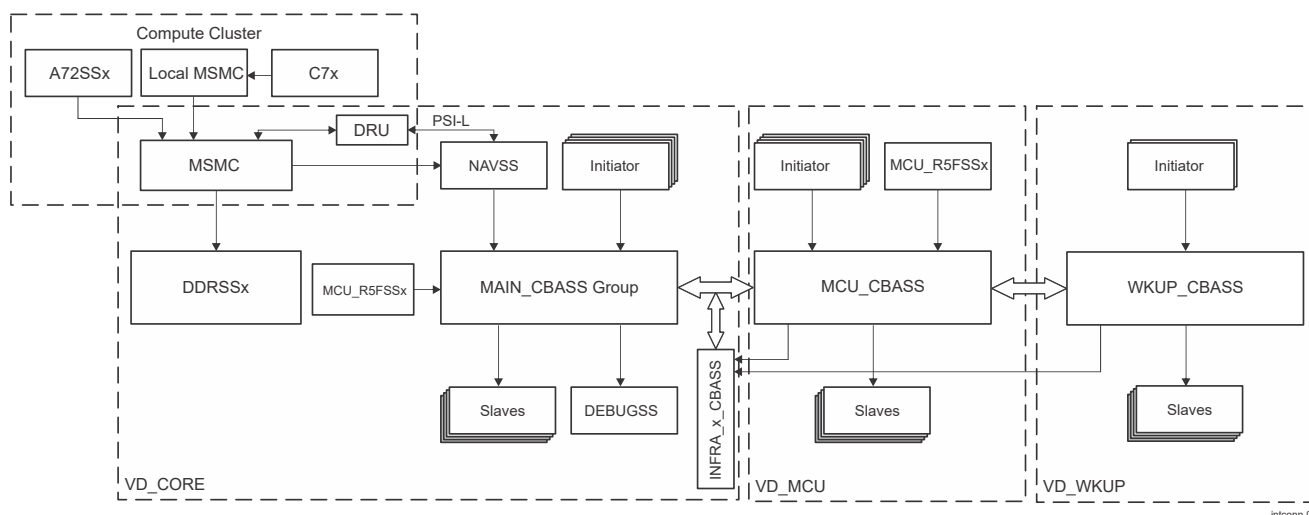

Figure 3-1. Device System Interconnect Overview

3.2 System Interconnect Functional Description

3.2.1 Quality of Service (QoS)

The device interconnect provides two mechanisms to achieve quality of service (QoS): parallel routing based on order ID and arbitration based on priority. The order ID has two main usages: to order execution of transactions and parallel paths selection. The parallel paths are defined as multiple paths between master and slave. If two or more slaves share same physical memory map assignment, it is considered parallel paths.

The CBASS_MAP_i[7-4] ORDERID bit field is for transactions for each master and each channel of the master. This allows different mapping not only for each master, but also for each channel of the master, if multiple channels are supported. The CBASS_MAP_i[7-4] ORDERID bit field specifies the initial order ID value. The ORDERIDx bit fields in CBASS_GRP_MAP1_j and CBASS_GRP_MAP2_j registers take the initial order ID value and result in a final order ID value, which is nothing more than a 4-bit identifier used for path routing. The final order ID is used to differentiate the paths to a slave and thus allowing load balancing of the traffic over each path.

The interconnect performs traffic routing and switching from a number of masters to a number of slaves. The masters send transactions. The interconnect decodes which slave is being accessed based on special signals and memory map and routes that transaction to the slave. The interconnect also arbitrates for a slave when there are multiple transactions being requested simultaneously. The arbitration is based on transaction priority. Once a transaction is selected, the interconnect sends the transaction to the slave. The transaction priority is controlled per master and per channel of the master through the CBASS_MAP_i[14-12] EPRIORITY bit field. The priority setting for each master can be done by any processor. Increasing the priority level for certain master can help the transaction from that master to have advantage on winning arbitration, therefore improving the latency and bandwidth for the transactions from that master.

Since the order ID is controlled from configuration registers, the user can re-partition the traffic among parallel paths to achieve better load balance adjusted for specific use cases. As order ID has routing implication for both command and return data, its configuration must not be changed during run time. Otherwise, the return data may be routed to wrong path and cause system hang. To avoid this, the system must be put into idle state with no traffic on the interconnect before reprogramming procedure.

Note

Route ID is not related to QoS. For route ID description, see [Section 3.2.2](#).

Note

There are no master modules on the INFRA_CBASS0 and INFRA_NS_CBASS0 interconnects.

The interconnect inside NAVSS0 uses order ID to provide multiple (at least two) parallel paths to DDR and a separate set of multiple (at least two) parallel paths to SRAM. NAVSS0 also provides multiple (at least two) parallel paths for the DMA traffic to SoC level, which can provide isolated DMA traffic paths. For more information, see *Navigator Subsystem (NAVSS)*.

The MSMC does not use order ID for routing purpose to provide separate physical paths for transaction. Instead, it provides two threads to isolate two classes of transactions: thread 0 and thread 2. The arbitration between these two threads is based on credits, and thread 2 has priority over thread 0 when both threads have credits available for transfer. In addition, there is bandwidth management scheme based on transaction priority and bandwidth starvation prevention mechanism. For more information, see *Multicore Shared Memory Controller (MSMC)*.

By default all masters send transactions with order ID = 0. All transactions with the same order ID execute in order if they are sent to the same slave or going through a common bridge. On the SoC level interconnect, the order ID is used to partition the transactions to MSMC and DDR data space into parallel routing paths. Further, the north bridge inside NAVSS0 provides multiple parallel paths to the compute cluster. Each path is separated by order ID value. All read commands towards MSMC and DDR sharing the same order ID and sharing the same master path from SoC side (including NAVSS0) provide read return data in order back to the master port.

The write response can be returned out of order for the same order ID value. Therefore, programming order ID has implications on overall system performance as well as achieving QoS for certain class of traffic. Multiple configurations are needed to make sure that the QoS goal is met.

For any write to address range 0x4500_0000 to 0x45FF_FFFF, it is recommended to read back the value after the write to make sure the write landed. The registers in this regions are mainly for firewall configuration, ISC/DMA credential configuration, QoS MMR configuration.

On QoS MMR configuration, in order to configure certain transaction to be the highest priority, the priority field needs to be set to zero for that transaction. In order to make sure that priority field is indeed to set to zero, the following sequence should be followed:

1. Read the priority field, if it is non-zero value, follow a write to overwrite priority field to be 0x0.
2. If read back priority field is zero, write to QoS MMR register to set priority field to be 0x7. Read back the same priority field. If the read back value is 0x7, write to QoS MMR register to set priority field to be 0x0. If the read back value is 0x0, it means this register is not implemented and priority setting is not working.

Note

See Appendix Spreadsheet for CBASS0 QoS MMR details.

3.2.2 Route ID

The route ID is used by the interconnect to route return status and data back to the transaction initiator. Each master has one or multiple unique route IDs assigned to it. The route ID has no other usage. There are no software controls for the route ID.

Note

See Appendix Spreadsheet for Route ID details.

3.2.3 Initiator-Side Security Controls and Firewalls

Firewalls (FW) and Initiator-side Security Controls (ISC) are important interconnect components that enable hardware isolation for freedom from interference or security uses. ISCs enable every transaction to be identified and tagged to precisely assign the source ID. Firewalls are downstream (target) components that provide the ability to filtering transactions based on the sideband information.

The device protection depends on firewalls. They are used to protect data and configuration spaces by managing the accesses to these memory regions. There are two types of firewalls - region based and channelized. There aren't channelized firewalls on system level. Only NAVSS0, MCU_NAVSS0 and DRU0 have channelized firewalls for the various DMA channels. Only region based firewalls are available on system level. See [Section 3.2.4.2.1](#) and [Section 3.2.4.2.2.1](#) for description of the region based and channelized firewalls.

Almost all slaves have a firewall right before the transaction reaches them. There are few exceptions such as WKUP_DMSC0, VPAC0, DMPAC0, NAVSS0 and MCU_NAVSS0 slave ports. These subsystems contain local interconnect with own firewalls inside the subsystem itself. The firewalls inside compute cluster (for A72SS0, C71SS0 and DRU) are also an exception. They are put on the master instead on the slave port side. To enable access for that master port to the slaves these master side firewalls must individually be programmed. Note that there is also a second firewall for C71SS0 that is put on the slave port side.

On devices supporting secure boot and secure DMSC, these components allow the SoC to support multi-tier security and provide segregation of secure and non-secure worlds. All configuration of ISCs and FWs are under exclusive control of DMSC, using a dedicated interconnect.

The number of ISC and Firewall blocks and placement of these blocks are based on the topology of each device. ISC and Firewall blocks are placed in host modules (AXI to VBUSM.C Bridge); or part of the interconnect (for example: CBASS).

Figure 3-2 presents a generic view of ISCs and Firewalls in SoC.

Figure 3-2. ISC and Firewall in SoC

3.2.3.1 Initiator-Side Security Controls (ISC)

Initiator-Side Security Control (ISC) modules are hosted at the initiator side where the transactions are sourced. ISC controls the security sideband attributes that are applied to outgoing transactions and have ability to override security values under exclusive control of DMSC.

ISC Capabilities:

- Attach Priv-ID to each bus transaction.
- Priv-ID is a source ID attached to identify the source of a transaction in the system.
- By default, each initiator in the system has a unique Priv-ID.
- Multiple modules can be assigned the same Priv-ID to form logical groups.
- Assert, De-assert or pass-through secure bit.
- Assert, De-assert or pass through Priv-bits.

ISCs are connected to the dedicated security VBUSP interconnect and can be exclusively configured by DMSC. ISC optionally can support region and channel number based security control, where, based on incoming channel or address, the associated security controls, are applied.

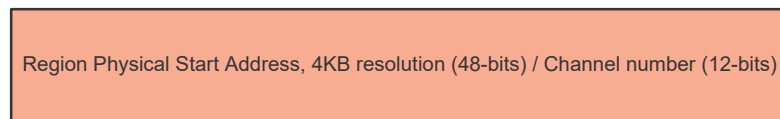

Figure 3-3 presents ISC config registers per region.

ISC Control Regs **per** region

E = Enable Region (0xA = Enabled)
L = Lock Config
C = Use Channel number, not address
D = Default region indicator
S = Make outgoing transaction secure (0xA = Enabled)
N = Make outgoing transaction Non-secure
R = Reserved
P = Do not replace Priv-ID, pass through PrivID
NOPRIV = Clear Outgoing PRIV Attribute
PRIV = Set Outgoing PRIV Attribute

Lower 12-bits valid in case of channel number

Not valid in case of channel number

Figure 3-3. ISC Config Registers per Region

Priv-ID is used to identify the logical source of transaction and is attached by ISC. The Priv-IDs are allocated based on subsystem as part of platform definition.

Note

See Appendix Spreadsheet for ISC and Priv-ID details.

3.2.3.1.1 Special System Level Priv-ID

This section describes Special Priv-IDs that must not be assigned to any ISC. These Priv-ID when encountered by various blocks like firewall have special meaning.

Table 3-1 presents Special Priv-IDs.

Table 3-1. Special Priv-IDs

Special Priv-IDs	Hex Value	Decimal Value
System Reserved Priv-ID	0xC1, 0xC2, 0xC4, 0xC6, 0xC7	193, 194, 196, 198, 199
Wild card Priv ID	0xC3	195
Block Priv ID	0xC5	197
DMA Reserved Priv-ID	0xC0	192

3.2.4 Firewalls (FW)

Firewalls play an important role in implementing overall SoC security by providing a means to allow or restrict access to device resources to any given master entity or Secure/Non-Secure/Priv/User world. Firewalls are placed at various data path points throughout the SoC to control access to protected asset (Peripheral, memory and so forth).

Firewalls ensure that assets can be protected and are only accessible by allowed master and in selected operation mode (Secure, Non-Secure, Priv, User, write, read and so forth). In case of firewall violations, the transaction is dropped and the appropriate violation code is registered with associated parameters.

There are three types of firewalls, Peripheral firewalls, Memory firewalls (referred as one group **Region Based Firewall** in the device-specific TRM) and Channelized firewalls.

Each Firewall module in the SoC has a unique Firewall ID that allows software to decode the source of each violation. The Firewall IDs are allocated based on subsystem as part of platform definition. The full SoC view of Firewall IDs for various Firewall modules are captured in each device spec.

3.2.4.1 Peripheral Firewalls (FW)

Peripheral firewall modules are placed in front of peripherals like UART, SPI and so forth. They protect access to the peripheral registers/memory and typically have firewall regions as number of regions supported by module that is being protected.

All Peripheral firewalls support 3 Priv-ID slots that allow multiple masters/initiators to access protected peripherals.

The peripheral firewall is configured using dedicated VBUSP port to CBASS that connects to DMSC private VBUSP interconnect.

Figure 3-4 presents Peripheral Firewall.

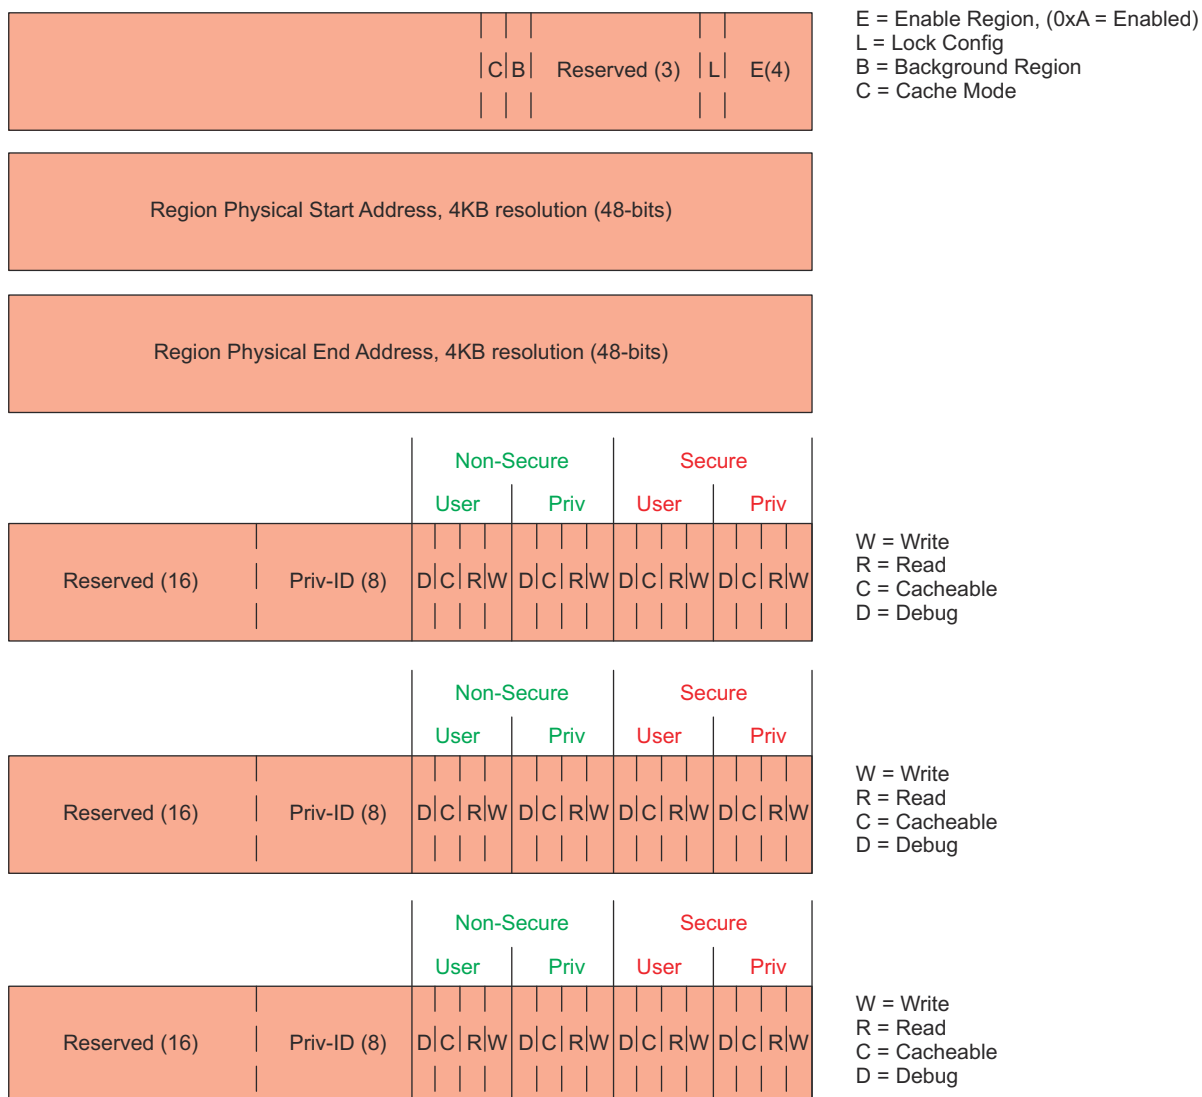

Figure 3-4. Peripheral Firewall

Each region is defined by start and end physical address and associated permission/control register as shown in Figure 3-5.

Firewall Control Regs **per** region

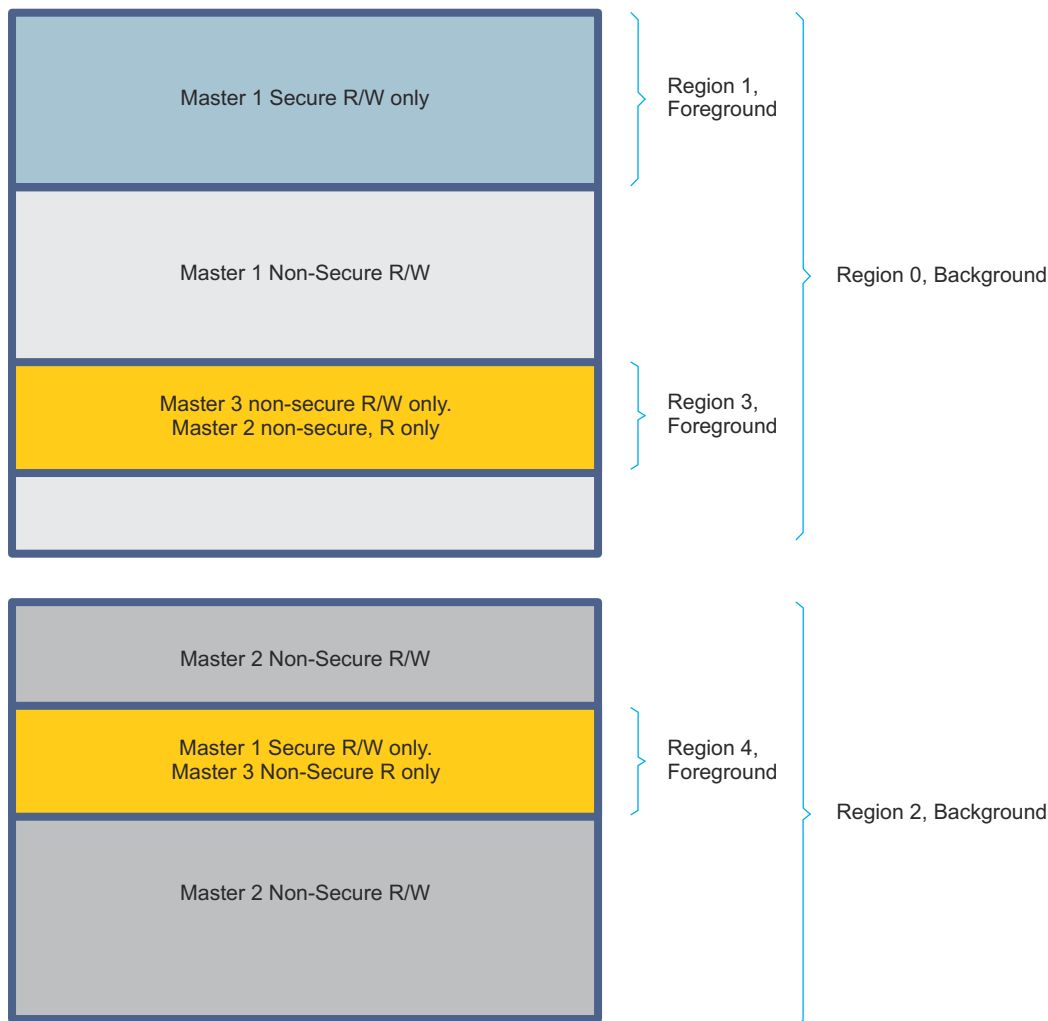

SA-SPRUI00-016

Figure 3-5. Peripheral Firewall Config Registers per Regions

A Peripheral's Firewall module can have one or more regions. In case there is more than 1 region, the registers are duplicated for each region.

If multiple regions are supported, a firewall configuration can be defined as either a Background or Foreground region depending on the setting of the Background (B) bit. Foreground regions can overlap background regions and their Firewall settings take precedence over the Background settings when there is overlap. However, background regions cannot overlap each other and foreground regions cannot overlap each other. A firewall error will result in case a memory transaction is made to the improper overlap regions.

Figure 3-6 presents peripherals firewall regions.

SA-SPRUI00-017

Figure 3-6. Peripherals Firewall Regions

In the above case, Region 0 and Region 2 are background regions (background bit set in control register). Region 1, Region 3 and Region 4 are **not** background (foreground) regions. In case the incoming transaction hits in address in Region 1, the permissions of Region 1 are applied to filter incoming transaction, thereby completely ignoring the permission of the background Region 0.

The following tables show the initiator and target firewalls, firewall IDs, physical base address of the corresponding firewall, number of firewall regions, and areas covered by the firewall. The firewall ID uniquely identifies each firewall. In case of firewall violation this ID is logged and can be read through the CBASS_EXCEPTION_LOGGING_HEADER0[23-8] SRC_ID field.

Note

See Appendix Spreadsheet for Target Firewalls details.

3.2.4.2 Memory or Region-based Firewalls

Memory/Data firewalls are designed to protect Memory (SRAM/DDR and so forth) and data regions (GPMC and so forth). Memory/Data firewalls have a defined firewall region count so that the memory can be partitioned into multiple firewall regions.

The architecture of Memory/Data firewalls is similar to Peripheral Firewalls, however, the Memory/Data firewall can have either 1 or 3 Priv-ID slots per region, with associated permissions. The number of Priv-ID slots is

determined based on placement of firewall block. Each region in this type of firewall is defined by a physical start and end address.

Figure 3-7 presents Memory/Data firewall config registers with 3 Priv-ID slots per region.

Firewall Control Regs **per** region

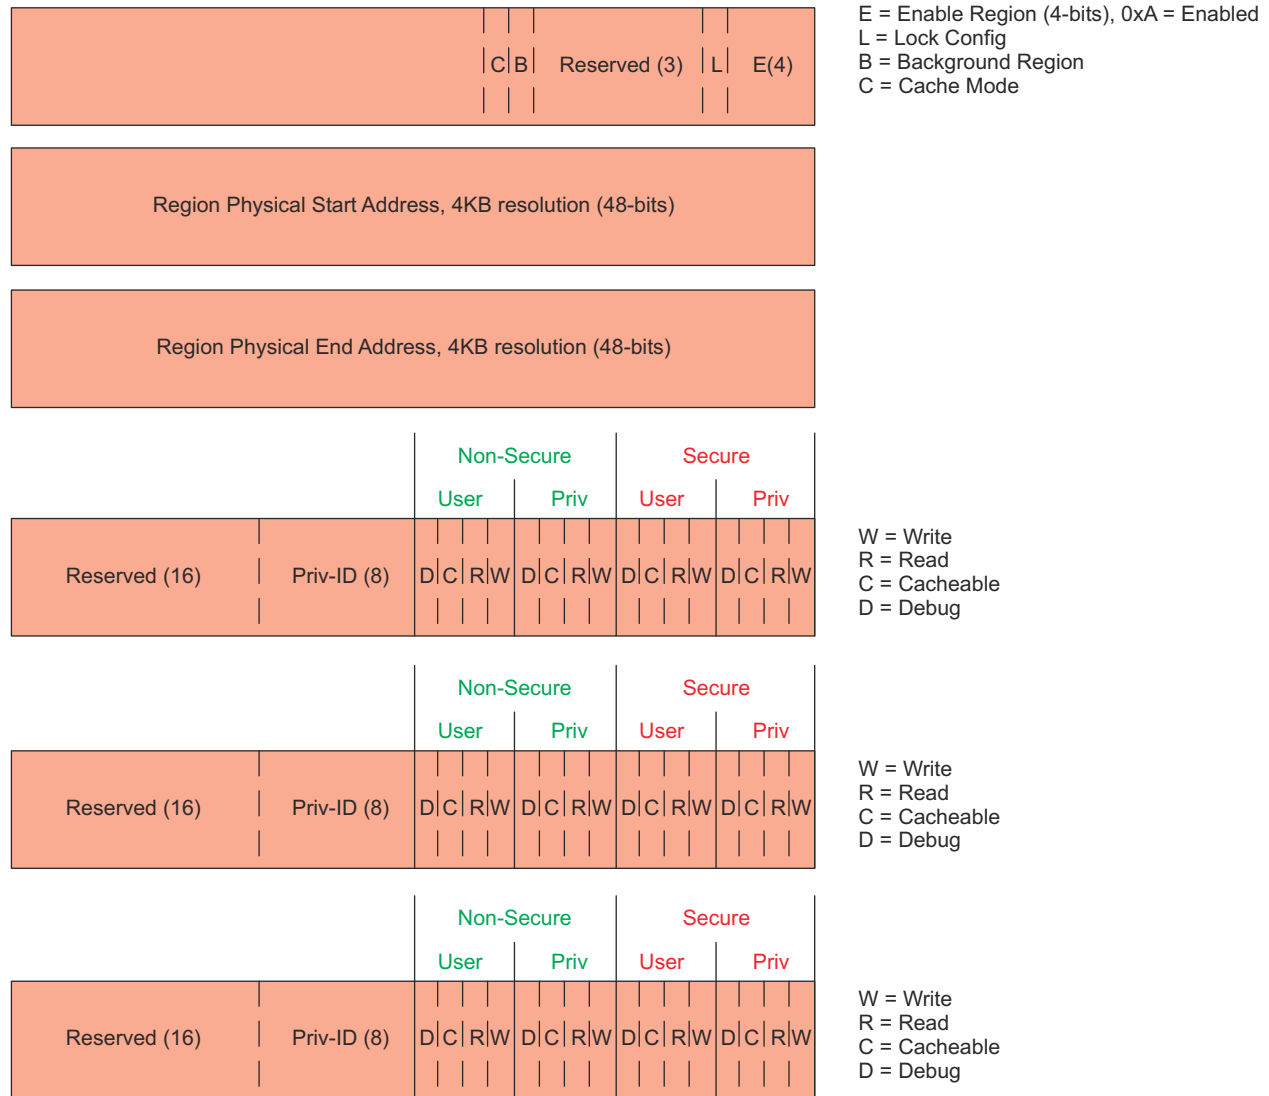

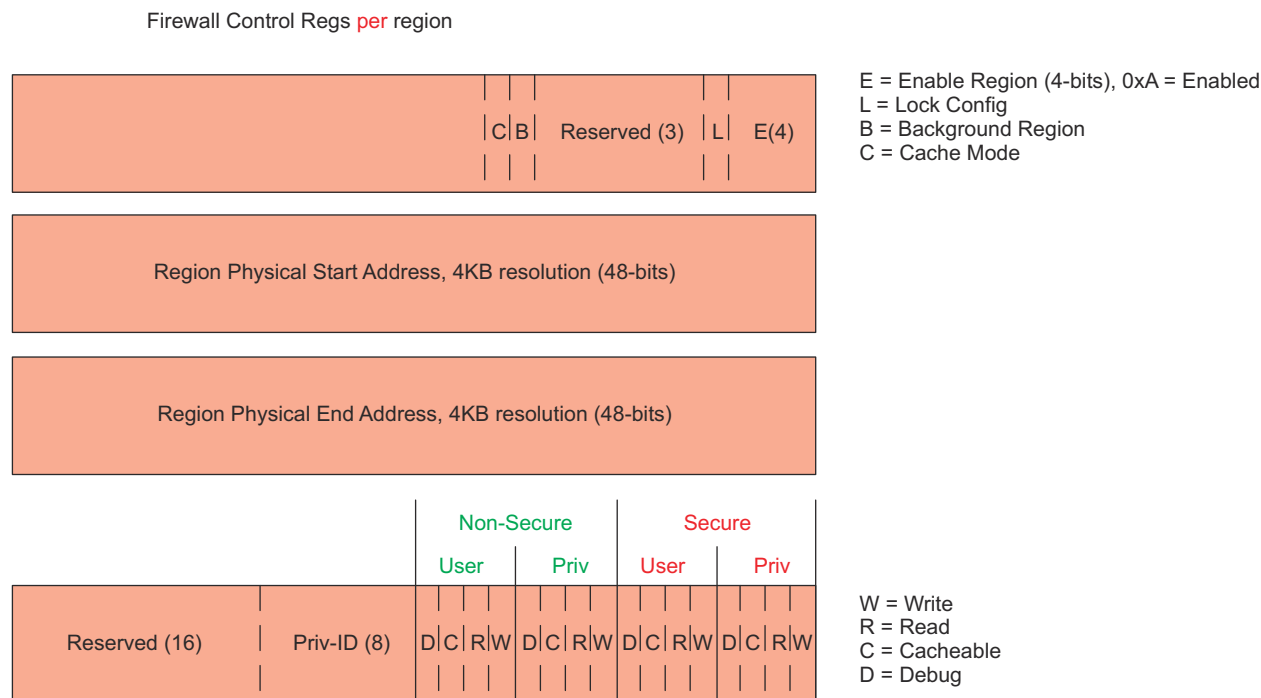

Figure 3-7. Memory/Data Firewall Config Registers with 3 Priv-ID slot per Region

Figure 3-8 presents Memory/Data firewall config registers with 1 Priv-ID slot per region.

SA-SPRUIIM0-019

Figure 3-8. Memory/Data Firewall Config Registers with 1 Priv-ID slot per Region

The Memory/Data firewall is configured using dedicated VBUSP port to CBASS/AXI to VBUSM.C Bridge/DRU that connects to DMSC private VBUSP interconnect.

Memory/Data Firewalls also support background regions as in peripheral firewalls.

3.2.4.2.1 Region Based Firewall Functional Description

The region based firewall provides a memory region based protection and isolation mechanism. For each defined memory region, it checks the transaction attributes such as secure vs non-secure, debug vs non-debug, supervisor vs user mode, read vs write and so on. The transaction is dropped, if it does not match the configuration and appropriate violation code is registered with offending parameters.

Host modules (for example, AXI2VBUSMC bridge or CBASSes) provide transaction attributes that are checked by the firewalls, which then determine if the transaction should be blocked or passed. The firewall implements filtering algorithm that compares these host incoming transaction parameters against the region policy to give block indication to the host. Firewall region registers configure the filtering mechanism which includes setting region address range, region permission registers and region control register. There are also firewall exception registers used for violation reporting and logging.

The region based firewall supports multiple regions. Each one is defined by address range and associated access permission. The minimum memory region size is 4KB. The firewall concurrently checks the incoming transaction against all enabled regions looking for violations.

Each firewall is associated with the following registers:

- CBASS_FW_REGION_i_CONTROL
- CBASS_FW_REGION_i_PERMISSION_0 to CBASS_FW_REGION_i_PERMISSION_2
- CBASS_FW_REGION_i_START_ADDRESS_L and CBASS_FW_REGION_i_START_ADDRESS_H

- CBASS_FW_REGION_i_END_ADDRESS_L and CBASS_FW_REGION_i_END_ADDRESS_H

Each region is defined by start and end physical address and associated permission and control registers. A firewall can have 1-24 regions. In case there is more than 1 region, then these registers are duplicated for all regions. Setting the CBASS_FW_REGION_i_CONTROL[3-0] ENABLE field to 0xA enables the region and makes firewall check active for this region. Setting to 0x1 the CBASS_FW_REGION_i_CONTROL[8] BACKGROUND bit indicates to the firewall that the region is background region. Setting to 0x1 the CBASS_FW_REGION_i_CONTROL[9] CACHE_MODE bit ignores cacheable check, so that it cannot fail. In this case the access check is performed based on the READ and WRITE bits in CBASS_FW_REGION_i_PERMISSION_x. Clearing CACHE_MODE enables the cacheable check, so that cacheable transactions are allowed only when the corresponding cacheable permission bit (CBASS_FW_REGION_i_PERMISSION_x [y_CACHEABLE]) is set. If the CBASS_FW_REGION_i_CONTROL[4] LOCK bit is set to 0x1, then the region configuration cannot be changed at all. This is one-time change. This bit is typically used for primary master to consume and lock its resources and then pass firewall control to secondary master.

In case two regions overlap, the CBASS_FW_REGION_i_CONTROL[8] BACKGROUND bit is used to select the appropriate permission to be used. The region whose BACKGROUND bit is 0x0 (foreground) takes precedence and its permissions are taken into effect. The background region is ignored.

Note

There can be only one background region per firewall. Foreground regions can have overlapping addresses only with the background region.

It is a software mistake to have overlapping regions with the BACKGROUND bit set to the same value (either background or foreground). Software must be careful to not configure two overlapping regions with the BACKGROUND bit set to the same value.

The firewall also checks if the transaction crosses a 4KB boundary. If so, the transaction is blocked regardless of any matching regions.

When a region is set to be debugable through the corresponding CBASS_FW_REGION_i_PERMISSION_x [y_DEBUG] bit, the firewall ignores the read and write checks for any debug transactions, so that it cannot fail. This allows debug breakpoints to be written out to code even in read-only regions.

When a region is set to be cacheable through the corresponding CBASS_FW_REGION_i_PERMISSION_x [y_CACHEABLE] bit and CACHE_MODE = 0x0, the firewall ignores the read and write checks for any transaction (cacheable or not), so that it cannot fail due to these checks. This allows a write allocated cache to read a cache line even in write-only regions. Due to caches not protecting user and supervisor data from each other, the firewall allows cacheable access to the region when either the user cacheable permission or the supervisor cacheable permission is set.

The firewall notifies the host that the transaction is blocked in case of the following violation conditions:

- All regions are disabled.
- Incoming address does not hit any region.
- Non-secure incoming read transaction attempting to access configured secure-only write/read region.
- Non-secure incoming write transaction attempting to access configured secure-only write/read region.
- Secure incoming read transaction attempting to access configured non-secure-only write/read region.
- Secure incoming write transaction attempting to access configured non-secure region.
- Incoming secure write transaction attempting to access configured secure read region. This check is ignored if the region is configured as cacheable.
- Incoming secure read transaction attempting to access configured secure write region. This check is ignored if the region is configured as cacheable.
- Incoming non-secure write transaction attempting to access configured non-secure read region. This check is ignored if the region is configured as cacheable.
- Incoming non-secure read transaction attempting to access configured non-secure write region. This check is ignored if the region is configured as cacheable.

- Incoming non-secure debug access to non-debugable secure region.
- Incoming non-secure debug access to non-debugable non-secure region.
- Incoming secure debug access to non-debugable secure region.
- Incoming secure debug access to non-debugable non-secure region.
- Incoming cacheable transaction attempting to access non-cacheable configured region.

All violation parameters caused the exception are logged in the firewall exception registers described in *Firewall Exception Registers*. Table 3-2 shows the mapping between the register fields and violation parameters. If the CBASS_EXCEPTION_LOGGING_CONTROL[0] DISABLE_F bit is set to 0x1, logging is disabled.

If violation occurs, the corresponding firewall notifies WKUP_DMSC0 driving high a dedicated signal. The notification (that is, the signal) can be masked by setting to 0x1 the CBASS_EXCEPTION_LOGGING_CONTROL[1] DISABLE_PEND bit. The firewall exception notification signal gets automatically cleared when the CBASS_EXCEPTION_LOGGING_DATA3 register is read. That signal can be manually set via the CBASS_EXCEPTION_PEND_SET[0] PEND_SET bit and cleared via the CBASS_EXCEPTION_PEND_CLEAR[0] PEND_CLR bit. Reading one of these two bits returns the status of the signal (that is, violation occurred or not).

Table 3-2. Firewall Violation Parameters

Field	Value	Description
CBASS_EXCEPTION_LOGGING_HEADER0[31-24] TYPE_F	0x1	Exception type for firewall violation. This is fixed for the SoC firewalls and is used by software to detect that this corresponding violation comes from a firewall.
CBASS_EXCEPTION_LOGGING_HEADER0[23-8] SRC_ID	0x-	Firewall ID. Unique for each firewall. This is used to identify the exact firewall that issued violation so that software detects the precise source.
CBASS_EXCEPTION_LOGGING_HEADER0[7-0] DEST_ID	0x-	Destination ID of node where the firewall violation has be to routed.
CBASS_EXCEPTION_LOGGING_HEADER1[31-24] GROUP	0x0	Exception group. This is used to group exceptions to category. All firewall exceptions are in one group.
CBASS_EXCEPTION_LOGGING_HEADER1[23-16] CODE	Exception code:	
	0x0	Reserved.
	0x1	No region enabled.
	0x2	Incoming address does not hit any active region and transaction is dropped.
	0x3	Priv-ID not authorized to access incoming address region, or Priv-ID not found in any slot for region.
	0x4	Cacheable error. A cacheable transaction attempting to read/write non-cached marked region.
	0x5	Debug error. A debug transaction attempting to read/write a non-allowed debug region.
	0x6	Read error. A Read transaction attempting to read from non-allowed read region.
	0x7	Write error. A Write transaction attempting to write from non-allowed write region.
	0x8	4KB crossing error. A transaction attempting to cross a 4KB boundary.
CBASS_EXCEPTION_LOGGING_DATA0[31-0] ADDR_L	0x-	Lower 32 address bits (31:0) of the incoming transaction
CBASS_EXCEPTION_LOGGING_DATA1[15-0] ADDR_H	0x-	Upper 16 address bits (47:32) of the incoming transaction

Table 3-2. Firewall Violation Parameters (continued)

Field	Value	Description
CBASS_EXCEPTION_LOGGING_DATA2[7-0] PRIV_ID	Not used	Incoming transaction parameters
CBASS_EXCEPTION_LOGGING_DATA2[8] SECURE	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[9] PRIV	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[10] CACHEABLE	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[11] DEBUG	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[12] READ	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[13] WRITE	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[27-16] ROUTEID	0x-	
CBASS_EXCEPTION_LOGGING_DATA3[9-0] BYTECNT	0x-	Byte count of the incoming transaction

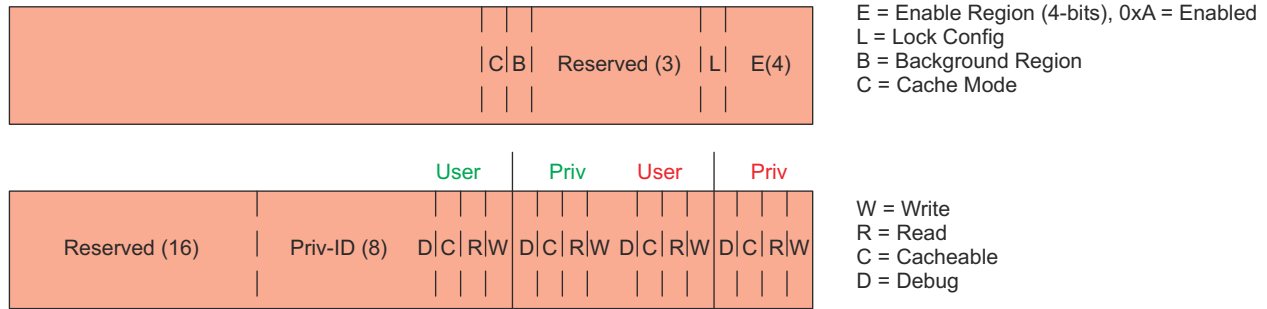

3.2.4.2.2 Channelized Firewalls

A Channelized firewall is designed to protect modules that have logical channels (Ring Accelerator and so forth, for example). These firewalls operate at the resolution of a channel and have no association with physical addresses. Each channel is defined as a logical control entity.

In case of channelized firewalls, the number of regions are less than or equal to number of logical channels and each typical channel/region is very small memory space (typically in Bytes, like 16 bytes). A channel is owned by one processing entity, hence only 1 Priv-ID slot is provided for each Channelized firewall along with associated permissions.

Figure 3-9 presents Channelized firewall config registers with 1 Priv-ID slot per region.

Firewall Control Regs **per** region

SA-SPRUM0-020

Figure 3-9. Channelized Firewall Config Registers with 1 Priv-ID slot per Region

The Channelized firewall is configured using dedicated VBUSP port to CBASS/Bridges that connects to DMSC private VBUSP interconnect.

Note

For more information about the interconnect firewalls, see *Interconnect Firewalls*.

3.2.4.2.2.1 Channelized Firewall Functional Description

The channelized firewall protects an address space that consists of multiple channels where each channel needs its own permissions. This is in contrast to the region based firewall which implements a number of regions that can protect a programmed address range. The channelized firewall extends this to a larger number of ranges that can be protected, but each range is no longer programmable and is instead fixed to a particular channel address range. This allows each channel to be owned and protected individually. The channels within same memory region have same size. The system can allocate each channel to a particular owner or owner groups with certain permissions and guarantee that others cannot access that channel. This protection is useful for either accessing data resources, or control for each resource. The channelized firewall provides an efficient way to implement access protection and isolation requiring finer granularity than the region based firewall.

Same as the region based firewall, the channelized firewall may also support multiple regions. Each region contains a number of channels that need to be protected individually and has size in bytes equal to the channel's data to protect. This allows multiple regions so that the firewall can protect a module containing multiple sets of registers that are each channelized and need separate protections, such as data access as well as control setup.

The transaction addresses are compared against region addresses to identify which region is being accessed. Then the offset within the region is used to identify the particular channel being accessed. If a valid channelized region is not decoded during the firewall check, then the transaction is passed through unmodified because the module may have other regions which are not channelized, but accesses to them are already protected by a region based firewall so the channelized one should not block them.

The permission check is performed just like for a region based firewall. The channelized firewall checks for user or supervisor privileged levels. It also checks for transactions that cross important boundaries and gives errors if violated. The first check is for a transaction crossing a 4KB address boundary. This is illegal on the bus, so the firewall checks for compliance. The second check is if the transaction crosses a channel boundary. The channelized firewall blocks a transaction accessing multiple channels in the same burst, as it cannot check the permission for the entire range of channels. The channelized firewall also supports error logging when a transaction fails the checks. It sends information about the type of error and the transaction that caused it.

The channelized firewall is associated with the following registers:

- *_CH_i_CONTROL, where "i" can be from 0 to 63 and denotes the channel. This register is equivalent to the CBASS_FW_REGION_i_CONTROL register of the region based firewall.
- *_CH_i_PERMISSION_x, where "i" can be from 0 to 63 and denotes the channel and "x" can be 0 to 2. This register is equivalent to the CBASS_FW_REGION_i_PERMISSION_x register of the region based firewall.

3.2.5 Null Error Reporting

The interconnect supports capturing null slave errors for reporting. A null slave error occurs when a transaction does not address any slaves based on the address map, resulting in the transaction returning error status. The null errors are captured into registers and an interrupt is generated. There is only one set of reporting registers, so only one error can be captured until cleared by software. The report captures some details of the transaction, such as the Route ID to identify the master involved and the address accessed. See *Null Error Reporting Registers* for details about the null error reporting registers.

3.2.6 Initiator-Target Connections

Table 3-4 , Table 3-5 , and Table 3-6 list the initiator and target end point connections on the CBASS0. A cell may contain one of the following:

- Y – There is a connection between this initiator and that target
- N – There is no connection between this initiator and that target.

Table 3-3. Compute Cluster Connectivity Matrix

Target	Initiator							
	A72 Corepac 0	A72 Corepac 1	Central DRU	AW-A C7x	AW-A DRU	AW-B C7x	AW-B DRU	System Initiator
MSMC L3 8MB	Y	Y	Y	Y	Y	Y	Y	Y

3.2.7 Timeout Gasket (TOG)

In a system with a mixture of ASIL-D and non-ASIL-D process running in parallel, it is important to isolate the impact of a fault from the non-ASIL-D process spreading to ASIL-D domain. When there is unrecoverable fault in the non-ASIL-D domain, the safety software should either have the capability to diagnose the fault and/or reset the fault components.

When the fault happens on the target interface side, the Target Time out Gasket (STOG) provides the capability to gracefully terminate the transactions and return error status back to the initiator, so the interconnect is not stalled due to the fault at the target side.

When the fault happens on the initiator interface side, the Initiator Time out Gasket (MTOG) shall provide the capability to flush out all the pending transactions while preventing the faulty initiator interface from issuing more transactions. It also has logic to track the idle state when all the pending transactions are completed. The IP can't be brought down or reset unless the initiator time out gaskets enters idle state. All the control mechanisms for the initiator side time out gasket come from chip level MMR. By default, the time out gasket is disabled. It requires safety software to enable it.

All the time out gaskets assert interrupts when there is a time out event. These events are be routed to ESM. MCU Pulsar manages timeout events for the gaskets inserted in WKUP/MCU domain and MAIN Pulsar manages time out events for the gaskets inserted in the MAIN domain, including the ones inserted inside MAIN NAVSS and compute cluster.

3.2.7.1 Location of Safety Gaskets

Initiator Timeout Gaskets (MTOGs) are inserted on all non-ASIL-D initiators (or in several cases group of initiators of a common safety level) in the SoC (except LED and Debug which should not activate in end-customer usage).

Target Timeout Gaskets (STOGs) are inserted either directly on the non-ASIL-D target or on a port to a group of non-ASIL-D targets.

A special case is insertion of snoop-only MTOGs on the MAIN Pulsar memory initiators. All of the four initiators from Pulsar (two CPU x two initiators each (Read and Write)) go through snoop-only MTOG. This is done to handle the special case of a fault in A72 Subsystem on a snoop transaction. If a cache snoop transaction from MSMC to the A72 subsystem hangs it could cause the requestor of the snoop to hang which could eventually cause the MAIN Pulsar to also hang since it funnels through the same path in the bus topology. The MTOG is required to handle this case.

In order to support MCU Pulsar perform XIP from flash (either OSPI or Hyperbus), the safety gasket is inserted for FSS's data target port to prevent any fault happen in external flash device causing MCU Pulsar to stall.

The Initiator-Target Connections, the System Interconnect chapter, show connectivity of all initiators to the STOGs.

3.2.7.2 Initiator Timeout Gasket (MTOG)

The MTOG provides the ability to isolate an initiator from the Bus Topology so that it does not the leave the Bus Topology with pending commands and responses while it undergoes a reset cycle to recover from the fault.

Table 3-7. MTOG Instances and Registers

MTOG Instance	Register Name	Register Description
MTOG0	CTRL_MMR_CFG0_MAIN_MTOG0_CTRL	Controls timeout operation of read transactions from the GIC master port
MTOG1	CTRL_MMR_CFG0_MAIN_MTOG1_CTRL	Controls timeout operation of write transactions from the GIC master port
MTOG4	CTRL_MMR_CFG0_MAIN_MTOG4_CTRL	Controls timeout operation of read transactions from the eMMC1 master port
MTOG5	CTRL_MMR_CFG0_MAIN_MTOG5_CTRL	Controls timeout operation of write transactions from the eMMC1 master port

Table 3-7. MTOG Instances and Registers (continued)

MTOG Instance	Register Name	Register Description
MTOG14	CTRL_MMR_CFG0_MAIN_MTOG14_CTRL	Controls timeout operation of transactions from the NavSS PVU to VIRTSS
MTOG16	CTRL_MMR_CFG0_MAIN_MTOG16_CTRL	Controls timeout operation of read transactions from the MAIN R5 Clstr0 Core0 VBUSM Memory master port
MTOG17	CTRL_MMR_CFG0_MAIN_MTOG17_CTRL	Controls timeout operation of write transactions from the MAIN R5 Clstr0 Core0 VBUSM Memory master port
MTOG18	CTRL_MMR_CFG0_MAIN_MTOG18_CTRL	Controls timeout operation of read transactions from the MAIN R5 Clstr0 Core1 VBUSM Memory master port
MTOG19	CTRL_MMR_CFG0_MAIN_MTOG19_CTRL	Controls timeout operation of write transactions from the MAIN R5 Clstr0 Core1 VBUSM Memory master port
MTOG20	CTRL_MMR_CFG0_MAIN_MTOG20_CTRL	Controls timeout operation of read transactions from the MAIN R5 Clstr1 Core0 VBUSM Memory master port
MTOG21	CTRL_MMR_CFG0_MAIN_MTOG21_CTRL	Controls timeout operation of write transactions from the MAIN R5 Clstr1 Core0 VBUSM Memory master port
MTOG22	CTRL_MMR_CFG0_MAIN_MTOG22_CTRL	Controls timeout operation of read transactions from the MAIN R5 Clstr1 Core1 VBUSM Memory master port
MTOG23	CTRL_MMR_CFG0_MAIN_MTOG23_CTRL	Controls timeout operation of write transactions from the MAIN R5 Clstr1 Core 1 VBUSM Memory master port
MTOG24	CTRL_MMR_CFG0_MAIN_MTOG24_CTRL	Controls timeout operation of real time transactions from High Speed IO masters
MTOG25	CTRL_MMR_CFG0_MAIN_MTOG25_CTRL	Controls timeout operation of non-real time transactions from High Speed IO masters
MTOG32	CTRL_MMR_CFG0_MAIN_MTOG32_CTRL	Controls timeout operation of Accelerator Cluster ASIL-B master accesses to MSMC (L2) SRAM
MTOG33	CTRL_MMR_CFG0_MAIN_MTOG33_CTRL	Controls timeout operation of Accelerator Cluster QueueManager master accesses to MSMC (L2) SRAM
MTOG34	CTRL_MMR_CFG0_MAIN_MTOG34_CTRL	Controls timeout operation of Accelerator Cluster ASIL-B master accesses to DDR for OrderIDs 0-4
MTOG35	CTRL_MMR_CFG0_MAIN_MTOG35_CTRL	Controls timeout operation of Accelerator Cluster QueueManager master accesses to DDR from OrderIDs 0-4
MTOG36	CTRL_MMR_CFG0_MAIN_MTOG36_CTRL	Controls timeout operation of Accelerator Cluster ASIL-B master accesses to DDR for OrderIDs 5-9
MTOG37	CTRL_MMR_CFG0_MAIN_MTOG37_CTRL	Controls timeout operation of Accelerator Cluster QueueManager master accesses to DDR for OrderIDs 5-9
MTOG38	CTRL_MMR_CFG0_MAIN_MTOG38_CTRL	Controls timeout operation of Accelerator Cluster ASIL-B master accesses to DDR for OrderIDs 10-15

Table 3-7. MTOG Instances and Registers (continued)

MTOG Instance	Register Name	Register Description
MTOG39	CTRL_MMR_CFG0_MAIN_MTOG39_CTRL	Controls timeout operation of Accelerator Cluster QueueManager master accesses to DDR for OrderIDs 10-15
MTOG40	CTRL_MMR_CFG0_MAIN_MTOG40_CTRL	Controls timeout operation of read transactions from the MAIN R5 Clstr2 Core0 VBUSM Memory master port
MTOG41	CTRL_MMR_CFG0_MAIN_MTOG41_CTRL	Controls timeout operation of write transactions from the MAIN R5 Clstr2 Core0 VBUSM Memory master port
MTOG42	CTRL_MMR_CFG0_MAIN_MTOG42_CTRL	Controls timeout operation of read transactions from the MAIN R5 Clstr2 Core1 VBUSM Memory master port
MTOG43	CTRL_MMR_CFG0_MAIN_MTOG43_CTRL	Controls timeout operation of write transactions from the MAIN R5 Clstr2 Core1 VBUSM Memory master port

For self-test the *MAIN_MTOG0_CTRL_FORCE_TIMEOUT* bitfield can be used. See Register Descriptions for further details.

3.2.7.2.1 MTOG Programming Sequence

3.2.7.2.1.1 Enable

1. Configure ESM handler
2. Configure and start Master Timeout Gasket
3. Wait for MTOG Interrupt

3.2.7.2.1.2 Self-Test

1. Configure ESM handler
2. Configure and start Master Timeout Gasket
3. Inject master timeout error
4. Wait for MTOG Interrupt
5. Disable ESM

3.2.7.3 Target Timeout Gasket (STOG)

In general, the reset input for STOG is shared with the reset of the protected side and the flush input with the reset of the unprotected side. Since the STOG is most often on CBASS target ports and the CBASS derives its reset from the primary domain reset, it implies the STOG reset is also derived from the reset of the domain it belongs to.

The self-test target addresses and self-test timeout values can be used to trigger STOG interrupt.

Region Name	Base Address	STOG	Reset	Flush	Self-Test Timeout Cycles	Self-Test Target Address
AM_NAVSS_TO_AC_NON_SAFE_STOG4_CFG	0x2610000	NAVSS VIRT to HWA RAMs	MAIN CBASS Reset	AC CBASS ASILB Reset	0x01000000	0x4F000000

3.2.7.3.1 STOG Flush Mode

Software flush is initiated by writing to the Flush Register (Base Address + 0x10).

Whenever in flush mode:

- All currently outstanding transactions will be flushed
- All new incoming commands will not be forwarded to the destination, and subsequently flushed
- All incoming responses from the destination side will be discarded.

In addition, if a command times out before it is ever accepted on the destination side of the bridge, the gasket will automatically enter Software flush mode (Flush Register (Base Address + 0x10) flush field set to 4'b1111). Software may use this MMR to subsequently turn flush mode off.

3.2.7.3.2 STOG Error Reporting

3.2.7.3.2.1 Timeout Error Reporting

If a transaction times out and a Transaction Timeout Interrupt is asserted (and there are no currently outstanding Interrupts) then the following registers are loaded with the information about the transaction that timed out:

- Direction/orderid
- Routeid/id
- Original Bytecnt / Current Bytecnt
- Address0
- Address1

The Timeout Error Info Register (Base Address + 0x30) register keeps track of how many Transaction Timeout Interrupts have occurred since the last one was serviced. Whenever a Transaction Timeout Interrupt occurs, the value is incremented (until saturated). If a Transaction Timeout Interrupt occurs and there is already one pending, then the counter will be incremented by one but the reporting information for the new transaction will be lost.

3.2.7.3.2.2 Command Timeout Error Reporting

If a transaction times out not because all of the responses didn't come back but because the command was never accepted in the first place, this is a Command Timeout. Note that a command timeout will ultimately lead to two interrupts, one when the command times out and is pushed onto the timeout queue and a second when the transaction times out from the queue. When the transaction timeout happens, the same information is recorded for reporting purposes.

3.2.7.3.2.3 Unexpected Response Reporting

If an Unexpected Response Interrupt is asserted (and there are no currently outstanding interrupts) then the following registers are loaded with information about the unexpected response:

- Direction/orderid
- Routeid/cid
- Bytecnt

The Unexpected Response Info Register (Base Address + 0x34) register keeps track of how many Unexpected Transaction Interrupts have occurred since the last one was serviced. Whenever an Unexpected Transaction Interrupt occurs, the value is incremented (until saturated). If an Unexpected Transaction Interrupt occurs and there is already one pending, then the counter will be incremented by one but the reporting information for the new transaction will be lost.

3.2.7.3.3 STOG Transaction Error Interrupt

The Transaction Error Interrupt signals that the gasket has detected an error on a transaction. The gasket will return an appropriate response to the source side, so the source will not immediately violate a safety goal, but it is assumed that something uncorrected has happened in the system. The system must treat this as a dangerous event and react accordingly. The specific response is up to the system integrator, but possibilities are discussed below. There are three possible causes of the Transaction Error Interrupt, transaction timeout, unexpected response, and command timeout. Software should query the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24) to determine the cause.

3.2.7.3.3.1 Transaction Timeout

If all of the responses to a transaction have not been received within the time allotted (programmed by the Timeout Value Register (Base Address + 0x10)) or if a transaction was never accepted (Command Timeout) and placed on the timeout queue, then a transaction is considered to have timed out. The interrupt indicates that the gasket is flushing the transaction and that information has been logged about the transaction that timed out in the following registers:

- Error Transaction Valid/Dir/ID Register (Base Address + 0x38)
- Error Transaction RouteID/OrderID Register (Base Address + 0x3C)
- Error Transaction Bytecnt Register (Base Address + 0x40)
- Error Transaction Upper Address Register (Base Address + 0x44)
- Error Transaction Lower Address Register (Base Address + 0x48)

When servicing a Transaction Timeout Error, software should perform the following steps:

1. Read the Timeout Error Info Register (Base Address + 0x30) to determine how many transaction timeouts have occurred since last serviced
2. Read the Error Transaction Valid/Dir/ID Register (Base Address + 0x38)
 - If the valid field is 0 or the type field is Unexpected Response, then these registers do not contain any information about the timed out transaction, skip to step 4
3. Read the information from the following registers:
 - Error Transaction RouteID/OrderID Register (Base Address + 0x3C)
 - Error Transaction Bytecnt Register (Base Address + 0x40)
 - Error Transaction Upper Address Register (Base Address + 0x44)
 - Error Transaction Lower Address Register (Base Address + 0x48)
 - Error Transaction Lower Address Register (Base Address + 0x48)
4. Write the number of timed out events serviced this ISR (read in step 1) to the Timeout Error Info Register (Base Address + 0x30)
5. Clear the interrupt by writing to the appropriate bit in the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24)

If the write in step 4 does not decrement the value to 0 (because a new transaction has timed out), then the interrupt will re-issue after the write in step 5.

This section only describes how to service the interrupt. It is up to the system integrator to decide what actions to take based on this information. Suggestions are:

- Log the information for debug purposes
- Determine the slave that is unresponsive and take appropriate action
 - Reset target slave
 - Reset main SoC
 - Reset whole device

3.2.7.3.3.2 Unexpected Response

If the gasket receives a response that it was not expecting then this interrupt will be triggered. See *Unexpected Response Reporting* for a discussion of unexpected responses. When this interrupt is triggered, information about the unexpected response will be in the following registers:

- Error Transaction Valid/Dir/ID Register (Base Address + 0x38)
- Error Transaction RouteID/OrderID Register (Base Address + 0x3C)
- Error Transaction Bytecnt Register (Base Address + 0x40)

When servicing an Unexpected Response Error, software should perform the following steps:

1. Read the Unexpected Response Info Register (Base Address + 0x34) to determine how many unexpected responses have occurred since last serviced
2. Read the Error Transaction Valid/Dir/ID Register (Base Address + 0x38)
 - If the valid field is 0 or the type field is Timeout Error, then these registers do not contain any information about the unexpected response, skip to step 4
3. Read the information from the following registers:
 - Error Transaction RouteID/OrderID Register (Base Address + 0x3C)
 - Error Transaction Bytecnt Register (Base Address + 0x40)
4. Write the number of unexpected responses serviced this ISR (read in step 1) to the Unexpected Response Info Register (Base Address + 0x34)
5. Clear the interrupt by writing to the appropriate bit in the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24)

If the write in step 4 does not decrement the value to 0 (because a new unexpected response has arrived), then the interrupt will re-issue after the write in step 5.

This section only describes how to service the interrupt. It is up to the system integrator to decide what actions to take based on this information. Suggestions are:

- Log the information for debug purposes
- Determine the slave that is unresponsive and take appropriate action
 - Reset target slave
 - Reset main SoC
 - Reset whole device

3.2.7.3.3.3 Command Timeout

A Command Timeout happens when a command is presented on the destination side but never accepted within the allotted time. See *Command Timeout Error Reporting*. When this happens, a Command Timeout interrupt is issued. When servicing a Command Timeout Error, software should perform the following step:

1. Clear the interrupt by writing to the appropriate bit in the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24)

When a Command Timeout occurs. The gasket automatically transitions to Software Flush mode (see *Flush Mode*). The system can assume that the target infrastructure is hung and take appropriate action. Suggested actions include:

- Transitioning to a safe state
- Re-setting the target domain to eliminate the hang
- Re-enable the gasket (disable software flush) and attempt further access.

3.2.7.3.4 STOG Programming Sequence

3.2.7.3.4.1 Initialization

Software should take the following steps when initializing the gasket.

1. Enable/Disable gasket as desired (Default enabled - Enable Register (Base Address + 0x08))
2. Set the timeout value as desired (Default max - Timeout Value Register (Base Address + 0x10))
3. Enable/Disable interrupts as desired (Default enabled - Error Interrupt Enabled Status/Clear Register (Base Address + 0x24))

3.2.7.3.4.2 Software Flush

If the system determines that it needs to flush all outstanding transactions (for instance, because the main SoC is in an error condition and is going to be reset), software may do this by writing to the Flush Register (Base Address + 0x10). Once all transactions are flushed, software should exit Flush mode. If the destination side is in reset, this should trigger hardware flush, keeping the gasket returning any transactions that arrive. The system should keep transactions from going to the gasket when the destination side is taken down as well.

4 Initialization

This chapter describes the steps for non-secure device initialization.

4.1 Initialization Overview	185
4.2 Boot Process	188
4.3 Boot Mode Pins	193
4.4 Boot Parameter Tables	223
4.5 Boot Image Format	232
4.6 Boot Modes	239
4.7 Boot Memory Maps	244

4.1 Initialization Overview

Figure 4-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip(s)
- **ROM code:** Responsible for finding, for downloading, and for executing the initial software (SBL)
- **Initial software:** Software that loads, prepares, and passes control to application software or to the high-level operating system (HLOS)
- **High-Level Operating System** or bare-metal application which runs on main processor(s)

init-003

Figure 4-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins, the associated configuration registers, and memory structures that are vital to the correct initialization of the device.

4.1.1 ROM Code Overview

ROM bootloader (or ROM Code) is a software that resides in a on-chip read-only memory (ROM) to assist the customer in transferring and executing their application code. The device has two ROM codes operating in tandem – the MCU ROM code, and the SMS ROM code.

In order to accommodate various system scenarios, the ROM Code supports several boot modes. These boot modes can be broadly classified as:

- Host boot modes
- Memory boot modes.

During a host boot, the device is configured to receive code from a host via the selected interface. Either the host writes the application code directly into internal memory or the ROM Code receives the application code on the selected interface and stores it in internal memory.

During a memory boot, the device transfers code from non-volatile memory to internal memory for execution.

In all boot modes, the entire boot operation can be partitioned into two sections:

1. Hardware initialization phase
2. Boot process.

During initialization, the ROM Code configures the device resources (PLLs, peripherals, pins) as needed to support the boot process. The resources used depend on the boot mode requirements.

During the boot process the boot image can be loaded into device memory and executed, or executed in place, depending on the boot peripheral. SMS will perform code verification and allow, or forbid, the image execution.

Main configuration source for boot after power-up are the BOOTMODE pins sampled automatically after reset release and stored in device status registers. At ROM Code startup, these pin values are read from the registers to create the boot peripheral list and the boot configuration tables used later to initialize and startup the PLLs and boot peripherals.

The ROM Code also provides a multi-stage boot mechanism.

4.1.2 Bootloader Modes

Table 4-1 shows the boot modes supported by ROM code.

Table 4-1. ROM Code Boot Modes

Boot Mode	Boot Media/Host	SoC Peripheral	Peripheral's Domain ⁽¹⁾	Can be a Backup Mode? ⁽²⁾	Notes
No-boot/Dev-boot	No media or host	None	N/A	N	No boot or development boot – debug modes
Serial NAND	Serial NAND flash	MCU_FSS0_OSPI0	MCU	N	On OSPI port
OSPI	OSPI flash	MCU_FSS0_OSPI0	MCU	N	On OSPI port
QSPI	QSPI flash/EEPROM	MCU_FSS0_OSPI0	MCU	N	On OSPI port
SPI	SPI EEPROM	MCU_FSS0_OSPI0	MCU	Y ⁽³⁾	On OSPI port
Hyperflash	Hyperflash NOR flash	MCU_FSS0_HPBO	MCU	N	-
Ethernet	External host	MCU_CPSW0	MCU	Y ⁽³⁾	In BOOTP mode. RGMII or RMII PHY
I2C	I ² C EEPROM	MCU_I2C0	MCU	Y	I2C slave boot is not supported
UART	External host	MCU_UART0 or WKUP_UART0	MCU	Y	XMODEM protocol
MMCSD	MMC/SD card	MMCSD0 or MMCSD1	MAIN	Y ⁽³⁾	Boot from User Data Area (UDA) or file system
eMMC	eMMC flash	MMCSD0 or MMCSD1	MAIN	N	Boot from boot partition with auto-fall back to file system
USB	External host	USB0	MAIN	Y ⁽³⁾	USB device mode boot using DFU (device firmware upgrade). Boot from USB flash drive is not supported. Boot is running on USB2.0 speeds.
PCIe	External host	PCIE1	MAIN	N	-
xSPI	xSPI flash	MCU_FSS0_OSPI0	MCU	N	On OSPI port
Fast-xSPI	xSPI flash	MCU_FSS0_OSPI0	MCU	N	On OSPI port

(1) Peripherals in the MCU domain are available for boot even when main domain is not powered.

(2) The peripheral can be selected also as a backup boot mode. A backup mode is tried if primary boot mode fails.

(3) When in normal boot flow (MCU Only = 0)

Note

Because different devices support different sets of peripherals, see the *device-specific Datasheet* to obtain the list of peripherals supported in your device.

4.1.3 Terminology

- **Boot Mode Pins:** Boot mode pins provide vital information to ROM code for boot. These pins must be properly set up before power ramp.
- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase.
- **Boot Header:** Optional structure that precedes the initial software and allows the redefinition of the ROM code default settings.
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase.
- **eFuse:** A one-time programmable memory location usually set at the factory.
- **Flash loader:** Downloaded software launched by the ROM code during the preflashing stage. It also programs an image in external memories.
- **GP device:** General-purpose device (SoC) or a non-secure device.
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software. This can be the SBL (secondary bootloader) responsible for loading an OS.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory.
- **Master CPU:** The Arm® Cortex® CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).

- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory.
- **ROM Code:** or ROM bootloader (RBL), the on-chip software in device ROM that executes first and implements booting.
- **ROM Code-controlled Boot Phase:** This phase covers the sequence operations from the time the platform releases the reset to the time first user- or customer-owned software starts execution. This phase is fully controlled by the device ROM code.
- **OCMC RAM memory:** On-chip RAM memory used by ROM code during boot and also for loading the booting image. ROM code is using MCU_MS0RAM0
- **Booting Parameter Table:** A logical structure stored in the on-chip RAM memory and contains information for the boot, such as the boot file name or an address to boot from.

4.2 Boot Process

4.2.1 MCU ROM Code Architecture

The MCU ROM code has the following components (see also [Figure 4-2](#)):

- Main
- Buffer manager
- X.509
- Log and Trace
- System
- Protocol
- Driver

Figure 4-2. MCU ROM Code Architecture

4.2.1.1 Main Module

The Main module contains the top level execution loop. This loop repeats until a boot image has been received or directed to sleep by the SMS. The main loop has three different execution sub-paths based on the boot peripheral.

- **Image Path** This path is used by the USB-DFU, PCIe, OSPI, Hyperflash, and QSPI boot modes. In these cases the image data can be directly read by both, MCU and SMS, in place.
- **Block Path** This path is used by the SPI, I2C, UART, eMMC, Ethernet, Serial NAND, and MMC/SD cards in raw mode. In this mode data is received from the peripheral in blocks. Blocks are accumulated in the boot buffer until a full X.509 certificate header has been received, at which point this full certificate and any subsequent blocks are passed to the SMS as they arrive.
- **Filesystem Path** This path is used by the MMC/SD cards in filesystem mode. This mode executes exactly like in the block path, except that the boot image location is defined by a filesystem.

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images.

4.2.1.2 X509 Module

The X509 module parses the boot header. The boot header is an X.509 certificate as defined in [RFC5280](#). Extensions specific to boot are described in [Section 4.5.2, X.509 Certificate](#).

This module also includes an OID decoder as well as defines OID values as C #define constants for any values that can be used during boot.

4.2.1.3 Buffer Manager Module

The buffer manager module is used to allocate buffers to hold boot data. The MCU code allocates a buffer when it is ready to read a block of data from the boot peripheral. Once the data is read the buffer ownership is passed to the SMS. When the SMS has completed processing the data in the buffer ownership is returned to the MCU, which then frees the buffer.

4.2.1.4 Log and Trace Module

The Log and Trace modules are not integral to the boot process. Instead, they provide ability to record operation of the ROM code and track unexpected occurrences.

Log and trace function is currently TI internal.

4.2.1.5 System Module

The system module provides services to other modules. These services are not directly related to boot drivers. The system module is the only module that operates in the supervisor mode of the MCU (a few services will run in user). The system module supports the following functions:

- Interrupt enable, disable, and service
- IPC
- Power
- Pinmux
- Clock
- Task switch

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images.

4.2.1.6 Protocol Module

The protocol modules provide implementation of high-level data transfer protocols. The BOOTP/TFTP and XMODEM protocols reside in this layer. These modules provide services as defined in well-known standards.

4.2.1.7 Driver Module

The driver module implements the low level peripheral drivers.

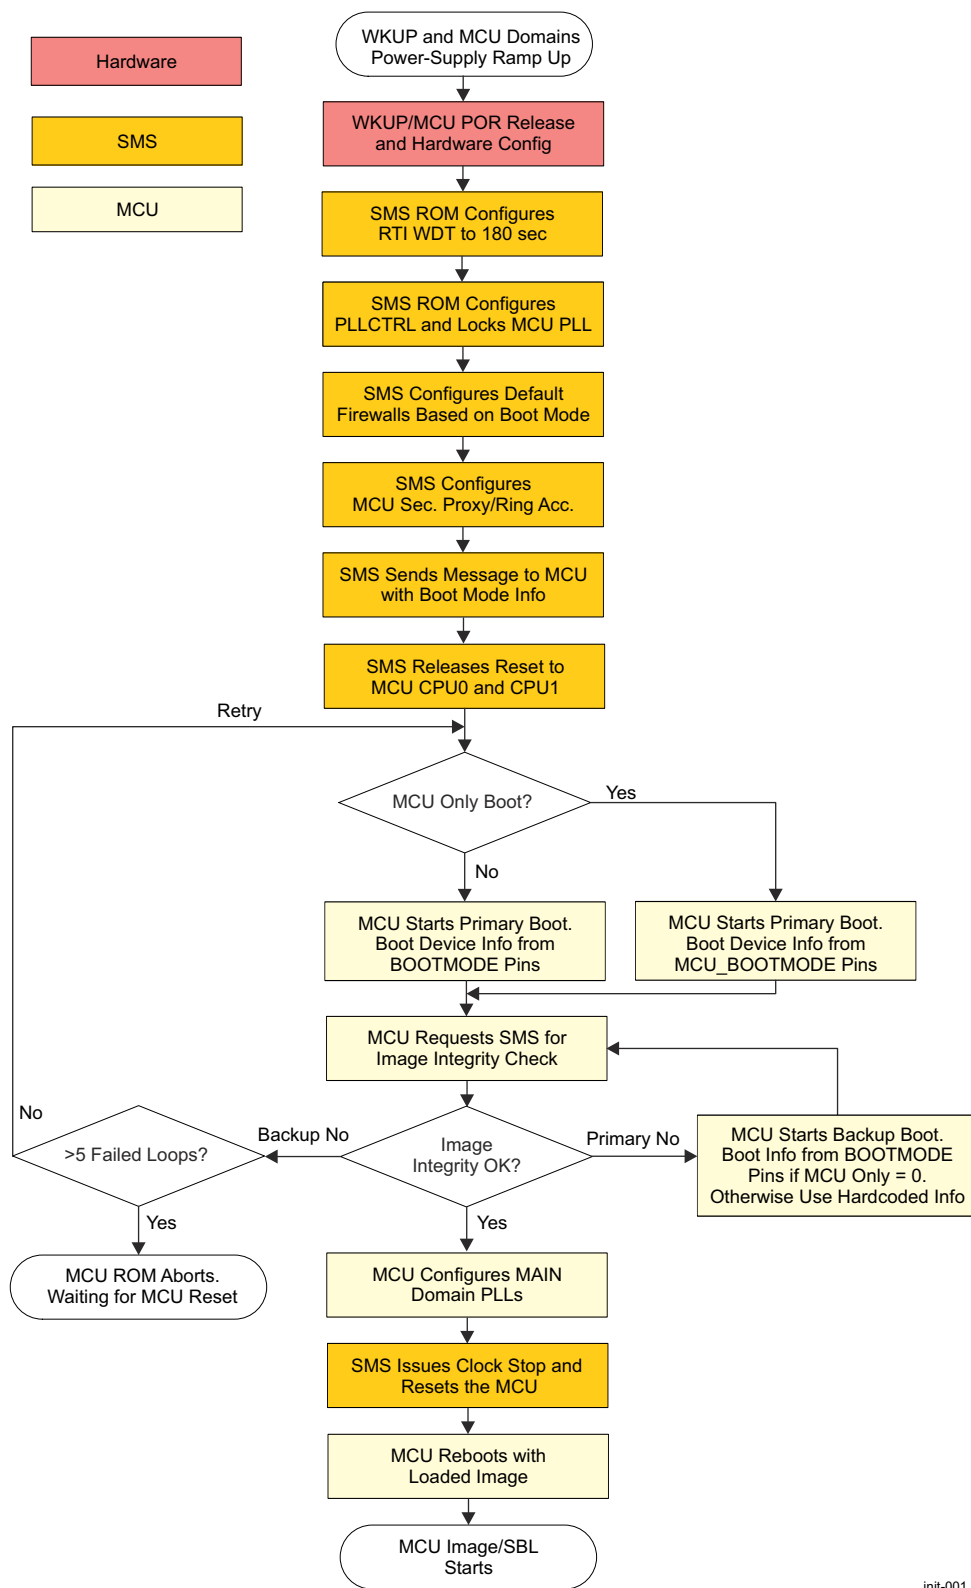

4.2.2 SMS ROM Description

In a general-purpose (GP) device, SMS ROM performs the following functions:

- Device management
- Configures the boot vectors (in BOOT_CFG) and controls reset release of MCU core. That is, SMS is the boot master of MCU core.
- IPC configuration via MCU_NAVSS rings and Secure Proxy
- PLL configuration (MCU subsystem and SA2UL)
- X509 certificate parsing
- SA2UL configuration to SHA512 for image integrity checks
- Test flow support – Wait-In-Reset commands
- SMS firmware loading

4.2.3 Boot Process Flow

The MCU boot process flow is shown in [Figure 4-3](#).

init-001

Figure 4-3. Boot Process

The values of (MCU_)BOOTMODE pins are latched into the Device Status register (CTRLMMR_WKUP_DEVSTAT) by hardware as the device comes out of global cold reset. When MCU Only boot was selected, only MCU_BOOTMODE pins are taken into account and only MCUSS set of peripherals are

available for boot. For more information how to set BOOTMODE and MCU_BOOTMODE pins, see [Section 4.3, Boot Mode Pins](#).

The SMS is the boot master of MCU. SMS performs the necessary configurations and releases MCU's reset for CPU0 and CPU1 simultaneously even when in split mode.

Note

SMS releases MCU's reset for CPU0 and CPU1 simultaneously regardless if MCU CPUs are in lockstep or split mode.

The MCU checks the boot mode pins and then configures the appropriate peripheral interface to get access to a boot image. A cursory check of the image is made, and the image is passed to SMS. SMS ROM then will perform code verification and route the boot image to the on-chip RAM. Once the image has been received, MCU enters a clean state and idles. SMS ROM code will assert reset to the MCU, redirect the boot vector to the newly loaded image, and release the reset. This restarts the MCU with the MCU ROM code fully disconnected.

The MCU ROM code executes only on initial power up (POR). On subsequent (warm) resets, the reset vector base address will point to run-time loaded code (the SBL), and not ROM.

Note

SMS ROM sets up a 3-minute watchdog timer (MCU_RTI0) timeout. During this time, the MCU boot needs to get completed, otherwise a WDT reset will occur. Once the MCU image is loaded (SBL/SPL), SMS ROM will restart the watchdog timer for additional 3 minutes upon entering the MCU SBL. The customer-provided MCU image needs to load and install the TI-provided SYSFW image into the SMS, which will manage the watchdog timer during run time.

Note

The following system conditions must be met at POR to perform device boot:

- USB cable plug must be inserted
- Ethernet PHY is powered up and out of reset
- The SD card cage must be powered before entering the SD card boot mode. A SD/MMC card with pre-loaded image must be inserted
- Memory devices must be up and ready (power ramped up and reset completed) at device startup:
 - eMMC
 - OSPI/QSPI/xSPI flash
 - SPI or I²C EEPROM
 - Hyperflash
 - Serial NAND

Failing to meet these requirements may result in boot fail and performing a backup boot (if available for that mode).

Figure 4-4. External Bootloader Tasks

Upon MCU reset and SBL execution start, SMS ROM restarts the RTI watchdog timer for additional 180 seconds of timeout. During that time, SBL must load the SMS firmware provided by TI otherwise a MCU reset will occur as a preventive measure against software misbehavior.

One of the SBL's main tasks is to load the SMS firmware. Only after this task is performed, SBL can load the other processor (A72s, R5s) image and request a reset release from SMS firmware for those cores.

4.2.4 MCU Only vs Normal Boot

Users can select a special (MCU only) boot flow, which can boot the MCU, even if the main domain is unpowered. The MCU-only boot differences versus the normal boot are described below:

Normal Boot — Requires minimum of:

- VDDS*_MCU
- VDD_MCU
- and VDD_CORE, VDD_CPU

voltage rails ON. Other voltage rails are optional.

Power domains for WKUP, MCUSS and Core domain are ON. Power domains required for the specified boot mode may be turned-on by the boot ROM code, if they are OFF by default.

MCU-Only Boot — Requires minimum of:

- VDDS*_MCU
- VDD_MCU

voltage rails ON. Other voltage rails are optional. Power domains for WKUP and MCUSS are ON (only R5 is switchable). Core domain is unknown (may be powered or unpowered). Only limited set of boot modes involving MCUSS peripherals are supported. Power domains required for the specified boot mode may be turned-on by the boot ROM code, if they are OFF by default

4.3 Boot Mode Pins

Boot Mode pins provide means to select the boot mode and options before the device is powered up. After every POR, they are the main source to populate the Boot Parameter Tables. See [Section 4.4, Boot Parameter Tables](#) for table list and description.

Boot mode pins can be divided into the following categories:

- **MCU_BOOTMODE[02:00]** – Denote system clock frequency (WKUP_HFOSC0) to ROM code for PLL configuration.
- **MCU_BOOTMODE[05:03]** – Select the requested boot (primary) mode after POR, that is, the peripheral/memory to boot from. These are the only pins which direct boot on MCU Only boot mode
- **MCU_BOOTMODE06** – MCU Only boot mode. In MCU Only boot, ROM code skips BOOTMODE pins and attempts boot only from MCU peripherals
- **MCU_BOOTMODE[09:08]** – These pins can select tests to be performed on power-up (POST). POST runs in hardware, before the ROM code starts
- **BOOTMODE0** – This pin allows for additional primary boot modes to be selected when in non-MCU Only (normal) mode
- **BOOTMODE[3:1]** – Select the backup boot mode, that is, the peripheral/memory to boot from, if primary boot device failed.
- **BOOTMODE[6:4]** – These pins provide optional configurations for primary boot and are used in conjunction with the boot mode selected. See [Section 4.3.2.3](#) and the corresponding boot mode section.
- **BOOTMODE7** – This pin provides optional configurations for the backup boot devices. See [Section 4.3.2.4](#) and the corresponding boot mode section.

Note

It is user's responsibility to set the boot mode pins (via pullups or pulldowns, and jumpers/switches) depending on the desired boot scenario.

System board must provide means to switch bootmode pin settings easily. In a field design, some pins may be hardcoded to 0 or 1 only after a careful evaluation (for example, if using MCU Only pin = 1).

Note

CTRLMMR_WKUP_DEVSTAT[23:16] register reflects the BOOTMODE pin values sampled after MCU_POR release.

CTRLMMR_WKUP_DEVSTAT[9:0] register reflects the MCU_BOOTMODE pin values sampled after MCU_POR release.

4.3.1 MCU_BOOTMODE Pin Mapping

The MCU_BOOTMODE pins are sampled during both, MCU-Only and normal boot. The MCU_BOOTMODE pins are the only pins sampled during MCU-only boot mode, that is, BOOTMODE pins are not considered. MCU_BOOTMODE pin mapping is shown in [Table 4-2](#).

Table 4-2. MCU_BOOTMODE Pin Mapping

MCU 9	MCU 8	MCU 7	MCU 6	MCU 5	MCU 4	MCU 3	MCU 2	MCU 1	MCU 0
POST Config ⁽¹⁾		OVRD ⁽²⁾	MCU Only	Primary Boot Mode A			PLL Config		

(1) POST function is not handled by ROM Code. It is executed in hardware before ROM Code starts.

(2) Pull MCU 7 to 0 on GP devices.

[Table 4-3](#) describes the MCU_BOOTMODE pins that need to be set according to the system clock provided to the device.

The ROM Code will configure any PLLs required during the boot process. The ROM Code does not have the ability to select HFOSC1 (in main domain) during initial boot, however the selection can be done through the boot certificate (see [Section 4.5, Boot Image Format](#)).

Table 4-3. PLL Reference Clock Selection

PLL Config Pins			Ref Clock (MHz)
MCU 2	MCU 1	MCU 0	
0	0	0	19.2
0	0	1	20
0	1	0	24
0	1	1	25
1	0	0	26
1	0	1	27
1	1	0	Reserved
1	1	1	No PLL setup ⁽¹⁾

(1) Only no-boot, Hyperflash, and OSPI modes are expected to function with PLL config = 7 (No PLL setup)

If MCU Only mode (boot from MCU domain only) needs to be selected, the MCU Only pin must be set to 1 (see [Table 4-4](#)).

Table 4-4. MCU Only Selection

MCU Only Pin	MCU Only Selection
MCU 6	
0	Normal boot mode. Both MCU_BOOTMODE and BOOTMODE pins are read by ROM code
1	MCU Only boot mode. Boot can proceed only from MCU peripherals

Power-On Self-Test sequence is executed as directed by pins shown in [Table 4-5](#). Dedicated eFuse bits may override the POST pins. See register CTRLMMR_WKUP_POST_OPT in section *WKUP_CTRL_MMR0 Registers* and POST section in the Safety Manual for details.

Table 4-5. POST Selection

POST Config Pins		POST Sequence
MCU 9	MCU 8	
0	0	DMSC LBIST followed by MCU LBIST followed by PBIST ^{(2) (3)}
0	1	DMSC LBIST and MCU LBIST in parallel followed by PBIST ⁽²⁾
1	0	DMSC LBISTReserved ⁽²⁾
1	1	POST bypass ⁽¹⁾

(1) eFuse may has been programmed so that these pins are overridden and a POST sequence is always executed (no bypass possible).

(2) This sequence may has been replaced by another via eFuse settings. See register CTRLMMR_WKUP_POST_OPT in section *WKUP_CTRL_MMR0 Registers* and POST section in Safety Manual, for details.

- (3) To determine if device under test supports LBIST POST, Register CTRLMMR_WKUP_POST_CFG0 (0x4300_C2C4); bit 31, which defines whether the PLL for FAST POST is enabled, can be read:
- [31] = 0, LBIST POST Timeout is expected on the device under test
 - [31] = 1, LBIST POST is expected to pass

Table 4-6 lists the boot modes (both primary and backup), available when MCU Only boot was selected. For normal boot modes, refer to Table 4-8 and Table 4-9

Table 4-6. Boot Mode Selection When MCU Only (MCU 6) = 1

Primary Boot Mode B Pin	Primary Boot Mode A Pins			Primary Boot Mode Selected	Backup Boot Mode Assigned ⁽¹⁾
	MCU 5	MCU 4	MCU 3		
0	0	0	0	Hyperflash	UART
0	0	0	1	OSPI	UART
0	0	1	0	QSPI	UART
0	0	1	1	xSPI	UART
0	1	0	0	Ethernet RGMII	I2C
0	1	0	1	Serial NAND	I2C
0	1	1	0	I2C	UART
0	1	1	1	UART	I2C
1	1	0	0	Ethernet RMII	I2C
1	1	1	0	SPI	UART
1	0	1	1	Fast xSPI	UART

- (1) When MCU Only = 1, backup mode is assigned per primary mode. In general, non-flash primary boot modes are backed up with flash modes, and flash primary modes use non-flash for backup.

4.3.2 BOOTMODE Pin Mapping

In normal boot operation (MCU Only = 0), the ROM execution is directed also through the main boot mode pins. This provides more flexibility and more booting peripherals to boot from. The Main domain must be powered and functional when MCU Only = 0.

Main boot mode pins are shown in [Table 4-7](#).

Table 4-7. BOOTMODE Pin Mapping

7	6	5	4	3	2	1	0
Backup Boot Mode Config	Primary Boot Mode Config			Backup Boot Mode			Primary Boot Mode B

4.3.2.1 Primary Boot Mode Selection

The primary boot mode is the first mode attempted after reset. [Table 4-8](#) lists all possible primary boot modes. Boot modes with Boot Mode B = 1 are available during normal boot only.

Table 4-8. Primary Boot Mode Selection When MCU Only (MCU 6) = 0

Primary Boot Mode B Pin	Primary Boot Mode A Pins			Boot Mode Selected
0	MCU 5	MCU 4	MCU 3	
0	0	0	0	Hyperflash
0	0	0	1	OSPI
0	0	1	0	QSPI
0	0	1	1	xSPI
0	1	0	0	Ethernet RGMII
0	1	0	1	Serial NAND
0	1	1	0	I2C
0	1	1	1	UART
1	0	0	0	MMC/SD card
1	0	0	1	eMMC
1	0	1	0	USB
1	1	0	0	Ethernet RMII
1	1	0	1	PCIe
1	1	1	0	SPI
1	0	1	1	Fast-xSPI
1	1	1	1	No-boot/Dev boot

4.3.2.2 Backup Boot Mode Selection When MCU Only = 0

With MCU Only = 0, the backup boot mode is selected via pins within the main BOOTMODE map. [Table 4-9](#) lists all possible backup boot modes when MCU Only = 0. For backup boot modes when MCU Only = 1, please refer to [Table 4-6](#).

Table 4-9. Backup Mode Selection When MCU Only (MCU 6) = 0

Backup Boot Mode Pins			Backup Boot Mode Selected
3	2	1	
0	0	0	None (no backup boot will be attempted)
0	0	1	USB – Device (DFU)
0	1	0	Reserved
0	1	1	UART
1	0	0	Ethernet
1	0	1	MMC/SD card
1	1	0	SPI

Table 4-9. Backup Mode Selection When MCU Only (MCU 6) = 0 (continued)

Backup Boot Mode Pins			Backup Boot Mode Selected
3	2	1	
1	1	1	I2C

4.3.2.3 Primary Boot Mode Configuration

When in normal boot flow (MCU Only = 0), it is possible to modify certain peripheral settings, such as chip-select, bus speed, and others, depending on the peripheral selected.

The mapping of configuration pins per boot mode is shown in [Table 4-10](#). See the respective sections for details.

Table 4-10. Primary Boot Mode Configuration (MCU 6 = 0)

Primary Boot Mode Config Pins ⁽¹⁾			Primary Boot Mode B Pin	Primary Boot Mode A Pins			Primary Boot Mode
6	5	4	0	MCU 5	MCU 4	MCU 3	
Speed			0	0	0	0	Hyperflash
Speed	RSVD	Csel	0	0	0	1	OSPI
Port	RSVD	Csel	0	0	1	0	QSPI
SFDP	Read Cmd	Mode	0	0	1	1	xSPI
0	Delay	Link stat	0	1	0	0	Ethernet RGMII
Reserved	Read Mode 2	Read Mode 1	0	1	0	1	Serial NAND
Bus reset	Reserved	Addr	0	1	1	0	I2C
		Port	0	1	1	1	UART
Port	Bus width	Fs/raw	1	0	0	0	MMC/SD card
Port	Bus width	Voltage	1	0	0	1	eMMC
Reserved	Mode	Lane Swap	1	0	1	0	USB
RSVD	RSVD	RSVD	1	0	1	1	Fast-xSPI
Clkout	Clk src	Reserved	1	1	0	0	Ethernet RMII
Reserved	Ssc	Clocking	1	1	0	1	PCIe
Port	Mode	Csel	1	1	1	0	SPI
Split	Arm/Thumb	No/Dev	1	1	1	1	No-boot/Dev boot

(1) Shaded cells are reserved pins for that boot mode.

4.3.2.4 Backup Boot Mode Configuration

When in normal boot flow (MCU Only = 0), it is possible to modify certain peripheral settings, such as chip-select, bus speed, and others depending on the peripheral selected.

The mapping of the backup configuration pin per boot mode selected is shown in [Table 4-11](#). See the respective sections for details.

Table 4-11. Backup Boot Mode Configuration (MCU 6 = 0)

Backup Boot Mode Config Pin ⁽¹⁾	Backup Boot Mode Pins			Backup Boot Mode
7	3	2	1	
	0	0	0	None (no backup boot will be attempted)
	0	0	1	USB – Device (DFU)
Port	0	1	0	Reserved
Port	0	1	1	UART
I/F	1	0	0	Ethernet
Port	1	0	1	MMC/SD card
	1	1	0	SPI

Table 4-11. Backup Boot Mode Configuration (MCU 6 = 0) (continued)

Backup Boot Mode Config Pin ⁽¹⁾	Backup Boot Mode Pins			Backup Boot Mode
	3	2	1	
7	1	1	1	I2C

(1) Shaded cells are don't cares and pins can take any value.

4.3.3 No-boot/Dev-boot Configuration

[Table 4-13](#) shows configuration pins assignment to functions when No-boot/Dev-boot was selected. In this mode, ROM code is bypassed and user is allowed to run his own code for development or debug.

MCU-only mode is not compatible with no-boot/dev-boot since the DebugSS is in the main domain.

Table 4-12. No-boot/Dev-boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Split	0	Split/Lockstep configuration of MCU R5 cores derived from efuse	N/A
		1	MCU R5 cores forced to split mode	
5	Arm/Thumb	0	ARM mode reset vectors	N/A
		1	Thumb mode reset vectors	
4	No/Dev	0	Development Boot	N/A
		1	No boot	

During the *Development boot* ($BOOTMODE[4] = 0$), the ROM code will act as if boot of the primary image has completed, and the ROM then will be waiting for a firmware load message from MCU R5. Thus user you can load a standard u-boot/SPL image to the R5 RAM. U-boot/SPL will then load the firmware and complete the full boot.

In *No-boot* ($BOOTMODE[4] = 1$), both the and MCU R5 ROMs are bypassed and both CPUs are held in a dummy branch-to-self loop. No-boot is the most minimal device touch state by the ROM - only minimal hardware configurations are done and none of the PLLs is locked/configured. No-boot is suitable if user wants to load his own PLL, Pad config, and other basic settings.

4.3.4 Hyperflash Boot Device Configuration

The following boot mode pin configuration and corresponding pin usage and mux configuration are shown below. This is the hyperflash single chip select configuration. It can be selected with MCU only active. If MCU only is not active, the main pins must be configured as shown. This is the only configuration that is supported on Hyperflash boot mode.

Table 4-13 shows configuration pins assignment to functions when boot mode is the Hyperflash mode.

Table 4-13. Hyperflash Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Speed	0	83 MHz DDR speed	0
		1	166 MHz DDR speed	
5	-	-	Don't care pin	-
4	-	-	Don't care pin	-

Table 4-14 summarizes the HyperBus pin configuration done by ROM code.

Table 4-14. HyperBus Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
MCU_OSPI0_CLK0	MCU_HYPERBUS0_CK	No	Up	0	Disable	1
MCU_OSPI0_LBCLK0	MCU_HYPERBUS0_CK _n	No	Up	0	Disable	1
MCU_OSPI0_DQS	MCU_HYPERBUS0_RWDS	No	Up	0	Enable	1
MCU_OSPI0_D0	MCU_HYPERBUS0_DQ0	No	Up	0	Enable	1
MCU_OSPI0_D1	MCU_HYPERBUS0_DQ1	No	Up	0	Enable	1
MCU_OSPI0_D2	MCU_HYPERBUS0_DQ2	No	Up	0	Enable	1
MCU_OSPI0_D3	MCU_HYPERBUS0_DQ3	No	Up	0	Enable	1
MCU_OSPI0_D4	MCU_HYPERBUS0_DQ4	No	Up	0	Enable	1
MCU_OSPI0_D5	MCU_HYPERBUS0_DQ5	No	Up	0	Enable	1
MCU_OSPI0_D6	MCU_HYPERBUS0_DQ6	No	Up	0	Enable	1
MCU_OSPI0_D7	MCU_HYPERBUS0_DQ7	No	Up	0	Enable	1
MCU_OSPI0_CSn0	MCU_HYPERBUS0_CSn0	No	Up	0	Disable	1
MCU_OSPI0_CSn1	MCU_HYPERBUS0_RESET _n	No	Up	0	Disable	1
MCU_OSPI0_CSn2	MCU_HYPERBUS0_RESET On	No	Up	0	Enable	2
MCU_OSPI0_CSn3	MCU_HYPERBUS0_INT _n	No	Up	0	Enable	2

4.3.5 OSPI Boot Device Configuration

Octal SPI flash memories support various protocols, and the OSPI boot mode of the device only supports a specific protocol defined below. Additionally, if the flash memory is compliant with JEDEC xSPI standards JESD251 and JESD216D, refer to [Section 4.3.8](#). The OSPI protocol is described according to bit-width (1 or 8) and data rate (S or D for *S*ingle Data rate or *D*ouble Data rate) for the Command/Address/Data segments of the protocol. The OSPI boot mode supports 1S-1S-8S mode. The Command and Address issued are 8 bits and 24 bits, respectively. The Read Command issued for OSPI mode is 0x8b, followed by zero for address and 8 dummy cycles. The frequency of operation is 33 MHz.

The following boot mode pin configuration and corresponding pin usage and mux configuration are shown below. This is the OSPI boot mode.

Primary boot mode B must be set to 0 if MCU only is set to 0.

[Table 4-15](#) shows configuration pins assignment to functions when boot mode is the Octal SPI.

Table 4-15. OSPI Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Speed	0	33 MHz using manual tap selection	0
		1	Reserved	
4	Csel	0	Boot Flash is on CS 0	0
		1	Boot Flash is on CS 1	

[Table 4-16](#) summarizes the OSPI pin configuration done by ROM code for OSPI boot device.

Table 4-16. OSPI Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
MCU_OSPI0_CLK0	MCU_OSPI0_CLK	Disable	Up	0	Disable	0
MCU_OSPI0_LBCLK0	MCU_OSPI0_LBCLK0	Disable	Up	0	Disable	0
MCU_OSPI0_DQS	MCU_OSPI0_DQS	Disable	Up	0	Enable	0
MCU_OSPI0_D0	MCU_OSPI0_D0	Disable	Up	0	Enable	0
MCU_OSPI0_D1	MCU_OSPI0_D1	Disable	Up	0	Enable	0
MCU_OSPI0_D2	MCU_OSPI0_D2	Disable	Up	0	Enable	0
MCU_OSPI0_D3	MCU_OSPI0_D3	Disable	Up	0	Enable	0
MCU_OSPI0_D4	MCU_OSPI0_D4	Disable	Up	0	Enable	0
MCU_OSPI0_D5	MCU_OSPI0_D5	Disable	Up	0	Enable	0
MCU_OSPI0_D6	MCU_OSPI0_D6	Disable	Up	0	Enable	0
MCU_OSPI0_D7	MCU_OSPI0_D7	Disable	Up	0	Enable	0
MCU_OSPI0_CSn0	MCU_OSPI0_CSn0	Disable	Up	0	Disable	0
MCU_OSPI0_CSn1	MCU_OSPI0_CSn1	Disable	Up	0	Disable	0

4.3.6 QSPI Boot Device Configuration

The QSPI boot mode supports the 1S-1S-4S mode only (Bit-width =1 Or 4, Single Data Rate). The Command and Address issued are 8 bits and 24 bits, respectively. The Read Command issued for QSPI is 0x6b, followed by zero for address and 8 dummy cycles. The frequency of operation supported is 33 MHz.

The following boot mode pin configuration and corresponding pin usage and mux configuration are shown below. This is the QSPI Port 0 boot mode.

Primary boot mode B and Primary Boot Mode Config 6 must be set to 0 if MCU only is set to 0.

Table 4-17 shows configuration pins assignment to functions when boot mode is the QSPI on OSPI mode.

Table 4-17. QSPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Port	0	Port 1	0
		1	Port 0	
4	Csel	0	Boot Flash is on CS 0	0
		1	Boot Flash is on CS 1	

Table 4-18 summarizes the OSPI pin configuration done by ROM code for QSPI boot device on port 0.

Table 4-18. QSPI Port 0 Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
MCU_OSPI0_CLK0	MCU_OSPI0_CLK	Disable	Up	0	Disable	0
MCU_OSPI0_D0	MCU_OSPI0_D0	Disable	Up	0	Enable	0
MCU_OSPI0_D1	MCU_OSPI0_D1	Disable	Up	0	Enable	0
MCU_OSPI0_D2	MCU_OSPI0_D2	Disable	Up	0	Enable	0
MCU_OSPI0_D3	MCU_OSPI0_D3	Disable	Up	0	Enable	0
MCU_OSPI0_CSn0	MCU_OSPI0_CSn0	Disable	Up	0	Disable	0
MCU_OSPI0_CSn1	MCU_OSPI0_CSn1	Disable	Up	0	Disable	0

Table 4-19. QSPI Port 1 Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
MCU_OSPI1_CLK	MCU_OSPI1_CLK	Disable	Up	0	Disable	0
MCU_OSPI1_D0	MCU_OSPI1_D0	Disable	Up	0	Enable	0
MCU_OSPI1_D1	MCU_OSPI1_D1	Disable	Up	0	Enable	0
MCU_OSPI1_D2	MCU_OSPI1_D2	Disable	Up	0	Enable	0
MCU_OSPI1_D3	MCU_OSPI1_D3	Disable	Up	0	Enable	0
MCU_OSPI1_CSn0	MCU_OSPI1_CSn0	Disable	Up	0	Disable	0
MCU_OSPI1_CSn1	MCU_OSPI1_CSn1	Disable	Up	0	Disable	0

4.3.7 SPI Boot Device Configuration

The SPI boot mode supports the 1S-1S-1S mode only (Bit-width =1, Single Data Rate). The Command and Address issued are 8 bits and 24 bits, respectively. The Read Command issued for SPI is 0x03, followed by zero for address and 0 dummy cycles. The frequency of operation supported is 4.156 MHz.

The following boot mode pin configuration and corresponding pin usage and mux configuration are shown below. This is the SPI Port 0 boot mode.

Table 4-20. MCU_BOOTMODE Pin Map SPI Port 0

9	8	7	6	5	4	3	2	1	0
Rsvd (not for boot use)			MCU Only	Primary Boot Mode A			PLL Config		
X	X	X			1		X	X	X

Table 4-21. BOOTMODE Pin Map SPI Port 0

7	6	5	4	3	2	1	0
Backup Boot Mode Config	Primary Boot Mode Config			Backup Boot Mode			Primary Boot B

Primary boot mode B and Primary Boot Mode Config 6 must be set to 0 if MCU only is set to 0.

[Table 4-22](#) shows configuration pins assignment to functions when boot mode is the SPI on OSPI port mode.

The SPI bus will be run at 4.156 MHz.

Table 4-22. SPI Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6 (7) ⁽¹⁾	Port	0	Port 0	N/A
		1	Port 1	
5	Mode	0	SPI Mode 0	N/A
		1	SPI Mode 3

MCU_OSPI1_D1	MCU_OSPI1_D1	Disable	Up	0	Enable	0
MCU_OSPI1_CSn0	MCU_OSPI1_CSn0	Disable	Up	0	Disable	0
MCU_OSPI1_CSn1	MCU_OSPI1_CSn1	Disable	Up	0	Disable	0

4.3.8 xSPI Boot Device Configuration

The xSPI protocol defines 1S-1S-1S mode for general backwards compatibility, and 8D-8D-8D for maximum throughput (where bit-width (1 or 8) and data rate (S or D for *S*ingle Data rate or *D*ouble Data rate).

For 1S-1S-1S mode of operation (Bit-width =1, Single Data Rate): The Command and Address issued are 8 bits and 24 bits, respectively. The Read Command issued is 0x0b followed by zero for address and 8 dummy cycles. The frequency of operation supported is 50 MHz.

For 8D-8D-8D mode of operation (Bit-width =8, Double Data Rate): The Command and Address issued are 8 bits and 32 bits, respectively. The Read Command issued is 0x0b or 0xee, followed by zero for address, 16 or 20 dummy cycles. The frequency of operation supported is 25 MHz. Additionally, the flash is expected to be configured in 8D mode out of POR through nonvolatile configuration register.

For SFDP mode, ROM starts operation in 1S-1S-1S mode, reads SFDP header from flash memory to get 8D-8D-8D switching sequence, Read Command, CMD Extension, and Byte Order. SFDP parsing of ROM is described below; on successful parsing, ROM issues an 8D-8D-8D command switching sequence and then reads the boot image in 8D-8D-8D mode with the read command specified in the SFDP header.

The following boot mode pin configuration and corresponding pin usage and mux configuration are shown below. This is the xSPI boot mode.

Table 4-25. MCU_BOOTMODE Pin Map xSPI

9	8	7	6	5	4	3	2	1	0
Rsvd (not for boot use)			MCU Only	Primary Boot Mode A			PLL Config		
X	X	X	X		1		X	X	X

Table 4-26. BOOTMODE Pin Map xSPI

7	6	5	4	3	2	1	0

4.3.9 Fast-xSPI Boot Mode Configuration

The Fast-xSPI boot mode is an extension of the xSPI boot mode where the OSPI PHY will be tuned in order to set the frequency of operation to 100MHz for 8D-8D-8D mode. Flash needs to support SFDP.

To support Fast-xSPI boot, ROM expects the tuning configuration in the last sector of flash which is determined by the flash device configuration. Absence of the configuration will cause ROM to switch the non-PHY based/ standard xSPI boot.

ROM will get the flash memory density (flash memory size **S**) and largest erase sector size (**E** bytes) from the BFPT table and calculates the beginning of last sector as E bytes from the end of flash. We call this location as start of the configuration data (**C0 = S - E**)

Supported Configurations:

1. ROM will support online PHY tuning as specified by the search bounds in the configuration data
2. ROM will support offline PHY tuning as specified by the delays in the configuration data

Selection between the two configurations is through magic words defined by ROM.

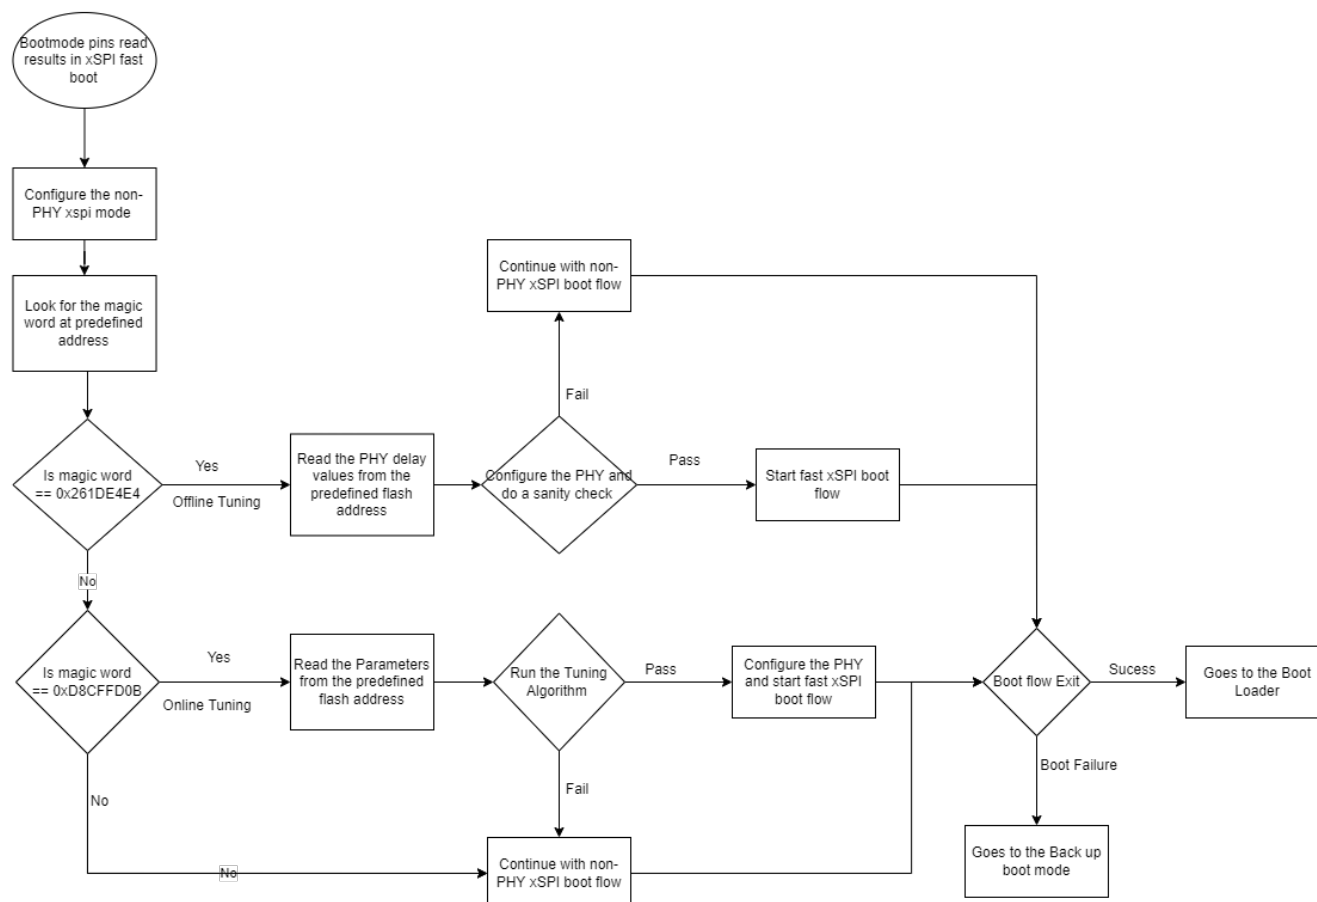

Figure 4-7. Fast-xSPI Control Flow

Table 4-29. Configuration Data for Fast-xSPI Boot

Offset from C0	Description
0 to 127	128 byte calibration pattern
128 to 131	4 byte Magic Word (defined by ROM). There are two distinct magic words to indicate <ul style="list-style-type: none"> Offline tuning - 0x261DE4E4 <ul style="list-style-type: none"> byte 128 - E4, 129 - E4, 130 - 1D, 131 - 26 Online tuning - 0xD8CFFD0B <ul style="list-style-type: none"> byte 128 - 0B, 129 - FD, 130 - CF, 131 - D8 The magic word is stored in little endian format. Absence of the magic word leads the ROM use the non-PHY mode.
132 to 135	4 byte unsigned int for clock frequency. Only 100Mhz is currently supported. ROM operates at 20 dummy cycles, so the flash should support the chosen frequency at 20 dummy cycles. The clock frequency is stored in little endian format. Any unknown clk freq leads ROM to the non-PHY mode. <p>eg:</p> <ul style="list-style-type: none"> 100Mhz - 100000000 - 0x5F5E100 <ul style="list-style-type: none"> byte 132 - 00, 133 - E1, 134 - F5, 135 - 05
136 to 139	4 bytes are reserved must be set to 0xFF
140 to 143	3 bytes for Tx_delay, Rx_delay, Rd_delay and one byte for padding. (Only used in case of offline tuning) Byte 135 - Padding must be set to 0xFF.

Table 4-29. Configuration Data for Fast-xSPI Boot (continued)

Offset from C0	Description
144 to 158	15 parameters (one byte each) (Only used in case of online tuning)

Table 4-30. Offline Tuning Parameters

Parameters	Offset from C0

4.3.10 I2C Boot Device Configuration

Table 4-35 shows configuration pins assignment to functions when boot mode is the I2C mode.

Table 4-35. I2C Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Bus reset	0	Hung bus reset attempt after 1 ms	0
		1	No hung bus reset attempted	
4	Address	0	EEPROM's address is 0x50	0
		1	EEPROM's address is 0x51	

The I²C bus is considered inactive if the data line is low and clock remains high for the specified timeout time. Recovery consists of driving the clock a stop condition is detected. A stop condition is a transition on the data line from 0 to 1 while the clock line is high. If the clock line is stuck low there is no way to take control of the bus.

Table 4-36 summarizes the I2C pin configuration done by ROM code for I²C boot device.

Table 4-36. I2C Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
MCU_I2C0_SCL	MCU_I2C0_SCL	Disable	Up	0	Enable	0
MCU_I2C0_SDA	MCU_I2C0_SDA	Disable	Up	0	Enable	0

4.3.11 MMC/SD Card Boot Device Configuration

Table 4-37 shows configuration pins assignment to functions when boot mode is the MMC/SD card mode.

Table 4-37. MMC/SD Card Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6 (7) ⁽¹⁾	Port	0	MMC Port 0	N/A
		1	MMC Port 1	
5	Bus Width	0		N/A
		1	1-bit bus width	
4	FS/Raw	0	Filesystem mode	N/A
		1	Raw Mode	

(1) When MMCSD was chosen as a backup mode and MCU Only = 0

Table 4-38 summarizes the MMC pin configuration done by ROM code for MMC/SD Card boot device on port 1.

Note

Note that MMC Port 0 has no pin mux.

Table 4-38. MMC/SD Card Port 1 Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
MMC1_DAT3 ⁽¹⁾	MMC1_DAT3	Disable	Up	0	Enable	0
MMC1_DAT2 ⁽¹⁾	MMC1_DAT2	Disable	Up	0	Enable	0
MMC1_DAT1 ⁽¹⁾	MMC1_DAT1	Disable	Up	0	Enable	0
MMC1_DAT0	MMC1_DAT0	Disable	Up	0	Enable	0
MMC1_CLKB	MMC1_CLK	Disable	Up	0	Enable	0
MMC1_CLK	MMC1_CLK	Disable	Up	0	Enable	0
MMC1_CMD	MMC1_CMD	Disable	Up	0	Enable	0
MMC1_SDCD	MMC1_SDCD	Disable	Up	0	Enable	0

(1) In 1-bit mode, only MMC1_DAT0 is configured.

4.3.12 eMMC Boot Device Configuration

Table 4-39 shows configuration pins assignment to functions when boot mode is the eMMC mode.

Table 4-39. eMMC Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Port	0	Port 0	N/A
		1		
5	Bus Width	0		N/A
		1	1-bit only	
4	Voltage	0	1.8V	N/A
		1	3.3V	

Note

Note that MMC Port 0 has no pin mux options.

4.3.12.1 eMMC Flash

To support eMMC boot mode across a device warm reset, eMMC flash has the following requirements:

1. The reset line must be connected to the eMMC flash input reset pin.
2. The eMMC flash ext_csd[162] RST_n_ENABLE must be set to the expected configuration for the warm-reset signal to propagate to the flash device for the boot process to succeed. Possible configurations are shown in Table 4-40.

Note

For warm_reset eMMC boot to function correctly, 0x1 must be written to RST_n_ENABLE in the ext_csd[162] Register. This will enable the RST_n signal.

Table 4-40. ext_csd[162] Register

Bit	Field	Type	Description
7:2	Reserved		Reserved
1:0	RST_n_ENABLE	R/W	0x0: RST_n signal is temporarily disabled (default) 0x1: RST_n signal is permanently enabled 0x2 RST_n signal is permanently disabled 0x3: Reserved

4.3.13 Ethernet Boot Device Configuration

Table 4-41 shows configuration pins assignment to functions when boot mode is the Ethernet RGMII mode.

Table 4-41. Ethernet RGMII Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Rsvd	0	Forced to 0 only.	0
5	Delay	0	RGMII with internal Tx delay	0
		1	RGMII with external Tx delay	
4	Link stat	0	MDIO PHY scan used for speed/duplex setup	0
		1	RGMII status register used for speed/duplex setup	

Table 4-42 shows configuration pins assignment to functions when boot mode is the Ethernet RMII mode.

Table 4-42. Ethernet RMII Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Clk out	0	50 MHz clock not generated on MCU_CLKOUT0	0
		1	50 MHz clock generated on MCU_CLKOUT0	
5	Clk src	0	External clock source	0
		1	Internal clock source	
4	Reserved	X	Not used	N/A

Table 4-43 shows configuration pins assignment to functions when boot mode is the Ethernet is the backup mode.

Table 4-43. Ethernet Backup Boot Configuration Field

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
7 ⁽¹⁾	Interface	0	RGMII with internal Tx delay	N/A
		1	RMII with external clock source	

(1) When Ethernet was chosen as a backup mode and MCU Only = 0

Table 4-44 summarizes the RGMII pin configuration done by ROM code for Ethernet boot device on RGMII port.

Table 4-44. RGMII Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
MCU_RGMII1_TX_CTL	MCU_RGMII1_TX_CTL	Disable	Down	0	Disable	0
MCU_RGMII1_RX_CTL	MCU_RGMII1_RX_CTL	Disable	Down	0	Enable	0
MCU_RGMII1_TD3	MCU_RGMII1_TD3	Disable	Down	0	Disable	0
MCU_RGMII1_TD2	MCU_RGMII1_TD2	Disable	Down	0	Disable	0
MCU_RGMII1_TD1	MCU_RGMII1_TD1	Disable	Down	0	Disable	0
MCU_RGMII1_TD0	MCU_RGMII1_TD0	Disable	Down	0	Disable	0
MCU_RGMII1_TXC	MCU_RGMII1_TXC	Disable	Down	0	Disable	0
MCU_RGMII1_RXC	MCU_RGMII1_RXC	Disable	Down	0	Enable	0
MCU_RGMII1_RD3	MCU_RGMII1_RD3	Disable	Down	0	Enable	0
MCU_RGMII1_RD2	MCU_RGMII1_RD2	Disable	Down	0	Enable	0
MCU_RGMII1_RD1	MCU_RGMII1_RD1	Disable	Down	0	Enable	0
MCU_RGMII1_RD0	MCU_RGMII1_RD0	Disable	Down	0	Enable	0
MCU_MDIO0_MDIO ⁽¹⁾	MCU_MDIO0_MDIO	Disable	Up	0	Enable	0
MCU_MDIO0_MDC ⁽¹⁾	MCU_MDIO0_MDC	Disable	Up	0	Disable	0

(1) Note that the MDIO pins are only configured if the link stat is detected via PHY scan.

Table 4-45 summarizes the RMII pin configuration done by ROM code for Ethernet boot device on RMII port.

Table 4-45. RMII Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
MCU_RGMII1_TX_CTL	MCU_RMII1_CRS_DV	Disable	Down	0	Enable	1
MCU_RGMII1_RX_CTL	MCU_RMII1_RX_ER	Disable	Down	0	Enable	1

MCU_MDIO0_MDC	MCU_MDIO_MDC	Disable	Up	0	Disable	0

4.3.14 USB Boot Device Configuration

Table 4-46 shows configuration pins assignment to functions when boot mode is the USB mode.

Table 4-46. USB Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
5	Mode	0	DFU (USB device firmware upgrade)	N/A
		1	Reserved	
4	Lane Swap	0	D+/D- lines are not swapped	N/A
		1	D+/D- lines are swapped	

Note

Note that USB pins do not have pin mux options.

4.3.15 PCIe Boot Device Configuration

Table 4-47 shows configuration pins assignment to functions when boot mode is the PCIe mode.

Table 4-47. PCIe Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
5		0		N/A
		1		
4	Clocking	0	PHY clock from external pins	N/A
		1	PHY clock from internal source	

Note

Note that PCIe SerDes pins do not have pin mux options.

4.3.16 UART Boot Device Configuration

ROM Code always configures the UART port to 115200 kbaud, 8-n-1 mode, and the XMODEM protocol is used to transfer the boot data.

Table 4-48. UART Boot Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Reserved	-	Not used	N/A
5	Reserved	-	Not used	N/A
4 (7) ⁽¹⁾	Port	0	MCU_UART (port 0)	0
		1	WKUP_UART (port 1)	

(1) When UART was chosen as a backup mode and MCU Only=0

Table 4-49 summarizes the UART pin configuration done by ROM code for UART host on port 0.

Table 4-49. UART Port 0 Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
WKUP_GPIO0_12	MCU_UART_TXD	Disable	Up	0	Disable	0
WKUP_GPIO0_13	MCU_UART_RXD	Disable	Up	0	Enable	0

Table 4-50 summarizes the UART pin configuration done by ROM code for UART host on port 1.

Table 4-50. UART Port 1 Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
WKUP_UART_TXD	WKUP_UART_TXD	Disable	Up	0	Disable	0
WKUP_UART_RXD	WKUP_UART_RXD	Disable	Up	0	Enable	0

4.3.17 Serial NAND Boot Device Configuration

Serial NAND defines 1S-1S-1S mode for general backwards compatibility, and 1S-1S-8S for maximum throughput (S here means *S*ingle Data rate). Serial NAND memory array is organized into pages of size 2KB/4KB. Read is a two-step process where a complete page is first read into flash's internal buffer/cache using Page read command and then the host controller reads from internal buffer in 1- or 4- or 8-bit mode using the read commands. Page read command that is issued is 0x13, followed by 24 address bits. The frequency of operation supported is 50 MHz.

For 1S-1S-1S mode of operation (Bit-width =1, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x0b, followed by address bits and 8 dummy cycles.

For 1S-1S-8S mode of operation (Bit-width =8, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x8b, followed by address bits and 8 dummy cycles. Additionally, flash is configured in 8-bit mode after POR through volatile configuration register if the manufacturer is Winbond.

For 1S-1S-4S mode of operation (Bit-width =4, Single Data Rate). The Command and Address issued are 8 bits and 16 bits respectively. The Read Command that is issued is 0x6b, followed by address bits and 8 dummy cycles.

Note that in 8-bit mode pin mux is done for all 8 OSPI data lines and in 4-bit/1-bit mode pin mux is done for 4 OSPI data lines. This is done to disable the HOLD functionality feature in 1-bit mode.

Serial NAND boot expects ECC to be auto-managed by the flash. Most of the flashes have the ECC enabled by default and can do 1-bit correction and 2-bit detection for ECC errors. ROM checks for 2-bit ECC error via status register 3 (address 0xC0) bit 5 after every page load. In case of 2-bit ECC error the boot will fail and ROM will take the fallback option.

Serial NAND boot also manages bad blocks that can be present in the flash at time of shipment or develop during the lifetime. Bad block marker is a non-FFh data byte stored at Byte 0 of spare area of Page 0 for each bad block and ROM checks for the same while reading the first page of a memory block. ROM will skip the particular block if it is marked as bad and move to the next one.

The following boot mode pin configuration and corresponding pin usage and mux configuration are shown below. This is the Serial NAND boot mode.

Note

Serial Nand driver in ROM does not support devices that have multiple planes, as they require special handling to read even-numbered blocks.

Table 4-51. Serial NAND Configuration Fields

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
4	Read Mode 1	0	OSPI/ 1-1-8 Mode (valid only when Read Mode 2 is 0)	0
		1	QSPI/ 1-1-4 mode (valid only when Read Mode 2 is 0)	
5	Read Mode 2	0	Reserved (Read mode is taken from Read Mode 1)	0
		1	SPI/ 1-1-1 mode (Read mode is taken from Read Mode 2 and Read Mode 1 is ignored)	

Table 4-52. Serial NAND Pin Usage

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Pinmux Sel
MCU_OSPI0_CLK	MCU_OSPI0_CLK	Disable	Up	0	Disable	0
MCU_OSPI0_LBCLKO	MCU_OSPI0_LBCLKO	Disable	Up	0	Disable	0
MCU_OSPI0_DQS	MCU_OSPI0_DQS	Disable	Up	0	Enable	0
MCU_OSPI0_D0	MCU_OSPI0_D0	Disable	Up	0	Enable	0

MCU_OSPI0_D7	MCU_OSPI0_D7	Disable	Up	0	Enable	0
MCU_OSPI0_CSn0	MCU_OSPI0_CSn0	Disable	Up	0	Disable	0
MCU_OSPI0_CSn1	MCU_OSPI0_CSn1	Disable	Up	0	Disable	0

4.3.18 PLL Configuration

ROM code must be aware of the reference clock provided to PLLs. That is, the speed of the quartz crystal, or the clock supplied by an external clock oscillator. On how to indicate the PLL reference clock, see [Table 4-3, PLL Reference Clock Selection](#).

See *Clock Management*, for the PLL reference clock scheme.

ROM code configures only PLLs which are required during boot. Therefore, if a PLL is required for the backup boot mode but not the primary boot mode, and if the backup boot mode never executes, then the PLLs required for backup boot are not enabled. [Table 4-53](#) lists the enabled PLLs according to module or boot peripheral.

Table 4-53. PLL Configuration by Boot Mode

MCU_PLL0	MCU_PLL1	MCU_PLL2	Main PLL0	Main PLL1	Main PLL2	Main PLL3	Boot Mode
✓		✓					Hyperflash
✓	✓						OSPI/QSPI/SPI/xSPI/Fast-xSPI
✓		✓					Ethernet
✓	✓						I2C
✓	✓						UART
✓			✓				eMMC/MMC/SD
✓			✓	✓			USB
✓			✓		✓		PCIe

Note

All clock frequencies are in megahertz.

4.3.18.1 MCU_PLL0, MCU_PLL2, Main PLL0, and Main PLL3

[Table 4-54](#) summarizes the ROM code settings used to configure MCU_PLL0, MCU_PLL2, Main PLL0, and Main PLL3 for the supported input clocks.

Table 4-54. PLL Configuration for MCU_PLL0, MCU_PLL2, Main PLL0, and Main PLL3

2000 MHz VCO frequency							
Ref clk	Refdiv	Pfd freq	Fbdiv	Frac	Vco	Delta	Postdiv
19.2	1	19.2	104		2000	3.97×10^{-8}	0 or 1
20	1	20	100	0	2000	0	0 or 1
24	1	24	83	5592405	2000	1.99×10^{-8}	0 or 1
25	1	25	80	0	2000	0	0 or 1
26	1	26	76	15486661	2000	5.50×10^{-8}	0 or 1
27	1	27	74	1242757	2000	4.42×10^{-8}	0 or 1

4.3.18.2 MCU_PLL1

The MCU_PLL1 is a fractional PLL configured with a VCO frequency of 2400 MHz.

Table 4-55. PLL Configuration for MCU_PLL1

2400 MHz VCO frequency							
Ref clk	Refdiv	Pfd freq	Fbdiv	Frac	Vco	Delta	Postdiv
19.2	1	19.2	125	0	2400	0	0
20	1	20	120	0	2400	0	0
24	1	24	100	0	2400	0	0
25	1	96		0	2400	0	0
26	1	26	92	5162220	2400	1.8×10^{-8}	0
27	1	27	88	14913081	2400	5.53×10^{-8}	0

4.3.18.3 Main PLL1

The main PLL is a fractional PLL configured with a VCO frequency of 1920 MHz.

Table 4-56. PLL Configuration for Main PLL1

1920 MHz VCO frequency							
Ref clk	Refdiv	Pfd freq	Fbdiv	Frac	Vco	Delta	Postdiv
19.2	1	19.2	100	0	1920	0	0
20	1	20	96	0	1920	0	0
24	1	24	80	0	1920	0	0
25	1	25	76	13421773	1920	4.77×10^{-8}	0
26	1	26	73	14196106	1920	5.04×10^{-8}	0
27	1	27	71	1864135	1920	6.62×10^{-8}	0

4.3.18.4 Main PLL2

Main PLL2 is an fractional PLL configured with a VCO frequency of 2400 MHz.

Table 4-57. PLL Configuration for Main PLL 2

1800 MHz VCO frequency							
Ref clk	Refdiv	Pfd freq	Fbdiv	Frac	Vco	Delta	Postdiv
19.2	1	19.2	125	0	2400	0	0
20	1	20	120	0	2400	0	0
24	1	24	100	0	2400	0	0
25	1	25	96	0	2400	0	0
26	1	26	92	5162220	2400	1.8×10^{-8}	0
27	1	27	88	14913081	2400	5.53×10^{-8}	0

4.3.18.5 HSDIV Values

MCU PLL0

- HSDIV0 - (2-1)

MCU PLL1

- HSDIV0 - (6-1)
- HSDIV1 - (40-1)
- HSDIV2 - (30-1)
- HSDIV3 - (50-1)
- HSDIV4 - (18-1)

MCU PLL2

- HSDIV0 - (8-1)
- HSDIV1 - (4-1)
- HSDIV2 - (10-1)
- HSDIV3 - (25-1)
- HSDIV4 - (6-1)

MAIN PLL0

- HSDIV0 - (4-1)
- HSDIV1 - (5-1)
- HSDIV2 - (10-1)
- HSDIV3 - (15-1)
- HSDIV4 - (25-1)
- HSDIV5 - (20-1)
- HSDIV6 - (5-1)
- HSDIV7 - (5-1)
- HSDIV8 - (5 - 1)

MAIN PLL1

- HSDIV0 - (10-1)
- HSDIV1 - (6-1)
- HSDIV2 - (10-1)
- HSDIV3 - (10-1)
- HSDIV4 - unused
- HSDIV5 - (5-1)
- HSDIV6 - (50 - 1)
- HSDIV7 - (40-1)
- HSDIV8 - (48-1)

MAIN PLL2

- HSDIV0 - unused
- HSDIV1 - (4-1)
- HSDIV2 - (12-1)
- HSDIV3 - (8-1)
- HSDIV4 - (24-1)
- HSDIV5 - unused
- HSDIV6 - (5-1)
- HSDIV7 - (12-1)

Note

HSDIV6 here now yields 240 Mhz instead of 225 Mhz.

4.3.18.6

Note

Note that the bringup and configuration of bootmode-specific PLLs by ROM code will result in a bootmode-specific device clocking setup which for example has an impact on which peripheral modules can readily be clocked and used by SBL/SPL prior to loading and bringing up System Firmware (SYSFW).

4.4 Boot Parameter Tables

The boot parameter tables direct the main module boot process. On cold boot the tables are created based on pin strapped values (see [Section 4.3, Boot Mode Pins](#)) and built-in data. The ROM Code supports two parameter tables stored as an array in a fixed memory address in the MSRAM, each of size 512 bytes. The ROM will attempt to boot using the primary table. On boot failure, ROM Code will retry using the second table.

Using two tables handles two cases.

- The first is in initial board manufacture where the primary boot table specifies boot from a flash device, and the flash is blank. ROM Code would then switch to the secondary boot mode which would receive the image externally (Ethernet, USB, PCIe, UART) and this image would flash the boot image.
- The second case is failure due to total flash corruption. In all flash parameter tables there exist backup addresses within the primary boot mode. This covers the problem of a flash update failure with a backup image present on the same flash device.

The boot tables reside at a fixed location in memory which is described in [Section 4.7.2, Global Memory Addresses Used by ROM Code](#).

4.4.1 Common Header

These boot parameter tables have certain parameters common across all the boot modes, while the rest of the parameters are unique to the boot modes. The common entries in the boot parameter table are shown in [Table 4-58](#).

Table 4-58. Boot Parameter Table Common Header

Byte Offset	Size (bytes)	Name	Description
0	2	Length	The length of the table
2	2	Checksum	Ones complement checksum over length bytes in the table. If 0 the checksum is not validated.
4	2	Peripheral	Identifies the boot peripheral and format of the table after the common header. See Table 4-59
6	2	Reserved	Reserved
8	4	Timeout	Timeout for this boot mode, in milliseconds
12	4	Magic	Magic value 0x01AD0911
16	40	PLL Config 0	PLL Configuration 0. See Table 4-60
56	40	PLL Config 1	PLL Configuration 1
96	40	PLL Config 2	PLL Configuration 2
136	40	PLL Config 3	PLL Configuration 3
176	40	PLL Config 4	PLL Configuration 4
216	40	PLL Config 5	PLL Configuration 5

[Table 4-59](#) lists the possible boot modes used in the boot parameter tables.

Table 4-59. Boot Peripheral Selection

Peripheral Field Value	Description
0	Sleep (No boot)
10	Ethernet Reserved
20	Ethernet BOOTP/TFTP (general)
21	Ethernet RGMII specific
22	Ethernet RMII specific
30	PCIe
31	PCIe 1-lane
32	PCIe 2-lane
40	I2C
50	SPI

Table 4-59. Boot Peripheral Selection (continued)

Peripheral Field Value	Description
60	UART
70	USB DFU
71	USB Reserved
72	USB Reserved
80	QSPI
85	OSPI
90	Hyperflash Reserved
100	MMC/SD Card (general)
101	eMMC (general)
102	MMC 1-bit
103	MMC 4-bit
104	MMC 8-bit
110	GPMC Reserved
120	UFS Reserved
150	Serial NAND
160	Fast-xSPI

4.4.2 PLL Setup

Table 4-60 through Table 4-64 describe the PLL configuration fields.

Table 4-60. Boot Parameter Table PLL Configuration

Byte Offset	Size (bytes)	Name	Description
0	1	Domain/cfg	See Table 4-61
1	1	PII number	PLL number indexed from 0. See for PLL numbers.
2	1	Input source	See Table 4-63
3	1	PII Type	This field must be 1 to indicate an SCPLL
4	4	Input Ref Clock	The PLL input clock, in Q16.16 format
8	4	Feed back divider, integer part	Integer value of feedback divider
12	4	Feed back divider, fractional part	Fractional portion of feedback divider. Total divider is the Integer part + (Fractional part / 2 ²⁴)
16	1	Ref divider	Input clock pre-divider
17	1	Post divider 1	Output post divider 1
18	1	Post divider 2	Output post divider 2
19	1	Reserved	Reserved
20	2	Hsdiv Enable	Bit map. A set bit indicates that the corresponding hsdiv is enabled.
22	2	Reserved	Reserved
24	16	Hsdiv[16]	Array of hs divider values.

Table 4-61. PLL Domain and Enable Configuration

7	6	5	4	3	2	1	0
Reserved		Enable		Reserved		Domain	

Table 4-62. PLL Domain and Enable Field Description

Field	Value	Description
Enable	0	PLL not configured
	1	PLL enabled only if currently disabled or in bypass
	2	PLL is unconditionally enabled. If currently enabled with a different configuration the PLL is first disabled
	3	PLL is unconditionally disabled

Table 4-62. PLL Domain and Enable Field Description (continued)

Field	Value	Description
Domain	0	PLL is in the MCU domain
	1	PLL is in the MAIN domain

Table 4-63. PLL Reference Source Bit Fields

7	6	5	4	3	2	1	0
Source Type				Source Index			

Table 4-64. PLL Reference Source Field Description

Field	Value	Description
Source Type	0	Source is HFOSC
	1	Source is external pin
	2	Reserved
	3-7	Reserved
Source Index	0-31	Source index (HFOSC[0-31] or pin[0-31], depending on Source Type) HFOSC[0] – WKUP_HFOSC0 HFOSC[1] – HFOSC1 (in MAIN domain) PIN[1] – EXT_REFCLK1 pin (not all PLLs, see <i>Clocking</i>)

4.4.3 PCIe Boot Parameter Table

Table 4-65 shows the boot parameter table for PCIe boot. Must be preceded with the common boot parameters described in Table 4-58.

Table 4-65. PCIe Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	portNum	From pins	Physical port number
260	4	AddrWid	64	PCIe address width
264	4	LinkRate	8000	Link rate in MHz
268	4	RefClkKHz	100000	Serdes reference clock in kHz
272	4	Nlanes	From pins	Number of PCIe lanes configured (link width)
276	4	Rsvd	4	Reserved
280	4	Rsvd	256	Reserved
284	4	Rsvd	256	Reserved
288	4	Rsvd	0	Reserved
292	4	Rsvd	0	Reserved
296	4	Vendor ID	0x104C	PCIe Vendor ID value (read from control registers)
300	4	Device ID	0xB00D	PCIe Device ID value (read from control registers)
304	4	Class code/revision ID	0x04800001	PCIe class code and revision ID value
308	4	Internal Clock	From Pins	If non-zero, internal (SoC) ref clock is used
312	4	sscEnable	1	Enable spread spectrum clock
316	4	RefSrc	From Pins	Selects serdes reference clock internal source. Refer to <i>Reference Clock Distribution</i> for details.

4.4.4 I2C Boot Parameter Table

Table 4-66 shows the boot parameter table for I2C boot. Must be preceded with the common boot parameters described in Table 4-58.

Table 4-66. I2C Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number

Table 4-66. I2C Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
257	1	Mode	From Pins	0x4E = I2C Master, 0x72 = I2C slave
258	1	Dev Addr	From Pins	I2C address when slave mode (0x10 or 0x11)
259	1	Reserved	0	Reserved
260	4	Mod Clock	0	I2C Module input clock. If 0, it is computed by ROM code.
264	2	Bus Freq	400	I2C Master mode bus frequency, in kHz
266	2	Bus Addr	From Pins	I2C Master mode storage device's address (0x50 or 0x51)
268	2	Read Index	0	Index to the active read offset (0 or 1)
270	2	Read Offset 0	0x0000	I2C Master mode read offset
272	2	Read Offset 1	0x8000	I2C Master mode backup read offset
274	2	Reserved	0	Reserved
276	2	Reserved	0	Reserved
280	2	Busy Timeout	From pins	Number of μ s before a bus recovery is attempted. In units of microseconds in Q3 number format. Value of 0 disables bus recovery attempts.

4.4.5 OSPI/QSPI/SPI Boot Parameter Table

Table 4-67 shows the boot parameter table for OSPI, QSPI, or SPI boot. Must be preceded with the common boot parameters described in Table 4-58.

Table 4-67. OSPI/QSPI/SPI Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero, the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 2, 4, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1, 2, 4, 8)
260	1	Data Width	From Pins	Number of pins used to received data (1, 2, 4, 8)
261	1	Address Size	24	16 (SPI only), 24, and 32 bits are the valid address sizes
262	1	Mode	0	OSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0–3)
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable DQS
269	1	Reserved	0	Reserved
270	2	Module Freq	0	The OSPI module frequency after PLL enable, in kHz. If 0, ROM code uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The OSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command
280	4	Tap Delay	0xFFFFFFFF	The read tap selection. If 0xFFFFFFFF, the ROM code will scan the taps to find the best delay. The result will then overwrite the value in this table.
284	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
288	4	notDAC	From pins	When 0, DAC mode is used
292	4	Read Index	0	Index to the active read address (0-1)
296	4	Read Addr 0	0x000000	The initial flash read address

Table 4-67. OSPI/QSPI/SPI Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
300	4	Read Addr 1	0x400000 (0x4000 SPI)	Backup read address
304	4	Reserved	0	Reserved
308	4	Reserved	0	Reserved

4.4.6 xSPI/Fast-xSPI Boot Parameter Table

Table 4-68 shows the boot parameter table for xSPI. Must be preceded with the common boot parameters described in *Boot Parameter Table Common Header*.

Table 4-68. xSPI Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1,8)
260	1	Data Width	From Pins	Number of pins used to received data (1,8)
261	1	Address Size	24	24 or 32 bits are the valid address sizes
262	1	Mode	0	QSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0-n) not the bitfield
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable dqs
269	1	ddrEnable	From pins	OSPI DDR mode operation
270	2	Module Freq	0	The QSPI module frequency after PLL enable, in kHz. If 0 the ROM uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The QSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command
280	1	SFDP	From Pins	Enables SFDP parser for 1S-1S-1S to 8D-8D-8D switching

Table 4-68. xSPI Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
282	4	Tap Delay	0xffffffff	The read tap selection. If 0xffffffff the ROM will scan the taps to find the best delay. The result will then overwrite the value in this table.
286	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
290	4	indac	From pins	When 0 XIP mode is used
294	4	Read Index	0	Index to the active read address
298	4	Read Addr 0	0	The initial flash read address
302	4	Read Addr 1	0x400000	Backup read address

4.4.7 Ethernet Boot Parameter Table

Table 4-69 is shown segmented into four sections:

1. The first section contains information required to configure the device hardware
2. The second section contains information used by the top level Ethernet module to execute the boot
3. The third section contains information for the Ethernet stack code.
4. The fourth section contains information for creating the BOOTP packet (vendor string, ID string and debug string), and holds information returned in the BOOTP response (Default route and file name)

Table 4-69 shows the boot parameter table for Ethernet boot. Must be preceded with the common boot parameters described in Table 4-58.

Table 4-69. Ethernet Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
Hardware Configuration Options				
256	2	Mod Freq	0	Module clock frequency, kHz. If 0, ROM code computes the value.
258	1	Port Num	0	Physical port number
259	1	Interface	From Pins	0 = RGMII with internal delay 1 = RGMII with external delay 2 = RMII
260	1	Init Level	0	0 = Initialize only not enabled modules 1 = Full ethernet sub-system initialization
261	1	Clock out enable	From pins	0x10 = MCU_CLKOUT enable 0x11 = MCU_CLKOUT disable
262	1	Clk out freq	From pins	0x20 = MCU_CLKOUT 25 MHz (RGMII) 0x21 = MCU_CLKOUT 50 MHz (RMII)
263	1	RMII Clk In	From pins	0x60 = RMII internal (SoC) clock 0x61 = RMII external clock
264	1	Port Enable	0x01	Bit map. A set bit indicates that the corresponding physical port will be enabled
265	1	Phy Query	From pins	0x30 = speed/duplex determined from RGMII status register 0x31 = MDIO used to query PHY 0x32 = Use fixed speed/duplex values from offset 266/267.
266	1	Speed		0x40 = full speed (1Gbit for RGMII, 100Mbit for RMII) 0x41 = slow speed (100Mbit for RGMII, 10Mbit for RMII)
267	1	Duplex		0x50 = full duplex 0x51 = half duplex
Main Level Boot Control				

Table 4-69. Ethernet Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
268	1	Bootp enable	1	0 = Image information already in this structure 1 = Use BOOTP to get boot image information
269	1	Reserved	0	Reserved
270	2	Bootp Timeout	4000	BOOTP timeout in milli-seconds
272	2	TFTP timeout	1000	TFTP timeout in milli-seconds
274	2	Bootp retries	10	Number of BOOTP retries before fail
276	2	TFTP retries	10	Number of TFTP retries before fail
278	2	Reserved	0	Reserved
Network Stack Configuration (plus TFTP server ID)				
280	6	MAC Address	From E-fuse	MAC address of the device
286	2	Reserved	0	Reserved
288	4	Device IP	0	IP address of the device. Valid only if BOOTP not enabled
292	4	Net Mask	0	Net mask. Valid only if BOOTP not enabled
296	4	Tftp server IP	0	TFTP server IP. Valid only if BOOTP not enabled
BOOTP send and receive Information				
300	20	Vendor String	"TI K3 Bootp Boot"	BOOTP request vendor string. Valid only if BOOTP not enabled
320	9	Client ID	1-mac-address-0	Client ID. See RFC1700
329	1	ID len	7	Client ID length
330	45	Debug array	SOC ID up to size available	Debug array output
375	1	Debug len	Varies	The number of valid bytes in debug array
376	4	Next hop	0	Next hop IP address. Valid only if bootp not enabled
380	4	Default Route	0	IP default route IP address. Valid only if bootp not enabled
384	128	Boot filename	0	Boot filename. Valid only if bootp not enabled

4.4.8 USB Boot Parameter Table

[Table 4-70](#) shows the boot parameter table for USB boot. Must be preceded with the common boot parameters described in [Table 4-58](#).

Table 4-70. USB Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Port	From pins	Physical port number. Always set to 0.
260	4	Reserved	0	Reserved
264	4	Base address 0	From pins (port)	Base address of USB subsystem (CMN)
268	4	Base address 1	From pins (port)	Base address of controller
272	4	phyBaseAddress	From pins (port)	Base address of USB PHY module
276	4	modRefClkKHz	varies	Module reference clock, in kHz
280	4	Vendor ID	0x0451	USB vendor ID. Read from control registers.
284	4	Product ID	0x6163	USB product ID. Read from control registers.
288	4	String Table addr	0x4182BCA8	Pointer to the string table in RAM
292	2	Vendor String offset	0	Offset to vendor string in string table
298	2	Prod string offset	32	Offset to product string in string table
300	2	Serial num string offset	64	Offset to serial number string in string table
302	2	Timeout	5000	USB timeout in milliseconds
304	2	Mode	1	1 = DFU ≠1 = Reserved
305	1	Lane reverse	0	Host mode only. Boot file name in Unicode characters

Table 4-70. USB Boot Parameter Table (continued)

Byte Offset	Size (bytes)	Name	Default Value	Description
306	2	Reserved	0	Reserved
308	4	Block size	4096	DFU block size

4.4.9 MMCSD Boot Parameter Table

Table 4-71 shows the boot parameter table for eMMC, MMC or SD card boot. Must be preceded with the common boot parameters described in Table 4-58.

Table 4-71. MMCSD Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	From Pins	Physical port number
257	1	eMMC	From Pins	0 = SD/MMC, else eMMC
258	1	bootAck	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode the controller expects a boot ack from the eMMC
259	1	Media	1 for eMMC 0 for SD/MMC	0 = auto detect card type 1 = MMC 2 = SD
260	1	busWidth	8 for eMMC From Pins for SD/MMC	Number of data pins (1, 4, or 8). If 0, max supported pins of the port are used.
261	1	bootAlt	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode, the controller uses the alt boot method (CMD1 with arg 0xFFFF_FFFA) to initiate data transfer
262	1	sigVolt	0x18 for port0 0x33 for port1	Sets the signal voltage for the controller. 0x18 = 1.8V 0x33 = 3.3V
263	1	Reserved	0	Reserved
264	4	Max Bus Freq	0	Max bus frequency in kHz. If 0, the value is determined by reading the CSD register from the card (still maxes out at 25 MHz)
268	4	refClkKHz	0	Module reference clock frequency, in kHz. If 0, the ROM code computes the value.
272	4	respTimeout	40000	The timeout period on initial card read, in milli-seconds, Q3 number format
276	128	Filename	"tiboot3.bin"	For SD/MMC, boot filename in 16-bit Unicode characters (max 64)
404	4	Mode	0x1144D091	0x1144D091 = file system boot 0x1144C180 = raw image boot
408	4	CardIsInit	0	0 = card not yet initialized 1 = card has been initialized
412	4	Rsvd	0	Reserved
416	4	RawIndex	0	Current active read offset (0 or 1)
420	4	Rsvd	0	Reserved
424	4	Raw Offset 0	0x000000	Raw read offset
428	4	Raw Offset 1	0x400000	Backup raw read offset
432	4	Rsvd	0	Reserved
436	4	Rsvd	0	Reserved

4.4.10 UART Boot Parameter Table

Table 4-72 shows the boot parameter table for UART boot. Must be preceded with the common boot parameters described in Table 4-58.

Table 4-72. UART Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Magic	0x49	Required Magic value
257	1	Protocol	63 (0x3F)	Specifies the transfer protocol = XMODEM
258	2	Reserved	0	Reserved
260	1	Max error Count	10	Error count resulting in boot abort
261	1	Ack timeout	3	Timeout in seconds on ack
262	1	Char timeout	20	Inter-character timeout in milliseconds
263	1	Reserved	0	Reserved
264	4	Port	From Pins	Physical port number
268	4	Mod Ref Clk	48000	Module reference clock, in kHz
272	4	Data Rate	115200	Baud rate (bps)
276	1	Parity	0	0=none, 1=odd, 2=even
277	1	Data bits	8	Only 8 data bit width is supported
278	1	Stop bits	2	Stop bits in Q7.1 format (2 = 1 stop bit)
279	1	Flow Control	0	0=none, 1= RTS/CTS
280	1	Over sample	16	Only 16× and 13× oversample are supported
281	1	Magic 2	0xB7	Required magic value

4.4.11 Hyperflash Boot Parameter Table

The configuration table for Hyperflash is shown in [Table 4-73](#). Must be preceded with the common boot parameters described in [Table 4-58](#).

Table 4-73. Hyperflash Boot Parameter Table

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port
257	1	Mode	0	0 = DDR, otherwise SDR
258	1	Csel	From pins	Chip select
259	1	nCsel	From pins	Number of valid chip selects
260	4	Rsvd	0	Reserved
264	2	RefFreqkHz	0	Module reference clock in kHz. 0 = ROM code computes the value
266	2	Rsvd	0	Reserved
268	4	busFreqkHz	From pins	Hyperflash bus frequency in kHz (83333 or 166666 kHz)
272	4	Base Address CS0	0	Offset to CS0 memory
276	4	Base Address CS1	0	Offset to CS1 memory
280	4	readIndex	0	Current active read offset (0 or 1)
284	4	Read offset 0	0x000000	Read offset 0
288	4	Read offset 1	0x400000	Read offset 1
292	4	Reserved	0	Reserved
296	4	Reserved	0	Reserved

4.5 Boot Image Format

4.5.1 Overall Structure

The boot image consists of an X.509 Certificate, which is optional for GP devices, followed immediately by a boot image blob.

X.509 Certificate (Variable Size) (Optional)
Boot Image Blob (Variable Size)

4.5.2 X.509 Certificate

The X.509 certificate is described in [RFC5280](#). Section 4.1 of the specification describes the format.

The X.509 fields relevant to the public boot (taken from RFC5280) are shown below.

```

Certificate ::= SEQUENCE {
    tbsCertificate      TBSCertificate,
    signatureAlgorithm  AlgorithmIdentifier,
    signatureValue      BIT STRING }
TBSCertificate ::= SEQUENCE {
    version             [0] EXPLICIT Version DEFAULT v1,
    serialNumber        CertificateSerialNumber,
    signature            AlgorithmIdentifier,
    issuer              Name,
    validity            Validity,
    subject             Name,
    subjectPublicKeyInfo SubjectPublicKeyInfo,
    issuerUniqueID      [1] IMPLICIT UniqueIdentifier OPTIONAL,
                        -- If present, version MUST be v2 or v3
    subjectUniqueID     [2] IMPLICIT UniqueIdentifier OPTIONAL,
                        -- If present, version MUST be v2 or v3
    extensions          [3] EXPLICIT Extensions OPTIONAL
                        -- If present, version MUST be v3
}
Extensions ::= SEQUENCE SIZE (1..MAX) OF Extension
Extension ::= SEQUENCE {
    extnID              OBJECT IDENTIFIER,
    critical            BOOLEAN DEFAULT FALSE,
    extnValue           OCTET STRING
                        -- contains the DER encoding of an ASN.1 value
                        -- corresponding to the extension type identified
                        -- by extnID
}

```

In general, an X.509 certificate contains a public key which has been signed by a private key. The public ROM code does not directly use the keys. In non-secure devices, the public key value is in general a don't care condition. The exception is certificates containing a degenerate RSA public key. GP devices with a degenerate RSA key allow for integrity checking of most (but not all) of the certificate.

The public MCU ROM only needs to extract some of information from the X.509 formatted structure:

- The total size of the X.509 Certificate
- The total size of the boot image

The total size of the X.509 Certificate is determined by reading the length of the sequence containing the certificate. The length of the image is determined by parsing the certificate to find the extension field which holds the image length.

The ROM defines several extensions that are used only by TI for boot. These are placed in the extensions field of the TBS certificate.

4.5.3 Organizational Identifier (OID)

OID (organizational identifier) values are represented as a tree structure. TI has the following node registered:

1.3.6.1.4.1.294: iso(1), identified-organization(3), dod(6), internet(1), private(4), enterprise(1), Texas Instruments(294)

ROM code adds the following branch after *Texas Instruments: device-boot(1)*. The OID values shown in this section are leaves off the device boot branch.

4.5.4 X.509 Extensions Specific to Boot

These values are not defined in any standard, but created by TI for boot.

4.5.4.1 Boot Info (OID 1.3.6.1.4.1.294.1.1)

This extension must be present on all boot images. It is from this extension that the image length is extracted.

```
bootInfo ::= SEQUENCE {
    cert_type:  INTEGER,      -- identifies the certificate type
    boot_core:  INTEGER,      -- identifies the boot core
    core_opts:  INTEGER,      -- 32 or 64 bit boot core target
    load_addr:  OCTET STRING, -- Global address image destination
    image_size: INTEGER,      -- Image size in bytes
}
```

Table 4-74. Certificate Type Values

Value	Description
0x0000_0001	Primary boot image
0x0000_0002	Firmware image

Table 4-75. Boot Core Values

Value	Description
0x00	Firmware (DMSC) image
0x08	DMSC certificate
0x10	MCU image
0x20	Reserved

Table 4-76. Core Options Bit Fields

31	2	1	0
Reserved		Split	Mode

Table 4-77. Core Options Field Description

Bits	Field	Value	Description
1	Split	0	Dual MCU set to lockstep (two cores in lockstep)
		1	Dual MCU set to split mode (two independent cores)
0	Mode	0	MCU starts execution in Arm® mode
		1	MCU starts execution in Thumb® mode

4.5.4.2 Image Integrity (OID 1.3.6.1.4.1.294.1.2)

```
imageIntegrity ::= SEQUENCE {
    sha_type:  OID,      -- Identifies the SHA type
    hash:      OCTET STRING -- The SHA of the boot image
}
```

4.5.5 Extended Boot Info Extension

J7AEP ROM supports a combined boot image boot flow. In this flow, a boot binary blob has both Secondary bootloader (SBL) and System Firmware (SYS-FW) embedded in the boot image with a single X509 certificate. This method helps with the following situations:

- Allows ROM to load and run both the bootloader and SYS-FW in parallel without any dependency.
- Optimizes ROM boot time by minimizing different x509 certificate parsing and authentication.

To support this combined boot format, ROM employs a new X509 extension called: `ext_boot_info`. It supports multiple boot components with a single certificate. It allows up to 5 components as part of this extension:

- Component1: Mandatory and should point to info about SBL binary
- Component2: Optional and if present should point to SYS-FW binary in all device types
- Component3: Optional (Load section to SBL, new certType)
- Component4: Optional (Load section to SYS-FW, new certType)
- Component5:
 - HS-FS and HS-SE non Prime devices. Mandatory and should point to SYS-FW Inner certificate
 - GP and HS-SE Prime devices. Optional (Load Section to SBL or SYS-FW)

This extended boot info extension replaces `boot_seq` (`boot_info`) and `image_integrity` extensions from the previous sections, and these should be exclusive in any given certificate.

ROM supports other extensions, such as `sw_rev` and `debug_info`, in both formats.

ROM selects the combined image flow based on the presence of `ext_boot_info` extension in the certificate and skips `boot_seq` (`boot_info`) and `image_integrity` extensions boot flow.

Having one component in `ext_boot_info` is same as legacy flow (that is, flow using `boot_seq` and `image_integrity`); for two or more components, ROM starts both SBL and SYS-SW, the third and fourth components are loaded by ROM to the allowed loading memory range of SBL and SYS-FW if there is no overlap in load address with executable binary info.

Each of the components can independently specify hash value of the binary, and ROM validates the hash on HS and GP if RSA degenerate key is used for signing.

Additionally, ROM rejects the full image if hash of any single component mismatches.

4.5.5.1 Impact on HS Device

For HS devices, ROM supports encryption of images optionally when specified with the Encryption extension.

Encryption - Encryption of the components must be specified with a new extension called `ext_boot_enc`. This is an optional extension that must be specified only if any of the components are encrypted with a customer key set. Specify a component number followed by encryption extension details for ROM to decrypt the given components. This extension is used only with combined boot image format (that is, using Extended Boot Info Extension).

Prime vs Non-Prime - The main difference between HS prime and non-prime devices is the presence of the SYS-FW Inner certificate. Extended boot info extension supports both prime and non-prime devices. ROM supports SYS-FW binary as Comp#2 in all device types; for HS-SE non-prime and HS-FS devices, the SYS-FW inner certificate is expected as another optional component in #3, 4, or 5.

4.5.5.2 Extended Boot Info Details

```
1.3.6.1.4.1.294.1.9=ASN1:SEQUENCE:ext_boot_info

4.5.5.3 Certificate / Component Types

ROM supports only the following component types; all other component types will be rejected.

- CompType 0x1 for SBL binary - compType = INTEGER:1
- CompType 0x2 for SYS_FW binary - compType = INTEGER:2
- CompType 0x3 for SYS_FW Inner Certificate - compType = INTEGER:3
- CompType 0x11 for SBL Memory load section - compType = INTEGER:17

Primary Image load section, that can be loaded in to SBL allowed memory range:

- CompType 0x12 for SYS_FW Memory load section - compType = INTEGER:18

SYS-FW load section, that can be loaded in to SYS-FW allowed memory range

4.5.5.4 Extended Boot Encryption Info

Extended Boot Encryption Info specifies the imageEncryption extension per component basis. This extension is not applicable for GP or HS-FS devices, and is optional for HS-SE devices if any components in the image are encrypted. In HS-FS and HS-SE non-prime devices, the SYS-FW binary encryption details are part of SYS-FW Inner certificate. This extension is applicable if either SBL, SYS-FW binary in HS-SE prime, or any binary blobs are encrypted in HS-SE devices.

```
1.3.6.1.4.1.294.1.10=ASN1:SEQUENCE:ext_enc_info

iterationCnt = INTEGER:2
salt = FORMAT:HEX,OCT:cccccccccccccccccaa84f29d6b68d0
```

4.5.5.5 Component Ordering

ROM supports fixed Component ordering for SBL- Binary and SYS-FW Cert and Binary.

For GP and HS-SE Prime devices, Comp#1 should be SBL binary, and Comp#2 should be SYS-FW binary.

For HS-FS and HS-SE non-Prime devices, Comp#1 should be SBL binary, Comp#2 should be SYS-FW Inner Certificate, and Comp#3 should be SYS-FW binary.

4.5.5.6 Memory Load Sections Overlap with Executable Components

Memory load sections for SBL and SYS-FW (CompType 0x11 and 0x12) the destination address and size should not overlap with the corresponding load and execute sections, and should also fall in the allowed memory range by ROM.

4.5.5.7 Device Type and Extended Boot Extension

X509 Extension	Component	GP Device	HS-FS	HS-SE non-prime	HS-SE Prime Device
ext_boot_info	Comp#1	SBL Binary	SBL Binary	SBL Binary	SBL Binary
	Comp#2	SYS-FW binary	SYS-FW binary	SYS-FW binary	SYS-FW binary
	Comp#3	SBL mem load section	SBL mem load section	SBL mem load section	SBL mem load section
	Comp#4	SysFW mem load section	SysFW mem load section	SysFW mem load section	SysFW mem load section
	Comp#5	N/A	SysFW inner certificate	SysFW inner certificate	N/A
ext_enc_info	Comp#1	N/A	N/A ¹	SBL encryption	SBL encryption
	Comp#2			N/A	SYS FW encryption
	Comp#3			SBL memory load Encryption	SBL memory load encryption
	Comp#4			Sys-FW memory load encryption	Sys-FW memory load encryption
	Comp#5			N/A ¹	NA

1. SYS-FW encryption in HS-FS and HS-SE (non Prime) are handled in SYS-FW Inner certificate and they are not part of the extended boot info extensions.

4.5.6 Generating X.509 Certificates

X.509 Certificates are generated using OpenSSL and a configuration script to supply values in the extension fields.

4.5.6.1 Key Generation

The SBL must always be signed with a given OpenSSL key - Secure and GP devices. Secure must have encryption and authentication, GP device must only have authentication. The key used for authentication can be random or specific. If a random key is generated and SBL is signed with this, the ROM will copy the SBL image for authentication using memcpy. With this key, ROM code will be directed to use DMA to load the SBL for authentication which saves boot time.

4.5.6.1.1 Degenerate RSA Keys

Degenerate RSA keys are valid RSA keys with the private exponent set to 1. This results in the signature field being equal to the digest, since in RSA:

$$\text{Signature} = \text{digest}^{\text{privExp}} \bmod n^{\text{privExp}} \bmod n^{\text{privExp}} \quad (1)$$

Where n is the key size. Since the hash used is SHA-512 and the signature is an ASN.1 sequence containing the OID defining which hash was used as well as the hash value, the degenerate RSA must have a value of n greater than the maximum digest size. Typically 1024-bit is chosen.

The following sequence is used to generate degenerate RSA keys:

1. Create a random RSA key:

```
openssl genrsa -out key.pem 1024
```

2. Convert to text:

```
openssl rsa -in key.pem -text -noout > key.txt
```

3. Create an asn1 template for the degenerate key called degenerateKey.txt. Simply copy the values for modulus, prime (listed as p in key.txt), prime 2 (listed as q), and coefficient (listed as coeff). Set the public and private key exponents to 1, as well as the values for e1 and e2. See the example below.
4. Convert the template to DER:

```
openssl asn1parse -genconf degenerateKey.txt -out degenerateKey.der
```

5. Sanity check the key:

```
openssl rsa -in degenerateKey.der -inform der -text -check
```

6. If there are no errors create the degenerate key pem file:

```
openssl rsa -in degenerateKey.der -inform der -outform pem -out degenerateKey.pem
```

An example degenerateKey.txt file is shown.

```
asn1=SEQUENCE:rsa_key
[rsa_key]
version=INTEGER:0
modulus=INTEGER<copied from key.txt>
pubExp=INTEGER:1
privExp=INTEGER:1
p=INTEGER:<copied from key.txt>
q=INTEGER<copied from key.txt>
e1=INTEGER:1
e2=INTEGER:1
coeff=INTEGER<copied from key.txt>
```

Note that when copying the multi-byte fields from key.txt it is necessary to remove the colons, concatenate the lines and add a preceding 0x.

4.5.6.2 Configuration Script

An example openssl configuration script is shown below. Not all extensions are required, but all possible are shown.

```
[ req ]
distinguished_name = req_distinguished_name
x509_extensions = v3_ca
prompt = no
dirstring_type = nobmp
[ req_distinguished_name ]
C = GB
ST = HI
L = Boston
O = Texas Instruments., Inc.
OU = DSP
CN = Bob
emailAddress = Bob@hou.ti.com
[ v3_ca ]
basicConstraints = CA:true
1.3.6.1.4.1.294.1.1 = ASN1:SEQUENCE:boot_seq
1.3.6.1.4.1.294.1.2 = ASN1:SEQUENCE:image_integrity
1.3.6.1.4.1.294.1.3 = ASN1:SEQUENCE:swrv
1.3.6.1.4.1.294.1.4 = ASN1:SEQUENCE:encryption
1.3.6.1.4.1.294.1.5 = ASN1:SEQUENCE:key_derivation
1.3.6.1.4.1.294.1.7 = ANSI:SEQUENCE:pllControl
1.3.6.1.4.1.294.1.8 = ANSI:SEQUENCE:debug
[ boot_seq ]
certType = INTEGER:1
bootCore = INTEGER:16
bootArchwidth = INTEGER:32
destAddr = FORMAT:HEX,OCT:bc934b00
```

```

imageSize = INTEGER:0x00004860
[ image_integrity ]
shaType = OID:1.3.14.3.2.26
shaValue = FORMAT:HEX,OCT:4cf4d59ef77b5d9ab28d2ceb3c9fe83cb52ae6d2
[ swrv ]
rollback = INTEGER:0x00010001
[ encryption ]
iv = FORMAT:HEX,OCT:00112233445566778899aabbccddeeff
Rstring = FORMAT:HEX,OCT:00112233445566778899aabbccddeeff101112131415161718191a1b1c1d1e1f
Icount = INTEGER:1
Salt = FORMAT:HEX,OCT:00112233445566778899aabbccddeeff
[ pllControl ]
pll0_num = INTEGER:0
pll0_cfg = FORMAT:HEX,OCT:00345678900
pll1_num = INTEGER:1
pll0_cfg = FORMAT:HEX,OCT:00345678900
[ debug ]
uid = FORMAT:HEX,OCT:00345678900
type = INTEGER:1
dbgE = INTEGER:0
secDbgEn = INTEGER:0

```

The certificate is then generated using the following openssl command:

```

openssl req -new -x509 -key <private_key_pem_file> -nodes -out <output_x.509_pem_file> -config
<config_file> -sha512

```

If a delegate key is being signed, then add the option -signkey <sign_key_pem_file> to the command above.

4.5.7 Image Data

The image data (blob) is considered simply as a byte stream. On devices that are multiple bytes wide (for example, PCIe) the image must be formatted so that all multi-byte fields match the endianness of the device. The MCU will always run in little endian mode.

4.6 Boot Modes

4.6.1 I2C Bootloader Operation

4.6.1.1 I2C Initialization Process

In the I2C boot mode, the ROM Code configures the MCU_I2C0 peripheral.

MCU_I2C0 can operate either in master mode or in slave mode. In the master mode, the boot master drives the I2C slave device where the image is stored. In the slave mode, the data transfer is driven by an external I2C master device. The master device is usually another SoC device or a FPGA.

A detailed summary of the I2C boot parameter table and the BOOTMODE pins definitions are listed in [Section 4.4.4, I2C Boot Parameter Table](#) and [Section 4.3.10, I2C Boot Device Configuration](#).

4.6.1.1.1 Block Size

ROM code will read 0x800 bytes before processing the data. The last block must be padded to the next 0x800 byte boundary and it must be padded with zeros.

4.6.1.1.2

The boot code does not support byte address to bus address wrapping. So the maximum image size that can be access is 64 kbytes. What this means is that if the read address is 0xFF00, the read size is 0x200 and the I2C bus address is 0x50, then 0x100 bytes will be read from 0xFF00 at bus address 0x50, followed by 0x100 bytes from 0x0000 at bus address 0x50. The bus address does not increment when the address rolls over.

4.6.1.2 I2C Loading Process

4.6.1.2.1 Loading a Boot Image From EEPROM

In this mode, the MCU_I2C0 peripheral is configured as I2C master.

ROM Code will start reading from the I2C EEPROM at the specified I2C bus address. This read will be done beginning at the specified base address offset. Data will be read in 2-KB chunks. The data will be stored at the address specified in the boot header. It will continue reading image data until a complete image has been read. When the complete image has been read, the ROM Code will branch to the start address of the image.

4.6.2 SPI Bootloader Operation

4.6.2.1 SPI Initialization Process

In the SPI boot mode, the ROM Code initializes the OSPI peripheral to SPI bus at 4.156 MHz. The image is read from the EEPROM connected to the corresponding OSPI port and chip-select. The the starting offset to be read can be provided by the user through the BOOTMODE pins ([Section 4.3.7, SPI Boot Device Configuration](#)). A detailed summary of the SPI boot parameter table and the boot configuration definitions are listed in [Section 4.4.5, OSPI/QSPI/SPI Boot Parameter Table](#).

4.6.2.2 SPI Loading Process

The SPI boot loading process is similar to the loading process explained in [Section 4.6.1.2.1, Loading a Boot Image From EEPROM](#), except that the image is read from a NOR flash. The data formats supported are also the same as in [Section 4.6.1.2, I2C Loading Process](#). All the other loading processes that are detailed for I2C master mode work for the SPI boot mode, too.

4.6.3 QSPI Bootloader Operation

4.6.3.1 QSPI Initialization Process

In the QSPI boot mode, the ROM Code initializes the OSPI peripheral in DAC mode. The image is read from the QSPI flash connected to the selected chip-select. See [Section 4.3.6, QSPI Boot Device Configuration](#) for OSPI port settings.

A detailed summary of the QSPI boot parameter table and the boot configuration definitions are listed in [Section 4.4.5, QSPI Boot Parameter Table](#).

4.6.3.2 QSPI Loading Process

QSPI boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

4.6.4 OSPI Bootloader Operation

4.6.4.1 OSPI Initialization Process

In the OSPI boot mode, the ROM Code initializes the OSPI peripheral in DAC mode. The image is read from the OSPI flash connected to the selected chip-select. See [Section 4.3.5, OSPI Boot Device Configuration](#) for OSPI port settings.

A detailed summary of the OSPI boot parameter table and the boot configuration definitions are listed in [Section 4.4.5, OSPI Boot Parameter Table](#).

4.6.4.2 OSPI Loading Process

OSPI boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

4.6.5 PCIe Bootloader Operation

4.6.5.1 PCIe Initialization Process

In the PCIe boot mode, the ROM Code configures the PCIe and SerDes from information it obtains from the boot parameter table, see [Section 4.4.3, PCIe Boot Parameter Table](#)

4.6.5.2 PCIe Loading Process

PCIe boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

PCIe Boot Flow:

Once the PCIe link is up in J7AEP, R5 Rom waits for two specific checks to continue the Boot sequence.

The Host (root complex) after copying the full image has to write the Start address(32bit) of the Image on the address location (0x41CF3FE0).

The Host (root complex) after copying the Full image, it has to write a Magic Word (0xB17CEAD9) on the address location (0x41CF3FE4).

4.6.6 Ethernet Bootloader Operation

4.6.6.1 Ethernet Initialization Process

When the device is set to boot through the Ethernet mode, the ROM Code configures PHY, NAVSS, and the CPSW. These initial configurations, as well as the interface mode (RMII, RGMII), are determined by querying the BOOTMODE pins, see [Section 4.3.13, Ethernet Boot Device Configuration](#), and the boot parameter table for the Ethernet boot, see [Section 4.4.7, Ethernet Boot Parameter Table](#).

The queue manager is setup to route the packets to queues polled by the ROM Code.

4.6.6.2 Ethernet Loading Process

After device configuration, the bootloader performs a standard BOOTP/TFTP boot. The device sends a BOOTP request with its MAC address to a host TFTP server to be assigned an IP from a pool of addresses. After this connection is established, the device is able to receive image data encapsulated in Ethernet packets, see [Section 4.6.6.2.1](#). Data received is stripped of its network headers and the boot data is stored in internal RAM. When the transfer completes and the image is found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

4.6.6.2.1 Ethernet Boot Data Formats

Ethernet boot uses the BOOTP/TFTP protocol for downloads. Only IPv4 is supported.

4.6.6.2.1.1 Limitations

- Received packets cannot be IP fragmented (should not be a problem in most systems since the BOOTP/TFTP packets have fixed lengths of small size)
- Only DIX Ethernet headers are supported.
- 802.3 with SNAP/LLC not supported
- DIX Ethernet with VLAN not supported

- 802.3 with VLAN and SNAP/LLC not supported

4.6.6.2.1.2 BOOTP Request

4.6.6.2.1.2.1 MAC Header (DIX)

- Destination MAC = value from parameter table (default is broadcast)
- Source MAC = value from parameter table (default is e-fuse value)
- Type = IPv4 (0x0800)

4.6.6.2.1.2.2 IPv4 Header

- Version = 4
- Header length = 0
- TOS = 0
- Len = computed during operation
- ID = 0x0001
- Flags + Fragment offset = 0
- TTL = 0x10
- Protocol = UDP (17)
- Header checksum = Computed during operation
- SRC IP = 0.0.0.0
- Dest IP = 255.255.255.255

4.6.6.2.1.2.3 UDP Header

- Source port = BOOTP client (68 decimal)
- Destination Port = BOOTP server (67 decimal)
- Length = computed during operation
- Checksum = computed during operation

4.6.6.2.1.2.4 BOOTP Payload

- Opcode = Request (1)
- HW Type = Ethernet (1)
- HW Addr Len = 6
- Hop Count = 0
- Transaction ID = 1
- Number of seconds = 0
- Client IP = 0.0.0.0
- Your IP = 0.0.0.0
- Server IP = 0.0.0.0
- Gateway IP = 0.0.0.0
- Client HW Address = Device MAC address (from parameter table)
- Server hostname = NULL
- Filename = NULL
- Option 60, Vendor ID string, from parameter table
- Option 61, Client ID string, from parameter table

4.6.6.2.1.2.5 TFTP

There are no ROM code specific TFTP configurations.

4.6.6.3 Ethernet Hand Over Process

Once the ROM Code receives the valid packet, it decodes it to get the image sections and loads them in the appropriate memory location. After the image is loaded and validated, the ROM Code starts the boot image execution.

4.6.7 USB Bootloader Operation

The USB boot mode is used to read the boot image from external USB host .

See [Section 4.3.14, USB Boot Device Configuration](#) and [Section 4.4.8, USB Boot Parameter Table](#) for the available configuration options.

More information about USB DFU protocol can be found at http://www.usb.org/developers/docs/devclass_docs/DFU_1.1.pdf.

After successful enumeration, the ROM Code will start reading from the external host as specified by the BOOTMODE pins. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

4.6.7.1 USB-Specific Attributes

4.6.7.1.1 DFU Device Mode

- Vendor ID = 0x451
- Product ID = 0x6168
- Device ID = 0

4.6.8 MMCSD Bootloader Operation

Only single data rate with backward compatible interface timing is supported.

See [Section 4.3.11](#), *MMCSD Boot Device Configuration* and [Section 4.4.9](#), *MMCSD Boot Parameter Table* for the available configuration options.

If the card type is set to autodetect, then an initial discovery phase is performed:

1. Send CMD 0. (GO IDLE, both for MMC and SD)
2. Send CMD 55. If the card responds then the card type is assumed to be SD and the boot attempt fails (the device do not support SD boot). On timeout the code sends CMD 1. If there is a response then the card type is MMC.

The ROM Code will start reading from the MMCSD memory boot sector, or filesystem, as specified by the BOOTMODE pins. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

4.6.9 UART Bootloader Operation

4.6.9.1 Initialization Process

In the UART boot mode, the selected UART module (port) is the only peripheral configured. The baud rate, data, parity, and stop bits are configured based on the information in the UART boot parameter table. The boot parameter table definitions and the boot configuration values that can be set are in [Section 4.3.16](#), *UART Boot Device Configuration* and [Section 4.4.10](#), *UART Boot Parameter Table*.

Once the ROM Code configures the UART, it sends the UART pings for few seconds, which can be seen in the host. The pings consist of an ASCII capital C character. The UART boot mode supports only the CRC mode of XMODEM and does not support CHECKSUM mode.

4.6.9.2 UART Loading Process

Before the ping from the device stops, load the boot image from the host using the XMODEM protocol.

4.6.9.2.1 UART XMODEM

The XMODEM protocol is used to transfer boot data. Only CRC mode is supported (not checksum), with both 128- and 1024-byte block sizes. The general, format of received frames is shown in [Table 4-78](#) and [Table 4-79](#).

Table 4-78. XMODEM 1024- and 128-byte Data Frames

STX	Block Num	Inv Block Num	1024 data bytes				CRC	CRC
SOH	Block Num	Inv Block Num	128 data bytes	CRC	CRC			

Table 4-79. XMODEM Data Frame Fields

Field	Value	Description
STX	0x02	The start character for 1024-byte CRC data blocks

Table 4-79. XMODEM Data Frame Fields (continued)

Field	Value	Description
SOH	0x01	The start character for 128-byte CRC data block
Block Num	0x01-0xFF – 0x00	The block number. The first block has value 1, and the block number wraps around 0xFF to 0
Inv Block Num	0xFE-0x00	The inverse block number (bit inverse of the block number)
CRC	Calculated	The 16-bit CRC generated from the polynomial 0x1021

The XMODEM protocol is implemented as a half-duplex protocol as shown in [Table 4-80](#).

Table 4-80. Example of XMODEM Transfer protocol

Transmitter Sends		Receiver Sends
	←	Ping ('C')
Frame 1	→	
	←	ACK (or NACK)
Frame 2	→	
	←	ACK (or NACK)
EOT	→	
	←	ACK (or NACK)

4.6.9.3 UART Hand-Over Process

Once the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

4.7 Boot Memory Maps

4.7.1 Memory Layout/MPU

Table 4-81 shows an overview of the MPU configuration. In the R5 MPU, higher numbered regions have priority, therefore in Table 4-81, where two regions overlap, the region on the right defines the memory attributes.

Table 4-81. Memory Layout/MPU

Memory Address	Regions			
0x0000_0000	Region 0 non-executable full access	Region 10		
0x0000_003F				
...				
0x4101_0000		Region 3 TCM User access	Region 4 TCM Priv access	
0x4101_0FFF				
0x4101_1000				
0x4101_7FFF				
...				
0x4180_0000		Region 1 ROM User access	Region 2 ROM Priv access	
0x4180_7FFF				
0x4180_8000				
0x4183_FFFF				
...				
0x41C0_0000		Region 5 RAM All access non-cacheable		
0x41CB_FFFF				
0x41CC_0000			Region 6 cacheable	
0x41CD_FFFF				
0x41CE_0000			Region 7 cacheable	
0x41CE_FFFF				
0x41CF_0000			Region 8 non-cacheable non-executable	
0x41CF_DFFF				
0x41CF_E000				
0x41CF_FFFF				Region 9 cacheable
...				
0xFFFF_FFFF				

4.7.2 Global Memory Addresses Used by ROM Code

The ROM code uses several global memory addresses that are useful for debugging. They are shown in Table 4-82.

Table 4-82. Global Memory Addresses

Group	Address	Size (bytes)	Content
Version	0x4182_FF80	64	ROM code version (stored in ROM)
Free MSRAM	0x41C0_0000	768k	Loadable space for SBL
Warning/Error Logs		512	Warning entries in cold boot
Warning/Error Logs		512	Severe entries in cold boot
Warning/Error Logs		256	Critical entries in cold boot
Message Logs		512	Circular message buffer
Message Logs		20	Circular message context log
Warning/Error Logs		512	Warning entries in warm boot
Warning/Error Logs		512	Severe entries in warm boot
Warning/Error Logs		256	Critical entries in warm boot
Warning/Error Logs		40	Cold boot log context

Table 4-82. Global Memory Addresses (continued)

Group	Address	Size (bytes)	Content
Warning/Error Logs		40	Warm boot log context
Warning/Error Logs		4	Active context pointer (not index) to one of the cold or warm contexts
Trace		24	Boot trace context
Trace		1024	Boot trace entry buffers
Parameter Tables		4	Parameter table index (currently active table, 0 or 1)
Parameter Tables		512	Parameter table 0
Parameter Tables		512	Parameter table 1

The ROM code version information is a structure shown in [Table 4-83](#)

Table 4-83. ROM Code Version

Field	Address	Size (bytes)	Value for PG1
Version Number	0x4182_FF80	4	
Version Date	0x4182_FF84	8	
Device Name	0x4182_FF8C	12	
Commit ID	0x4182_FF98	40	"ff0ea75aac317ea6042724fe775412bca006e697"

4.7.3 Memory Reserved by ROM Code

ROM code reserves all of TCM B (BTCM) and the upper memory address of on-chip RAM (MCU_MSRAM0). The initial section of MCU_MSRAM0 is available for the booted image. This is the only memory available for the boot image since neither MSMC nor TCM A (ATCM) is powered up or available for the boot image.

[Table 4-84](#) shows ROM code memory usage.

Table 4-84. Memory Reserved By ROM Code

Memory	Address	ROM Code Usage
TCM B (BTCM)	0x0000	Reserved by ROM Code
	0x7FFF	
MCU_MSRAM0	0x41C0_0000	Free for boot image
	0x41CB_FFFF	
	0x41CC_0000	Reserved by ROM Code
	0x41CF_FFFF	

5 Device Configuration

5.1 Control Module (CTRL_MMR)

5.1.1 CTRL_MMR Overview

The CTRL_MMR modules on the device control top-level device behavior in various states. They contains registers for configuration, bootstrap signals, I/O pad multiplexing, clock selection, and many others. There are three CTRL_MMR modules in this device - CTRL_MMR0 which resides in MAIN domain, MCU_CTRL_MMR0 in MCU domain, and WKUP_CTRL_MMR0 in the WKUP domain.

There is also a PLL control module that has registers to control the configuration of the device PLLs.

5.1.2 CTRL_MMR Functional Description

The following sub-sections provide summary and description for most of the registers which are part of the CTRL_MMR0 module memory space. The rest of the registers are described in the corresponding chapters where the functionality associated with particular CTRL_MMR0 register is covered in more detail.

5.1.2.1 Register Partitions

The CTRL_MMR0 memory space is divided into the partitions shown in [Table 5-1](#).

Table 5-1. CTRL_MMR0 Register Partitions

Partition ⁽¹⁾	Description	Proxy0 Offset Range	Proxy1 Offset Range
Partition 0	General configuration and IPC regs	0000h to 1FFFh	2000h to 3FFFh
Partition 1	IP control/status regs	4000h to 5FFFh	6000h to 7FFFh
Partition 2	Clock control/status regs	8000h to 9FFFh	A000h to BFFFh
Partition 3	BIST control/status regs	C000h to DFFFh	E000h to FFFFh
Partition 5	DDR frequency Control	1 4000h to 1 5FFFh	1 6000h to 1 7FFFh
Partition 7	MAIN I/O Pad Configuration regs	1 C000h to 1 DFFFh	1 E000h to 1 FFFFh

(1) Not listed partitions are reserved and not used.

The MCU_CTRL_MMR0 memory space is divided into the partitions shown in [Table 5-2](#).

Table 5-2. MCU_CTRL_MMR0 Register Partitions

Partition ⁽¹⁾	Description	Proxy0 Offset Range	Proxy1 Offset Range
Partition 0	General configuration and IPC regs	0000h to 1FFFh	2000h to 3FFFh
Partition 1	IP control/status regs	4000h to 5FFFh	6000h to 7FFFh
Partition 2	Clock control/status regs	8000h to 9FFFh	A000h to BFFFh
Partition 3	BIST control/status regs	C000h to DFFFh	E000h to FFFFh

The WKUP_CTRL_MMR0 memory space is divided into the partitions shown in [Table 5-3](#).

Table 5-3. WKUP_CTRL_MMR0 Register Partitions

Partition ⁽¹⁾	Description	Proxy0 Offset Range	Proxy1 Offset Range
Partition 0	General configuration and IPC regs	0000h to 1FFFh	2000h to 3FFFh
Partition 1	IP control/status regs	4000h to 5FFFh	6000h to 7FFFh
Partition 2	Clock control/status regs	8000h to 9FFFh	A000h to BFFFh
Partition 3	BIST control/status regs	C000h to DFFFh	E000h to FFFFh
Partition 5	Power Management regs	1 4000h to 1 5FFFh	1 6000h to 1 7FFFh
Partition 6	Power and reset control and status	1 8000h to 1 9000h	1 A000h to 1 B000h
Partition 7	WKUP I/O Pad Configuration regs	1 C000h to 1 DFFFh	1 E000h to 1 FFFFh

5.1.2.2 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register PADCONFIGn is associated only with one pad and configures features such as:

- Pin multiplexing
- Wakeup
- Debounce and Schmitt Trigger
- Deep sleep
- Driver and Receiver Enables
- IO Isolation

The selection of functions available on each pad is enumerated in table “*Pin Multiplexing*” of the device-specific Datasheet. The desired function is selected via the MUXMODE field of the associated pad configuration register.

5.1.2.3 Kick Protection Registers

There are Kick and Proxy registers associated with each CTRL_MMR register partition. This section describes the Kick registers. For information about the Proxy registers see [Section 5.1.2.4](#).

The Kick registers provide a protection mechanism which prevents spurious writes from changing the values of its registers. The LOCKi_KICK0 and LOCKi_KICK1 registers are used for this purpose. A write is required first to the LOCKi_KICK0[31-1] KEY field and then to the LOCKi_KICK1[31-0] KEY field with exact data values to unlock the protection mechanism. Once released then all registers within Partition “i” having write permissions can be written to. The read only registers are still read only. An indication for unlocked Partition “i” is when the LOCKi_KICK0[0] UNLOCKED bit is set to 1h. When the protection mechanism is locked (indicated by LOCKi_KICK0[0] UNLOCKED = 0h) none of the registers within Partition “i” can be written to. They can only be read.

The following values must be written to the Kick registers to unlock each partition “i”:

- LOCKi_KICK0 = 68EF 3490h
- LOCKi_KICK1 = D172 BC5Ah

Writing any other data value to either of these registers locks the protection mechanism and blocks any writes to the registers that reside in Partition “i”.

Note

In order to ensure that all registers from all partitions are write protected, software must always re-lock the protection mechanism after completing the register writes.

The following registers are exceptions and are not write protected by the LOCKi_KICK0 and LOCKi_KICK1 registers:

- The *Inter-processor Communication Registers* described in [Section 5.1.2.6](#).
- The *Kick Protection Registers* described in this section.

The *Inter-processor Communication Registers* registers are not write protected in order to reduce the access latency.

5.1.2.4 Proxy Addressing Registers

There are Kick and Proxy registers associated with each CTRL_MMR partition. This section describes the Proxy registers. For information about the Kick registers see [Section 5.1.2.3](#).

The Proxy registers provide proxy addressing, allowing each of the CTRL_MMR registers to be accessed through two different addresses - Proxy0 and Proxy1. Each partition is 16KB. The first 8KB are for Proxy0 addresses, and the second 8KB are for Proxy1 addresses. The Proxy0 address is intended as the normal read and write access address. The Proxy1 address provides exclusive register write control.

When a bit from the Px_CLAIMy[31-0] PROXY1_CLAIMED field is set to 1h, a register becomes read-only at its Proxy0 address and may only be written through its Proxy1 address. The Proxy registers themselves may always be read through their Proxy0 address but may only be written through their Proxy1 address.

The **x** (representing the partition) and **y** indices can be calculated through the following equations:

- $x = \text{INT}(\text{HEX2DEC}(\text{address_offset})/16384)$
- $y = \text{INT}(\text{MOD}(\text{HEX2DEC}(\text{address_offset}), 16384)/128)$

where:

- INT() rounds down to the nearest integer
- HEX2DEC() converts from hexadecimal to decimal
- MOD() returns the remainder of $\text{HEX2DEC}(\text{address_offset})/16384$

5.1.2.5 CTRL_MMR Interrupts

Each CTRL_MMR module has an associated ACCESS_ERR_0 interrupt request. The interrupt requests are associated with the following registers:

- INTR_RAW_STATUS — interrupt raw status register
- INTR_ENABLED_STATUS_CLEAR — interrupt status register
- INTR_ENABLE — interrupt enable register
- INTR_ENABLE_CLEAR — interrupt disable register

The following applies for the interrupt behavior of each CTRL_MMR module:

- The CTRL_MMR module asserts its interrupt line only if the interrupts are enabled by setting to 1h the corresponding bits in the INTR_ENABLE register. These interrupts can be disabled by setting to 1h the corresponding bits in the INTR_ENABLE_CLEAR register.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting to 1h the corresponding bit in the INTR_ENABLED_STATUS_CLEAR register which also clears the corresponding bit in the INTR_RAW_STATUS register. The status flags in the INTR_RAW_STATUS register are set even if the corresponding interrupt is disabled unlike those in the INTR_ENABLED_STATUS_CLEAR register, which are set only if the corresponding interrupt is enabled.
- An interrupt is also generated by the CTRL_MMR, if certain bit in the INTR_RAW_STATUS register is set to 1h and the corresponding interrupt is enabled through the INTR_ENABLE register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled the corresponding raw flag in the INTR_RAW_STATUS register is set to 1h when an IRQ condition occurs.
- Even if interrupts are not enabled, a status bit in the INTR_RAW_STATUS register can also be cleared by setting to 1h the corresponding bit in the INTR_ENABLED_STATUS_CLEAR register.

Table 5-4 lists the interrupt events which can assert the (ACCESS_ERR_0) interrupt lines.

Table 5-4. CTRL_MMR Events

Event	Description
PROXY_ERR	Proxy violation interrupt. Occurs when a write is attempted through the Proxy0 address of register whose associated CLAIM bit is set.
LOCK_ERR	Lock violation interrupt. Occurs when writing to a register in a locked CTRL_MMR partition.
ADDR_ERR	Addressing violation interrupt. Occurs when accessing an illegal address inside the CTRL_MMR module.
PROT_ERR	Protection violation interrupt. Occurs when a register is accessed without the required secure/privilege level permissions.

When an error event as described in Table 5-4 occurs, the error associated details are captured in the FAULT_ADDRESS, FAULT_TYPE_STATUS and FAULT_ATTR_STATUS registers. FAULT_ADDRESS contains the address of the first fault access. FAULT_TYPE_STATUS and FAULT_ATTR_STATUS contain status attributes associated with the first fault access. To clear the contents of these three registers and allow them to latch the attributes of the next fault the FAULT_CLEAR[0] CLEAR bit must be set to 1h.

5.1.2.6 Inter-processor Communication Registers

The inter-processor communication registers in the CTRL_MMR modules are used for generating interrupts to the device cores. Any master having access to these registers can generate an interrupt by writing 1h to the IPC_SETx[0] bits. The interrupt is cleared when 1h is written to the IPC_CLRx[0] bits. These registers provide also a *Source ID* facility through the IPC_SETx[31-4] IPC_SRC_SET and IPC_CLRx[31-4] IPC_SRC_CLR bit fields by which up to 28 different sources of interrupts can be identified. Allocation of the source bits to source processor and meaning is entirely based on software convention. Virtually, anything can be a source for these fields as this is completely controlled by software.

Writing 1h to an IPC_SRC_SET bit sets to 1h both the IPC_SRC_SET and corresponding IPC_SRC_CLR bit. Writing 1h to an IPC_SRC_CLR bit sets to 0h (clears) both the IPC_SRC_CLR and corresponding IPC_SRC_SET bit. The same logic applies also to the IPC_SETx[0] IPC_SET and IPC_CLRx[0] IPC_CLR bits. Table 5-5 and Table 5-6 shows the mapping between the inter-processor communication (IPC) registers and device cores.

Table 5-5. CTRL_MMR0 IPC Registers to Device Core Mapping

IPC Register Instance "x" ¹ CTRL_MMR0_IPC_SETx CTRL_MMR0_IPC_CLRx	Device Core
0	C7SS0
1	C7SS1
8	A72SS0 core 0
9	A72SS0 core 1
16	R5FSS0 core 0
17	R5FSS0 core 1
18	R5FSS1 core 0
19	R5FSS1 core 1

1. Not listed IPC register instances are reserved and not used.

Table 5-6. MCU_CTRL_MMR0 IPC Registers to Device Core Mapping

IPC Register Instance "x" ¹ MCU_CTRL_MMR0_IPC_SETx MCU_CTRL_MMR0_IPC_CLRx	Device Core
0	MCU R5 core0
1	MCU R5 core1
8	DMSC

1. Not listed IPC register instances are reserved and not used.

Note

For latency reasons the IPC registers are not write protected by KICK registers which means that they can be written to without a need for performing unlocking procedure as described in [Section 5.1.2.3](#).

5.1.2.7 Timer IO Muxing Control Registers

Not all timer inputs and outputs are pinned out of the device. Through the timer I/O muxing registers, the inputs and outputs of each TIMER module in a domain can be made available on the TIMER IO device pads in that same domain.

Each TIMER module input in a domain can be configured to be driven by one of the TIMER IO pads in that domain through the corresponding bits in the TIMERx_CTRL registers.

Additionally, each of the TIMER IO pads in a domain can be configured to be driven by any of the TIMER module outputs in that domain through the corresponding bits in the TIMERIOx_CTRL registers.

For more information about each timer, see [Section 12.9.3 Timers](#).

5.1.2.8 EHRPWM/EQEP Control and Status Registers

The CTRL_MMR registers which provide control and status information for the EHRPWM/EQEP modules are shown in [Table 5-7](#).

Table 5-7. Summary of the EHRPWM/EQEP Control and Status Registers

Register	Description
EPWM0_CTRLx	Time base clock, source of PWM synchronization input and other controls for the EHRPWMx ⁽¹⁾ module
SOCA_SEL SOCB_SEL	Start of Conversion output source
EQEP_STAT	Provides EQEPx phase error status information

- (1) The terms "EPWM" and "EHRPWM" are interchangeable in this section.

5.1.2.9 Clock Muxing and Division Registers

The CLKSEL, OBSCLKx, and CLKOUT registers within the CTRL_MMR modules are dedicated to clock muxing and division for some device modules. Related information can also be found in *Clocking*.

5.1.2.10 Module Control Registers

There are CTRL registers within the CTRL_MMR module that are control other modules within the device. These CTRL registers supplement the registers present inside the module itself, providing additional module functions.

5.1.2.11 DDRSS Dynamic Frequency Change Registers

There are registers within the CTRL_MMR module that are used to dynamically change the DDR clock frequency to support LPDDR4 Frequency Set Point (FSP). These registers are shown in [Table 5-8](#). For more information, see *DDRSS Dynamic Frequency Change Interface* in *Memory Controllers*.

Table 5-8. DDRSS Dynamic Frequency Change Registers

Register Name
CHNG_DDR4_FSP_REQx
CHNG_DDR4_FSP_ACKx
DDR4_FSP_CLKCHNG_REQx
DDR4_FSP_CLKCHNG_ACKx
MULTI_DDR_CFGx
DDR_CFG_LOAD

5.1.2.12 MAC Address Registers

Each device has a unique 48-bit MAC address which is stored in the MAC_ID0/1 registers shown in [Table 5-9](#).

Table 5-9. MAC Address Registers

Bit Field	Description
MAC_ID0[31-0] MACID_LO	Contains the first, second, third and fourth octets of the MCU_CPSW0 MAC address
MAC_ID1[15-0] MACID_HI	Contains the fifth and sixth octets of the MCU_CPSW0 MAC address

5.1.2.13 Feature Registers

The DEVICE_FEATUREx and FEATURE_STATx registers within the CTRL_MMR module provide status information regarding whether specific device modules and features are enabled or disabled.

5.1.2.14 Power and Reset Related Registers

There are several registers within the CTRL_MMR moduels related to power and reset control (CTRL) and status (STAT).

Reset-related registers:

- RESET_SRC_STAT: Indicates which reset occurred
- MAIN_POR_TO_CTRL: Sets the MAIN PORz hardware timeout period
- POR_RST_CTRL: Controls POR behavior
- WARM_RST_CTRL: Controls Warm Reset behavior
- RST_STAT: Indicates the reset status

Power-related registers:

- PRGx_CTRL/STAT: PRG module control and status of the POK and POR over/undervoltage detectors
- POR_POK*_CTRL/STAT: Control and status of the POR module over/undervoltage detectors
- POK*_CTRL/STAT: Control and status of the POK module over/undervoltage detectors
- GLDTC_CTRL/STAT: Control and status of the PGD module voltage glitch detectors

5.1.2.15 I/O Debounce Control Registers

Some device pads have debounce logic. The DBOUNCE_CFGx registers are used to configure the debounce period.

The DBOUNCE_CFG1 register contains the debounce period for pads with PADCONFIGx[13-11] DEBOUNCE_SEL fields set to 1h. The DBOUNCE_CFG2 register contains the debounce period for pads with PADCONFIGx[13-11] DEBOUNCE_SEL fields set to 2h and so on. The DBOUNCE_CFG6 register contains the debounce period for pads with PADCONFIGx[13-11] DEBOUNCE_SEL fields set to 6h.

Note

The debounce logic is not associated with all signals that can be multiplexed on a pad. Only certain signals can use it.

For information about the PADCONFIGx registers, see *Pad Configuration Registers*.

[Table 5-10](#) shows the debounce period values to load in the DBOUNCE_CFGx[5-0] DB_CFG field.

Note

The debounce clock selection should happen before the consumer of the debounced signals is enabled as the clock multiplexers for the debounce logic are NOT glitch-free.

Note

ADC trigger input signals offer debounce logic that can be enabled via the centralized PADCONFIG registers. The PADCONFIG registers corresponding to ADCx_AIN0 are used to control the debounce time for all ADCx_AINn pads.

Table 5-10. Debounce Period Values

DBOUNCE_CFGx[5-0] DB_CFG Decimal Value	GPIO Case (32.768kHz (1))	EQEP Case (20MHz ⁽¹⁾)	DBOUNCE_CFGx[5-0] DB_CFG Decimal Value	GPIO Case (20MHz ⁽¹⁾)	EQEP Case (250MHz ⁽¹⁾)
	Delay[ms]	Delay[μs]		Delay[μs]	Delay[ns]
0	bypassed	bypassed	32	0.05	4
1	1.95	3.2	33	0.1	8
2	2.93	4.8	34	0.15	12

31	156.25	256	63	256	20.48

(1) These are the debounce logic clock frequencies.

5.1.3 Control Module Registers

Note

Some single-bit fields in the following register descriptions do not explicitly state how to interpret values of 0 and 1. For these fields, the interpretation is:

- 0h: Description is FALSE
- 1h: Description is TRUE

5.2 Power

This chapter describes the power-management architecture implemented in the device.

The Power Management is presented in several general sections - Power Management Subsystems, including both System and Control Modules; Device Power States; Dynamic and Thermal Management.

5.2.1 Power Management Overview

Power management architecture of the device is built over three levels of power controls: clock-, power-, and voltage supplies to the subsystem modules, namely domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch).

A set of Power Domains (PD) are defined for the device, where clock and power supplies to the domain may be controlled by Power Sleep Controllers (PSC). One or multiple power domains may share a single power supply, this level of grouping are referred as Voltage Domains (VD). Some voltage domains may be turned off by externally switching off the power supplies to these domains. The hierarchical relationship is summarized in [Section 5.2.2](#).

Figure 5-1 shows the overview of the common power management of the device.

power-001

Figure 5-1. Overview of Common Power Management

5.2.2 WKUP_PSC0 Device-Specific Information

[Table 5-11](#) provides the device-level view with module asSoCiations to the clock, power, and voltage domains.

Table 5-11. PSC0 Power Management Device Level Layout

5.2.3 Power Management Subsystems

This section provides an overview of how three Power blocks work together; the three blocks are: Power On Reset module (POR), Power OK module (POK), and the POK Reset Generator – Ping-Pong module (PRG_PP) and a PRG without Ping-Pong (PRG).

5.2.3.1 Power Subsystems Overview

5.2.3.1.1 POK Overview

POK modules are responsible for accurately detecting average voltage levels.

Two types of POK modules are implemented in this family of devices - POK and POK_SA.

POK module is capable of monitoring a range of supplies and indicating a failure within the programmable upper and lower threshold limits for the supply being monitored. POKs are used to monitor 3.3 V, 1.8 V and core supply levels with programmable threshold levels.

[Figure 5-2](#) shows the concept of the POK. It is a comparator with a fixed 0.45V and the voltage to be monitored. The voltage-to-be-monitored is defined based upon a CTRL register (see *POK Related Registers*) and the silicon hook-up of the POK. The POK has three possible input voltage ports – VDD_MON3P3, VDD_MON1P8, and VDD_MON. The effect of the CTRL register depends upon which of these three ports is selected (defined in [Table 5-18](#)); for example, a threshold value of 0x28 in the threshold register would create a different threshold voltage depending upon:

- How the POK was hooked-up (i.e. VDD_MON3P3, VDD_MON1P8, or VDD_MON) see *POK Modules and Monitored Voltages*.
- Whether the POK is selected for undervoltage detection or overvoltage detection as determined by bit 7 in the POK CTRL register (e.g. CTRL_MMR_POR_VDDR_MCU_UV_CTRL)

The POK output triggers high (i.e. indicating a fail condition) when:

- Under-voltage: the monitored voltage (divided based upon CTRL registers) is less than 0.45V. The CTRL register tables translate the input voltage back to a monitored voltage level (see [Table 5-18](#)). If the monitored voltage falls below the trip point, the POK outputs HIGH, (i.e. FAIL).
- Over-voltage: the monitored voltage (divided based upon CTRL registers) is greater than 0.45V. The CTRL register tables translate the input voltage back to a monitored voltage level (see [Table 5-18](#)). If the monitored voltage rises above the trip point, the POK outputs HIGH, (i.e. FAIL).

When the monitored voltage threshold is changed, the new threshold settles within 9us.

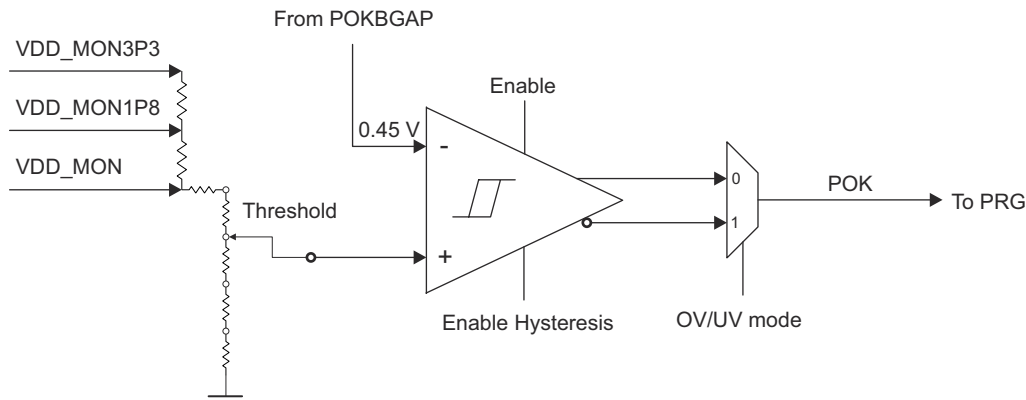

[Figure 5-2](#) also shows a mux on the output of the comparator. The mux is configured based upon the selection of under-voltage or over-voltage and is used to maintain the proper polarity of the fail signature.

Note

POK_SA (used only on VMON1_ER_VSYS) directly compares the monitored voltage to 0.45V.

Two other features of the POK diagram (i.e. [Figure 5-2](#) and [Figure 5-3](#)) need some explanation:

- The comparator can be enabled or disabled individually; note, that once enabled, the comparator output is continuous (though as shown below in is sampled and filtered). The comparator enable settling time is 15us.
- Hysteresis is applied to the comparator input. In general, it is expected that the monitored voltage is far away from the reference and that the hysteresis is moot.

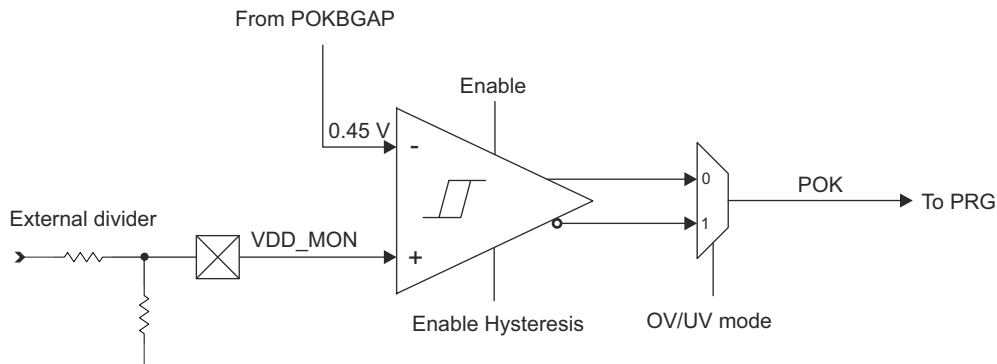

pok-001

Figure 5-2. POK Block Diagram

Table 5-14. POK Programmable Features

Programmable Feature	Bitfield in the POK Dedicated Register
POK hysteresis enable	[31] HYST_EN
POK over- or under-voltage detection mode	[7] OVER_VOLT_DET
POK trim bits for voltage comparator threshold	[6-0] POK_TRIM

Like the POK, the POK_SA is a comparator with 0.45V reference; however, voltage division must occur in hardware on the PCB before the monitored voltage is applied to VMON1_ER_VSYS.

pok-002

5.2.3.1.2 PRG / PRG_PP Overview

The POKs are both controlled by and send their output back through the PRG(_PP) module; the PRG(_PP) module, all of which reside in the WKUP domain.

1. Controls the POKs – enable / disable, over-volt / under-volt / ping-pong
2. Samples the continuous output
3. Filters the output

Each POK is controlled, sampled, and filtered by a specific PRG(_PP) (see *POK Modules and Monitored Voltages*) and the control register within that PRG(_PP) is where the POKs are controlled (e.g. CTRL_MMR_PRG_POR_CTRL).

1. Control of the POKs: The POK threshold voltage and hysteresis enable are set in CTRL registers defined in *POK Related Registers*. The PRG(_PP) controls how these POKs are enabled / disabled and how the threshold are applied:
 - Enable / Disable has both;
 - a. A global control –POK_EN_SEL (e.g. CTRL_MMR_PRG_PP_MCU_CTRL[15]). POK_EN_SEL disables all controlled POKs when 0 and gives control to the per-POK enable when 1.
 - b. A per-POK enable (e.g. CTRL_MMR_PRG_PP_MCU_CTRL[1]. POK_VDDR_MCU_EN)

To enable a given POK, both levels of enable are required to be set.

- The options on how thresholds are applied to the POK is the key difference between the PRG_PP and PRG modules. The PRG_PP module will be described in this bullet and then the restriction imposed by the PRG module will be addressed. The PRG_PP can be configured in any of three modes, shown in [Table 5-19](#).
- Sampling the POKs: The POKs are sampled by a divided-down CLK_12M_RC (WKUP_RC_OSC_12M from the internal RC oscillator). The sampling clock is nominally 12.5MHz (though because it is an RC-generated clock, the frequency is not precise). This input clock is divided by 16 so that sampling records the POK output on the rising edge every ~1.25us.
- Filtering the output: The output is filtered by means of the DEGLITCH_SEL bitfield (e.g. CTRL_MMR_PRG_PP_MCU_CTRL[17:16]). The bitfield allows the user to select a window of 5us, 10us, 15us or 20us; the POK must be in a FAIL state for ALL samples within the filter window in order for the POK output from the PRG to be seen as FAIL.

Note

DEGLITCH_SEL defines number of samples; the precise duration of the filter is not well controlled.

- For example, the 5us deglitch window samples the POK 4 times and ALL 4 samples must FAIL before the PRG propagates FAIL to the system.
- For example, the 20us deglitch window samples the POK 16 times and ALL 16 samples must FAIL before the PRG propagates FAIL to the system.

Note

PRG in POR does not support ping-pong.

Table 5-19. PRG_PP Modes

Mode:	Example Register / Bitfield
Each POK can be configured to apply the <u>undervoltage</u> threshold continuously. 1. OV_SEL is cleared; the threshold voltage is taken from *UV_CTRL 2. POK_PP_EN is cleared	CTRL_MMR_POK_VDDR_MCU_UV_CTRL CTRL_MMR_PRG_PP_MCU_CTRL[9]. POK_VDDR_MCU_OV_SEL = 0 CTRL_MMR_PRG_PP_MCU_CTRL[19] POK_PP_EN = 0
Each POK can be configured to apply the <u>overvoltage</u> threshold continuously. 1. OV_SEL is set; the threshold voltage is taken from *OV_CTRL 2. POK_PP_EN is cleared	CTRL_MMR_POK_VDDR_MCU_OV_CTRL CTRL_MMR_PRG_PP_MCU_CTRL[9]. POK_VDDR_MCU_OV_SEL = 1 CTRL_MMR_PRG_PP_MCU_CTRL[19] = 0
All POK can be configured to apply the <u>undervoltage</u> threshold then the <u>overvoltage</u> threshold iteratively (ping-pong) 1. All OV_SEL are cleared 2. POK_PP_EN is set; the threshold voltage is taken from *UV_CTRL in the UV phase; the threshold voltage is taken from *OV_CTRL in the OV phase	CTRL_MMR_POK_VDDR_MCU_UV_CTRL CTRL_MMR_POK_VDDR_MCU_OV_CTRL CTRL_MMR_PRG_PP_MCU_CTRL[10:8] = 000b CTRL_MMR_PRG_PP_MCU_CTRL[19] = 1

5.2.3.1.3 POR Overview

The POR module should be viewed as a transparent wrapper to the PRG / POKs instantiated within *except* for the following points:

- The bandgap which supplies all POKs is within the POR. The bandgap generates an untrimmed voltage / current after MCU_PORz is released. In order to apply the device-specific trim to the bandgap, the user must set CTRL_MMR_POR_CTRL[7]. TRIM_SEL. The bandgap requires a 100us settling time (during which POK / PRG configuration may occur).
- The device-specific bandgap trim is stored in CTRL_MMR_POR_BANDGAP_CTRL and it is recommended to not modify this trim value.
- The threshold controls for the POKs within the POR are also enabled when TRIM_SEL is set.
- As noted above, the PRG within the POR does not support ping-pong application of thresholds; these POKs monitor a fixed threshold.

5.2.3.1.4 POK / PRG(_PP) /POR Overview

Summarizing this section: The POK block diagram shows a comparator with:

Element of POK	Point of control
resistor divider	*POK*_CTRL registers
hysteresis enable	
comparator enable	*PRG*_CTRL
mux on the output	*POK*_CTRL registers

The output of the POR / PRG_PP / POK voltage monitoring goes to the ESM. Each undervoltage / overvoltage condition has its own bit in the ESM, and the ESM can be programmed to respond to these bits as an interrupt and/or to generate an external signal to the system.

5.2.3.1.5 Timing

As noted in above, there are three timings that are critical:

- 100-us bandgap settling
- 15-us POK enable settling can be concurrent to 100-us bandgap settling
- 9-us POK threshold settling which can be concurrent to both the 100-us bandgap settling and the 15us POK settling

Figure 5-4 shows the sampled POK output to the ESM when the POK threshold is ping-ponged.

- A POK settling time of 1.25-us clocks is fixed in the design; this provides settling for the new threshold voltage when the POK is ping-ponged
- The deglitch (filter) time can be chosen as {4, 8, 12, 16} 1.25-us clock cycles.
- One 1.25-us clock period provides an update window to the ESM.

In this case, the ESM sees an update of the POK threshold every $(+ \{4, 8, 12, 16\} + 1) \times 1.25[\mu s]$. Since the ESM sees an update of a threshold every ~us to every ~us, the UV and OV flags are individually being updated every ~us to every -us.

In the case where the PRG does not ping-pong, a fixed threshold is applied. The deglitch (filter) time can be chosen as {4, 8, 12, 16} 1.25-us clock cycles. The filter is a sliding window that evaluates the filtered output every 1.25-us based upon the last n samples ($n = \{4, 8, 12, 16\}$). In this case, the ESM sees an update of the POK threshold every 1.25 us.

The POKs are sampled by a divided-down CLK_12M_RC (WKUP_RC_OSC_12M from Section 5.4.4.1.2). The sampling clock is nominally 12.5 MHz (though because it is an RC-generated clock, the frequency is not precise). This input clock is divided by 16 so that sampling records the POK output on the rising edge every ~1.25 us.

Figure 5-4. Timing for POK with Ping-Pong and Deglitch of 5us

5.2.3.1.6 Restrictions

1. POK monitoring occurs within the initial POK settling (from enable). It is therefore required that the initial state of the POK after enable should be discarded; further, the ESM should be configured for its system response after the initial results during the settling time are discarded.
2. Within a PRG, all POKs must ping-pong or all monitor a static threshold
3. It is not advised to change the threshold from UV to OV while the POK is enabled

5.2.3.2 Power System Modules

5.2.3.2.1 Power OK (POK) Modules

5.2.3.2.1.1 POK Programming Model

5.2.3.2.2 PoR/Reset Generator (PRG_PP) Modules

5.2.3.2.2.1 PRG_PP Overview

A PRG_PP (Ping-Pong) module is responsible for implementing enable/disable controls, POK Ping-Pong operation, and event/interrupt masking logic on all POK outputs. [Table 5-20](#) shows PRG_PP modules allocation within device domains.

Table 5-20. PRG_PP Allocation within Device Domains

Module Instance	Domain		
	WKUP	MCU	MAIN
PRG_PP_MCU	✓	-	-
PRG_PP_POR	✓	-	-
PRG_PP_MAIN	✓	-	-

5.2.3.2.2.2 PRG_PP Programming Model

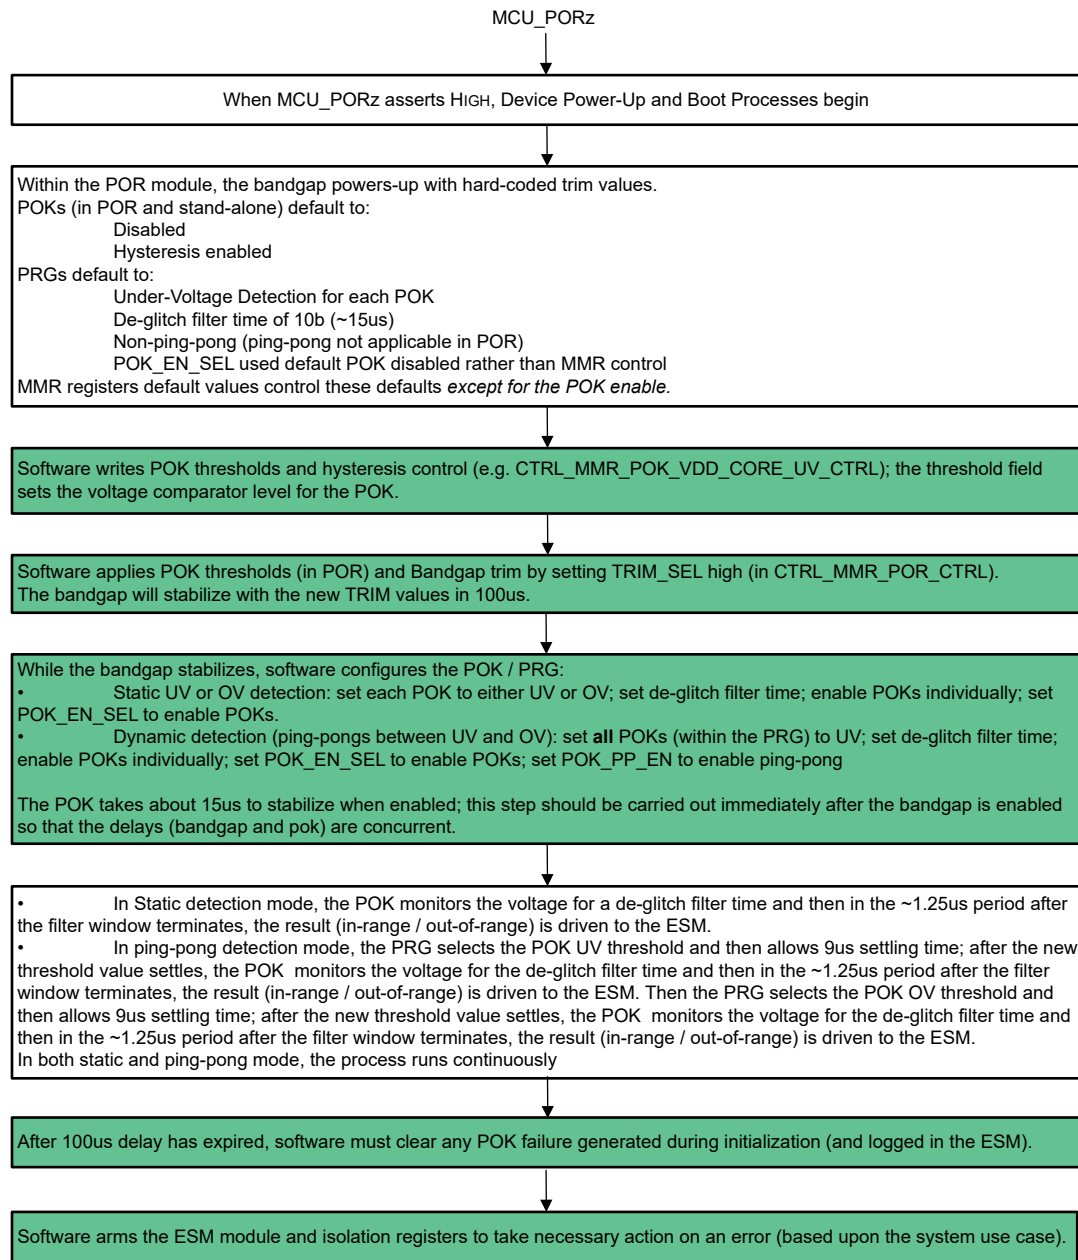

Figure 5-5. PRG_PP Programming Flow

The PRG_PP modules registers used to control and monitor the status of POK modules are:

- CTRL_MMR_PRG_POR_CTRL
- CTRL_MMR_PRG_PP_MCU_CTRL
- CTRL_MMR_PRG_PP_MAIN_CTRL

For more information about control registers, see *Control Module (CTRL_MMR)*.

5.2.3.2.3 Power Glitch Detect (PGD) Modules

A Power Glitch Detect (PGD) circuit is used to detect short duration “glitches” on the core and MPU power supplies. The PGD provides a low output when no glitch is detected and a high output when a glitch is detected.

Figure 5-6 shows the PGD block diagram.

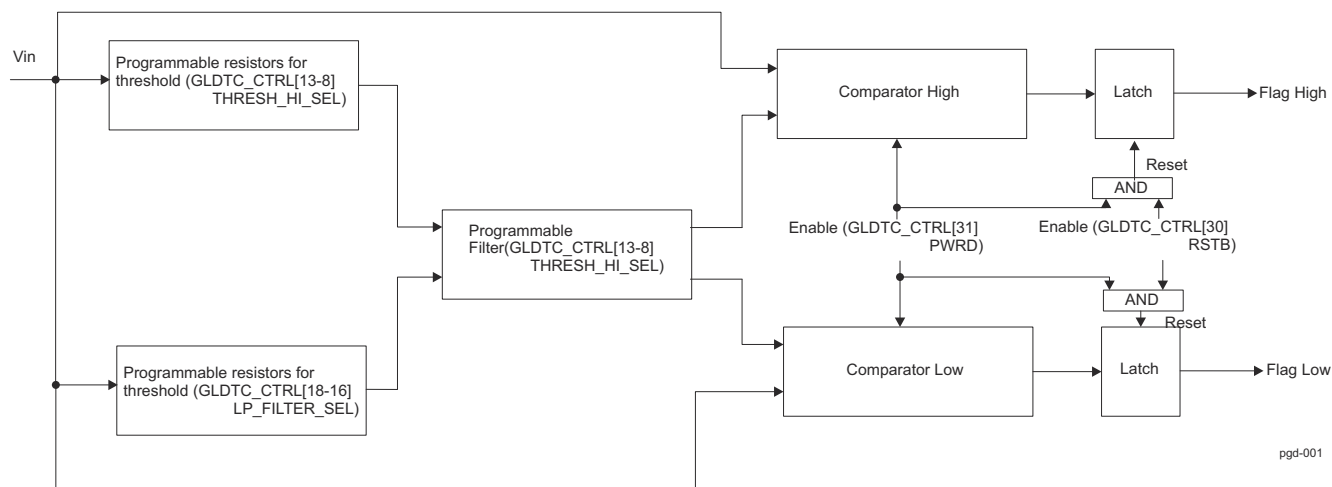

Figure 5-6. PGD Block Diagram

Table 5-21 summarize the PGD integration.

Table 5-21. PGD Integration Summary

Module Instance	Monitored Voltage	PGD Control/Status Registers
IPGD_VDD_MCU_CORE	VDD_MCU	CTRL_MMR_VDD_MCU_GLDTC_CTRL CTRL_MMR_VDD_MCU_GLDTC_STAT

IPGD_VDD_CPU1_CORE	VDD_CORE	CTRL_MMR_VDD_CPU1_GLDTC_CTRL CTRL_MMR_VDD_CPU1_GLDTC_STAT

Note

A flag status bit in corresponding STAT register is cleared by clearing the [30] RSTB bit in the corresponding CTRL register, see for STAT and CTRL registers for a certain PGD module.

5.2.3.2.4 Voltage and Thermal Manager (VTM)

5.2.3.2.4.1 VTM Overview

This section describes the Voltage and Thermal Manager (VTM) module in the device.

In the same way that PRGs control and provide output from the POKs, the VTM controls and outputs signals from temperature sensors that are spread around the die. VTM provides the control, status as well as interrupt and event generation related to integrated temperature sensors and thermal events programmed by the user. VTM also contains a set of memory mapped registers that store device-specific operating voltages (AVSVNOM) set during device testing. These values may be used for the system AVS software to adjust operating voltages for the device to achieve optimal operating power.

The device supports one VTM module - WKUP_VTM0. [Table 5-22](#) shows VTM module allocation within device domains.

Table 5-22. VTM Module Allocation within Device Domains

Module Instance	Domain		
	WKUP	MCU	MAIN
WKUP_VTM0	✓	-	-

5.2.3.2.4.1.1 VTM Features

VTM module supports the following features:

- AVS-Class0 only
- Supports up to 8 temperature monitors
- Programming of temperature-crossing thresholds
- Signals when programmed thresholds are exceeded - up to 3 alerts:
 - Three full reference 10-bit temperature threshold points, THPT1, THPT2 and THPT0.
- Supports up to 8 temperature monitors
- Allows resolution of 0.5°C for temperature reading and threshold point temperature alert/interrupt generation.
- Supports PMIC/LDO set-up with Class-0 VDD-VID settings
- Support of tentative customization of OPP voltage per device (in support of multiple OPPs)
- AVS-voltage or thermal management for up to 8 voltage domains
- Maximum temperature alert
- Supports one shot sampling mode and continuous monitoring mode for the sensors

Note

The VTM of this family of devices has only 7 temperature sensors and 3 voltage domains.

The 'j' notation in the following registers increment from 0 to 6 to map to the 7 temp sensors on the SoC. (Refer to [Table 5-27](#)):

- TMPSENS_CTRL_j
- TMPSENS_STAT_j
- TMPSENS_TH_j
- TMPSENS_TH2_j

The 'j' notation in the following registers increment from 0 to 2 to map to the 3 voltage domains on the SoC (refer to [Table 5-23](#)):

- VD_EVT_SEL_SET_j
- VD_EVT_SEL_CLR_j

5.2.3.2.4.1.2 VTM Not Supported Features

- No support for AVS-Class0 with temperature compensation (AVS0 + TC)
- No integrated I2C inside VTM
- No direct hardware triggering of I2C transactions by VTM
- No support for voltage and thermal management of IO voltage domains
- No oversampling of the temperature reading

- No support for eFuse defaults of all register values

5.2.3.2.4.2 VTM Functional Description

In the same way that PRGs control and provide output from the POKs, the VTM controls and outputs signals from several temperature sensors that are spread around the die. The VTM provides three interrupts / ESM inputs to the system as well as a warm reset.

The temperature sensor is configured to run off a clock frequency between 1.15MHz and 1.25MHz. The frequency is obtained by dividing-down HFOSC0 or the internal RC clock; the expected usage is that the temperature sensors use HFOSC0 (TSENS_CLK_DIV is the divider). The temperature sensor will sample the temperature on a period defined by VTM_VTM_SAMPLE_CTRL.

When the temperature sensor is enabled, it senses the temperature and reports the temperature as a 10-bit value.

- The raw 10-bit value is reported in VTM_VTM_TMPSENS_STAT_j;
- It is also compared to pre-defined thresholds (each temperature sensor has its own set thresholds set in VTM_VTM_TMPSENS_TH_j and VTM_VTM_TMPSENS_TH2_j) ;
- It is also compared to a pre-defined global threshold set in VTM_VTM_MISC_CTRL2.

Each of these comparisons can be individually enabled (VTM_VTM_TMPSENS_CTRL_j and VTM_VTM_TMPSENS_CTRL_j within mmr_vbusp_cfg2). Additionally, each temperature sensor has status bits for these comparator outputs in VTM_VTM_TMPSENS_STAT_j.

The comparator functionality that drives the interrupts and warm reset work only when the sensor is configured for continuous mode; continuous operation becomes a de facto requirement (and is set in VTM_VTM_TMPSENS_CTRL_j[4].CONT within mmr_vbusp_cfg2 – that is, the mode is set for *each* temperature sensor).

Interrupts / ESM inputs:

The comparator thresholds shall always configured so that TH2 > TH1 > TH0. The concept is:

- TH1 is configured as an early alarm to indicate that the temperature is greater than the threshold defined in VTM_VTM_TMPSENS_TH_j[25-16] TH1_VAL.
- TH2 is configured as a warning to indicate that the temperature is greater than the threshold defined in VTM_VTM_TMPSENS_TH2_j[9-0] TH2_VAL. The concept is that TH1 indicates that the processor is getting hot; TH2 demands immediate attention.
- TH0 is configured to trigger when the sensor detects the temperature less than the threshold defined in VTM_VTM_TMPSENS_TH_j[9-0] TH0_VAL. This interrupt indicates that the thermal mitigations can be relaxed because the temperature has fallen below the original TH1 level.

LT_TH0_INT, if enabled, will get triggered always when the temperature being read is less than TH0, regardless of whether TH1 interrupt and TH2 interrupt are enabled or have ever been triggered. Therefore if TH0 interrupt is generated, then firmware/software is responsible to enable the TH0 interrupt only as part of the interrupt service routine of TH1 and TH2. Otherwise it will keep triggering when is not needed.

Warm Reset input:

Similar to the interrupts / ESM inputs, the warm reset generation is triggered off a threshold defined in VTM_VTM_MISC_CTRL2[9-0] MAXT_OUTRG_ALERT_THR. The reset will be released when the compared temperature drops below VTM_VTM_MISC_CTRL2[25-16] MAXT_OUTRG_ALERT_THR0.

VTM muxing of the temperature comparisons:

The VTM is configured by voltage domains. At this level, all the interrupt / ESM inputs from each temperature sensor can be enabled or disabled; as an example, the comparator outputs from temperature sensor 0 can be ignored in voltage domain 0. The enable is configured with the VTM_VTM_VD_EVT_SEL_SET_j and VTM_VTM_VD_EVT_SEL_CLR_j registers. At the voltage domain-level, the enabled comparator results are combined by interrupt / ESM signal. The combined comparator result can be observed in VTM_VTM_VD_EVT_STAT_j. As is shown in the following table, j increments over voltage domains for these registers (see [Table 5-23](#)). The registers TMPSENS_*_j map to the individual temp sensors, as shown in [Table 5-27](#).

Table 5-23. VTM Voltage Domains

Register Group	Voltage Domain
WKUP_VTM_*_VD_*_0	VDD_MCU
WKUP_VTM_*_VD_*_1	VDD_CORE
WKUP_VTM_*_VD_*_2	VDD_CPU_AVS
others	Unused

After the temperature sensors are combined at a voltage domain level, the outputs from each voltage domain are enabled at the top level of the VTM with VTM_VTM_GT_TH2_INT_EN_SET / VTM_VTM_GT_TH2_INT_EN_CLR, VTM_VTM_GT_TH1_INT_EN_SET / VTM_VTM_GT_TH1_INT_EN_CLR, and VTM_VTM_LT_TH0_INT_EN_SET / VTM_VTM_LT_TH0_INT_EN_CLR. At this top level of the VTM, the status of these signals is checked and cleared with VTM_VTM_GT_TH2_INT_RAW_STAT_SET / VTM_VTM_GT_TH2_INT_EN_STAT_CLR, VTM_VTM_GT_TH1_INT_RAW_STAT_SET / VTM_VTM_GT_TH1_INT_EN_STAT_CLR, and VTM_VTM_LT_TH0_INT_RAW_STAT_SET / VTM_VTM_LT_TH0_INT_EN_STAT_CLR.

VTM control of the global comparison that generates a warm reset:

The global comparison that generates a warm rest is enabled at each temperatures sensor with WKUP_VTM_TMPSENS_CTRL_j[11] within mmr_vbusp_cfg2. Additionally, there is a global enable for this signal in WKUP_VTM_MISC_CTRL[0].

AVS voltage definition:

The VTM also contains the Adaptive Voltage Scaling (AVS) voltage for the VDD_CPU domain. Since the VDD_CPU domain is defined by voltage domain 2, the registers of interest are VTM_VTM_VD_DEVINFO_2 and VTM_VTM_VD_OPPVID_2. If VTM_VTM_VD_DEVINFO_2[12] AVS0_SUP is set, then the device should set the voltage defined in VTM_VTM_VD_OPPVID_2[15-8] OPP_1. The voltage is encoded according to the table below:

5.2.3.2.4.2.1 VTM Temperature Status and Thermal Management

VTM module provides temperature reading and interrupt/alert information for thermal management.

5.2.3.2.4.2.1.1 10-bit Temperature Values Versus Temperature

[Table 5-25](#) shows a table lookup method for translating code to temperature from temperature monitors which correspond to the temperature measured read from the VTM0_VTM_TMPSENS_STAT_J [9-0] DATA_OUT

bitfields. Table 5-25 also provides the values for the temperatures coded in VTM0_VTM_MISC_CTRL2 [25-16] MAXT_OUTRG_ALERT_THR0 and VTM0_VTM_MISC_CTRL2 [9-0] MAXT_OUTRG_ALERT_THR thresholds.

Table 5-25. Temperature Translation Table

Parameter Type	Value								
Temperature [°C] (rounded)	-40	-25	0	25	50	75	100	125	150
Temperature [°C] (unrounded)	-40.03	-24.95	0.01	25.02	49.94	75.03	100.02	124.97	150.00
DATA_OUT Code	28	77	164	260	366	485	620	773	949

Table 5-26 shows a table that gives coefficients of polynomial to calculate code or temperature. The equation to calculate code or temperature is:

$$y = a4 \times x^4 + a3 \times x^3 + a2 \times x^2 + a1 \times x + a0$$

Table 5-26. Equation Method to Calculate Code or Temperature

Function	Unit	Coefficient				
		a4	a3	a2	a1	a0
Code = f(Temperature)	Decimal value of code	4.9847E-08	1.6972E-05	6.8759E-03	3.6509E+00	1.6407E+02
Temperature = f(Code)	°C	-9.2627E-12	6.0373E-08	-1.7058E-04	3.2512E-01	-4.9002E+01

5.2.3.2.4.2.2 VTM Temperature Driven Alerts and Interrupts

All 3 alerts from the 7 (5 shown in sketch) temperature monitors are available as inputs of the mask and alert merging logic block of each voltage domain, such that the temperature monitors that are relevant to each voltage domain can be selected as the contributors to the generation of the 3 combined interrupts in each voltage domain (5 shown in sketch; 3 in SoC). This logic is presented in Figure 5-7. The THERM_MAXTEMP_OUTRANGE_ALERT is not shown in this figure. Notice that the same temperature sensor can contribute to more than one voltage domain and each voltage domain can have multiple sensors contributing to the interrupt generation in that VD, see WKUP_VTM_VD_EVT_SET_j and WKUP_VTM_VD_EVT_CLR_j registers.

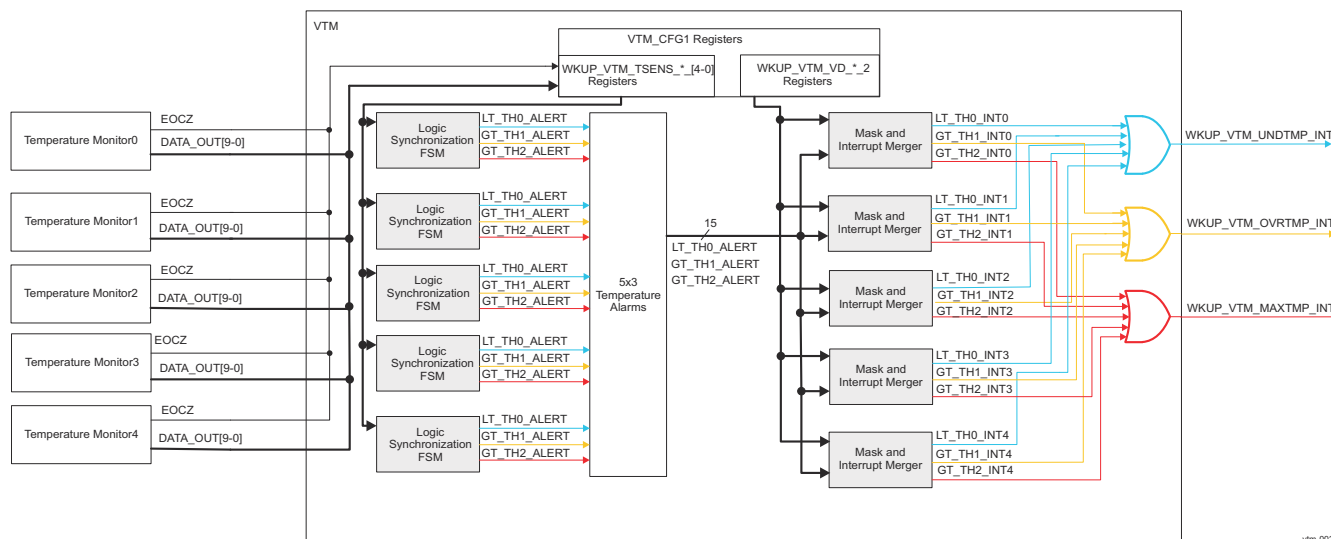

Figure 5-7. VTM Alert and Interrupt Generation

Note

The interrupts are only active when the sensor is in continuous mode. A one-shot sampling of the sensor will not trigger any interrupts.

Table 5-27 presents the connection of VTM TEMPSSENSOR registers groups to voltage domains.

Table 5-27. VTM TEMPSSENSOR Register Groups Mapping to Voltage Domains

Register Group	Voltage Domain
WKUP_VTM_TMPSENS_*_0	Near MCU_R5FSS in VDD_MCU
WKUP_VTM_TMPSENS_*_1	On VDD_MCU / VDD_CPU boundary near A72 (in VDD_MCU)
WKUP_VTM_TMPSENS_*_2	Near GPU in VDD_CORE
WKUP_VTM_TMPSENS_*_3	On VDD_CORE / VDD_CPU boundary near C7x / MMA (in VDD_CORE)
WKUP_VTM_TMPSENS_*_4	On VDD_CORE / VDD_CPU boundary near A72 (in VDD_CORE)
WKUP_VTM_TMPSENS_*_5	On VDD_CORE / VDD_CPU boundary near C7x / MMA (in VDD_CORE)
WKUP_VTM_TMPSENS_*_6	Near LPDDR4 in VDD_CORE (DDR)
Others	Unused

5.2.3.2.4.2.3 VTM ECC Aggregator

Note

For more information about ECC Aggregator functionality, see *ECC Aggregator*.

5.2.3.2.4.2.4 VTM Programming Model

5.2.3.2.4.2.4.1 VTM Maximum Temperature Outrange Alert

THERM_MAXTEMP_OUTRANGE_ALERT is used at the device level in order to generate device warm reset. The alert is asserted when the device overheats and exceeds the maximum temperature limit specified for the device, namely 125°C.

The following is the sequence to assert the THERM_MAXTEMP_OUTRANGE_ALERT:

1. For the output to go active ('1'), the VTM has to be configured to operate with at least one of its temperature sensors enabled, and WKUP_VTM_TMPSENS_CTRL_j[11] MAXT_OUTRG_EN = 1 for the corresponding enabled sensor.
2. In addition, WKUP_VTM_MISC_CTRL[0] ANYMAXT_OUTRG_ALERT_EN has to be set to '1'.
3. With the previous configuration set and at least one of the temperature sensors properly configured, and enabled, if the temperature of the die ever exceeds the programmed value in WKUP_VTM_MISC_CTRL2, the VTM output will be driven '1' once the sensor detects the programmed maximum temperature.
4. At the device level the VTM output, THERM_MAXTEMP_OUTRANGE_ALERT, will drive the PLL controllers into warm reset state with the PLL controllers entering warm reset condition, at the same time that all the PLLs go into clock bypass mode.
5. By the actions described in No.4, the device will considerably reduce its power consumption, which over the passing of a few seconds will cause the device to reduce its temperature.
6. The VTM sensor continues to read the temperature and once the code corresponding to the programmed value in WKUP_VTM_MISC_CTRL2[25-16] MAXT_OUTRG_ALERT_THR0 is detected the VTM drives THERM_MAXTEMP_OUTRANGE_ALERT = 0.
7. After No.6 is fulfilled, the PLL controllers no longer have the THERM_MAXTEMP_OUTRANGE_ALERT driving the warm reset request and thus the PLL controllers bring the SoC out of reset and the boot sequence re-starts. At the same time the PLLs get out of bypass mode and start with their target programmed frequencies for the boot process.

Note

THERM_MAXTEMP_OUTRANGE_ALERT output of VTM is mapped to WKUP_VTM_MISC_CTRL[0] ANY_MAXT_OUTRG_ALERT_EN.

Notice that exceeding of the programmed value in WKUP_VTM_MISC_CTRL2[9-0] MAXT_OUTRG_ALERT_THR boundary doesn't result in a PORz (cold reset) event, but instead a warm reset event. Otherwise if cold reset is applied to the MCU/WKUP domains of the device, the VTM will be fully reset and the output THERM_MAXTEMP_OUTRANGE_ALERT will be cleared to '0' immediately.

5.2.3.2.4.2.4.2 Sensors Programming Sequences**Sensors Control Modifications Sequence:**

1. Write changes to registers.
2. Wait for 900ns to 1us (long enough for sensor period of slowest 1.15 MHz sensor clock plus some extra).
3. New changes can be written to registers.

Reset Sensors Sequence:

1. Set the WKUP_VTM_TMPSENS_CTRL_j[6] CLRZ bit to enable the sensor (so that it has the ENA input high).
2. Wait for 900ns to 1us for the sensor clock to toggle and register the updated ENA pin.
3. Clear WKUP_VTM_TMPSENS_CTRL_j[6] CLRZ to disable and reset the sensor (as it requires an ENA transition from 1 to 0 to reset initially) .
4. Wait for 900ns to 1us for the sensor clock to toggle and register the updated ENA pin.
5. Now the sensor can be configured and enabled normally.

5.2.3.2.4.2.5 AVS-Class0

Adaptive Voltage Scaling (AVS) Class 0 is a procedure for lowering the voltage on certain device power rails. AVS Class 0 attempts to normalize the power consumption across all devices. The optimal voltage for each AVS supported rail of each device is determined after analysis in the factory, based on the strength of the device during manufacturing. This value is written in the device eFuse where it can be read through dedicated registers.

AVS can be enabled by system software after primary boot. Refer to *AVS Support* on how to enable AVS based on these registers.

5.2.4 Dynamic Power Management

5.2.4.1 AVS Support

The device supports only Adaptive Voltage Scaling (AVS) Class 0. This is a procedure for lowering the voltage on certain device power rails. AVS-Class0 attempts to normalize the power consumption across all devices. The optimal voltage for each AVS supported rail of each device is determined after analysis in the factory, based on the strength of the device during manufacturing. This value is written in the device eFuse where it can be read through dedicated registers.

The following supplies support AVS-Class0:

- VDD_CPU_AVS

The AVS voltage for a supply is an E-fuse VID value located in the corresponding WKUP_VTM_VD_OPPVID_j register in the VTM module. *VID Bit-field Values and Their Corresponding Voltage* lists the mapping of the supplies to the VTM control registers. Separate VID values are fused for the different OPPs that the supply supports. For more information about OPPs supported by a supply in the device, see the device-specific DataSheet.

The AVS functionality can be enabled and performed by software after the primary boot of the device is finished. Typically, the voltage adjustment of AVS operation is done as secondary boot software.

5.3 Reset

This chapter describes the device reset management.

Terminology

- DMSC - Device Management Security Controller
- PSC - Power Sleep Controller
- LPSC - Local Power Sleep Controller
- ESM - Error Signaling Module
- Isolation – the module is exempted from reset

5.3.1 Reset Overview

Resets bring the device or part of the device to a known state after events such as power-up or hardware or software requests.

Figure 5-8 shows an overview of the reset architecture.

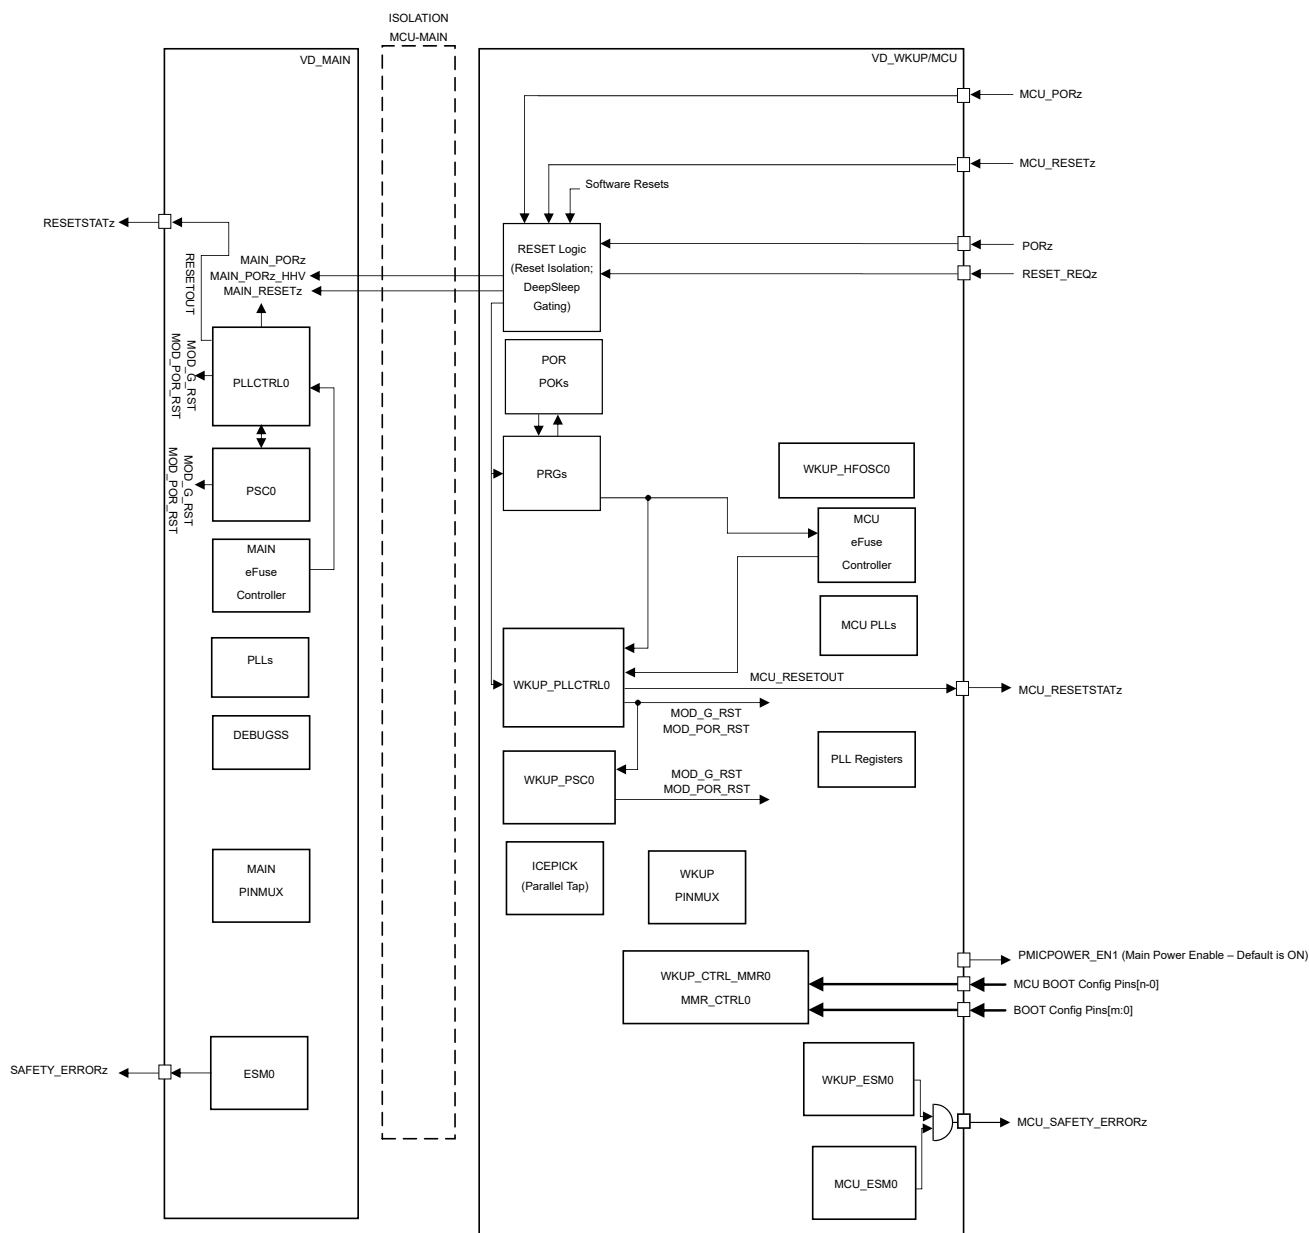

Figure 5-8. Reset Architecture

Note

For power modules used in the reset see:

- For internal PORz detection, see *Power on Reset (POR) Module*, in *Power*.
- For Power Reset Generator (PRG), see *Power Reset Generator (PRG) Modules*, in *Power*.
- For POK, see *POK Modules*, in *Power*.
- For Power Glitch Detector (PGD), see *Power Glitch Detector (PGD) Modules*, in *Power*.

Note

For information about Boot modes and Boot configuration pins, see *Initialization*.

Note

MOD_POR_RST[n] and MOD_G_RST[n] are connected to certain modules. For more information which is the number of the LPSC of a certain module, see its specific chapter.

5.3.2 Reset Modules

5.3.3 Reset Sources

Table 5-29 summarizes the resets supported by device.

Table 5-29. Reset Supported in the Device

Reset Source	Type	Sequence (Effect)
MCU_PORz	Input (control) pin Master Power-on-Reset input (active low) to the entire device. Effects all domains – WKUP, MCU, and MAIN No isolation possible.	See Section 5.3.7.2, MCU_PORz Sequence .
MCU_RESETz	Input (control) pin Master Warm Reset input (active low) to the entire device. Effects all domains – WKUP, MCU, and MAIN Modules configured for isolation in the MAIN domain are isolated although the WKUP/MCU domain is not isolated from the MAIN domain.	See Section 5.3.7.3, MCU_RESETz Sequence .
PORz	Input (control) pin Power-on-Reset input (active low) to the MAIN domain. Effects MAIN domain WKUP/MCU should be isolated from the MAIN domain	See Section 5.3.7.4, PORz Sequence .
RESET_REQz	Input (control) pin Warm Reset Request input (active low) to the MAIN domain Effects MAIN domain WKUP/MCU should be isolated from the MAIN domain. Additionally, modules within the MAIN domain may be isolated.	See Section 5.3.7.5, RESET_REQz Sequence .
SW_MCU_WARMRST	Software reset: equivalent to MCU_RESETz pin CTRLMMR_WKUP_MCU_WARM_RST_CTRL ⁽¹⁾	See Section 5.3.7.3, MCU_RESETz Sequence .

Table 5-29. Reset Supported in the Device (continued)

Reset Source	Type	Sequence (Effect)
SW_MAIN_POR	Software reset: equivalent to PORz pin CTRLMMR_WKUP_POR_RST_CTRL ⁽¹⁾	See Section 5.3.7.4, PORz Sequence .
SW_MAIN_WARMRST	Software reset: equivalent to RESET_REQz pin CTRLMMR_WKUP_MAIN_WARM_RST_CTRL ⁽¹⁾	See Section 5.3.7.5, RESET_REQz Sequence .
WKUP_DMSC0 COLD RST	Internal event: equivalent to MCU_RESETz	See Section 5.3.7.3, MCU_RESETz Sequence .
WKUP_DMSC0 WARM RST	Internal event: equivalent to MCU_RESETz	See Section 5.3.7.3, MCU_RESETz Sequence .
Thermal Over-temperature (VTM)	Internal event: equivalent to MCU_RESETz (except that PLL behavior is different)	See Section 5.3.7.3, MCU_RESETz Sequence .
Debug Reset		
Local Resets	Local reset is a reset that is applied to any given module in a module domain or to a CPU and/or its megamodule (any tightly coupled controllers delivered with the CPU) and their associated local watchdog timers.	

(1) These registers are part of the WKUP CTRL_MMR domain, see *Control Module (CTRL_MMR)*.

5.3.4 Reset Status

[Table 5-30](#) summarizes the reset status of the device.

Table 5-30. Reset Status

Reset Status	Type/Description
MCU_RESETSTATz	Output pin Indicates release of internal reset on the WKUP/MCU domain Released synchronous with start of WKUP_DMSC0 ROM code execution.
RESETSTATz	Output pin Indicates release of internal reset on the MAIN domain
THERMAL_RST	Software bit in CTRLMMR_WKUP_RESET_SRC_STAT ⁽¹⁾
DEBUGSS_RST	
COLD_OUT_RST	
WARM_OUT_RST	
PORZ_PIN	
RESET_REQZ_PIN	
MCU_RSTZ_PIN	
SW_MAIN_POR	
SW_MAIN_WARMRST	
SW_MCU_WARMRST	
MAIN_RST_DONE	Software bit in
MCU_RST_DONE	CTRLMMR_WKUP_RST_STAT ⁽¹⁾

(1) These registers are part of the WKUP CTRL_MMR domain, see *Control Module (CTRL_MMR)*.

5.3.5 Reset Control

[Table 5-31](#) lists the reset control registers.

Table 5-31. Reset Control

Reset Control	Control Register ⁽¹⁾
WKUP_DMSC0 Timeout control	CTRLMMR_WKUP_MAIN_POR_TO_CTRL (0 – 500 μ s in 100 μ s increments)
POR_RST_ISO_DONE_Z	CTRLMMR_WKUP_POR_RST_CTRL

Table 5-31. Reset Control (continued)

Reset Control	Control Register ⁽¹⁾
SOC_WARMRST_ISO_DONE_Z	CTRLMMR_WKUP_MAIN_WARM_RST_CTRL

(1) These registers are part of the WKUP CTRL_MMR domain, see *Control Module (CTRL_MMR)*.

5.3.6 BOOTMODE Pins

The MCU_BOOTMODE pins and BOOTMODE direct the MCU_R5FSS boot (first stage boot). MCU_BOOTMODE pins are latched based upon the rising edge of MCU_PORz.

For more details on Bootmode pins, see *Initialization*.

5.3.7 Reset Sequences

5.3.7.1 MCU_PORz Overview

On MCU_PORz,

- the WKUP_DMSC0 is powered and clocked;
- the MCU_R5FSS0 is powered but not clocked;
- all processors on the MAIN side are powered down (and clock-gated):
 - Dual A72 MPU Sub-systems
 - R5FSS

The general behavior for coming out of an MCU_PORz reset is:

- Hardware initialization

ROM Boot Loader (or ROM Code): the purpose of the ROM Boot Loader is to load and check integrity of the Secondary Boot Loader (or application image).

- WKUP_DMSC0 Code executes, setting up MCU_R5FSS0 clocks and configuring security. WKUP_DMSC0 code passes Boot info to MCU_R5FSS0 and releases the MCU_R5FSS0 clocks.
- The Bootmode pins define the peripherals involved in the boot and the associated media (see ROM Code boot modes). The media holds the secondary boot loader (SBL) or the entire application image. The WKUP_DMSC0 firmware needs to be incorporated in this code. For MCU_R5FSS ROM functional description, refer to *Initialization*.
- Once the Secondary Boot Loader has been verified, the WKUP_DMSC0 issues a clock stop to the MCU_R5FSS0 and resets the MCU_R5FSS0.

Secondary Boot Loader: the secondary boot loader configures the device for application.

The previous description gives the high-level behavior for the MCU_PORz reset. Other resets are almost a subset of this procedure. [Section 5.3.7.2](#), [Section 5.3.7.3](#), [Section 5.3.7.4](#), and [Section 5.3.7.5](#) explain this sequence in more detail.

5.3.7.2 MCU_PORz Sequence

MCU_PORz and PORz must be held low until:

- All supplies have ramped to proper levels
- WKUP_HFOSC0 has a stable amplitude that propagates clocks into the core

If the supplies and clock are already stable, MCU_PORz and/or PORz must be held active (low) for a minimum of 1.2 μ s.

1. When MCU_PORz is asserted low, WKUP_CTRL_MMR0 and MCU_CTRL_MMR0 registers are reset; a bit within the WKUP_CTRL_MMR0 registers is reset which allows PORz to propagate to the MAIN domain without delay. In the MAIN domain, CTRL_MMR0 registers are reset.
2. The MCU_BOOTMODE pins are latched on the rising edge of MCU_PORz.
3. The release of MCU_PORz begins a read of fuse values to register files; several different chains of e-fuse values are registered in parallel read sequences. Values are consumed by different blocks at various points in this sequence. In parallel and based upon the release of PORz, the MAIN domain e-fuse controller initiates a read of its e-fuse values.
4. LBIST/PBIST checks of the WKUP_DMSC0 and MCU_R5FSS0 cores and memories are run in the WKUP/MCU domain; in the MAIN domain, the BIST engines are controlled by the application software.
5. WKUP_PSC0 is initialized (and PSC0 in the MAIN domain is initialized); concretely, the PSC modules (both WKUP_PSC0 and PSC0) configure default power states and LPSC (clocking) states.
6. After power domain and clock domain initialization is completed, PSC modules release resets to the device (MOD_POR_RST, MOD_G_RST).
7. WKUP_DMSC0 is removed from reset; WKUP_DMSC0 ROM code execution begins. At this time MCU_RESETSTATz is de-asserted.
8. WKUP_DMSC0 executes WKUP_DMSC0 ROM.
 - a. Configures MCU_PLL0, MCU_PLL0_HSDIV1, and WKUP_PLLCTRL0 (proper clock frequency for MCU_R5FSS0).
 - b. Configures firewalls and message manager.

- c. Uses the message manager to pass Boot info to MCU_R5FSS0 ROM.
9. MCU_R5FSS0_CORE0 is released from reset and begins to execute ROM
 - a. Based upon the value of MCU_BOOTMODE pins , the R5F ROM code configures peripherals and PLLs to enable loading the external code.
 - b. Secondary boot-loader is loaded from external memory
 - c. MCU ROM requests WKUP_DMSC0 for loaded code authentication
 - d. WKUP_DMSC0 stops clocks to MCU_R5FSS0
 - e. WKUP_DMSC0 issues an MCU_R5FSS0 reset
 - f. MCU_R5FSS0_CORE0 begins executing secondary boot-loader.

At the end of this sequence, MCU_R5FSS0 is executing the secondary bootloader. The control of the device now passes to the customer code.

Note

On warm resets (except those caused by a VTM Thermal over-temperature), the output of various PLLs are either bypassed or left unaffected. For more details, see [Section 5.3.8, PLL Behavior on Reset](#).

Note

Reset Isolated domains are isolated during a MCU_RESETz (or any warm reset) event.

5.3.7.3 MCU_RESETz Sequence

MCU_RESETz release requires:

- All supplies have ramped to proper levels
- WKUP_HFOSC0 has a stable amplitude that propagates clocks into the core

MCU_RESETz must be held active (low) for a minimum of 1.2 μ s.

When MCU_RESETz is asserted low, it is also immediately passed to the MAIN domain (similar to MCU_PORz asserting PORz).

1. Much of the device is reset. Blocks that are not reset:
 - a. Internal 12.5 MHz oscillator
 - b. External HF oscillator
 - c. Power monitoring circuitry (Bandgap, POR, POK, PGD, PRG)
 - d. I/O cells and I/O pad configuration registers
 - e. SERDES
 - f. efuse Controller/storage
 - g. PLLs
 - h. Voltage Temperature Module
 - i. Global Timebase Counter (GTC)
 - j. Boot Mode Latches
 - k. Debug Components
 - l. PSRAM

Another group of modules is partially reset:

- a. PSC
 - b. WKUP_DMSC0
 - c. Debug
 - d. STM
 - e. MCU_CPSW0 (CPSW2G)
 - f. Probe
2. When MCU_RESETz is released, PSC modules release MOD_G_RST to the device.
 3. WKUP_DMSC0 is removed from reset; WKUP_DMSC0 ROM code execution begins. At this time MCU_RESETSTATz is de-asserted.
 4. WKUP_DMSC0 executes ROM.

- a. Configures MCU PLL0, MCU PLL0 HSDIV1, and WKUP PLLCTRL0 (proper clock frequency for MCU_R5FSS0).
- b. Configures firewalls and message manager.
- c. Uses the message manager to pass Boot info to MCU
5. MCU_R5FSS0_CORE0 is released from reset and begins to execute ROM
 - a. Based upon the value of MCU_BOOTMODE pins, the MCU ROM code configures peripherals and PLLs to enable loading the external code.
 - b. Secondary boot-loader is loaded from external memory
 - c. MCU ROM requests WKUP_DMSC0 for loaded code authentication
 - d. WKUP_DMSC0 stops clocks to MCU_R5FSS0
 - e. WKUP_DMSC0 issues MCU reset
 - f. MCU_R5FSS0_CORE0 begins executing secondary boot-loader.

At the end of this sequence, MCU_R5FSS0 is executing the secondary bootloader. The control of the device now passes to the customer code.

5.3.7.4 PORz Sequence

PORz release requires:

- All supplies have ramped to proper levels
- WKUP_HFOSC0 has a stable amplitude that propagates clocks into the core

PORz must be held active (low) for a minimum of 1.2 μ s.

If PORz is asserted with MCU_PORz, then PORz propagates to the MAIN domain immediately.

If PORz is asserted independent of MCU_PORz, then the user code must have setup:

- CTRLMMR_WKUP_POR_RST_CTRL[0] POR_RST_ISO_DONE_Z (high) in order to block the PORz from immediate propagation and
- CTRLMMR_WKUP_MAIN_POR_TO_CTRL[2:0] TIMEOUT_PER in order to configure the timeout, after which PORz is unconditionally propagated to MAIN domain.

PORz sequence is:

1. When PORz is asserted low, hardware in the WKUP/MCU domain recognizes the PORz and generates an interrupt to WKUP_DMSC0 and MCU. Reset hardware latches the PORz low level.
2. User software is responsible for isolating WKUP/MCU domain from the MAIN domain.
The details of the isolation are application specific and are carried out in software. Connections between the WKUP/MCU domain and the MAIN domain include:
 - LPSC_WKUPMCU2MAIN - LPSC4 (WKUP_PSC0)
 - LPSC_MAIN2WKUPMCU - LPSC5 (WKUP_PSC0)
 - Communications channel: MCSPI3 is connected as a master to MCU_MCSP11; MCSPI4 is directly connected as a slave to MCU_MCSP12.
 - WKUP_GPIOMUX_INTRTR0
 - MAIN2MCU_LVL_INTRTR0
 - MAIN2MCU_PLS_INTRTR0
 - WKUP_ESM0
 - MCU_ESM0

When the isolation is complete, MCU_R5FSS0 or WKUP_DMSC0 must write CTRLMMR_WKUP_POR_RST_CTRL[0] POR_RST_ISO_DONE_Z low to allow the PORz signal to propagate.

3. The release of PORz begins a read of eFuse values to register files; several different chains of e-fuse values are registered in parallel read sequences. Values are consumed by different blocks at various points in this sequence.
4. PSC0 is initialized; specifically, PSC0 module configures default power states and LPSC (clocking) states.
5. After power domain / clock domain initialization is completed, PSC modules release resets to the device (MOD_POR_RST, MOD_G_RST).
6. CTRLMMR_WKUP_RST_STAT[0] MAIN_RST_DONE is asserted.

At the end of this sequence, MCU_R5FSS can read the CTRLMMR_WKUP_RST_STAT[0] MAIN_RST_DONE bit and begin re-configuring the MAIN domain.

5.3.7.5 RESET_REQz Sequence

RESET_REQz release requires:

- All supplies have ramped to proper levels
- WKUP_HFOSC0 has a stable amplitude that propagates clocks into the core

RESET_REQz must be held active (low) for a minimum of 1.2 μ s.

Like the PORz sequence, it is necessary to have configured CTRLMMR_WKUP_MAIN_WARM_RST_CTRL[0] SOC_WARMRST_ISO_DONE_Z high in order to block the reset request from immediately propagating. Unlike the PORz sequence, there is no timeout. Also, unlike the PORz sequence, some clock domains within given power domains can be configured to ignore the RESET_REQz signal.

1. When RESET_REQz is asserted low, hardware in the WKUP/MCU domain recognizes the RESET_REQz and generates an interrupt to WKUP_DMSC0 and MCU_R5FSS0. Reset hardware latches the RESET_REQz low level.
2. User software is responsible for isolating WKUP/MCU domain from the MAIN domain. The details of the isolation are application specific and are carried out in software. Connections between the WKUP/MCU domain and the MAIN domain include:
 - LPSC_WKUPMCU2MAIN - LPSC4 (WKUP_PSC0)
 - LPSC_MAIN2WKUPMCU - LPSC5 (WKUP_PSC0)
 - Communications channel: MCSPI3 is connected as a master to MCU_MCSP11; MCSPI4 is directly connected as a slave to MCU_MCSP12.
 - WKUP_GPIOMUX_INTRTR0
 - MAIN2MCU_LVL_INTRTR0
 - MAIN2MCU_PLS_INTRTR0
 - WKUP_ESM0
 - MCU_ESM0

When the isolation is complete, MCU_R5FSS0 or WKUP_DMSC0 must write CTRLMMR_WKUP_MAIN_WARM_RST_CTRL[0] SOC_WARMRST_ISO_DONE_Z low to allow the RESET_REQz signal to propagate.

3. Power domains are not reset by RESET_REQz if-and-only-if a LPSC in the power domain is configured to be reset isolated. Otherwise, power domains and clock domains are reset by RESET_REQz.

Note

As an example of how to read tables in the PSC: Device Power-Management Layout Section, in *Power*, PSC0 Power Management Device-Level Layout shows that PD_R5FSS_0 is assigned Power Domain Index 24 with LPSCs 93, 94, and 95 controlling clocks/resets to circuitry within this power domain. PSC0 Power Domain Features shows that power domain 24 is OFF by default (if isolation does not block the reset). PSC0 LPSC Features shows that LPSC 93, 94, and 95 are OFF by default *but* LPSC 93 and 94 can be configured for reset isolation.

If Reset isolation is selected for LPSC 93 and 94, resets and clocks are not affected by the RESET_REQz signal. Power Domain 24 cannot be reset when the LPSCs are active. Note that LPSC 95 **is** reset.

If Reset isolation is not selected for either LPSC 93 or 94, resets propagate to LPSC 93, 94, and 95; the clocks are stopped to these LPSCs (since their default state is OFF). Power Domain 24 is reset to its OFF state.

4. After power domain / clock domain initialization is completed, PSC modules release resets to the non-isolated parts of the device (MOD_POR_RST, MOD_G_RST).
5. CTRLMMR_WKUP_RST_STAT[0] MAIN_RST_DONE is asserted.

At the end of this sequence, MCU_R5FSS0 can read the CTRLMMR_WKUP_MAIN_WARM_RST_CTRL[0] SOC_WARMRST_ISO_DONE_Z bit and begin re-configuring the MAIN domain.

Note

On warm resets (except those caused by a VTM Thermal over-temperature), the output of various PLLs are either bypassed or left unaffected. For more details, see [Section 5.3.8, PLL Behavior on Reset](#).

5.3.8 PLL Behavior on Reset

[Table 5-32](#) summarizes the PLL behavior on reset.

Table 5-32. PLL Behavior on Reset

Reset Type	PLL Behavior	
	MCU Domain PLLs	MAIN Domain PLLs
MCU_PORz	All PLLs are reset	All PLLs are reset
PORz	All PLLs are unaffected	All PLLs are reset
MCU_RESETz or RESET_REQz (or other warm resets except VTM Thermal over-temperature event)	All PLL outputs are bypassed (to the reference input frequency into the PLL), see Table 5-33 .	Some PLL outputs are bypassed (to the reference input frequency into the PLL) and other PLLs are unaffected, see Table 5-33 .
Warm reset triggered by a VTM thermal over-temperature event	All PLL outputs are bypassed	All PLL outputs are bypassed

Table 5-33. PLL Behavior on Warm Resets, Except VTM Event

Not-bypassed (unaffected)	Bypassed
PLL1	MCU_PLL0
PLL2	MCU_PLL1
PLL3	MCU_PLL2
PLL16	PLL0
PLL17	PLL4
PLL19	PLL5
	PLL6
	PLL7
	PLL8
	PLL9
	PLL12
	PLL14
	PLL25
	PLL26
	PLL27
	PLL28

The warm reset event bypasses the PLL (that are to be bypassed) while the warm reset is asserted; after the warm reset is released, the PLL switches from bypass to using the PLL again. If the user wants to maintain bypassed PLLs in the bypass mode (for example, to control current slews on the board in a reset event); there are control bits to configure the PLL in this way:

- For MCU_PLL_[2:0]:
CTRLMMR_WKUP_MCU_PLL_CLKSEL[23] BYP_WARM_RST = 0
CTRLMMR_WKUP_MCU_PLL_CLKSEL[31] BYPASS_SW_OVRD = 1
- For bypassed PLLs in the MAIN domain:
CTRLMMR_WKUP_MAIN_PLLn_CLKSEL[23] BYP_WARM_RST = 0
CTRLMMR_WKUP_MAIN_PLLn_CLKSEL[31] BYPASS_SW_OVRD = 1

The behavior with PLLs configured as defined above is:

- the BYPASS_SW_OVRD bit (= 1) enables the following behavior:

- the PLL currently is not in bypass mode (for example, the PLL clock propagates) because `BYP_WARM_RST` is 0
- when a warm reset occurs, the PLLs configured to bypass automatically set the `BYP_WARM_RST` to 1. This setting (with `BYPASS_SW_OVRD` = 1) maintains the bypass state after the warm reset is released.

When software is ready to use the PLL, the `BYP_WARM_RST` is cleared back to 0.

5.4 Clocking

This chapter describes the clock architecture of the device.

5.4.1 Clocking Overview

Various external clock inputs/outputs are needed to drive the device. Summary of these input clock signals is as follows:

- High frequency oscillators inputs
 - OSC1_XO/OSC1_XI — external main crystal interface pins connected to internal oscillator which sources reference clock. Provides reference clock to PLLs within MCU domain and MAIN domain. This high-frequency oscillator is used to provide audio clock frequencies to MCASPs.
 - WKUP_OSC0_XO/WKUP_OSC0_XI — external main crystal interface pins connected to internal oscillator which sources reference clock. Provides reference clock to PLLs within WKUP and MAIN domain.
- Low frequency digital input
 - WKUP_LF_CLKIN - Low Frequency 32k digital clock input, optionally sourced from an external PMIC or other clock source. This SoC does not support a LFOSC crystal input.
- General purpose clock inputs
 - MCU_EXT_REFCLK0 - optional external System clock input (MCU domain).
 - EXT_REFCLK1 — optional external System clock input (MAIN domain).
- Peripheral clocks - refer to the Signal Descriptions for peripheral specific clocks

5.4.2 Modules Controlled by PLL

Table 5-34. Modules Controlled by PLL

5.4.4 Overview

To satisfy the various subsystems requirements, the device features multiple clock sources and clock generators:

- External Crystal Drivers
- Internal Oscillator
- Phase-Locked Loop circuits (PLLs)
- Dividers

Figure 5-9 shows the device top-level clock diagram. The clocking is divided into two clocking domains - WKUP/ MCU, and MAIN.

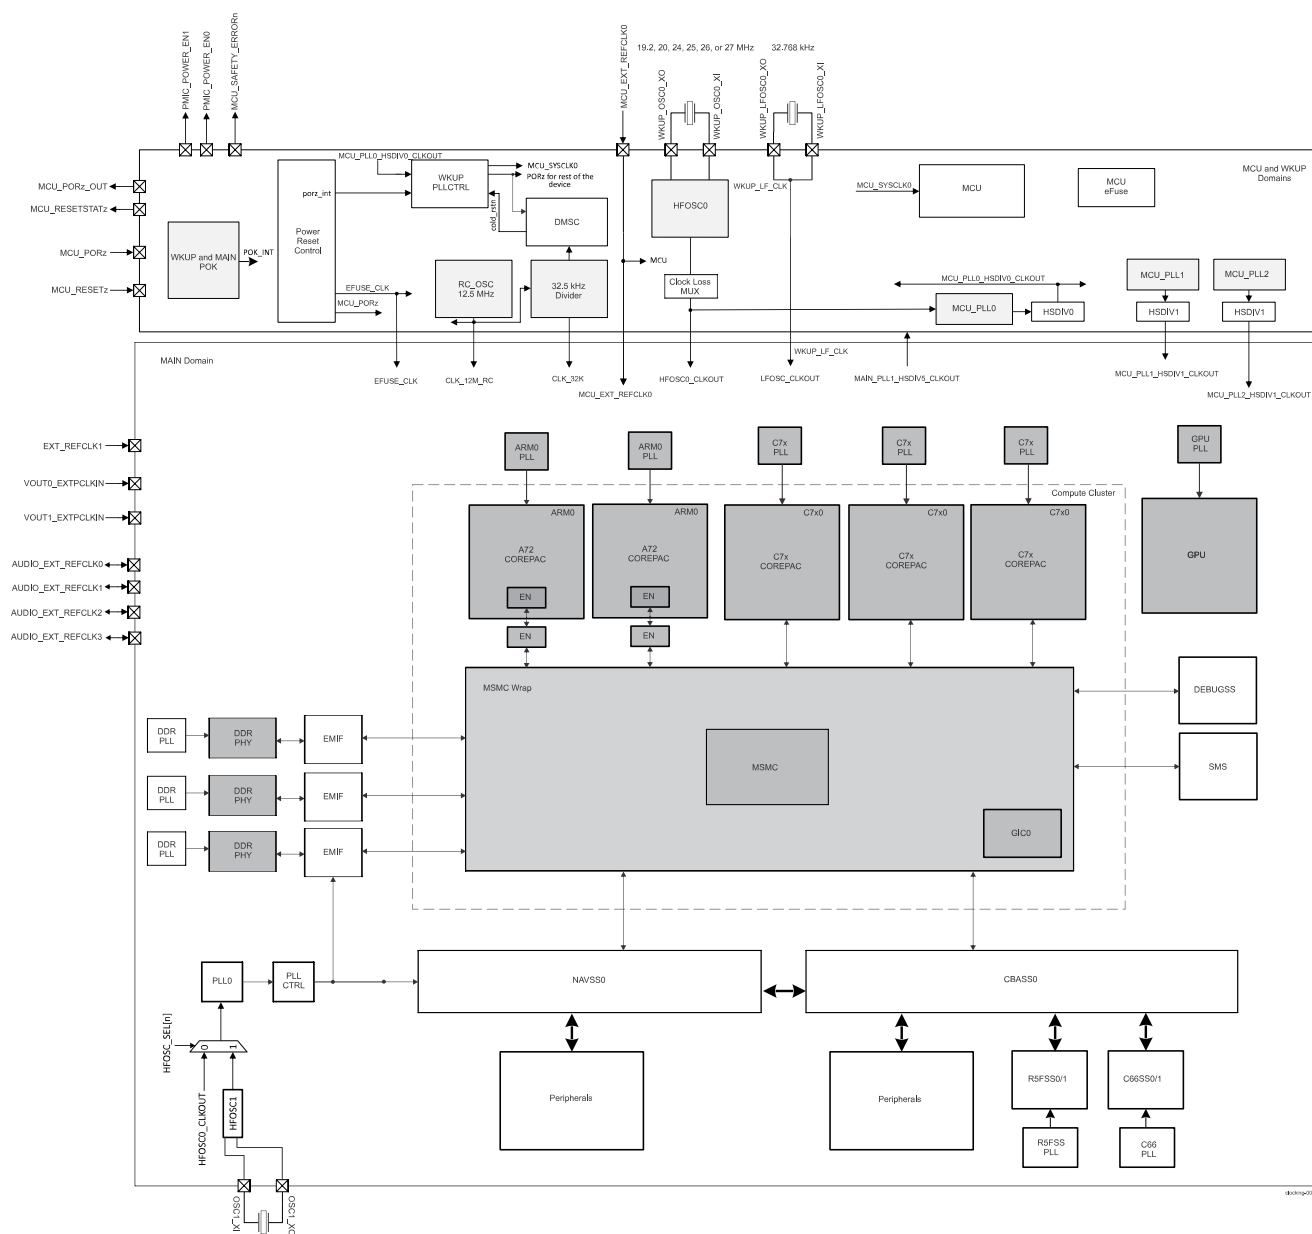

Figure 5-9. Top-Level Clock Diagram

5.4.5 Clock Inputs

5.4.5.1 Overview

Various external clock inputs are needed to drive the device. Summary of these input clock signals is given below. Some of those inputs are bidirectional and are marked as inputs/outputs in the summary:

- High frequency oscillators
 - WKUP_OSC0_XO/WKUP_OSC0_XI — external main crystal interface pins of the internal oscillator which sources a reference clock. Provides reference clock to PLLs within WKUP/MCU and MAIN domain.
 - OSC1_XO/OSC1_XI — external main crystal interface pins connected to internal oscillator which sources reference clock. Provides reference clock to PLLs within MAIN domain. This high-frequency oscillator is used to provide audio clock frequencies to MCASPs.
- Low frequency oscillator
 - Low frequency digital input – WKUP_LF_CLKIN - Low Frequency 32k digital clock input, optionally sourced from an external PMIC or other clock source. This SoC does not support a LFOSC crystal input.
- General purpose clock inputs
 - MCU_EXT_REFCLK0 — optional external system clock input (MCU domain).
 - EXT_REFCLK1— optional external system clock input (MAIN domain). Optionally PLL4 (AUDIO0 PLL).
- External video pixel clock inputs
 - VOUT0_EXTCLKIN — optional for the DPI0 port of DSS.
- External CPTS reference clock inputs
 - MCU_CPTS0_RFT_CLK — CPTS reference clock inputs for MCU_CPTS_RFT_CLK.
 - CPTS0_RFT_CLK — CPTS reference clock inputs for CPTS_RFT_CLK.
- External audio reference clock input/output pins. For more information which clocks may be sourced as an outputs to the pins, see [Section 12.5.2, Multichannel Audio Serial Port \(MCASP\)](#).
 - AUDIO_EXT_REFCLK0
 - AUDIO_EXT_REFCLK1

Note

Other clock inputs that are routed directly to the subsystems are described in the respective subsystem chapters.

5.4.5.2 Mapping of Clock Inputs

[Table 5-36](#) lists the mapping for the device clock inputs.

Table 5-36. Mapping for Input Sources

Domain	Clock	Ball Mapping	Frequency List / Range	Type
WKUP	WKUP_HFOSC0_CLK	WKUP_OSC0_XI WKUP_OSC0_XO	19.2, 20, 24, 25, 26, or 27 MHz	External Clock / Crystal Pins
	WKUP_LF_CLKIN	WKUP_GPIO0_67	Intended to be low frequency ~32KHz	LVC MOS
	MCU_EXT_REFCLK0	WKUP_GPIO0_10	Up to 100 MHz	LVC MOS
MAIN	HFOSC1_CLK	OSC1_XI OSC1_X0	19.2, 20, 24, 25, 26, or 27 MHz For audio applications: 22.5792 MHz or 24.576 MHz	External Clock / Crystal Pins
	EXT_REFCLK1	EXT_REFCLK1	Up to 100 MHz	LVC MOS

[Table 5-37](#) lists the internal RC-oscillator sources.

Table 5-37. Internal RC Oscillator Input Sources

Domain	RC Oscillator	Clock	Frequency
WKUP	WKUP_RC_OSC_12M	CLK_12M_RC	12.5 MHz

5.4.6 Clock Outputs

The device provides several system clock outputs. Summary of these output clock signals is as follows:

- **MCU_CLKOUT0**
 - Reference clock output for Ethernet PHYs (50 MHz or 25 MHz)
- **MCU_SYSCLKOUT0**
 - MCU_SYSCLK0 is divided by 4 and then sent out of the device as a LVCMOS clock signal (MCU_SYSCLKOUT0). This signal can be used to test if the main chip clock is functioning or not. This signal should not be used as a clock source for external devices on a board.
- **MCU_OBSClk0**
 - On the clock output MCU_OBSClk0, oscillators and PLLs clocks can be observed for tests and debug. This signal should not be used as a clock source for external devices on a board.
- **SYSClkOUT0**
 - SYSClk0 is divided by 4 and then sent out of the device as a LVCMOS clock signal (SYSClkOUT0). This signal can be used to test if the main chip clock is functioning or not. This signal should not be used as a clock source for external devices on a board.
- **CLKOUT**
 - Reference clock output for Ethernet PHYs (50 MHz)
- **OBSClk[1:0]**
 - On the clock output OBSClk0/1, oscillators and PLLs clocks can be observed for tests and debug.

Other clock outputs, that are routed directly from subsystems to device pins, are described in the respective module chapter.

Observation clock pins - MCU_OBSClk0, OBSClk0, OBSClk1, and OBSClk2 serve the following purposes:

- During testing, PLLs on the device are configured to output all operating frequencies desired by each module to characterize PLL performance.
- System debug: during debug, clocks from various PLLs can be inspected for possible clues. Example clock glitches, lock loss etc.

Note

Maximum frequency supported on both MCU_OBSClk0, OBSClk0, OBSClk1, and OBSClk2 pins is 200 MHz. Hence the divider at the output of each OBSClk mux must be programmed to meet this limitation.

Unlike the OBSClk pins which can select several different clocks for output, system clock pins (MCU_SYSClkOUT0 and SYSClkOUT0) are hardwired to dedicated clock resources (see [Section 5.4.6.2](#))

5.4.6.1 Observation Clock Pins

5.4.6.1.1 MCU_OBSClk0 Pin

MCU_OBSClk0 output is controlled by CTRLMMR_WKUP_MCU_OBSClk_CTRL register in the WKUP_CTRL_MMR0 module; for more information about control registers, see *Control Module (CTRL_MMR)*. Two muxes are connected in series - MCU_OBSClk0_MUX0 and MCU_OBSClk0_MUX1, see [Figure 5-10](#).

Figure 5-10. MCU_OBSClk Muxes Diagram

How to select the output of MCU_OBSCLK0_MUX1 is described in [Table 5-38](#).

Table 5-38. MCU_OBSCLK0_MUX1 Output Clock Selection

CTRLMMR_WKUP_MCU_OBSCLK_CTRL ⁽²⁾ [3-0] CLK_SEL	MCU_OBSCLK0_MUX1 Output Clock Selection ⁽¹⁾
0x0	CLK_12M_RC
0x1	0 (GND) ⁽³⁾
0x2	MCU_PLL0_HSDIV0_CLKOUT
0x3	WKUP_PLLCTL_OBSCLK (MCU_PLL0 input reference clock)
0x4	MCU_PLL1_HSDIV1_CLKOUT
0x5	MCU_PLL1_HSDIV2_CLKOUT
0x6	MCU_PLL1_HSDIV3_CLKOUT
0x7	MCU_PLL1_HSDIV4_CLKOUT
0x8	MCU_PLL2_HSDIV0_CLKOUT
0x9	CLK_32K
0xA	MCU_PLL2_HSDIV1_CLKOUT
0xB	MCU_PLL2_HSDIV2_CLKOUT
0xC	MCU_PLL2_HSDIV3_CLKOUT
0xD	MCU_PLL2_HSDIV4_CLKOUT
0xE	WKUP_HFOSC0_CLKOUT
0xF	WKUP_LF_CLKIN

- (1) Software-controlled 4-bit divider is used to obtain the divided versions of the clocks passed to MCU_OBSCLK1 mux
(2) For more information about control registers, see *Control Module (CTRL_MMR)*.
(3) GND - ground

The value of the software-controlled 4-bit divider is determined by register CTRLMMR_WKUP_MCU_OBSCLK_CTRL[11-8] MCU_OBSCLK_CTRL_CLK_DIV in the WKUP_CTRL_MMR0 module; for more information about control registers, see *Control Module (CTRL_MMR)*.

Note

MCU_OBSCLK1_MUX0 is provided as a low jitter output for WKUP_HFOSC0_CLK. In this configuration, CTRLMMR_WKUP_MCU_OBSCLK_CTRL[3:0] should be configured as 0001b (1, selecting a logical low signal) and CTRLMMR_WKUP_MCU_OBSCLK_CTRL[24] should be configured as 1.

5.4.6.1.2 OBSCLK0, OBSCLK1, and OBSCLK2 Pins

The OBSCLK0, OBSCLK1, and OBSCLK2 output pins are controlled simultaneously, so that the three pins are connected to the same signal. OBSCLK0, OBSCLK1, and OBSCLK2 outputs are controlled by CTRLMMR_OBSCLK0_CTRL register in the CTRL_MMR0 module; for more information about control registers, see *Control Module (CTRL_MMR)*. [Figure 5-11](#) shows a block diagram of internal OBSCLK0 mux connections.

Note

OBSCLK2 has lot more jitter due to PD limitations/long routing. If the intent is to use OBSCLK2 to do anything beyond just observe clock toggle, customers should switch to OBSCLK0 or OBSCLK1.

Figure 5-11. OBSCLK0 Muxes Diagram

Table 5-39. OBSCLK0_MUX1_CLKOUT

(1) Software-controlled 8-bit divider is used to obtain the divided versions of the clocks passed to output pins

(2) For more information about control registers, see *Control Module (CTRL_MMR)*.

(3) GND - ground

The value of the software-controlled 8-bit divider is determined by register CTRLMMR_OBSCLK0_CTRL[15-8] OBSCLK_CTRL_CLK_DIV; for more information about control registers, see *Control Module (CTRL_MMR)*.

5.4.6.2 System Clock Pins

5.4.6.2.1 MCU_SYSCLKOUT0

MCU_SYSCLK0 is divided by 4 and then send out of the device as a LVCMOS clock signal (MCU_SYSCLKOUT0).

Note

MCU_SYSCLKOUT0 cannot be used as a clock source for external devices on the board.

5.4.6.2.2 SYSCLKOUT0

SYSCLK0 is divided by 4 and then send out of the device as a LVCMOS clock signal (SYSCLKOUT0). This signal can be used to test if the specific device clock is functioning or not.

Note

SYSCLKOUT0 cannot be used as a clock source for external devices on the board.

5.4.7 Device Oscillators

The device has the possibility to source clocks of two external high-frequency oscillators - WKUP_HFOSC0 and HFOSC1 and one external low-frequency clock input - WKUP_LF_CLKIN. The device has one internal RC oscillator - WKUP_RC_OSC_12M.

5.4.7.1 Device Oscillators Integration

5.4.7.1.1 Oscillators with External Crystal

By default, HFOSC1 is disabled, while WKUP_HFOSC0 is enabled after PORz.

All device oscillators with external crystals support a bypass mode. In this mode, an external clock can be driven on the XI Pin.

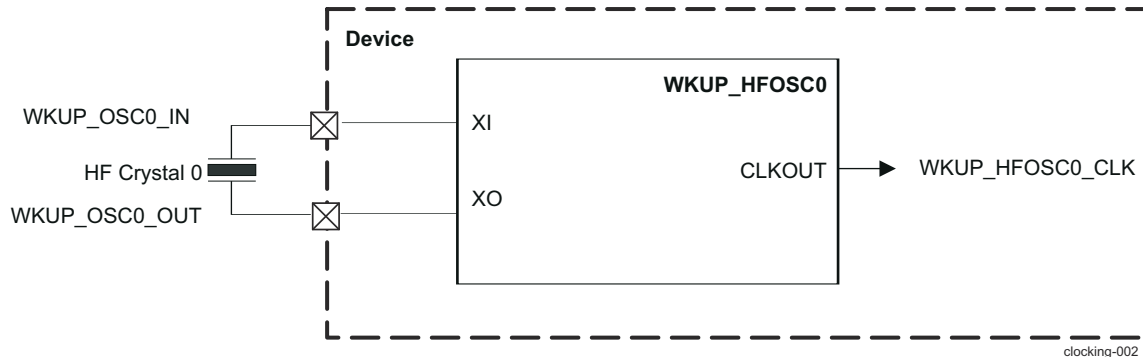

Figure 5-12. WKUP_HFOSC0 Integration Diagram

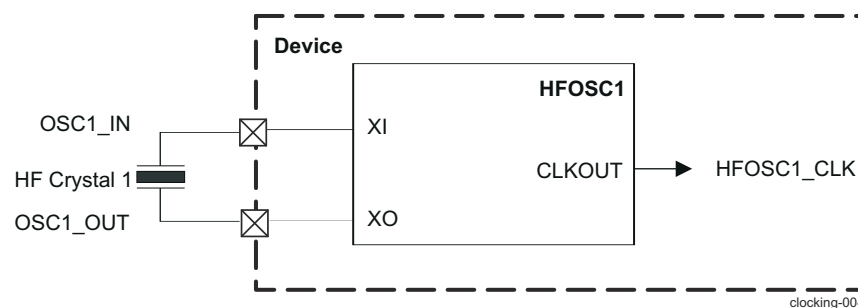

Figure 5-13. HFOSC1 Integration Diagram

5.4.7.1.2 Internal RC Oscillator

WKUP_RC_OSC_12M in always oscillate mode.

The 12.5-MHz RC clock output (WKUP_RC_OSC_12M) is used by the on-chip Reset Glue logic, Power Reset Generator (PRG) circuits, WKUP_HFOSC0 Loss Circuits, Dual Clock Comparator (DCC) and Timer Modules.

Note

An output clock of WKUP_RC_OSC_12M is further divided down to generate a 32-kHz clock (CLK_32K). This clock is used by WKUP_DMSC0 and Timer Modules.

The actual value of the derived CLK_32K will vary with PVT variations. For more information, see the device-specific Datasheet.

If an application needs accurate 32.768-kHz clock, then use the WKUP_LF_CLKIN external clock input.

5.4.7.2 Oscillator Clock Loss Detection

The device supports WKUP_HFOSC0 clock loss circuitry to detect when WKUP_HFOSC0_CLK stops toggling. If CTRLMMR_WKUP_MCU_PLL_CLKSEL[8] CLKLOSS_SWITCH_EN is set and WKUP_HFOSC0_CLK stops toggling condition is detected, the reference clock is switched from WKUP_HFOSC0_CLKOUT to WKUP_CLK_12M_RC to allow the device to operate with a slower clock. The WKUP_HFOSC0_CLK stops toggling condition is reported as an error to WKUP_ESM0 regardless of the value of CTRLMMR_WKUP_MCU_PLL_CLKSEL[8] CLKLOSS_SWITCH_EN. Integration diagram of WKUP_HFOSC0 clock loss detection is presented in Figure 5-14.

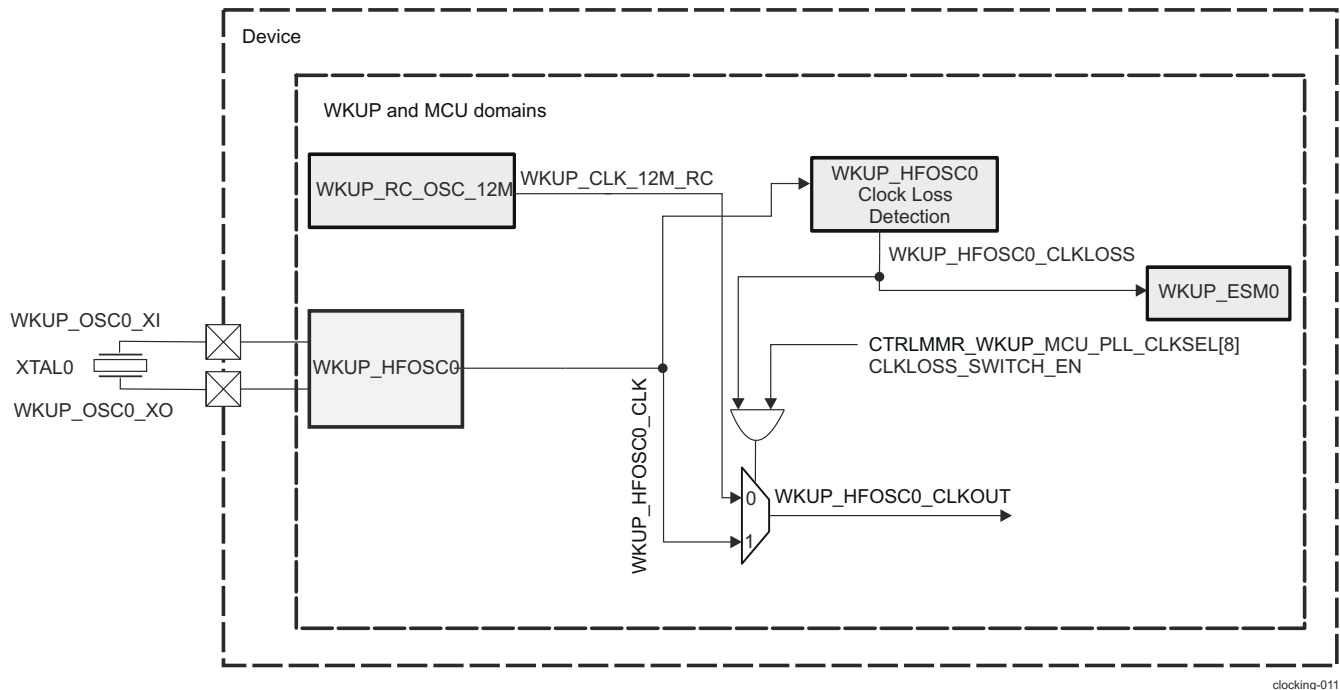

Figure 5-14. WKUP_HFOSC0 Clock Loss Detection Integration Diagram

WKUP_ESM0 can optionally generate an interrupt to WKUP_DMSC0 and MCU_R5FSS so they can save some critical contents such as error logging to scratch pad memory or external flash. ESM must also be configured to report this error on the SAFETY_ERRORn pin.

WKUP_HFOSC0 clock loss is a catastrophic failure since this clock is the most critical system clock. During the clock loss condition an external system intervention is required.

The clock loss mux is not a glitch free mux. The mux control is synchronized to the CLK_12M_RC clock. Since WKUP_HFOSC0_CLK has stopped switching the mux should transition to RC Clock without producing glitches.

Hence it is important to ensure that MCU_SAFETY_ERRORn is pulled low during this error condition. In clock-loss condition, the device reports the error to the external device through MCU_SAFETY_ERRORn pin - the pin is driven Low. The recovery mechanism is up to the external system (such as a PMIC to take action). For example, it can try a full system power cycle to see if the system recovers. If the system does not recover then, it has to take some other action such as to check system clocks, external crystal, supply rails.

PLL will lose the lock when clock loss is detected. During this time 12.5-MHz RC clock is output through the bypass muxes. The PLL will relock to a new frequency based on 12.5 MHz.

In an event of clock glitch which may potentially hang the device, then the WKUP_DMSC0 watchdog timer will expire and will generate an internal reset for the whole device.

5.4.8 PLLs

Phase-Locked Loop circuits (PLLs) in the device are clock generator PLLs, which multiply the lower-frequency reference clock up to the operating frequency of the respective subsystem(s).

5.4.8.1 WKUP and MCU Domains PLL Overview

There are total three PLLs in the device in WKUP/MCU domain:

- MCU_PLL0 (MCU R5FSS PLL) with WKUP_PLLCTRL0
- MCU_PLL1 (MCU PERIPHERAL PLL)
- MCU_PLL2 (MCU Command Platform Ethernet Switch (CPSW) PLL).

Overview of the device PLLs with their reference clock options in WKUP/MCU domain is shown on [Figure 5-15](#). For more specific information about PLLs see [Section 5.4.8.5, PLLs Device-Specific Information](#).

5.4.8.2 MAIN Domain PLLs Overview

356 J784S4 AM69x TDA4VH TDA4AH TDA4VP TDA4AP
J742S2 AM69x-27 TDA4VPE TDA4APE Processors
Texas Instruments Families of Products

- PLL0 (MAIN PLL) with PLLCTRL0
- PLL1 (PER0 PLL)
- PLL2 (PER1 PLL)
- PLL3 (CPSW9G PLL)
- PLL4 (AUDIO0 PLL)
- PLL5 (VIDEO PLL)
- PLL6 (GPU PLL)
- PLL7 (C7x PLL)
- PLL8 (ARM0 PLL)
- PLL 9 (ARM1 PLL)
- PLL12 (DDR PLL)
- PLL14 (R5FSS PLL)
- PLL16 (DSS PLL0)
- PLL17 (DSS PLL1)
- PLL19 (DSS PLL3)
- PLL25 (VISION PLL)
- PLL26 (DDR1)
- PLL27 (DDR2)
- PLL28 (DDR3)

Overview of the device PLLs with their reference clock options in MAIN domain is shown on [Figure 5-16](#) and [Figure 5-17](#). For more specific information about PLLs see [Section 5.4.8.5, PLLs Device-Specific Information](#).

Note

The external muxes of choosing the reference clocks are glitch-free muxes.

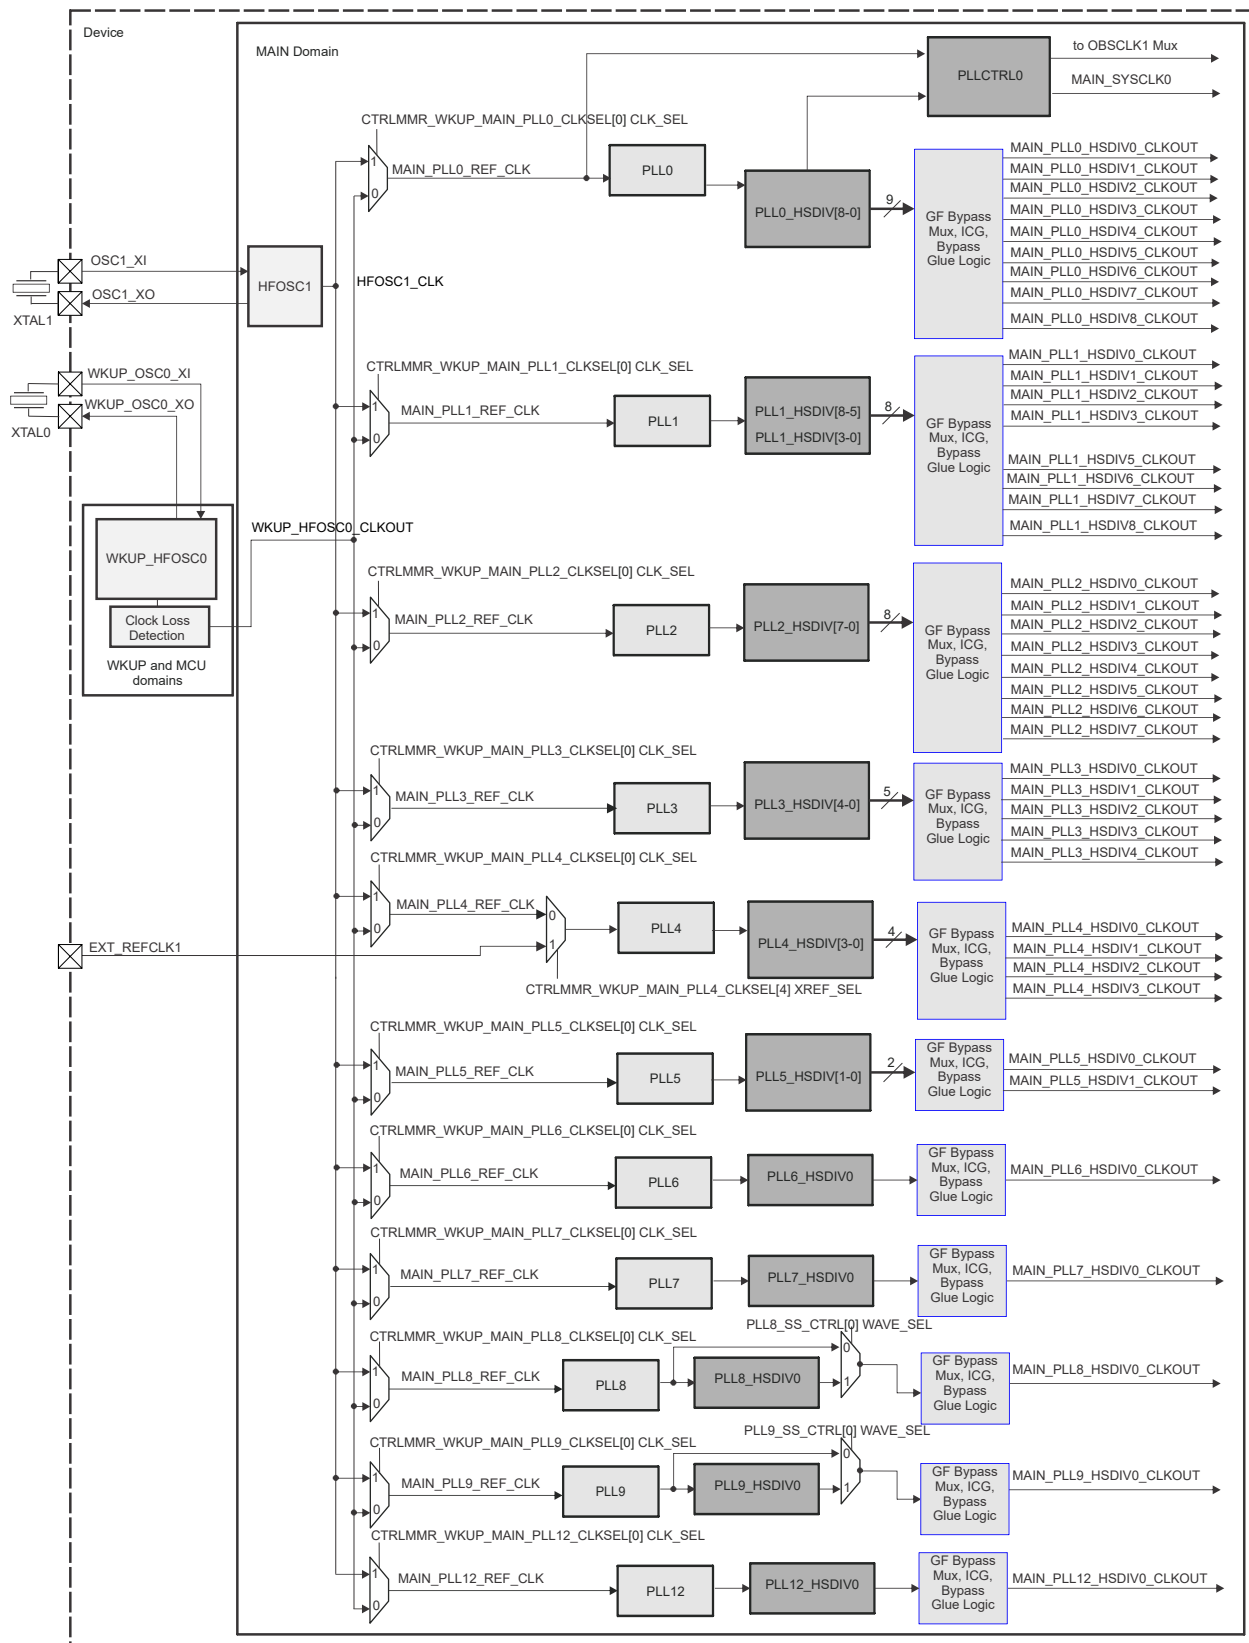

Figure 5-16. MAIN Domain PLLs Integration - Part 1

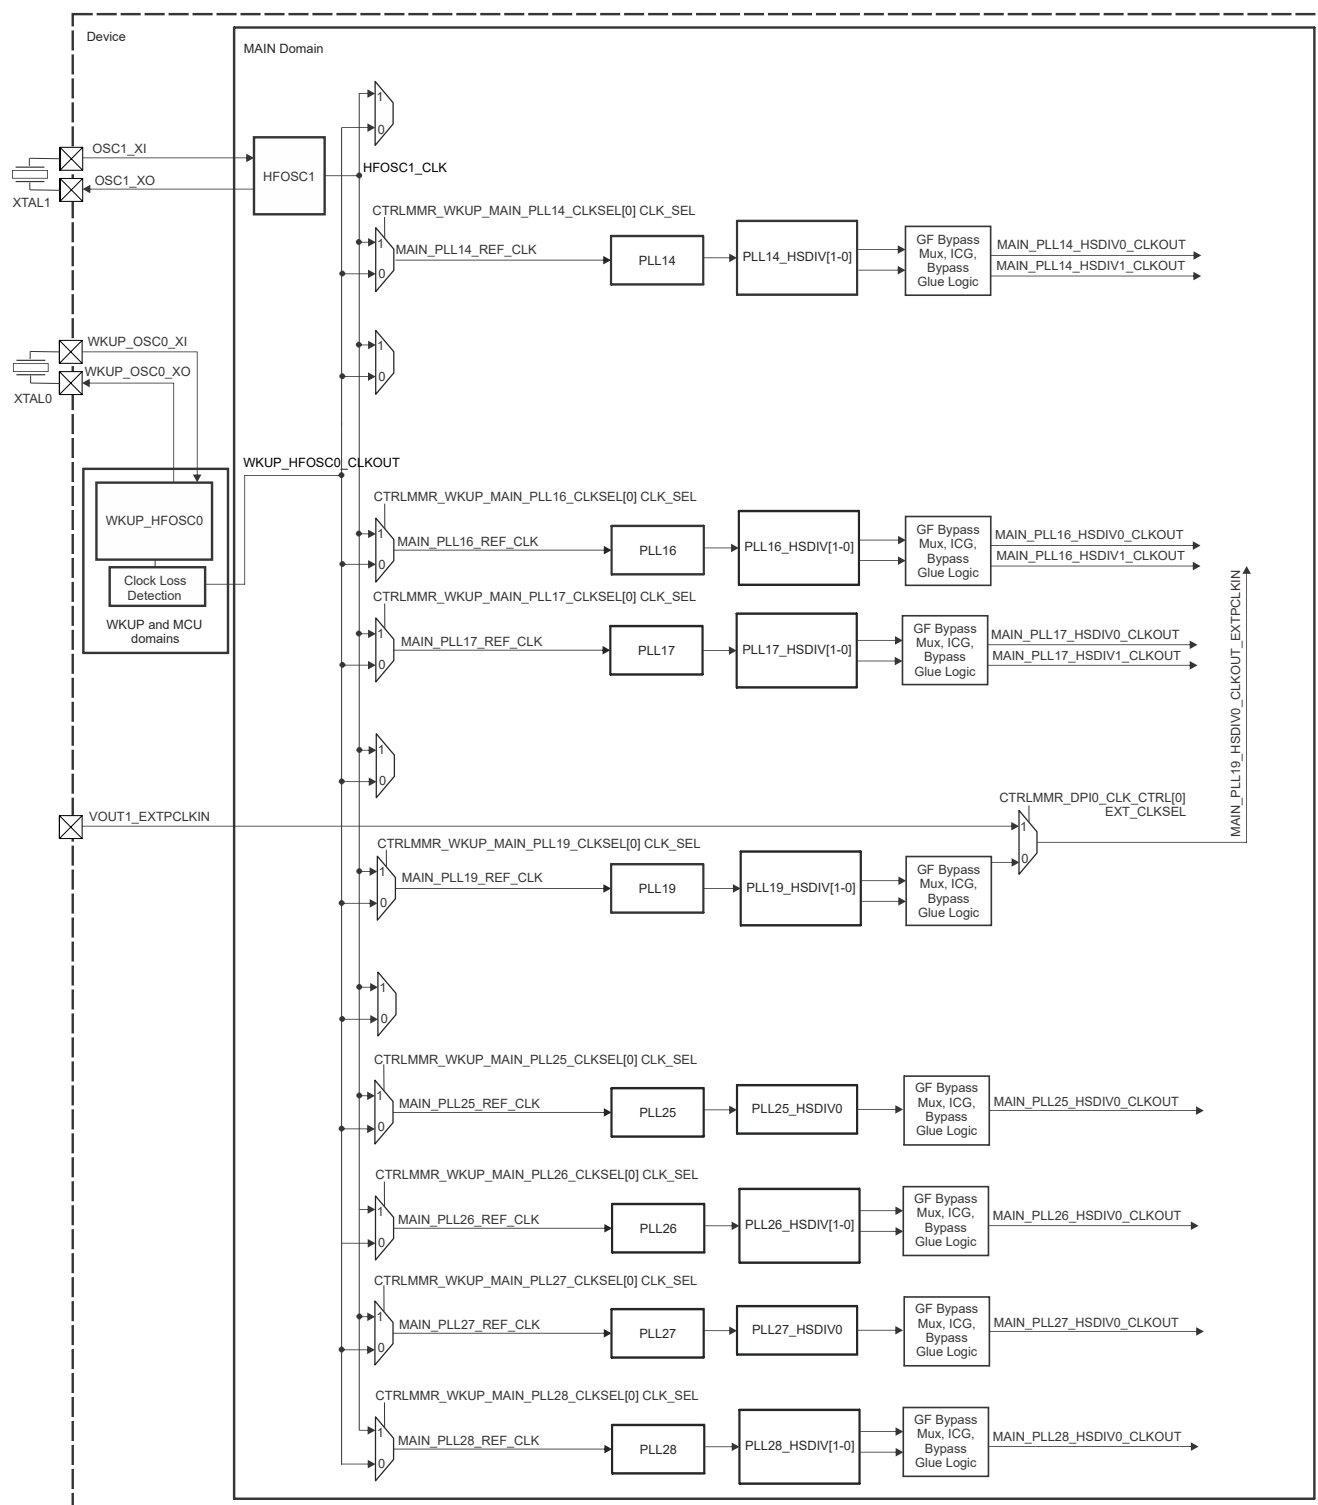

Figure 5-17. MAIN Domain PLLs Integration - Part 2

5.4.8.3 PLL Reference Clocks

5.4.8.3.1 PLLs in MCU Domain

The reference clocks MCU_PLL0_REF_CLK, MCU_PLL1_REF_CLK and MCU_PLL2_REF_CLK for the PLLs in MCU domain is chosen between the internal high-frequency (HF) oscillator with external crystal,

WKUP_HFOSC0, and 12.5-MHz free-running RC oscillator. The selection for all PLLs is made through CTRLMMR_WKUP_MCU_PLL_CLKSEL[8] CLKLOSS_SWCH_EN, see [Table 5-41](#).

Table 5-41. PLL MCU Domain Reference Clock Selection - WKUP_HFOSC0_CLKOUT Selection

CTRLMMR_WKUP_MCU_PLL_CLKSEL ⁽²⁾ [8] CLKLOSS_SWCH_EN	MCU_PLLn_REF_CLK ⁽¹⁾
0 (default)	WKUP_HFOSC0_CLK
1	WKUP_CLK_12M_RC if clock loss is detected or WKUP_HFOSC0_CLK if clock loss is not detected

(1) n = 0, 1, 2

(2) For more information about control registers, see *Control Module (CTRL_MMR)*.

5.4.8.3.2 PLLs in MAIN Domain

Each PLL in MAIN domain has a dedicated register CTRLMMR_WKUP_MAIN_PLLn_CLKSEL in WKUP_CTRL_MMR0 to choose its reference clock.

MAIN_PLLn_REF_CLK (n = 0 to 8, 12 to 19, 23 to 25) clock source is selected by means of CTRLMMR_WKUP_MAIN_PLLn_CLKSEL[0] CLK_SEL bit; for more information about control registers, see *Control Module (CTRL_MMR)*. The encoding of CLK_SEL is shown in [Table 5-42](#).

Table 5-42. PLL MAIN Domain Reference Clock Selection

CTRLMMR_WKUP_MAIN_PLLn_CLKSEL ⁽¹⁾ [0] CLK_SEL	MAIN_PLLn_REF_CLK Selection ⁽¹⁾
0 (default)	WKUP_HFOSC0_CLK
1	HFOSC1_CLK

(1) n = 0 to 8, 12 to 19, 23 to 25

PLL4 (AUDIO0 PLL) input reference clocks have additional selection via mux configured in the CTRLMMR_WKUP_MAIN_PLL4_CLKSEL[4] XREF_SEL in WKUP_CTRL_MMR0 (see [Table 5-43](#)); for more information about control registers, see *Control Module (CTRL_MMR)*.

Table 5-43. PLL4 (AUDIO0 PLL) Clock Selection

CTRLMMR_WKUP_MAIN_PLL4_CLKSEL[4] XREF_SEL	PLL4 (AUDIO0 PLL) Ref Selection
0 (default)	MAIN_PLL4_REF_CLK already selected via MAIN_PLL4_REF_CLK[0] CLK_SEL
1	EXT_REFCLK1 (external clock input on device pins)

5.4.8.4 Generic PLL Overview

To generate high-frequency clocks, the device supports multiple on-chip PLLs controlled directly by the Top-level Clocking:PLLTS16FFCLAFRACF2.

Note

This chapter discusses only the PLLs that are directly controlled by the Top-level Clocking. The other PLLs embedded in and managed by other subsystems are described in their respective subsystems.

5.4.8.4.1 PLLs Output Clocks Parameters

[Figure 5-18](#) shows the functional architecture of a generic PLL for PLLTS16FFCLAFRACF2.

Figure 5-18. Generic PLL Functional Diagram for PLLTS16FFCLAFRAC2 Type

5.4.8.4.1.1 PLLs Input Clocks

As shown in [Figure 5-18](#) for each type of PLL:

- FREF: Reference clock input is used to generate the synthesized clock but can also be used as the bypass clock for some outputs of the PLL whenever the PLL enters bypass mode. It is mandatory for the PLL clock synthesis.

5.4.8.4.1.2 PLL Output Clocks

5.4.8.4.1.2.1 PLLTS16FFCLAFRAC2 Type Output Clocks

[Table 5-44](#) describes the output clocks of PLLTS16FFCLAFRAC2.

Table 5-44. PLLTS16FFCLAFRAC2 Output Clocks

Output	Description	Frequency
FOUTP	Positive phase VCO output (no post divider)	$((\text{FREF} / \text{REFDIV}) * (\text{FBDIV} + \text{FRAC}))$
FOUTN	Negative phase VCO output (no post divider)	$((\text{FREF} / \text{REFDIV}) * (\text{FBDIV} + \text{FRAC}))$
FOUTPOSTDIV	VCO-divided clock output.	$\text{FOUTP} / (\text{POSTDIV1} * \text{POSTDIV2})$
CLKSSCG	Clock to SSMOD	$(\text{FREF} / \text{REFDIV})$

Where:

- REFDIV is the software-configured division ratio binary value.
- FBDIV is the software-configured division ratio binary value.
- FRAC is the software-configured fractional division.
- POSTDIV1 is the software-configured division ratio binary value.
- POSTDIV2 is the software-configured division ratio binary value.

Note

POSTDIV1 and POSTDIV2 valid values are from 1 to 7. To ensure correct operation, POSTDIV1 must always be programmed to a value equal to or greater than POSTDIV2.

Note

For device-specific information about clock output parameters and synthesized clocks, see [Table 5-49](#) and [Table 5-51](#).

5.4.8.4.1.2.2 PLL Lock

PLL module outputs a lock status signal to indicate that the PLL has achieved frequency lock. When the PLL detects no cycle slips between the feedback clock (FFB) and reference clock FPDF (FREF/ REFDIV[5-0]) for 128 consecutive cycles, it asserts the lock signal high. When the PLL detects any cycle slip, lock signal will go low and stays low until it detects no cycle slip for 128 consecutive cycles. This lock signal is captured in <PLL_name>_STAT[0] LOCK bit. Software can read this bit to determine if the PLL has achieved frequency lock before selecting the PLL clock through external bypass mux.

When PLL losses lock, there is a hardware mechanism to automatically bypass the PLL clock to the reference clock (FREF) using the external glitch free mux. BYP_ON_LOCKLOSS bit in <PLL_name>_CTRL register enables this automatic bypass mode on PLL lock loss. When the PLL re-locks, the glitch free mux switches to PLL clock out.

The PLL lock signal is also routed to ESM module for error reporting. ESM can be configured to generate interrupts to MCU_R5FSS/R5FSS and WKUP_DMSC0 and assert Low on SAFETY_ERRORn pin on PLL Lock loss for further action.

5.4.8.4.1.2.3 HSDIVIDER

A PLL may contain up to 16 HSDIVIDER modules to produce more clocks with divided ratio based on the PLL synthesized clock frequency. HSDIVIDER provides only one output. The HSDIVIDER output clock frequency is given by the equations in [Table 5-45](#).

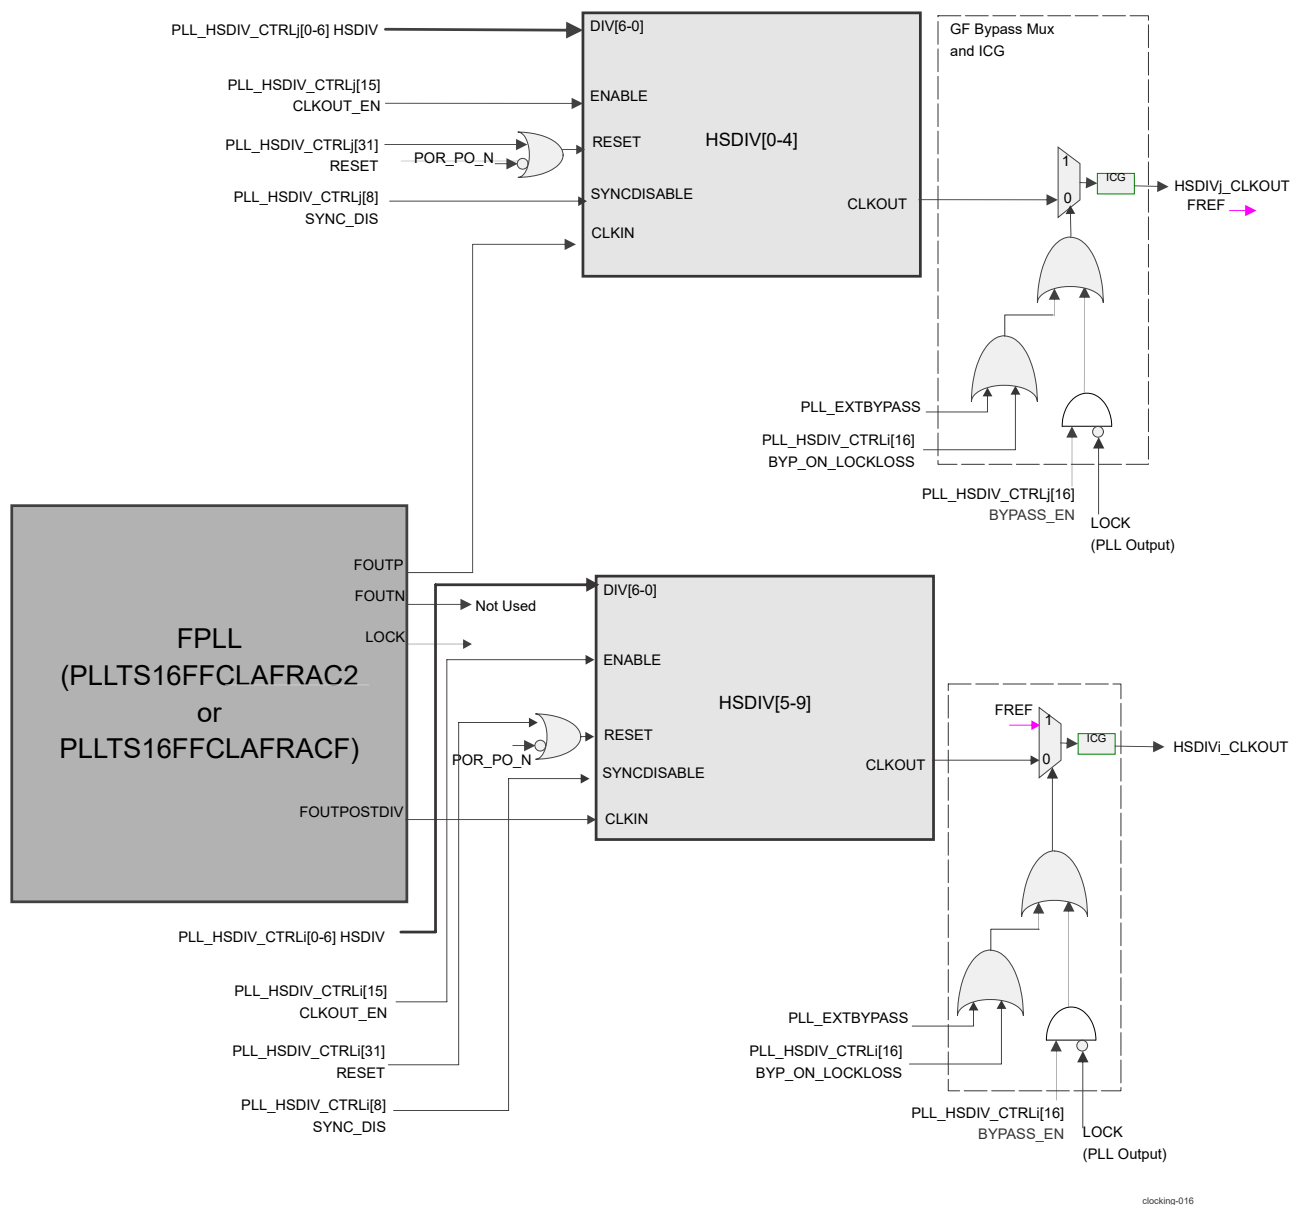

Table 5-45. HSDIV_CLKOUT Frequency With PLL State

Equation	PLL Mode
$\text{HSDIV_CLKOUT} = \text{FOUTP} / (\text{HSDIV} + 1)$	Locked
$\text{HSDIV_CLKOUT} = \text{FREF}$	Before lock or during reload

Where:

- FOUTP is the PLL lock frequency. In case of PLLTS16FFCLVDESKEWC PLL, FOUTP is substituted with FOUT1X.
- HSDIV is the software-configured division ratio binary value.

[Figure 5-19](#) describe the connection between a HSDIV and a specific type of PLL. Signals related only to this connections are shown in both figures.

(1) $i = 0$ to 4; $j = 5$ to 9

Figure 5-19. PLLTS16FFCLAFRACF2 and HSDIV Connection

5.4.8.4.1.2.4 ICG Module

ICG module ensures that when a particular HSDIV is not enabled the HSDIV clock output is gated off. This is a hardware module with no software control.

5.4.8.4.1.2.5 PLL Power Down

PLLTS16FFCLAFRACF2 is disabled with MCU PLLn CTRL[15] PLL EN or PLLn CTRL[15] PLL EN.

5.4.8.4.1.2.6 PLL Calibration

PLLTS16FFCLAFRACF 2 has acalibration feature. The calibration settings are done via <PLL Name> CAL CTRL register. The calibration status can be monitored by reading

<PLL_Name>_CAL_STAT register. For more information about device-specific information about calibration feature, see [Table 5-53](#).

5.4.8.4.2 PLL Spread Spectrum Modulation Module

Spread Spectrum Modulation (SSMOD) modules on the device reduces Electro Magnetic Interference (EMI). It is a fully-digital circuit, used to modulate the frequency of the selected fractional PLLs. Programming options include selection of center spread or down spread, modulation depth, and modulation shape. The default modulation profile is triangular.

All PLLs in this family of device have SSMOD module, except for PLL24, which is the only PLL of PLLTS16FFCLVDESKEWC type.

SSMOD in the PLL is performed by changing the feedback divider (FRAC and FBDIV) in a triangular pattern. This varies the frequency of the output clock in a triangular pattern. The frequency of this pattern is the modulation frequency (f_m). It is programmed as a ratio of the CLKIN/4.

Note

Spread Spectrum modulation and calibration cannot be enabled together because calibration cannot be enabled when the PLL is configured for fractional mode.

Figure 5-20 shows a diagram of the spreading generation block.

Figure 5-20. Spreading Generation Block Diagram

Note

f_c is the original output clock frequency.

f_m is the spreading frequency.

This additional block generates the required waveform used to reduce EMI. This waveform is then modulated with the initial signal to add some controlled deviation to the clock signal frequency, which spreads the energy of the clock and its harmonics into a band of frequencies, and then reduces EMI. SSMOD_DOWNSPREAD can control the position of the generated signal. It is controlled by the <PLL_name>_CTRL[4] DOWNSPREAD_EN

bit of the corresponding registers. If the DOWNSPREAD_EN bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0.

The value of SSMOD_FREQ controls the rate of the generated signal. It can be programmed as a ratio of the reference clock: $f_{\text{ref}} / 4$. The value that must be programmed is calculated as follows:

$\text{ModFreqDivider} = f_{\text{ref}} / (4 \times f_m)$, where $f_m < f_{\text{ref}} / 70$, $f_{\text{ref}} = f_{\text{inp}} / (1+N)$, and f_{inp} is the input clock for the PLL.

5.4.8.4.2.1 Definition of SSMOD

The aim of the SSMOD is to add a variation to the frequency of an original clock, which spreads the generated interference over a larger band of frequencies.

In theory, SSMOD means that the clock signal is varied around the desired frequency. For example, for a 1 GHz clock, the frequency might be 999.5 MHz at one time and 1.0005 GHz at another. Doing this constantly causes the power of the tone to be spread out more over a broader band of tight frequencies (centered at the desired tone). To realize this constant variation on the original signal, a modulation with an additional signal (called spreading waveform) is realized.

Creating an SSMOD by spreading the initial clock frequency is done by defining the following parameters:

- The spreading frequency (deviation), which is the ratio of the range of spreading frequency over the original clock frequency.

5.4.8.4.2.2 SSMOD Configuration

Table 5-46 describes the PLL SSMOD control bitfields. Figure 5-21 describes the connection between a SSMOD and a PLL.

Table 5-46. SSMOD related bitfields

Parameter	Register	Description
SSMOD enable control	<PLL_name>n_SS_CTRL[31] BYPASS_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[31] BYPASS_EN)	Enable/disable the PLL SSMOD feature.
Type of spread	<PLL_name>n_SS_CTRL[4] DOWNSPREAD_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[4] DOWNSPREAD_EN)	Selects center spread or down spread clock variance
Modulation divider	<PLL_name>n_SS_SPREAD[19-16] MOD_DIV (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[19-16] MOD_DIV)	Input clock divider. This divider sets the modulation frequency.
Spread Depth	<PLL_name>n_SS_SPREAD[4-0] SPREAD (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[4-0] SPREAD)	Sets the spread modulation depth.

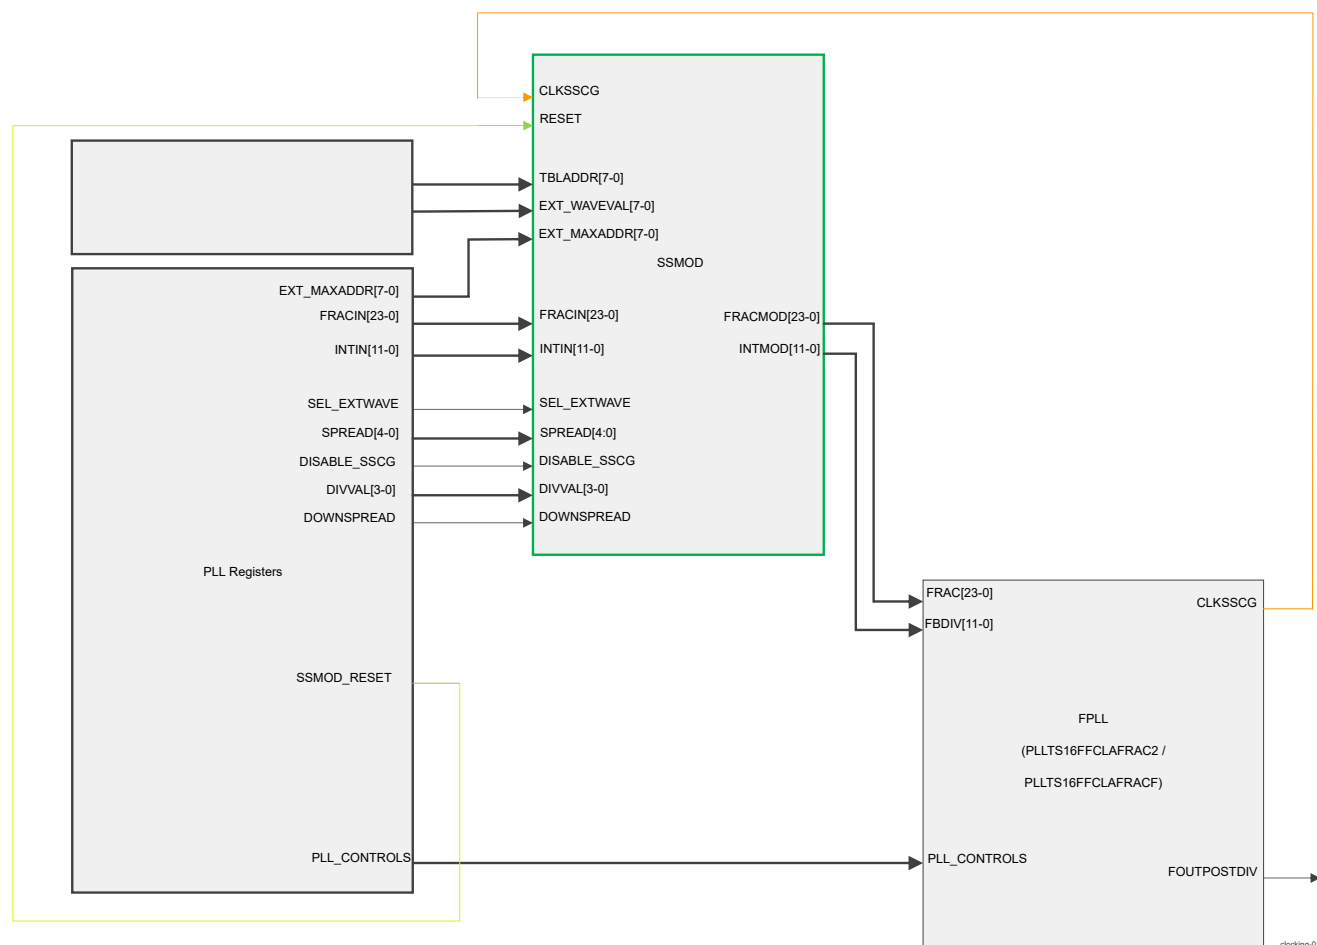

Figure 5-21. PLL and SSMOD Connection

5.4.8.5 PLLs Device-Specific Information

Table 5-47 lists the basic information of each of the three MCU PLLs.

Table 5-47. Basic Information of MCU_PLL0, MCU_PLL1, and MCU_PLL2

PLL name	Type	SSMOD Available	HSDIV Available	Input clock	Comments
MCU_PLL0	PLLTS16FFCLAFRACF2	Yes, see Table 5-46 for more information on SSMD related bitfields/bits	HSDIV0 and HSDIV1	WKUP_HFOSC0_CLKOUT	See (1) , (2) , and (3)
MCU_PLL1	PLLTS16FFCLAFRACF2	Yes, see Table 5-46 for more information on SSMD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, HSDIV3, and HSDIV4	WKUP_HFOSC0_CLKOUT	See (1) , (2) , and (3)
MCU_PLL2	PLLTS16FFCLAFRACF2	Yes, see Table 5-46 for more information on SSMD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, HSDIV3, and HSDIV4	WKUP_HFOSC0_CLKOUT	See (1) , (2) , and (3)

5.4.8.5.1 SSMOD Related Bitfields Table

Table 5-46 lists SSMOD related bitfields for all three types of PLLs.

5.4.8.5.2 Clock Synthesis Inputs to the PLLs

Table 5-49 lists the clock synthesis parameters for PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF types.

Table 5-49. Clock synthesis Parameters for PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF Types

Parameter Name	Register
FBDIV	<PLL_name>_FREQ_CTRL0[11-0] FB_DIV_INT (For example, MCU_PLL0 - MCU_PLL0_FREQ_CTRL0[11-0] FB_DIV_INT)
FRAC	<PLL_name>_FREQ_CTRL1[23-0] FB_DIV_FRAC (For example, MCU_PLL0 - MCU_PLL0_FREQ_CTRL1[23-0] FB_DIV_FRAC)
POSTDIV2	<PLL_name>_DIV_CTRL[26-24] POST_DIV2 (For example, MCU_PLL0 - MCU_PLL0_DIV_CTRL[26-24] POST_DIV2)
POSTDIV1	<PLL_name>_DIV_CTRL[18-16] POST_DIV1 (For example, MCU_PLL0 - MCU_PLL0_DIV_CTRL[18-16] POST_DIV1)
REFDIV	<PLL_name>_DIV_CTRL[5-0] REF_DIV (For example, MCU_PLL0 - MCU_PLL0_DIV_CTRL[5-0] REF_DIV)

Table 5-50 lists the clock synthesis parameters for PLLTS16FFCLVDESKEWC type.

Note

For PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF types - POSTDIV1 and POSTDIV2 values are from 1 to 7. To ensure correct operation, POSTDIV1 must always be programmed to a value equal to or greater than POSTDIV2.

Table 5-50. Clock synthesis Parameters for PLLTS16FFCLVDESKEWC Type

Parameter Name	Register
FBDIV	<PLL_name>_DIV_CTRL[13-12] FB_DIV (For example, PLL24 - PLL24_PLL_DIV_CTRL[13-12] FB_DIV)
POSTDIV	<PLL_name>_DIV_CTRL[10-8] POST_DIV (For example, PLL24 - PLL24_PLL_DIV_CTRL[10-8] POST_DIV)
REFDIV	<PLL_name>_DIV_CTRL[1-0] REF_DIV (For example, PLL24 - PLL24_PLL_DIV_CTRL[1-0] REF_DIV)

Note

For PLLTS16FFCLVDESKEWC type:

- REFDIV and FBDIV valid values are 1, 2, and 4.
- POSTDIV valid values are 1, 2, 4, 8, 16, 32, 64, and 128.

5.4.8.5.3 Clock Output Parameter

Table 5-51 lists the control/status bit fields for output clocks.

Table 5-51. Clock Output Parameter for PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF Types

Clock Output/Divider	Parameter Name	Control/Status Bit Field
<PLL_name>_CLKOUT, <PLL_name>_HSDIVj_CLKOUT ⁽¹⁾	Control	<PLL_name>_CTRL[31] BYPASS_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[31] BYPASS_EN)
<PLL_name>_HSDIVj_CLKOUT ⁽¹⁾	Control	<PLL_name>_HSDIV_CTRL[15] CLKOUT_EN (For example, MCU_PLL0 - MCU_PLL0_HSDIV_CTRL[15] CLKOUT_EN and MCU_PLL0_HSDIV_CTRL[15] CLKOUT_EN)
<PLL_name>_HSDIVj_CLKOUT ⁽¹⁾	Divider control	<PLL_name>_HSDIV_CTRL[6-0] HSDIV (For example, MCU_PLL0 - MCU_PLL0_HSDIV_CTRL[6-0] HSDIV and MCU_PLL0_HSDIV_CTRL[6-0] HSDIV)
PLL bypass mux	Control	<PLL_name>_CTRL[16] BYPASS_ON_LOCKLOSS (For example, MCU_PLL0 - MCU_PLL0_CTRL[16] BYPASS_ON_LOCKLOSS)
Enable 4-phase clock generator	Control	<PLL_name>_CTRL[5] CLK_4PH_EN (ignored if <PLL_name>_CTRL[4] CLK_POSTDIV_EN = 0) (For example, MCU_PLL0 - MCU_PLL0_CTRL[5] CLK_4PH_EN)
Post divide CLK enable	Control	<PLL_name>_CTRL[4] CLK_POSTDIV_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[4] CLK_POSTDIV_EN)

Table 5-53. Recalibration Feature Parameters (continued)

Recalibration feture	Parameter Name	Control/Status Bit Field
Output of the calibration block	Status	<PLL_name>_CAL_STAT[11-0] CAL_OUT (For example, PLL12 - PLL12_CAL_STAT[11-0] CAL_OUT)

5.4.8.6 PLL and PLL Controller Connection

Two PLL Controllers are implemented in the device - PLLCTRL0 and WKUP_PLL_CTRL0. They are respectively related to PLL0 and MCU_PLL0. The PLL Controllers manage the clock ratios, alignment, and gating for the system clocks.

Figure 5-22. PLL and PLL Controller

Note

PLLCTRL_POSTDIV is not supported in this family of devices.

Note

The PLL Controllers registers can be accessed by any master in the device.

A SYSCLK0 clock out of a PLLCTRL is the only synchronous clock in that domain. That means
- MCU_SYSCLK0 out of WKUP_PLLCTRL is the synchronous CBASS clock in MCU domain and
SYSCLK0 out of Main PLLCTRL is the synchronous CBASS clock in Main domain.

5.4.8.7 System Clocks Operating Frequency Ranges

Table 5-54 lists the operating frequency ranges for the system clocks of the device.

Table 5-54. System Clocks Operating Frequency Range

System Clocks	Minimum Operating Frequency (MHz)
MCU_PLL0 (MCU TBD PLL) with WKUP_PLLCTRL0	1500 MHz to 3200 MHz
MCU_PLL1 (MCU PERIPHERAL PLL)	1500 MHz to 3200 MHz
MCU_PLL2 (MCU CPSW PLL)	1500 MHz to 3200 MHz
PLL0 (MAIN PLL) with PLLCTRL0	1500 MHz to 3200 MHz
PLL1 (PER0 PLL)	1500 MHz to 3200 MHz
PLL2 (PER1 PLL)	1500 MHz to 3200 MHz
PLL3 (CPSW9G PLL)	1500 MHz to 3200 MHz
PLL4 (AUDIO0 PLL)	1500 MHz to 3200 MHz
PLL5 (VIDEO PLL)	1500 MHz to 3200 MHz
PLL6 (GPU PLL)	1500 MHz to 3200 MHz

Table 5-54. System Clocks Operating Frequency Range (continued)

System Clocks	Minimum Operating Frequency (MHz)
PLL7 (C7x PLL)	1500 MHz to 3200 MHz
PLL8 (ARM0 PLL)	1500 MHz to 3200 MHz
PLL9 (ARM1 PLL)	1500 MHz to 3200 MHz
PLL12 (DDR PLL)	1500 MHz to 3200 MHz
PLL14 (PULSAR PLL)	1500 MHz to 3200 MHz
PLL16 (DSS PLL0)	1500 MHz to 3200 MHz
PLL17 (DSS PLL1)	1500 MHz to 3200 MHz
PLL19 (DSS PLL3)	1500 MHz to 3200 MHz
PLL25 (VISION PLL)	1500 MHz to 3200 MHz
PLL27 (DDR2)	1500 MHz to 3200 MHz
PLL28 (DDR3)	1500 MHz to 3200 MHz

(1) Supported input reference clock frequencies to the PLL are 19.2/24/25/26 MHz only.

(2) Interconnect clock on DSS is CPU/4. This will range from 100 MHz to 250 MHz.

(3) When Main PLL is configured to 400 MHz mode, DSS can only support a max pixel clock of 74.25 MHz. For lower resolution displays the DSS clock can be lower than 74.25 MHz.

5.4.8.8 Recommended Clock and Control Signal Transition Behavior

All clocks and strobe signals must transition between V_{IH} and V_{IL} (or between V_{IL} and V_{IH}) in a monotonic manner. Monotonic transitions are more easily ensured with faster switching signals. Slower input transitions are more susceptible to glitches due to noise, and special care must be taken for slow input clocks.

5.4.8.9 Interface Clock Specifications

Interface Clock Terminology

The interface clock is used at the system level to sequence the data and to control transfers accordingly with the interface protocol.

Interface Clock Frequency

The two interface clock characteristics are:

- The maximum clock frequency
- The maximum operating frequency

The interface clock frequency documented here is the maximum clock frequency, which corresponds to the maximum frequency programmable on this output clock. This frequency defines the maximum limit supported by the Device IC and does not take into account any system consideration (PCB, peripherals).

The system designer must take into account these system considerations and the Device IC timing characteristics to properly define the maximum operating frequency that corresponds to the maximum frequency supported to transfer the data on this interface.

5.4.8.10 PLL, PLLCTRL, and HSDIV Controllers Programming Guide

5.4.8.10.1 PLL Initialization

5.4.8.10.1.1 Kick Protection Mechanism

Note

PLL configuration registers are write-protected at power-up. Software must first un-lock the PLLn_LOCKKEY0 and PLLn_LOCKKEY1 registers prior to writing to any chip-level registers.

The un-lock process shall follow the steps:

1. Write value 0x68EF3490 to PLLn_LOCKKEY0 register.
2. Write value 0xD172BC5A to PLLn_LOCKKEY1 register.

After these two steps a write access to the PLL registers is allowed. Writing any other data value to either of these two registers locks the kicker mechanism and blocks any writes to the PLL registers.

Note

In order to ensure that all PLL registers are write protected, software must always re-lock the kicker mechanism after completing the register writes.

5.4.8.10.1.2 PLL Initialization to PLL Mode

Note

For validated set of parameters that can be programmed to PLLs, please refer to the device-specific Datasheet.

Initially, the device powers up in PLL bypass mode. The bypass mux is a glitch free mux and is located outside the PLL module. PLL_EXTBYPASS bit controls the bypass mux section. During Power-up, the bypass mux defaults to select FREF clock (PLL clock bypass mode).

During boot, WKUP_DMSC0 ROM programs the MCU_PLL0 to a valid frequency based on the crystal frequency and BOOTMODE pin settings. WKUP_DMSC0 then waits for PLL to be locked by checking the PLL LOCK status bit. WKUP_DMSC0 ROM programs PLL_EXTBYPASS bit to '0' to disable the bypass mode to propagate MCU_PLL0 clock to WKUP_PLLCTRL0. At this point WKUP_DMSC0 brings MCU_R5FSS out of reset to complete the reset of the boot process. R5FSS software configures the remaining PLLs and bring them out of bypass mode.

5.4.8.10.1.3 PLL Programming Requirements

- A PLL VCO frequency must be set to > 1500 MHz
 - For best PLL performance, maximize VCO frequency where possible.
- A PLL Reference clock frequency must be > 10 MHz.
- REFDIV[5:0] must be set to "000001".

5.4.8.10.1.3.1 PLL Calibration Procedure

PLL calibration is intended to reduce a specific form of PLL jitter in which a large correction is present on each reference clock edge. In this case, the calibration logic smooths the correction so that the change to the PLL operation is not as abrupt and therefore it reduces jitter related to the reference clock.

In <PLL_name>_CAL_CTRL register:

- CAL_IN = 0
- CAL_CNT = 2
- CAL_BYP = 0
- FAST_CAL = 1

Then, set CAL_EN = 1

Wait for <PLL_name>_CAL_STAT[31] CAL_LOCK to be asserted. The CAL_LOCK signal requires a timeout; if the signal is NOT asserted within 2.3ms, the user may continue to use the PLL but should not change CAL_CNT or FAST_CAL (in the next step).

Then, the use may (it is not required):

- change CAL_CNT from 2 to 7
- change FAST_CAL from 1 to 0

These optional changes increase the duration for which the calibration solution is measured from $2^2 + 5$ reference clock periods to $2^7 + 5$ reference clock periods.

Calibration cannot be used when the PLL is configured for fractional mode; specifically, this restriction means that PLL_CTRL[1] = 0.

5.4.8.10.2 Entire Sequence for Programming PLLCTRL, HSDIV, and PLL

Table 5-55 shows the entire sequence of programming PLLCTRL, HSDIV, and PLL from an unknown state to a defined non-spread-spectrum state.

Table 5-55. Programming Sequence of PLLCTRL, HSDIV, and PLL

Step	Description
Unlock PLL registers	<PLL_Name>_LOCKKEY0 (= 0x68EF3490) <PLL_Name>_LOCKKEY1 (= 0xD172BC5A)
If PLL0	Configure PLLCTRL block into bypass mode PLLCTL[0] PPLEN = 0 PLLCTL[5] PPLENSRC = 0

5.5 Module Integration

5.5.1 ADC

Table 5-56. ADC Instances

Instances	WKUP Domain	MCU Domain	MAIN Domain
MCU_ADC[1:0]		√	

5.5.1.1 ADC Unsupported Features

The integration of the ADC module in this Device supports all module features.

5.5.1.2 ADC Integration Details

ADC Hardware Event Selection

Each ADC module has a HW EVENT input that provides the ability to trigger ADC sampling based on a hardware event rather than through software. Muxes are provided to select the hardware trigger from external pins, periodic timer events, or eHRPWM start of conversion events.

This event selection is described in controlled by the MCU_ADCn_CTRL_TRIG_SEL (n=0,1) field of the MCU_CTRL_MMR0_MCU_ADCn_CTRL (n=0,1) registers in the Control Module (CTRL_MMR), with the default selection being each ADC's associated EXT_TRIGGER pin.

ADC GPI Integration

Each ADC module can be configured either as 8 analog inputs, or 8 digital inputs. To enable digital input mode, the MCU_ADCn_CTRL_GPI_MODE_EN (n=0,1) bit of the MCU_CTRL_MMR0_MCU_ADCn_CTRL (n=0,1) registers in the Control Module (CTRL_MMR) can be set to '1'. This enables the ADC pins to be used as general purpose digital inputs with some restrictions:

- ADC pins support only 1.8V logic levels
- These may be used as GPI only not as GPIO (no output buffer)
- Speed is limited to a 200 MHz switching rate

- All ADC inputs will operate as either digital or analog inputs as a group (no individual selection)
- The GPI_MODE_EN selection cannot be switched dynamically (desired operation should be selected before enabling the ADC)

ADC Reference Integration

The ADC0/1 REFN and REFP voltage references are pinned out on this device. See the below table for details on associated device pins and PCB recommendations.

ADC Reference	Device Pin	Recommend PCB Connection ⁽¹⁾
ADC0 REFP	MCU_ADC0_P	VDDA_ADC0
ADC0 REFN	MCU_ADC0_N	VSS
ADC1 REFP	MCU_ADC1_P	VDDA_ADC1
ADC1 REFN	MCU_ADC1_N	VSS

(1) TI recommends minimizing the shared impedance of the ADC References and VDDA_ADC[1:0] / VSS.

5.5.2 ATL

Instance	WKUP Domain	MCU Domain	MAIN Domain
ATL0			√

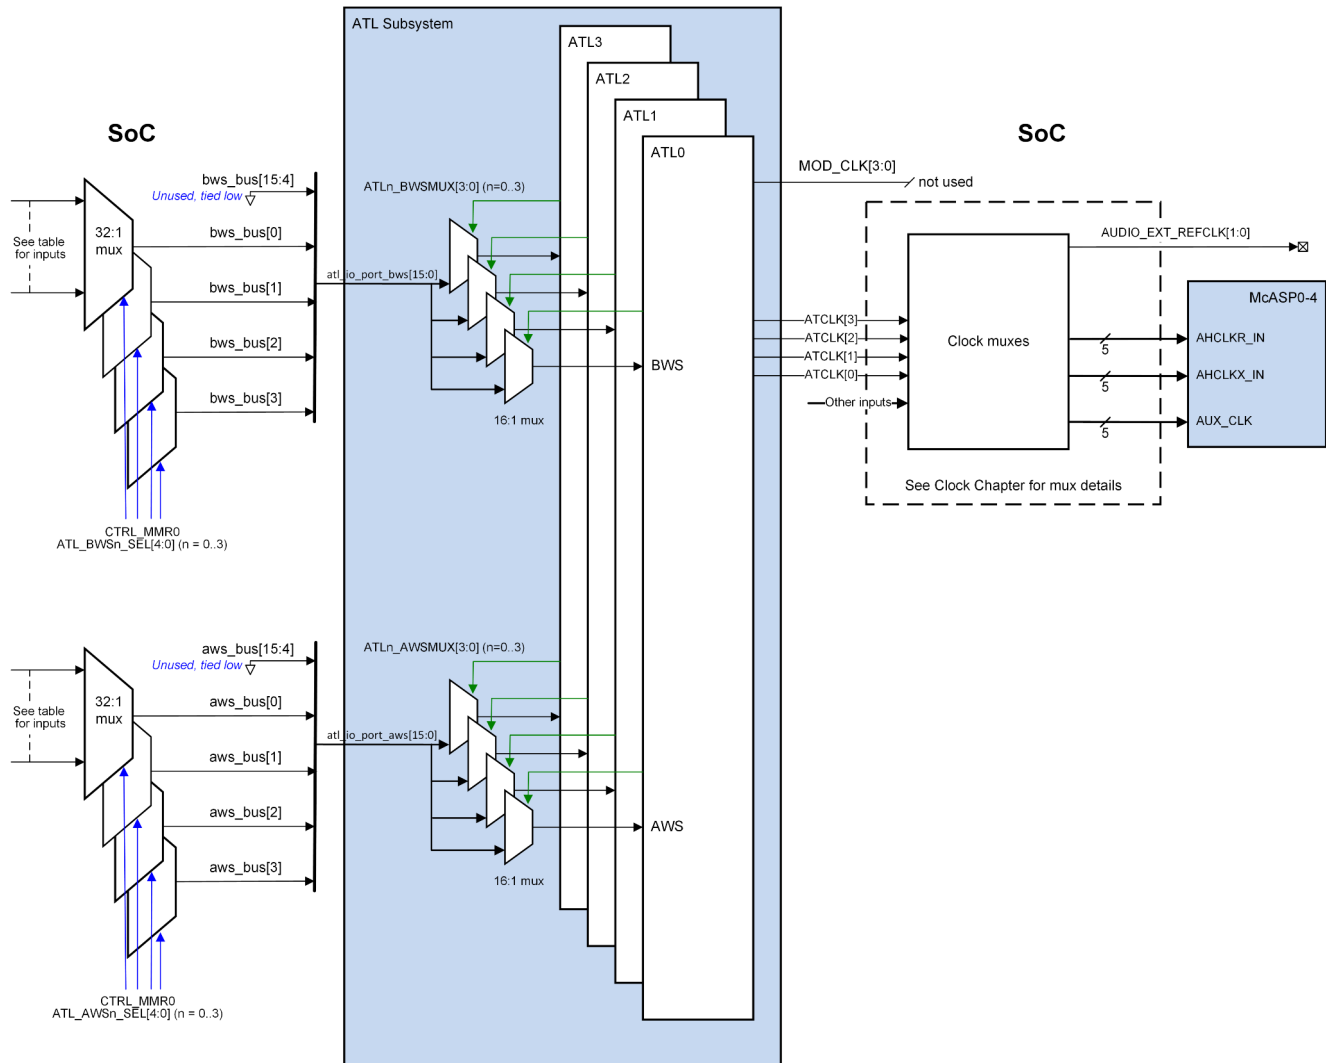

5.5.2.1 ATL Unsupported Features

The ATL module features listed below are not supported by the integration on this device:

- MOD_OUT[3:0] Modem Clock (MODCLK) outputs are unused and unconnected

5.5.2.2 ATL Integration Details

The adjusted audio clock (ATCLK) outputs of the ATLSS may be selected to drive the AUDIO_EXT_REFCLK[1:0] pins to serve as the master clock of an audio dac, fed back to McASP AHCLKX/R inputs to drive AFSX/R and ACLKX/R dividers, or selected as McASP AUXCLK sources as illustrated below. See the clocking section for additional details.

The ATL subsystem includes internal muxes to choose 1 of 16 possible sources of AWS and BWS inputs for each of the four ATL instances. These internal muxes are controlled by the ATL module's `ATLn_AWSMUX` and `ATLn_BWSMUX` registers and are only used to select one AWS and one BWS source from `atl_io_port_aws` and `atl_io_port_bws` for each of ATL instance. Device level muxes are used to choose a word select source from up to 32 possible inputs for each.

The following table shows Baseband I2S word select (BWS) input sources for each of the 4 ATL modules in the ATL subsystem ($n = 0-3$):

CTRL_MMR0 ATL_BWS n _SEL[4:0]	Source Signal Name	Mode	CTRL_MMR0 ATL_BWS n _SEL[4:0]	Source Signal Name	Mode
0	<code>mcasp0_afsr_pad_in</code>	McASP0 ASYNC	16	<code>mcasp4_afsx_pad_in</code> 1 2	McASP4 SYNC
1	<code>mcasp1_afsr_pad_in</code>	McASP1 ASYNC	17	tied 1'b0	Reserved
2	<code>mcasp2_afsr_pad_in</code>	McASP2 ASYNC	18	tied 1'b0	Reserved
3	<code>mcasp3_afsr_pad_in</code>	McASP3 ASYNC	19	tied 1'b0	Reserved
4	<code>mcasp4_afsr_pad_in(1)</code>	McASP4 ASYNC	20	tied 1'b0	Reserved
5	tied 1'b0	Reserved	21	tied 1'b0	Reserved
6	tied 1'b0	Reserved	22	tied 1'b0	Reserved
7	tied 1'b0	Reserved	23	tied 1'b0	Reserved
8	tied 1'b0	Reserved	24	<code>AUDIO_EXT_REFCLK0_IN</code>	External Clock Source 0

CTRL_MMR0 ATL_BWS n _SEL[4:0]	Source Signal Name	Mode	CTRL_MMR0 ATL_BWS n _SEL[4:0]	Source Signal Name	Mode
9	tied 1'b0	Reserved	25	AUDIO_EXT_REFCLK1_IN	External Clock Source 1
10	tied 1'b0	Reserved	26	tied 1'b0	Reserved
11	tied 1'b0	Reserved	27	tied 1'b0	Reserved
12	mcasp0_afsx_pad_in(2)	McASP0 SYNC	28	tied 1'b0	Reserved
13	mcasp1_afsx_pad_in(2)	McASP1 SYNC	29	tied 1'b0	Reserved
14	mcasp2_afsx_pad_in(2)	McASP2 SYNC	30	tied 1'b0	Reserved
15	mcasp3_afsx_pad_in(2)	McASP3 SYNC	31	tied 1'b0	Reserved

1. Usage Note: McASP4 is intended for use with eDP but may be used as an additional general purpose transmit/receive audio stream if the clock pins are available in the pinmux.
2. FAQ: In SYNC mode, McASP uses the AFSX signal to clock both receiver and transmitter, which is why AFSX shows up in the BWS table.

The following table shows Audio I2S word select (AWS) input sources for each of the 4 ATL modules in the ATL subsystem ($n = 0-3$):

CTRL_MMR0 ATL_AWS n _SEL[4:0]	Source Signal Name	Mode	CTRL_MMR0 ATL_AWS n _SEL[4:0]	Source Signal Name	Mode
0	mcasp0_afsx_pad_in	McASP0 ASYNC	16	mcasp4_afsx_pad_in1	McASP4 SYNC
1	mcasp1_afsx_pad_in	McASP1 ASYNC	17	tied 1'b0	Reserved
2	mcasp2_afsx_pad_in	McASP2 ASYNC	18	tied 1'b0	Reserved
3	mcasp3_afsx_pad_in	McASP3 ASYNC	19	tied 1'b0	Reserved
4	mcasp4_afsx_pad_in(1)	McASP4 ASYNC	20	tied 1'b0	Reserved
5	tied 1'b0	Reserved	21	tied 1'b0	Reserved
6	tied 1'b0	Reserved	22	tied 1'b0	Reserved
7	tied 1'b0	Reserved	23	tied 1'b0	Reserved
8	tied 1'b0	Reserved	24	AUDIO_EXT_REFCLK0_IN	External Clock Source 0
9	tied 1'b0	Reserved	25	AUDIO_EXT_REFCLK1_IN	External Clock Source 1
10	tied 1'b0	Reserved	26	tied 1'b0	Reserved
11	tied 1'b0	Reserved	27	tied 1'b0	Reserved
12	mcasp0_afsx_pad_in	McASP0 SYNC	28	tied 1'b0	Reserved
13	mcasp1_afsx_pad_in	McASP1 SYNC	29	tied 1'b0	Reserved
14	mcasp2_afsx_pad_in	McASP2 SYNC	30	tied 1'b0	Reserved
15	mcasp3_afsx_pad_in	McASP3 SYNC	31	tied 1'b0	Reserved

1. Usage Note: McASP4 is intended for use with eDP but may be used as an additional general purpose transmit/receive audio stream if the clock pins are available in the pinmux.

5.5.3 CPSW2G

Table 5-57. CPSW2G Instances

Instance	WKUP Domain	MCU Domain	MAIN Domain
CPSW2G0			√
MCU_CPSW2G0		√	

5.5.3.1 CPSW2G Unsupported Features

The CPSW2G module features listed below are not supported by the integration on this device:

- Maximum frame size of 9600 bytes
- GMII Mode
- SGMII Mode
- MACSEC
- Synchronous Ethernet

5.5.3.2 MCU_CPSW2G0 Integration Details

RMII Clocking

The Device integrates both internal and external clock source options in RMII mode. However, the internal clock source option is **UNSUPPORTED** by the Device integration. Figure 5-23 presents the high level view of the two clocking options.

Figure 5-23(a) shows the **UNSUPPORTED** internal clock source for RMII clock. It is a 50 MHz clock source that is provided by the Device on the MCU_CLKOUT0 pin. This clock source routes on the PCB to both the Device MCU_RMII1_REF_CLK input and the external Phy RMII clock input.

Figure 5-23(b) shows the **SUPPORTED** external clock source option for the RMII clock. In this case a 50 MHz clock is available on the PCB (possibly from an oscillator or from the Ethernet Phy). This externally generated clock source is routed to both the Device MCU_RMII1_REF_CLK input and the external Phy RMII clock input. In both cases, the Device MCU_RMII1_REF_CLK is an input. The difference between the two cases is simply that in the **UNSUPPORTED** Figure 5-23(a) the Device provides a 50 MHz clock source on a separate pin.

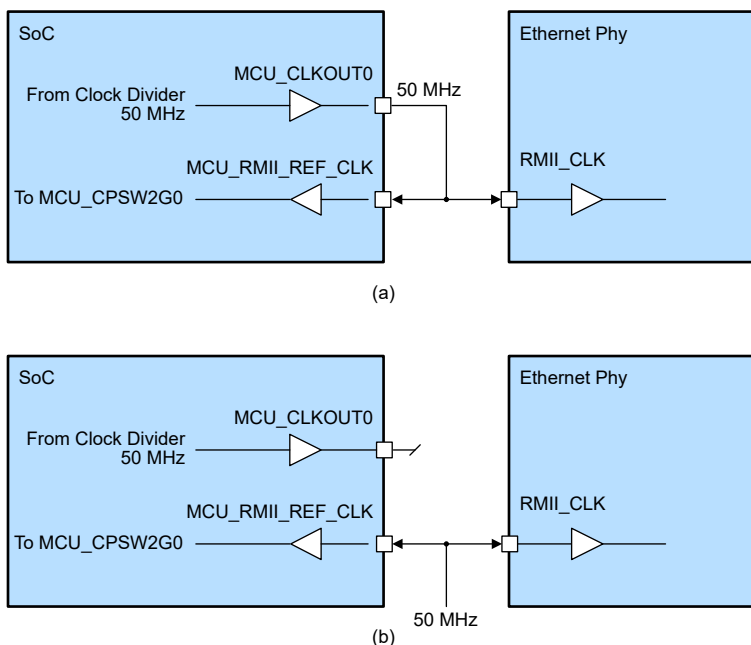

Figure 5-23. Clocking Options in RMII Mode

5.5.3.3 CPSW2G0 Integration Details

RMII Clocking

The Device integrates both internal and external clock source options in RMII mode. However, the internal clock source option is **UNSUPPORTED** by the Device integration. Figure 5-24 presents the high level view of the two clocking options.

Figure 5-24(a) shows the UNSUPPORTED internal clock source for RMII clock. It is a 50 MHz clock source that is provided by the Device on the CLKOUT pin. This clock source routes on the PCB to both the Device RMII_REF_CLK input and the external Phy RMII clock input.

Figure 5-24(b) shows the SUPPORTED external clock source option for the RMII clock. In this case a 50 MHz clock is available on the PCB (possibly from an oscillator or from the Ethernet Phy). This externally generated clock source is routed to both the Device RMII_REF_CLK input and the external Phy RMII clock input. In both cases, the Device RMII_REF_CLK is an input. The difference between the two cases is simply that in the UNSUPPORTED Figure 5-24(a) the Device provides a 50 MHz clock source on a separate pin.

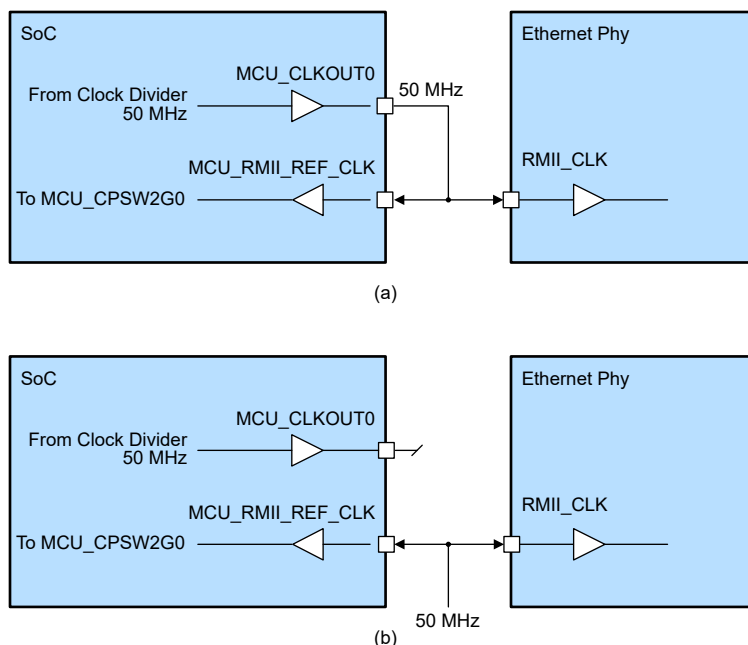

Figure 5-24. Clocking Options for RMII Mode

5.5.4 CPSW9G

Table 5-58. CPSW9G Instances

Instance	WKUP Domain	MCU Domain	MAIN Domain
CPSW9G0			√

5.5.4.1 CPSW9G0 Unsupported Features

The CPSW9G module features listed below are not supported by the integration on this device:

- Maximum frame size of 9600 bytes
- GMII/RMII/RGMII Mode
- MACSEC
- Synchronous Ethernet
- 1G and 10G gigabit half-duplex
- Interspersed Express Traffic (IET) in RMII mode
- Rate limiting in half-duplex mode
- Dual VLAN switch operations
- Cut Through Switching
- Software reset on CPRGMII, CPRMII, PCSR

5.5.4.2 CPSW9G0 Integration Details

See "Serializer/Deserializer (SerDes)" for CPSW9G0 connections to SerDes in this device.

5.5.5 CSI_RX

Table 5-59. CSI_RX Instances

Instances	WKUP Domain	MCU Domain	MAIN Domain
CSI_RX[2:0]			√

5.5.5.1 CSI_RX Unsupported Features

The CSI_RX module features listed below are not supported by the integration on this device:

- Line Count Error Interrupt (Streams 1-3)
- Frame Mismatch Error Interrupt (Streams 1-3)
- Frame Count Error Interrupt (Streams 1-3)
- FCC Stop Interrupt (Streams 1-3)
- FCC Start Interrupt (Streams 1-3)
- Line/Byte Interrupt (Streams 1-3)
- Timer / Timer Interrupt (Streams 1-3)

5.5.5.2 CSI_RX Integration Details

Each CSI_RX is driven by a dedicated instance of a MIPI D-PHY Receive module. The D-PHY is contains its own bus interface for configuration rather than being configured through the CSI_RX module to which it is connected. All instances of CSI_RX have dedicated DMA interfaces (PSI-L) and therefore can stream to memory. The DMA interface supports up to 32 channels. Likewise, all instances of the CSI_RX module can be configured to retransmit to the CSI_TX module for diagnostic purposes. The streaming interface between each CSI_RX and CSI_TX supports up to 4 channels.

The Device supports flexible mapping of VP0/VP1 to any CAL0_i streaming input of the VPAC instances. Any one of the CSI_RX VP0 ports can be selected to feed the CAL0_i streaming input of the VPAC0 directly. Any one of the VP1 ports can be selected to feed the CAL0_i input of VPAC1.

5.5.6 CSI_TX

Table 5-60. CSI_TX Instances

Instances	WKUP Domain	MCU Domain	MAIN Domain
CPSW9G0			√

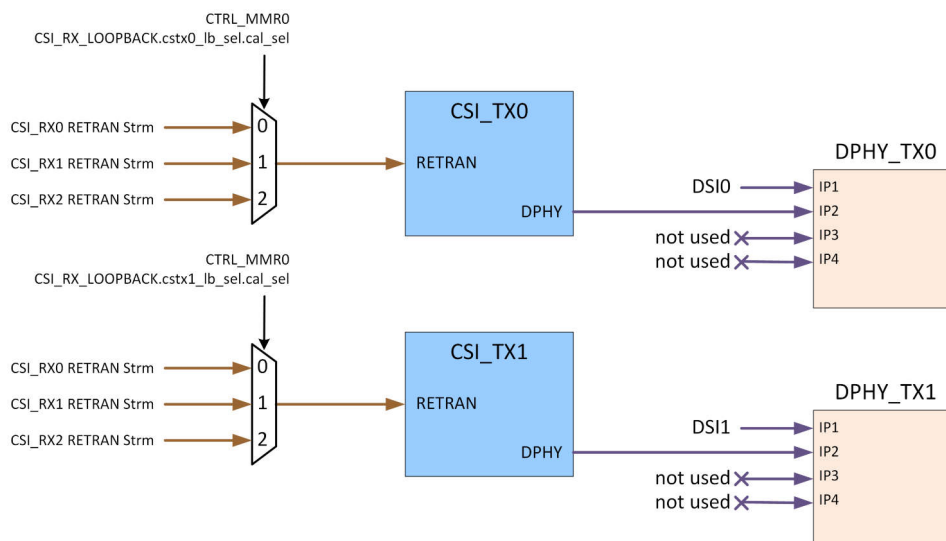

5.5.6.1 CSI_TX Unsupported Features

The CSI_TX module features listed below are not supported by the integration on this device:

- CSI2 ver2.0 scrambling
- CSI2 ver2.0 optional no LP (low power state) between packets
- Cropping
- Pixel Processing
- Multiple Active Input Streams
- 3 Lane Support

5.5.6.2 CSI_TX Integration Details

The CSI_TX module is able to transmit CSI-2 protocol image data from memory or retransmit the video stream of any of the three CSI_RX modules. The CTRL_MMR0 CSI_RX_LOOPBACK register is used to select the mapping of CSI_RX receiver stream to each CSI_TX transmitter. Each CSI_TX shares a MIPI transmit PHY (DPHY_TX) with a DSI Video output.

5.5.7 DCC

Table 5-61. DCC Instances

Instances	WKUP Domain	MCU Domain	MAIN Domain
MCU_DCC[1:0]		√	
DCC[9:0]			√

5.5.7.1 DCC Unsupported Features

The integration of the DCC module in this Device supports all module features.

5.5.7.2 DCC Integration Details

There are no additional DCC module integration details.

5.5.8 DMTIMER (Timer)

Table 5-62. DMTIMER Instances

Instances	WKUP Domain	MCU Domain	MAIN Domain
MCU_DMTIMER[9:0]		√	
DMTIMER[19:0]			√

5.5.8.1 DMTIMER (Timer) Unsupported Features

The DMTIMER (Timer) module features listed below are not supported by the integration on this device:

- Atomic 64-bit timer value read of cascaded timers

5.5.8.2 DMTIMER (Timer) Integration Details

Timer Resolution

The Timer resolution and interrupt period are dependent on the selected input clock and clock prescale value. Example resolutions for common clock values are shown in [Table 5-63](#).

Table 5-63. Timer Resolution and Maximum Range

Clock	Prescaler	Resolution	Interrupt Period Range
32.768 KHz	1 (min)	31.25 μ s	31.25 μ s to 36 hr, 35 mins
	256 (max)	8 ms	8 ms to 391 days, 22 hr, 48 mins
27 MHz	1 (min)	42 ms	42 ms to 179 sec
	256 (max)	10.67 μ s	10.67 μ s to 12 hr, 44 mins

Timer Cascading

Each odd numbered Timer instance within the MCU Domain may be optionally cascaded with the previous even numbered Timer instance to form an up to 64-bit timer.

- MCU_DMTIMER1 may be cascaded to MCU_DMTIMER0
- MCU_DMTIMER3 may be cascaded to MCU_DMTIMER2
- ...
- MCU_DMTIMER9 may be cascaded to MCU_DMTIMER8

Each odd numbered Timer instance within the MAIN Domain may be optionally cascaded with the previous even numbered Timer instance to form an up to 64-bit timer.

- DMTIMER1 may be cascaded to DMTIMER0
- DMTIMER3 may be cascaded to DMTIMER2

...

DMTIMER19 may be cascaded to DMTIMER18

When cascaded, MCU_DMTIMER_n acts as a 32-bit prescaler to MCU_DMTIMER_[n+1]. The MCU_DMTIMER_n must be configured to generate a PWM output edge at the desired rate to increment the MCU_DMTIMER_[n+1] counter. The same cascading rules apply for MAIN Domain DMTIMERS.

Timer IO Multiplexing

The Device provides 10 MCU_TIMERIO pins and 8 TIMERIO pins to be used as Timer Capture inputs or as Timer PWM outputs. In order to provide maximum flexibility, the 10 MCU_TIMERIO pins may be used with any of the 10 MCU_DMTIMER[9:0] instances, and the 8 TIMERIO pins may be used with any of the 20 DMTIMER[19:0] instances. System-level muxes configured in the CTRL_MMRs are used to control the capture source pin and PWM output source for each MCU_DMTIMER and DMTIMER instance.

5.5.9 DPHY_RX

Table 5-64. DPHY_RX Instances

Instances	WKUP Domain	MCU Domain	MAIN Domain
DPHY_RX[2:0]			√

5.5.9.1 DPHY_RX Unsupported Features

The DPHY_RX module features listed below are not supported by the integration on this device:

- Swapping of Clock & Data Lanes

5.5.9.2 DPHY_RX Integration Details

The DPHY_RX is a point-to-point connection to the CSI_RX interface.

5.5.10 DPHY_TX

Table 5-65. DPHY_TX Instances

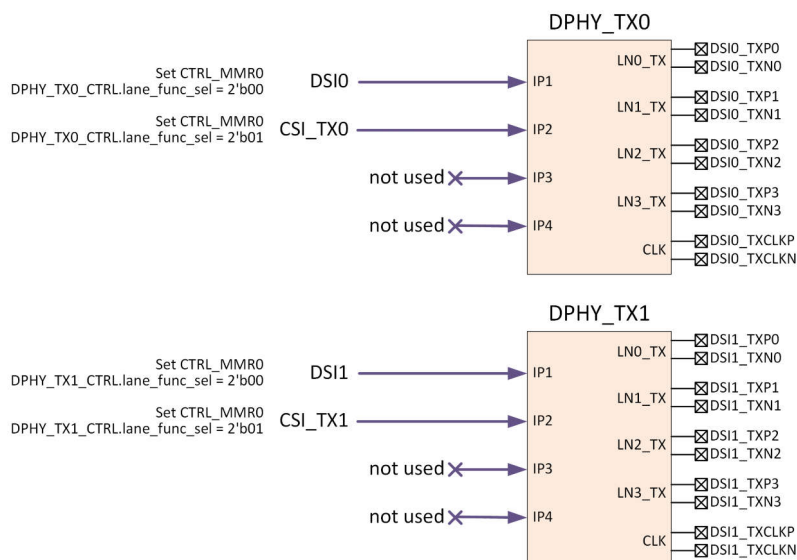

Instances	WKUP Domain	MCU Domain	MAIN Domain
DPHY_TX[1:0]			√

5.5.10.1 DPHY_TX Unsupported Features

The integration of the DPHY_TX module in this Device supports all module features.

5.5.10.2 DPHY_TX Integration Details

Each DPHY_TX provides the physical interface for either a MIPI DSI display or a MIPI CSI_TX video output. The output source is selected using the appropriate DPHY_TX_n_CTRL register in CTRL_MMR0.

5.5.11 DSS/DSI

Instance	WKUP Domain	MCU Domain	MAIN Domain
DSS			√
DSI[1:0]			√

5.5.11.1 DSS Unsupported Features

None.

5.5.11.2 DSI Unsupported Features

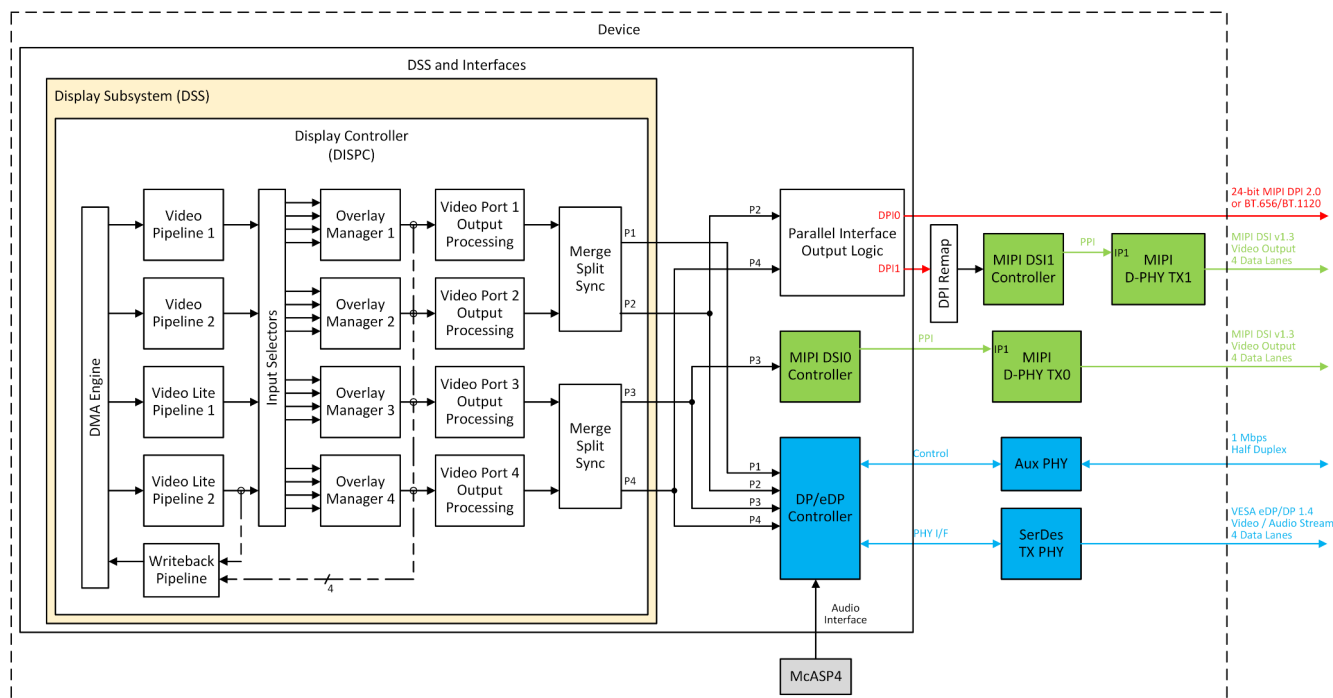

- DSI1 does not support 30-bit or 36-bit data
- DSI1 does not support security enforcement

5.5.11.3 DSS/DSI Integration Details

DSS7 is capable of driving multiple displays in parallel through a combination of interfaces:

- DPI Parallel Interface
- Up to two MIPI Display Serial Interface (DSI) ports
- One embedded Display Port (eDP) controller

The following diagram shows how the 4 video outputs (P[4:1]) of the DSS are mapped to the various display peripherals on the device. The DSS internal registers determine which of the display peripherals are allowed to output content at any time so that content protection is supported through the DSS built-in security capabilities.

5.5.11.3.1 DSS Pixel Clock Sourcing

Three PLLs (PLL16, PLL17, and PLL19) are allocated to the DSS for sourcing the pixel clocks (`dpi_[3:0]_in_clk.`) (See clocking chapter for details.) PLL16/PLL17 should be the primary high-resolution display `pclk` sources (e.g. enabling 2.5K or 4K display output). PLL19 is associated closely with the DPI0 port. When `dpi_1` or `dpi_3` is selected to drive the DPI0 port, the `dpi_0/3_in_clk` must be sourced from this PLL. When DPI0 is not enabled, PLL19 can be used to source the pixel clock of other display outputs.

The PLL19 clock source can alternatively be driven by an external pixel clock input pin. This allows the DSS DPI output to be generated in genlock with an external clock source. The external pixel clock source for PLL19 HSDIV0_CLKOUT is selected by setting MMR_CTRL0_DPI0_CLK_CTRL[EXT_CLKSEL]=1.

5.5.12 eCAP

Instance	WKUP Domain	MCU Domain	MAIN Domain
eCAP[2:0]			√

5.5.12.1 eCAP Unsupported Features

None.

5.5.12.2 eCAP Integration Details

Each eCAP capture event comes from a dedicated external pin which can optionally be configured as an asymmetrical PWM output.

The eCAP module timebases can be synchronized using sync input signals. The eCAP module synchronization signals are connected in a daisy-chain fashion allowing each eCAP to be synchronized to the previous instance in the chain. Additionally, eCAP0 can be hardware synchronized to the ePWM5 as shown in the synchronization detail below.

5.5.13 ePWM

Instance	WKUP Domain	MCU Domain	MAIN Domain
ePWM[5:0]			√

5.5.13.1 ePWM Unsupported Features

- High-resolution extension
- No on-chip digital comparators are provided. Module comparator high/low limit inputs for ePWMA/B are not used. Trip events are supported through TripZOne inputs.

5.5.13.2 ePWM Integration Details

Additional integration details for the ePWM modules on J7AEP and J7AHP are detailed in the following sections.

ePWM Synchronization

The ePWM SYNCI inputs allow the timebase (TBCNT) of an ePWM module to be synchronized with another ePWM module or other event. This allows the addition of lead/lag phase control to waveforms generated by the other ePWM module. On J7AEP/J7AHP, ePWM[2:0] SYNCI inputs are daisy-chained together to allow synchronization to each other or to an external SYNCI input pin. The ePWM[5:3] SYNCI inputs are also daisy-chained together and may be synchronized to a separate external SYNCI input pin, or to ePWM[2:0] as shown below:

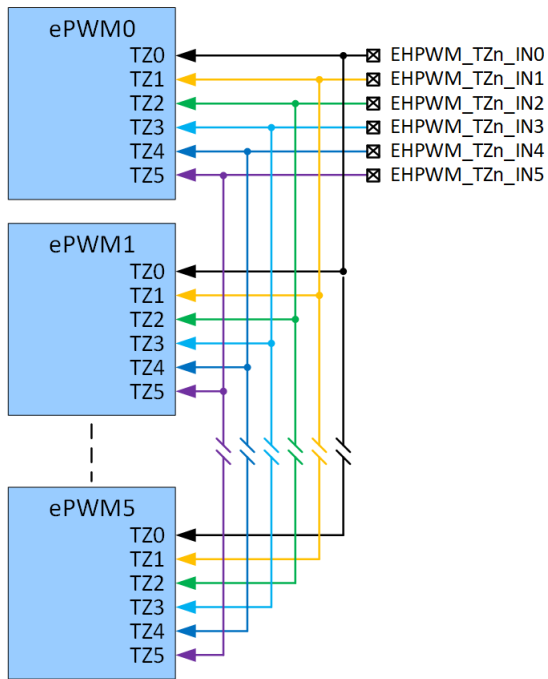

ePWM SOC Outputs

The ePWM modules provide Start of Conversion (SOCA, SOCB) events that can be used to trigger the on-chip ADCs or off-chip modules. On J7AEP/J7AHP, the SOCA and SOCB events from each ePWM module are ORed together allowing any of the 6 ePWMS to act as the SOCA or SOCB event generator:

ePWM Tripzone

Each ePWM supports 6 tripzone event inputs. On J7AEP/J7AHP, each tripzone input to all six ePWM modules are tied to a common TZn input pin allowing any ePWM trip event to be triggered by any of the six input pins.

ePWM Timebase Clock Synchronization

The ePWM modules include a timebase counter for pre-scaling the input clock to generate the TBCLK (timebase clock) used to clock the PWM. The timebase counter is enabled via the ePWM TBCLKEN input. This input is driven (high) through the associated CTRL_MMR0 PWM n _CTRL_tb_clken register bit (where n is the ePWM instance). In order for multiple ePWM module timebase counters to be started synchronously, the TBCLKEN inputs can also be driven by the CTRL_MMR0 SUP_CTRL7_epwm n _tb_clken bits. Using the SUP_CTRL7 register allows multiple ePWM TBCLKEN inputs to be enabled with a single register write. The two tb_clken sources are ORed together so that setting the bit in either location will enable the associated ePWM's timebase counter:

5.5.14 ESM

Instance	WKUP Domain	MCU Domain	Main Domain
WKUP_ESM0	√		
MCU_ESM0		√	
ESM0			√

5.5.14.1 ESM Unsupported Features

The integration of the ESM module in this WKUP and MAIN Domains supports all module features.

The ESM module features listed below are not supported by the integration in the MCU Domain on this Device:

- ERR_O output to a device pin (ERR_O is instead connected as an event to WKUP_ESM0), along with ERR_O output PWM Mode

5.5.14.2 ESM Integration Details

The ERR_O output of the MAIN Domain ESM0 drives the SOC_SAFETY_ERRORn pin directly to indicate a MAIN Domain safety error condition to an external device. The ESM0 ERR_O error output is also connected to the MCU_ESM0 as an error event input. Both Level and PWM Mode are supported on the SOC_SAFETY_ERRORn output signal if the ESM0 ERR_O is not monitored by MCU_ESM0. However, only Level Mode is allowed if the ESM0 ERR_O error signal is actively monitored by the MCU_ESM0 module.

The MCU_ESM0 ERR_O error output is connected to the WKUP_ESM0 as an error event input, but it is not directly connected to a Device pin. Only Level Mode is allowed for the MCU_ESM0 ERR_O error output.

The ERR_O output of WKUP_ESM0 drives the MCU_SAFETY_ERRORn pin directly to indicate a WKUP Domain safety error condition to an external device. This pin can also indicate MCU Domain and MAIN Domain safety error conditions via daisy-chaining of the Device ESM modules, provided that the Events corresponding to those daisy-chained ERR_O outputs are enabled.

[Figure 5-25](#) describes the integration of the ESM Modules in the Device.

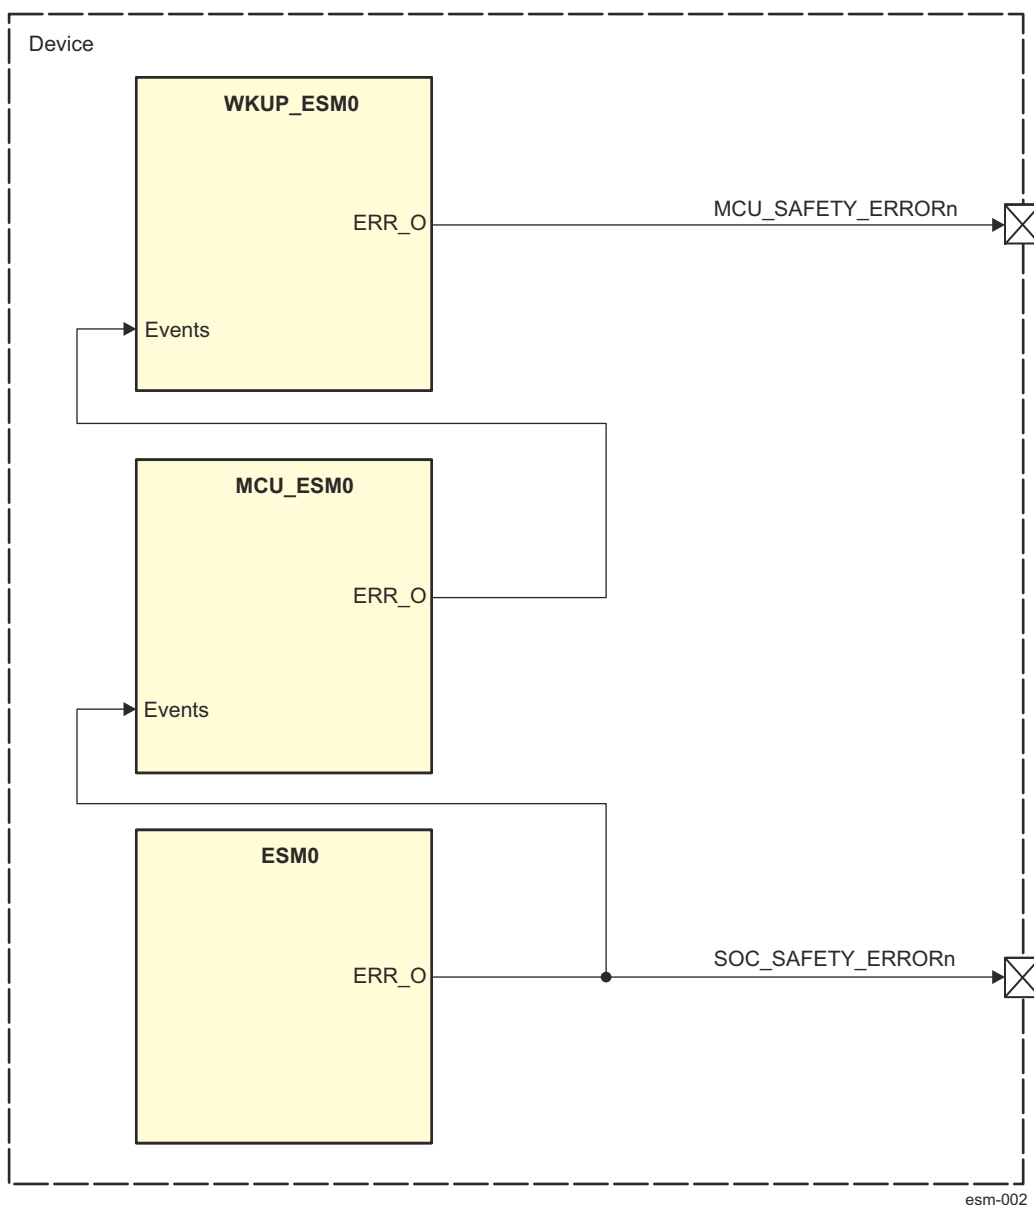

Figure 5-25. ESM Module Integration

5.5.15 FSS

There are no additional FSS integration details.

5.5.16 GPIO

Instance	WKUP Domain	MCU Domain	Main Domain
WKUP_GPIO[1:0]	√		
GPIO[6,4,2,0]			√

5.5.16.1 GPIO Unsupported Features

The GPIO module features listed below are not supported by the integration on this Device:

- Not all GPIOs are pinned out

5.5.16.2 GPIO Integration Details

GPIO Interrupts

All GPIO interrupts are mapped to a series of event multiplexing Interrupt Router (INTRTR) modules. These multiplexors allow any one of the available GPIO interrupts to be selected and passed on as an event to the various processor interrupt controllers and DMA controllers. Event selection is controlled through associated registers within each INTRTR.

The GPIO Bank interrupts represent a consolidation of all 16 GPIO interrupts associated with each bank. These are also selectable through the INTRTR event multiplexors and can be used to increase the total number of events available to a processor at the expense of full event granularity.

GPIO Multiplexing

The device has six instances of GPIO modules. The GPIO modules are integrated in two groups.

- Group one: WKUP_GPIO0 and WKUP_GPIO1. On I/O pins, this group is named WKUP_GPIO0.
- Group two: GPIO0, GPIO2, GPIO4, and GPIO6. On I/O pins, this group is named GPIO0.

The corresponding groups I/O pins are multiplexed within each group modules.

The GPIO pins are grouped into banks (16 pins per bank and 9 banks per module), which means that each GPIO module provides up to 144 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 288 (2 group instances x (9 banks x 16 pins)) I/O pins. Because WKUP_GPIOu_[89:143] (u = 0, 1), and GPIO n_[66:143] (n = 0, 2, 4, 6) are reserved in this device, general purpose interface supports up to 155 I/O pins.

GPIO Virtualization

The GPIO module does not support virtualization. Therefore, two or more physical GPIO modules are instantiated within the MAIN and WKUP Domains to provide virtualization and/or isolation of GPIO control between safety-critical and non-safety-critical subsystems. The Device maps each GPIO signal from each GPIO Module in a Domain to the same pins, allowing any of the GPIO Modules in the Domain to control the pin via the VGPISEL fields of the associated PADCONFIG registers. The GPIO interrupts/events are selected between the GPIO instances based on the same VGPISEL fields. The bank interrupts from the GPIO instances are not multiplexed.

Enabling GPIO as a Wakeup Source

During Device DeepSleep power saving mode, the GPIO functional clock is powered down. This would prevent the WKUP_GPIO module from detecting transitions on GPIO pins to be used as wakeup from DeepSleep events. In order to prevent this issue, special clocking and vbus control are implemented as part of the WKUP_GPIO integration to allow GPIO transition to remain detectable.

A clock mux is provided to allow the GPIO VBUS_CLK to be switched to an on-chip clock source prior to gating of the standard clock source (MCU_SYSCLK0/8) and power-down of the off-chip HFOSC0 oscillator. This clock mux is controlled by WKUP_CTRL_MMR0 register bits. Because there is no asynchronous bridge between the WKUP_GPIO module and the WKUP CBASS, the module register may only be accessed when it is clocked using the synchronous MCU_SYSCLK0/8 clock source. Prior to switching the clock source to prepare for DeepSleep, all VBUS accesses to the WKUP_GPIO module must be blocked through the dedicated LPSC using a clock stop request. Note that when wakeup functionality for the WKUP_GPIO is enabled, (through a

WKUP_CTRL_MMR bit), this clock stop request will not actually propagate to the WKUP_GPIO module (or stop its clock.) Instead, it will be fed back to the LPSC as a clock stop acknowledged. This will cause the associated WKUP_CBASS0 to route all future WKUP_GPIO register accesses to a null endpoint. The WKUP_GPIO LPSC must be maintained in CLKSTOP mode until MCU_SYSCLK0/8 is fully restored upon wakeup from DeepSleep and the WKUP_GPIO clock mux has finished switching back to the normal VBUS clock source.

The following are the steps required (expected to be performed by the SMS) to enable WKUP_GPIO wakeup events prior to DeepSleep entry:

- Determine which events are to be used for DeepSleep wakeup and enable the interrupts through the corresponding GPIO SET_RIS_TRIG and SET_FALL_TRIG registers. Disable non-wakeup interrupts through the corresponding CLR_RIS_TRIG and CLR_FALL_TRIG registers.
- Set the WKUP_GPIO_CTRL_wake_en bit in the WKUP_CTRL_MMR to enable DeepSleep LPSC operation.
- Disable further VBUS access to the WKUP_GPIO through the LPSC clock stop request.
- Change the WKUP_GPIO clock source to CLK_32K or CLK_12M_RC as desired by setting the WAKE_CLK_SEL field in the CTRL_MMR_WKUP_GPIO_CLKSEL register. (Wait at least one clock cycle of the new clock to ensure switch has occurred.)
- Perform normal DeepSleep entry routine (enable SMS wakeup events, clock gate MCU clocks, power down oscillators, etc.)

Once in deep sleep mode, any GPIO transition (low to high or high to low) intended to cause a wakeup must be maintain at its new value for at least 2 of the selected functional clock (CLK_32K or CLK_12M_RC) maximum periods to ensure proper detection. (Note that process variance of the RC clocks must be taken into account). The detected event will be latched in the GPIO INSTAT register and the gpio_lvl_intr wakeup event sent to the SMS to trigger the wakeup FSM.

After wakeup, the SMS must restore the MCU_SYSCLK0/8 operation to allow the wakeup source event to be latched within the SMS. Once this is done the SMS may restore access to the WKUP_GPIO module by reversing the steps above:

- Change the WKUP_GPIO clock source back to MCU_SYSCLK0/8 using the WKUP_GPIO_CLKSEL_clkssel bit in the WKUP_CTRL_MMR. (Wait at least 1 of the previously selected clock cycles to ensure glitch-free switch is complete.)
- Re-enable vbus access to the WKUP_GPIO through the LPSC clkstop request.

The specific GPIO source(s) of the wakeup event may be determined by reading the GPIO INSTAT register and cleared by writing 1's to the set bits of the same register.

5.5.17 GPMC

Instance	WKUP Domain	MCU Domain	MAIN Domain
GPMC0			√

5.5.17.1 GPMC Unsupported Features

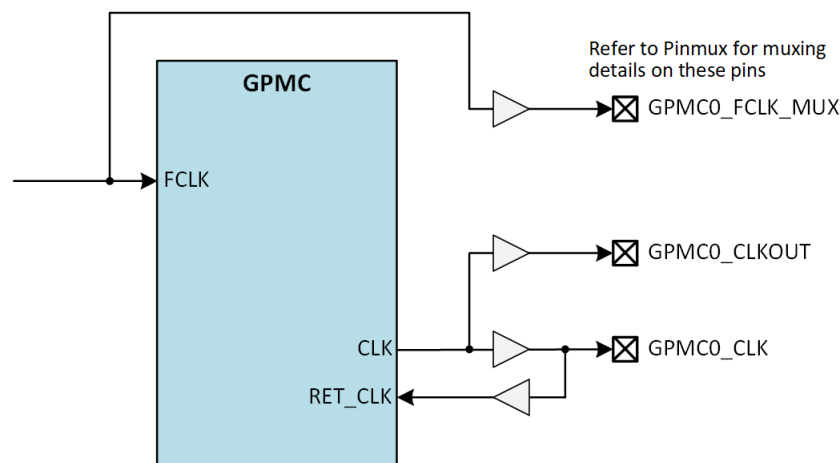

- 32-bit data path to external memory device (only 16 data lines are pinned out)
- Chip select regions 4-7 (only CS0-3 are pinned out)
- 28-bit memory device addressing (only A[24:0] are pinned out)
- DMA FIFO operation (FIFO operation may be controlled through interrupt synchronization only)

5.5.17.2 GPMC Integration Details

When using synchronous interface protocols, the GPMC_CLK output only toggles during the read or write access cycle. In some applications, it may be desirable to have a continuous clock running at the GPMC interface clock frequency for clocking attached devices. This option is enabled by an optional clock path from the GPMC functional clock input to the GPMC_CLKOUT pin. This clock output (GPMC_FCLK_MUX) can be selected through the standard MUXMODE selection of the GPMC_CLKOUT pin PADCONFIG control register. (See device Pin Muxing for details.).

Note that when using synchronous interface protocols with the continuous clock option described above, the programmer should ensure that the GPMC outputs are timed to the same frequency. (GPMC_CONFIG1_x

GPMCFCLKDIVIDER = 0). The GPMC_CLK is also output to two pads for signal integrity reasons. One pad is intended for board level use and one is for IO loopback.

5.5.18 GPU

Instance	WKUP Domain	MCU Domain	MAIN Domain
GPU0			√

5.5.18.1 GPU Unsupported Features

- No memory coherency is provided between the GPU and ARM72 or C7x processor cores.

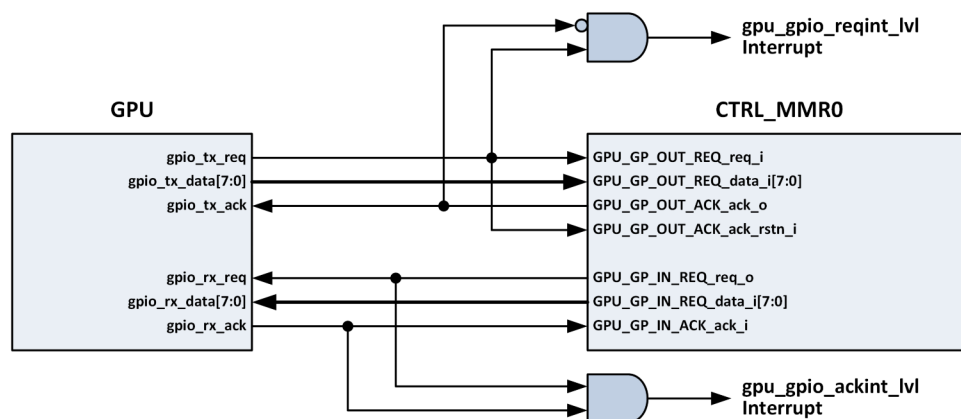

5.5.18.2 GPU Integration Details

GPU Firmware Processor General Purpose Interface Details

The Firmware Processor General Purpose Interface of the GPU allows for messages to be passed between the GPU and another processor Core on the SoC. The interface consists of two channels:

- Firmware Processor Transmit (Output) Channel
 - Data (8 bits) provided by GPU to another CPU on the SOC
 - Data transfers are initiated by the GPU asserting gpio_tx_req
 - Receipt of Data is Acknowledged by the other CPU asserting gpio_tx_ack
 - When the GPU receives the Acknowledge from the other CPU, it deasserts gpio_tx_req
 - When the other CPU sees gpio_tx_req deasserted, it deasserts gpio_tx_ack
- Firmware Processor Receive (Input) Channel
 - Data (8 bits) provided by another CPU to the GPU
 - Data transfers are initiated by the other CPU asserting gpio_rx_req
 - Receipt of Data is Acknowledged by the GPU asserting gpio_rx_ack

On J7AEP and J7AHP, the GPU's general purpose interface is exposed to each of the SoC CPUs through CTRLMMR0 registers with interrupt signaling in each direction:

GPU Firmware Transmit (output) Channel Operation

The GPU Transmit Channel allows the GPU firmware processor to send data to an external CPU on the SoC. It operates as follows (see diagram):

1. When the GPU Firmware Processor enters the 'send' state, it begins by driving gpio_tx_data[7:0] with valid data ('data1') and driving gpio_tx_req active. The GPU will drive these signals in the same GPU clock cycle. The firmware then transitions to the wait_ack state where it remains until it sees gpio_tx_ack asserted.
2. Assertion of the gpio_tx_req signal while gpio_tx_ack is low causes an interrupt request on gpu_gpio_reqint.
3. One of the other CPUs on the SoC responds to the interrupt by entering an ISR
4. As a result of the interrupt (shown here as within the ISR, but not required to be) the CPU reads from the GPU_GP_OUT_REQ register in the CTRL_MMIO module. The read returns the output data and the active state of the gpio_tx_req signal.
5. After reading the transmitted data, the CPU writes to the GPU_GP_OUT_ACK register to set the ack bit.
6. Setting GPU_GP_OUT_ACK_ack bit causes the gpio_tx_ack signal to be asserted.
7. The interrupt gpu_gpio_reqint interrupt is cleared by the assertion of gpio_tx_ack.
8. The GPU Firmware processor enters the 'end' state to terminate the transaction.
9. The GPU Firmware processor terminates the transaction by de-asserting gpio_tx_req. Valid data is no longer required to be output on gpio_tx_data[7:0]
10. The gpio_tx_req de-assertion resets the CTRL_MMIO GPU_GP_OUT_ACK_ack bit and clears the GPU_GP_OUT_REQ_req bit.
11. The GPU_GP_OUT_ACK_ack bit reset de-asserts the gpio_tx_ack signal completing the handshake and returning the GPU GPIO to the idle state from which a new transfer may begin.

GPU Firmware Receive (Input) Channel Operation

The GPU Receive Channel allows an external CPU on the SoC to send data to the GPU firmware processor. It operates as follows (see diagram):

1. The CPU must poll the GPU_GP_IN_ACK.ack bit for '0' at the beginning of the send operation, to ensure that the GPU has released the gpio_rx_ack signal. If this step is skipped and the GPU still has gpio_rx_ack asserted, then a gpu_rx_ackint interrupt will be sent to the CPU immediately before the GPU has read the GPIO data.
2. After verifying that gpio_rx_ack is de-asserted the CPU may continue the GPIO send process.
3. The CPU writes the send data in GPU_GP_IN_REQ_data[7:0] bits and sets the GPU_GP_IN_REQ_req bit.
4. The setting of the GPU_GP_IN_REQ.req bit causes the gpio_rx_req GPU input to be asserted.
5. The GPU Firmware processor sees gpio_rx_req asserted and enters the GPIO receive state.
6. The GPU Firmware processor reads the valid data from the gpio_rx_data[7:0] inputs
7. The GPU Firmware processor enters the GPIO ack state
8. The GPU Firmware processor acknowledges data read completion by asserting gpio_rx_ack which sets the GPU_GP_IN_ACK.ack bit.
9. The assertion of both gpio_rx_req and gpio_rx_ack activates the gpu_gpio_ackint interrupt
10. The enabled interrupt causes the CPU to enter into the ISR
11. In the ISR, the CPU clears the GPU_GP_IN_REQ_req bit
12. Clearing of GPU_IN_REQ_req de-asserts gpio_rx_req.
13. Upon gpio_rx_req de-assertion, the GPU Firmware processor enters the ackn state
14. The GPU Firmware processor deasserts the gpio_rx_ack signal.
15. De-assertion of gpio_rx_ack clears the GPU_GP_IN_ACK_ack bit enabling initiation of a new transfer
16. Shows that CPU must poll the GPU_GP_IN_ACK_ack bit for '0' at the beginning of the send operation, to ensure that the GPU has released the gpio_rx_ack signal. It must not set GPU_GP_IN_REQ.req here or an extra gpu_gpio_ackint will be generated.
17. Shows that the CPU has polled GPU_GP_IN_ACK_ack low and may begin a new transfer.

GPU Power Management

The GPU includes a power management control interface to allow the GPU integrated firmware processor to interact with the SoC power management solution in order to throttle GPU power during idle time. A general description of the power management procedure is as follows:

- The GPU Firmware processor initiates a power control operation by outputting the type, domain, and gpu mask values to indicate the type of request and activating the pwrctrl_req output. This generates a gpu_pwrctrl_req interrupt to the SoC Power Management (PM) processor.
- The PM processor reads the requested command from the associated GPU_PWR_REQ register.
- The PM processor will execute the requested Power Control request (through standard LPSC control processes).
- Upon completion of the command the PM processor will set the complete (if successful) or abort (if unsuccessful) bits of the associated GPU_PWR_ACK register.
- Upon receiving an active complete or abort input, the GPU Firmware processor will de-assert the pwrctrl_req output clearing the interrupt and clearing the GPU_PWR_ACK complete and abort bits.

5.5.19 I2C

Table 5-66. I2C Instances

Instances	WKUP Domain	MCU Domain	MAIN Domain
WKUP_I2C0	√		
MCU_I2C[1:0]		√	
MCSP[6:0]			√

5.5.19.1 WKUP_I2C0 Unsupported Features

The WKUP_I2C0 module features listed below are not supported by the integration on this device:

- SCCB protocol
- DMA mode

- Debug suspend mode request real time

5.5.19.2 MCU_I2C[1:0] Unsupported Features

The MCU_I2C[1:0] module features listed below are not supported by the integration on this device:

- SCCB protocol
- High speed (3.4 MBPS) operation not supported on MCU_I2C1
- Full I2C electrical compliance on MCU_I2C1, which is implemented using standard LVCMOS I/Os
- DMA mode
- Debug suspend mode request real time
- Clockstop Wakeup Interrupt Connected to DMSC, but instances are in an always on domain.

5.5.19.3 I2C[6:0] Unsupported Features

The I2C[6:0] module features listed below are not supported by the integration on this device:

- SCCB protocol
- High speed (3.4 MBPS) operation on I2C[6:1]
- Full I2C electrical compliance on I2C[6:1], which are implemented using standard LVCMOS I/Os
- DMA mode
- Debug suspend mode request real time

5.5.19.4 I2C Integration Details

WKUP_I2C0, MCU_I2C0, and I2C0 use a an I2C Open Drain Buffer that supports I2C High Speed Mode when operating at 1.8V. At 3.3V the IO does not operate in HS Mode nor does it enable its current source, regardless of the HSMODE and HSMCSE state. There is also a current source on the I2C Open Drain Buffers that will increase the rise time of the open-drain pin by actively pulling up the pin. This signal is controlled by an MMR bit because only one device (the HS Mode Master) may enable its pullup on SCL. The SDA pin uses the same I2C Open Drain Buffer, but the active pullup on SDA is never enabled.

The remaining I2C interfaces on the Device use a standard LVCMOS buffers rather than I2C Open Drain Buffers, and therefore do not support I2C High Speed Mode.

5.5.20 I3C

Instance	WKUP Domain	MCU Domain	Main Domain
MCU_I3C0		√	

5.5.20.1 I3C Unsupported Features

The I3C module features listed below are not supported by the integration on this Device:

- DMA service of I3C FIFOs
- Legacy I2C devices with true Open-Drain I/Os or emulated Open-Drain I/Os
- GPIO Interface

5.5.20.2 I3C Integration Details

I3C Clock Frequency

The MCU_I3C0 interface operates at the MCU R5FSS clock frequency /6 which is nominally 166 MHz. The recommended clock divider stings for the MCU_I3C0 instance based on this clock for the SDR/HDR-DDR push-pull mode are:

- I3C Effective clock frequency = 11.9 MHz
 - 166 MHz / 14
 - CTRL0_i3c value = 1
 - CTRL1_pp_low value = 3
 - Duty Cycle – 28.6% High
- I3C Effective clock frequency = 11.1 MHz
 - 166 MHz / 15
 - CTRL0_i3c value = 2

- CTRL1_pp_low value = 1
 - Duty Cycle – 40% High
- I3C Effective clock frequency = 10.4 MHz
 - 166 MHz / 16
 - CTRL0_i3c value = 3
 - CTRL1_pp_low value = 0
 - Duty Cycle – 50% High

5.5.21 LBIST

5.5.22 MCAN

Instance	WKUP Domain	MCU Domain	Main Domain
MCU_MCAN[1:0]		√	
MCAN[17:0]			√

5.5.22.1 MCAN Unsupported Features

The MCAN module features listed below are not supported by the integration on this Device:

- Debug DMA (Instead, debug messages can be read through the RX FIFO)
- TX DMA Channels 3-31 (Only TX DMA Channels 0-2 have associated PDMA channels)

5.5.22.2 MCAN Integration Details

There are no additional MCAN module integration details.

5.5.23 MMCSD

Instance	WKUP Domain	MCU Domain	MAIN Domain
MMCSD0 (8-bit)			√
MMCSD1 (4-bit)			√

5.5.23.1 MMCSD Unsupported Features

Note that MMCSD0 and MMCSD1 are actually two different IP modules. MMCSD0 IO is fixed at 1.8V for eMMC only. MMCSD1 supports both 1.8V and 3.3V IO and can be used for eMMC, SD, or SDIO interface.

- MMCSD1 does not pin out the SD Card busy LED control signal

5.5.23.2 MMCSD Integration Details

The MMCSD1 module interfaces directly to IO cells that support the SDIO standard. By default, these IOs are controlled by other functions muxed onto these pins. The MMCSD1 will need to be released from reset and an MMR (PHY_CTRL_1_REG) inside EMMCSD4 will need to be programmed to switch the final stage pin muxing before MMC1 may be used.

5.5.24 McASP

Instance	WKUP Domain	MCU Domain	MAIN Domain
McASP[4:0]			√

5.5.24.1 McASP Unsupported Features

- Direct Audio Muting functions (AMUTE and AMUTEIN signals are not pinned out)
- Full 16 channel support on all McASP instances. (Note that channel availability on any McASP instance ultimately a function of pin muxing selection)
 - 16 Channels on McASP1 (only 5 channels, AXR[4:0] are pinned out)
 - 16 Channels on McASP2 (only 5 channels, AXR[4:0] are pinned out)
 - 16 Channels on McASP3 (only 3 channels, AXR[2:0] are pinned out)
 - 16 Channels on McASP4 (only 5 channels, AXR[4:0] are pinned out)

5.5.24.2 McASP Integration Details

AHCLKX and AHCLKR Clock Sources

The McASP AHCLKX and AHCLKR inputs may be driven either by device clock input pins (those with associated AHCLK clock muxing) or by the ATL output clocks. The AHCLKX and AHCLKR outputs do not have

explicit output pins. Instead the device AUDIO_EXT_REFCLK[1:0] pins may be driven either by the associated McASP AHCLK outputs or by the ATL output clocks. See the clocking section for details.

Cross-McASP Synchronization using Frame Sync Feedback

In order to align frame syncs across McASPs that may be feeding DACs with different formats but the same frequency, the frame sync of McASP_x can be optionally fed into a receive data pin of McASP_y. The device includes a multiplexor to allow any McASP transmit or receive frame syn to be connected to receive channels 14 & 15 of any other McASP:

If this serializer is enabled as a receiver, then the frame sync of McASP_x will appear as receive data for McASP_y. For example, with both McASPs configured for 16-bit data, 2 slots, one might make the conclusions shown in the table below based on receive data. Note that the purpose here is not to actually 'receive' the accurate frame sync as data that is processed. Rather, it is to inspect the relative timing of the frame syncs, and then make an adjustment to the width of the bit clock of McASP_x until perfect (ex. #4 from Table 31-9) or good enough alignment (ex. #3, #5) is achieved.

To adjust the McASP transmit bit clock, the CLKADJ bits 17:16 of the ACLKXCTL register can be used to lengthen (write 2'b10) or reduce (write 2'b01) the McASP bit clock period in a one-shot fashion. After each adjustment the frame sync should be checked again and the process repeated until the two frame syncs are aligned. For example, if McASP_y frame sync is leading McASP_x frame sync, the expectation would be to write 2'b01 to McASP_x's CLKADJ bits, which will shorten one bit clock period of McASP_x and cause the next frame sync to occur one input clock cycle earlier (input clock to McASP internal transmit clock divider). This would be repeated until the two Frame Syncs are within optimal alignment.

This process is expected to be carried out once, before any audio transfers occur. It is not intended to be used for sample rate conversion but rather initial phase alignment of transmit data across McASPs. It should also be noted that exact alignment as represented in the table may not actually be ideal. For example, there may be filtering delay inside the DACs that are fed by the McASPs. If the filter delay between two DACs is different, an offset in alignment of the frame syncs may actually be what is needed to align the analog audio output across channels. One positive of this mechanism is that any arbitrary alignment of frame sync signals can be achieved to within +/- 1 bit clock by adjusting the target value for the "Received At McASP_y" column.

Sample	Received at McASP _y	Alignment Conclusion (assumes active low frame sync)
1	1110_0000_0000_0000_0001_1111_1111_1111	Frame Sync of McASP _y Leads Frame Sync of McASP _x Slightly
2	0000_0000_0000_0011_1111_1111_1111_1100	Frame Sync of McASP _y Lags Frame Sync of McASP _x Slightly
3	1000_0000_0000_0000_0111_1111_1111_1111	Frame Syncs are aligned to within +/- 1 Bit Clock
4	0000_0000_0000_0000_1111_1111_1111_1111	
5	0000_0000_0000_0001_1111_1111_1111_1110	

Enhanced Display Port Audio

Note that the eDP uses McASP4 AXR[3:0] exclusively to provide audio data to the DisplayPort interface. If the eDP function is not required, McASP4 is available for general usage.

5.5.25 McSPI

Table 5-68. McSPI Instances

Instances	WKUP Domain	MCU Domain	MAIN Domain
MCU_MCSPI[2:0]		√	
MCSPI[7:0]			√

5.5.25.1 MCSPI Unsupported Features

The MCSPI module features listed below are not supported by the integration on this device:

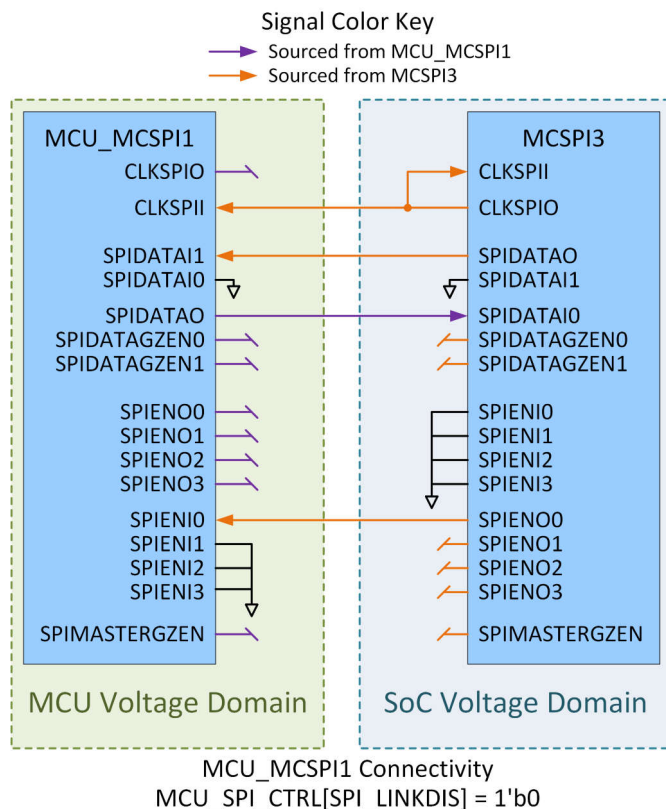

- Target mode wakeup
- Retention during power down
- MCU_MCSPI2 External pins
- MCSPI4 External pins and Initiator mode and Channels 1,2,3

5.5.25.2 MCSPI Integration Details

MAIN-MCU SPI Connectivity

The MCU_MCSPI1 and MCU_MCSPI2 modules include internal connectivity to the MCSPI3 and MCSPI4 modules in the MAIN SoC domain. By default, the MAIN MCSPI3 is connected as Initiator to MCU_MCSPI1 as Target. Alternatively, MAIN MCSPI3 and MCU_MCSPI1 can be pinned out externally. System-level muxes controlled by MCU_SPI1_CTRL[SPI1_LINKDIS], MCU_SPI1_CLKSEL[MSTR_LB_CLKSEL], and SPI3_CLKSEL[MSTR_LB_CLKSEL] allow MCU_MCSPI1 inputs to be controlled from either the I/O pin inputs or the MCSPI3 module.

When the MCU_SPI_CTRL[SPI1_LINKDIS] bit is 1'b0 (default), MCU_MCSPI1 is linked internally to MCSPI3, as shown below:

When the MCU_SPI_CTRL[SPI1_LINKDIS] bit is 1'b1, both MCU_MCSP1 and MCSPI3 operate independently using device pins. The device PINMUX must be appropriately programmed to select the desired MCSPI signal functions.

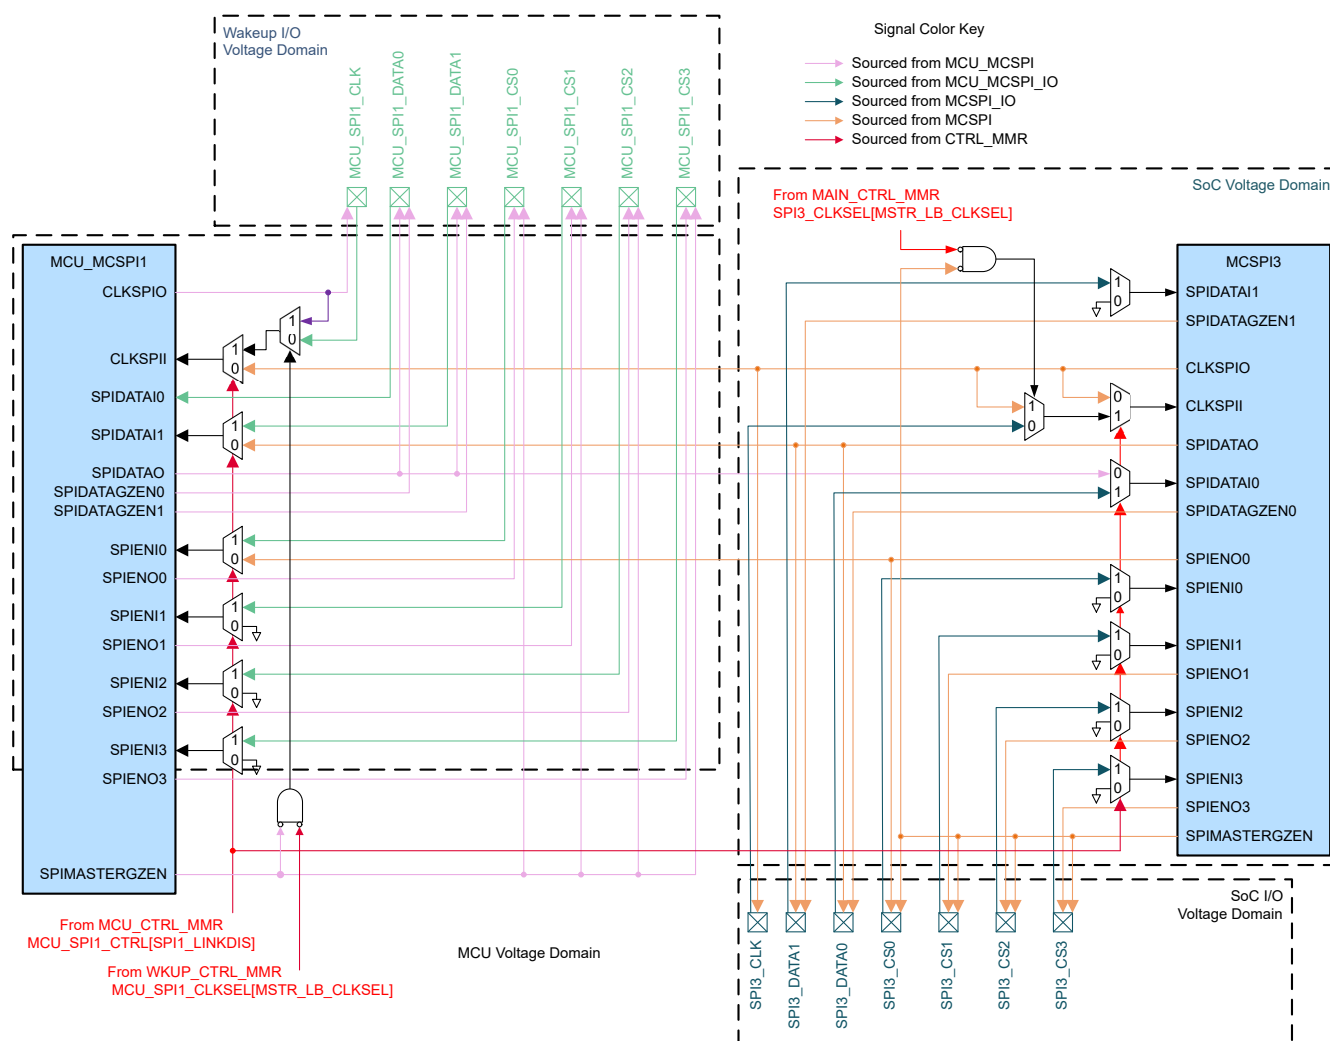

Figure 5-26. MCU_MCSP1 Connectivity Details

The MCU_MCSP12 and MCSPI4 modules are not pinned out externally, but MCSPI4 is connected directly as a Target to the MCU_MCSP12 module as an Initiator as shown in [Figure 5-27](#).

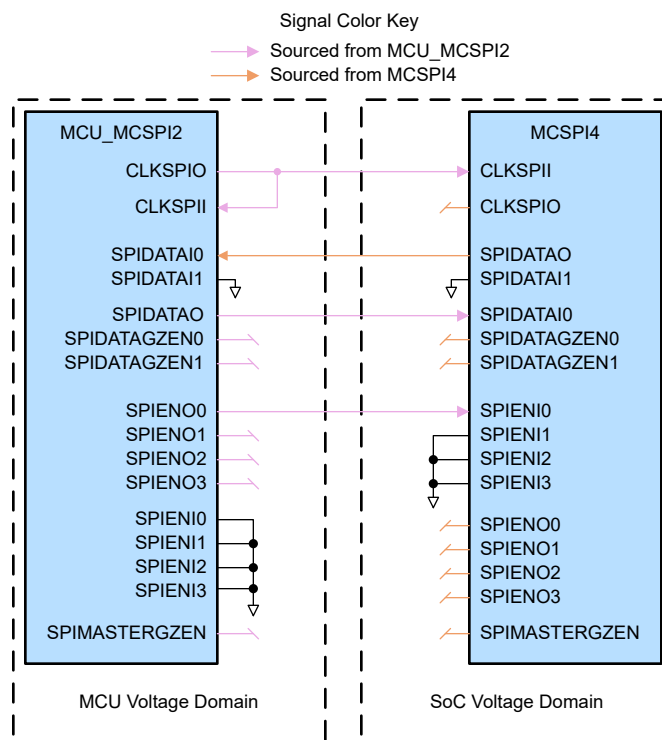

Figure 5-27. MCSPI4 Connectivity Details

5.5.26 Navigator Subsystem (NAVSS)

This section contains the integration details for the NavSS modules on this device. For Further information, see the *Navigator Subsystem (NAVSS)* section of the *Data Movement Architecture* chapter.

5.5.26.1 Module Allocations

Table 5-69. NAVSS Allocation within Device Domains

5.5.26.2.3 VBUSM Route ID Table

The VBUSM Master routelds are listed in [Table 5-72](#).

Table 5-72. VBUSM Route IDs

VBUSM Interface	Route Id(s)	Order Id(s)
MSMC0_MST	0-127	8-15
MSMC1_MST	255	0-15
NAV_DDR0		

Table 5-72. VBUSM Route IDs (continued)

VBUSM Interface	Route Id(s)	Order Id(s)
NAV_DDR1		
NAV_SRAM0		
NAV_SRAM1		
PROXY0	160	0-15
SEC_PROXY0	216	0-15
RINGACC0.DST	200	0-15
UDMA0.MEM0	168	0-15
UDMA0.MEM1	169	0-15
UDMA0.UMEMW	170	0-15
UDMA0.UMEMR	171	0-15

5.5.26.2.4 NAVSS Interrupt Router Configuration

The Interrupt Router is not configured with an INTD (no_intd = 1), it performs only interrupt muxing.

Please see the *Interrupts (inputs)* sheet of the Appendix Spreadsheet for the NAVSS Interrupt Router (NAVSS0_INTR_0) Input Mappings, and the *Interrupts (outputs)* sheet for the connections of the NAVSS Interrupt Router (NAVSS0_INTR_0) Outputs.

5.5.26.2.5 NAVSS Ring Accelerator Configuration

Each UDMA-P has an associated dedicated Ring Accelerator that is accessible by it alone (not accessible by other subsystems). The UDMA-P configuration is listed in [Table 5-73](#).

Table 5-73. RINGACC Configuration Parameters

Module Instance	Parameters		
	Ring Count	Number of Monitors	Proxy Target Base
NAVSS0_UDMASS_RINGACC0	1024	32	0x000038000000

[Table 5-74](#) shows the RINGACC ring mapping.

Table 5-74. RINGACC Ring Mapping

Mapping	Rings	Description
NAVSS0_UDMASS0_UDMAP0 Transmit	ring[340:0]	UDMAP0 Transmit Channels
NAVSS0_UDMASS0_UDMAP0 Receive	ring[422:341]	UDMAP0 Receive Channels
General Purpose	ring[767:423]	General-purpose rings
NAVSS0_SEC_PROXY0	ring[877:768]	SEC_PROXY0 rings
General Purpose	ring[1023:878]	General-purpose rings

5.5.26.3 MCU Navigator Subsystem (MCU NAVSS)

5.5.26.3.1 Global Event Map

The global event map for all navigator events is shown in [Table 5-70](#).

5.5.26.3.2 PSIL System Thread Map (All NAVSS)

Endpoints in MCU_NAVSS0 can be paired with NAVSS0 and visa versa as shown in [Table 5-71](#) (source/destination pairs). The configuration proxy in each subsystem can configure any endpoint in the map on either subsystem without restriction.

5.5.26.3.3 MCU NAVSS VBUSM Route ID Table

The VBUSM Master routelds are listed in [Table 5-75](#).

Table 5-75. MCU VBUSM Route IDs

VBUSM Interface	Route ID(s)	Order ID(s)
MSMC0_MST	0-127	8-15
MSMC1_MST	255	0-15
NAV_MCU_DST0		
PROXY0	3616	0-15
SEC_PROXY0	3640	0-15
RINGACC0.DST	3624	0-15
UDMA0.MEM0	3584	0-15
UDMA0.MEM1	3585	0-15
UDMA0.UMEMW	3586	0-15
UDMA0.UMEMR	3587	0-15

5.5.26.3.4 MCU NAVSS Interrupt Router Configuration

The Interrupt Router is not configured with an INTD (no_intd = 1), it performs only interrupt muxing.

See the *Interrupts (inputs)* sheet of the Appendix Spreadsheet for the MCU NAVSS Interrupt Router (MCU_NAVSS0_INTR_ROUTER_0) Input Mappings, and the *Interrupts (outputs)* sheet for the connections of the MCU NAVSS Interrupt Router (MCU_NAVSS0_INTR_ROUTER_0) Outputs.

5.5.26.3.5 MCU NAVSS UDMASS Interrupt Aggregator Configuration

Table 5-76. Interrupt Aggregators Parameters

Module Instance	Parameters				
	VINTR ⁽¹⁾	SEVI ⁽²⁾	GEVI ⁽³⁾	LEVI ⁽⁴⁾	MEVI ⁽⁵⁾
MCU_NAVSS0_UDMASS_INTR_AGGR 0	256	1536	256	12 (4 + 8 external)	128

- (1) VINTR – Number of Virtual Interrupt outputs. These are connected to the interrupt router inputs. Value can be read from INTA_INTCAP/UDMA_INTA_INTCAP register.
- (2) SEVI – Number of Main (Steerable) Events. Value can be read from INTA_INTCAP/UDMA_INTA_INTCAP register.
- (3) GEVI – Number of Countable Events. Value can be read from INTA_AUXCAP/UDMA_INTA_AUXCAP register.
- (4) LEVI – Number of Local Event inputs. Value can be read from INTA_AUXCAP/UDMA_INTA_AUXCAP register.
- (5) MEVI – Number of Multicast Events. Value can be read from INTA_AUXCAP/UDMA_INTA_AUXCAP register.

Note

4 local (LEVI) pulse interrupts are from the MCRC0 module.

If EVENT_PEND_INTR[3:0] needs to be converted to level interrupts, then UDMASS_INTR_AGGR0 can be used to generate events to the PSILSS. PSILSS would route events back to the interrupt aggregator to be turned into level output interrupts.

See the *Interrupts (inputs)* sheet of the Appendix Spreadsheet for the MCU NAVSS UDMASS Interrupt Aggregator (MCU_NAVSS0_UDMASS_INTA_0) Input Mappings, and the *Interrupts (outputs)* sheet for the connections of the MCU NAVSS UDMASS Interrupt Aggregator (MCU_NAVSS0_UDMASS_INTA_0) Outputs.

5.5.26.3.6 MCU NAVSS UDMA Configuration

Table 5-77 shows the UDMA configuration parameters in this SoC.

Table 5-77. UDMA Configuration Parameters

Module Instance	Parameters ⁽¹⁾				
	tchan_cnt	rchan_cnt	echan_cnt ⁽²⁾	hchan_cnt	rflow_cnt ⁽³⁾
MCU_NAVSS0_USMASS_UDM APO	48	48	0	2	96

- (1) Parameter values can be read from the capabilities registers. See CAP2 and CAP3 registers.
- (2) External UTC channel count

(3) Rx flow table entry count

5.5.26.3.7 MCU NAVSS Ring Accelerator Configuration

Each UDMA-P has an associated dedicated Ring Accelerator that is accessible by it alone (not accessible by other subsystems). The UDMA-P configuration is listed in [Table 5-78](#).

Table 5-78. RINGACC Configuration Parameters

Module Instance	Parameters		
	Ring Count	Number of Monitors	Proxy Target Base
MCU_NAVSS0_UDMASS_RINGACC0	286	32	0x00002B000000

[Table 5-79](#) shows the RINGACC ring mapping.

Table 5-79. RINGACC Ring Mapping

Mapping	Rings	Description
MCU_NAVSS0_UDMASS_UDMAP0 Transmit	ring[47:0]	48 UDMA_P0 transmit channels
MCU_NAVSS0_UDMASS_UDMAP0 Receive	ring[95:48]	48 UDMA_P0 receive channels
General purpose	ring[255:96]	General-purpose rings
MCU_NAVSS0_SEC_PROXY0	ring[285:256]	SEC_PROXY0 rings

Note

For Ring Accelerator functional description, see *Ring Accelerator*.

[Table 5-80](#) shows the MSRAM configuration parameters set during SoC design. MSRAM0 is accessible only from the secure proxy (dst) and ring accelerator (DST port). MSRAM1 is accessible only from the ring accelerator (DST port).

Table 5-80. MSRAM Configuration Parameters

Module Instance	Parameters		
	Depth	Width	Base Address
MCU_NAVSS0_UDMASS_MSRAM0	3594	64	0x000028000000
MCU_NAVSS0_UDMASS_MSRAM1	4096	64	0x000028010000

5.5.26.3.8 MCU NAVSS Proxy Configuration

[Table 5-81](#) shows the Proxy configuration parameters set during SoC design.

Table 5-81. Proxy Configuration Parameters

Module Instance	Parameters				
	Proxies ⁽¹⁾	Buffer Size ⁽²⁾	Target	Channels ⁽³⁾	Sizes ⁽⁴⁾
MCU_NAVSS0_PROXY0	64	256	MCU_NAVSS0_RINGACC0	286	4096

(1) Number of proxy threads supported. Can be read off from the CONFIG read-only register

(2) Number of bytes per proxy buffer

(3) Number of channels for the target

(4) Number of bytes per channel supported for the target

Note

For Proxy functional description, see *Proxy*.

5.5.26.3.9 MCU NAVSS Secure Proxy Configuration

[Table 5-82](#) shows the Secure Proxy configuration parameters set during SoC design.

Table 5-82. Secure Proxy Configuration Parameters

Module Instance	Parameters				
	Proxies ⁽¹⁾	Message Size ⁽²⁾	Target	Channels ⁽³⁾	Sizes ⁽⁴⁾
MCU_NAVSS0_SEC_PROXY0	90	64	MCU_NAVSS0_RING ACC0	30	4096

- (1) Number of proxy threads supported. Can be read off from the CONFIG read-only register
 (2) Number of bytes per message. Can be read off from the CONFIG read-only register
 (3) Number of channels for the target
 (4) Number of bytes per channel supported for the target

Note

For Secure Proxy functional description, see *Secure Proxy*.

5.5.26.4 Block Copy DMA (BCDMA)

This section contains the integration details for the BCDMA module on this device. For Further information, see the *Block Copy DMA (BCDMA)* section of the *Data Movement Architecture* chapter.

5.5.26.4.1 Features Not Supported

The following features are not supported on this family of devices:

- The BCDMA instance does not have any Block-Copy only channels
- BCDMA channels cannot be used with any generic peripherals, they are dedicated for CSI-Rx and CSI-Tx only

5.5.26.4.2 Module Allocations

Table 5-83. BCDMA Allocation Across Device Domains

Instance	WKUP Domain	MCU Domain	Main Domain
NAVSS0_BCDMA0	-	-	√ (NAVSS)

5.5.26.4.3 BCDMA Configuration

Table 5-84 shows the UDMA configuration parameters in this SoC.

Table 5-84. BCDMA Configuration Parameters

Module Instance	Parameters ⁽¹⁾					
	tchan_cnt ⁽²⁾	rchan_cnt ⁽³⁾	echan_cnt ⁽⁴⁾	hchan_cnt ⁽⁶⁾	uchan_cnt ⁽⁷⁾	rflow_cnt ⁽⁵⁾
NAVSS0_BCDMA0	0	32	16	0	0	0

- (1) Parameter values can be read from the capabilities registers. See UDMA_CAP2 and UDMA_CAP3 registers.
 (2) Total internal Tx channel count (Normal- + High- + Ultra-high capacities)
 (3) Total internal Rx channel count (Normal- + High- + Ultra-high capacities)
 (4) External UTC channel count
 (5) Rx flow table entry count
 (6) High-capacity + Ultra-high capacity channel count
 (7) Ultra-high capacity channel count

5.5.27 PBIST

5.5.28 PCIE

Table 5-188. PCIE Instances

Instances	WKUP Domain	MCU Domain	MAIN Domain
PCIE[3:0]			√

5.5.28.1 PCIE Unsupported Features

The PCIE module features listed below are not supported by the integration on this device:

- Address translation services (ATS)
- Quality of Service
- x4 link on PCIE[3:2], since only 2 lanes on each have SerDes connections

5.5.28.2 PCIE Integration Details

See "Serializer/Deserializer (SerDes)" for PCIE connections to SerDes in this Device.

5.5.29 R5FSS

Instance	WKUP Domain	MCU Domain	Main Domain
MCU_R5FSS[0]		√	
R5FSS[2:0]			√

5.5.29.1 R5FSS and MCU_R5FSS Unsupported Features

The MCU_R5FSS module features listed below are not supported by the integration on this Device:

- VBUSM Peripheral Port
- VBUSM Virtual Peripheral Port

The integration of the R5FSS modules in this Device supports all module features.

5.5.29.2 MCU_R5FSS Integration Details

Requirements for Changing PULSAR Clock Frequency

MCU_R5FSS supports either 1 GHZ or 333 MHz for its core speed, and the interface clock is fixed at 333MHz. Core frequency switching between 1 GHZ and 333 MHz is controlled through a CTRL_MMR bit to change the core to interface clock ratio from 3:1 to 1:1. The below software sequence shall be followed to prevent clock misalignment:

1. Place the R5 cores in WFI mode. (Alternatively, the MCU_R5FSS power domain can be powered down.)
2. Change the core to interface clock ratio by modifying the associated CTRL_MMR register.
3. Generate an interrupt to the R5 cores to release them from WFI mode (If alternate Step 1 method was used, Power up MCU_R5FSS domain, and follow the MCU bring up sequence based on split or lock-step mode.)

5.5.29.3 R5FSS Integration Details

The R5FSS has two physical and three logical low latency peripheral ports:

- VBUSM Peripheral Port - Split logically into Normal and Virtual Ports
- VBUSP Peripheral Port

The CPU requires the Virtual Peripheral Port to be mapped to a subset of (or complete) range of the Normal Peripheral Port. The Virtual Peripheral Port is disabled by default, and must be enabled by a System Control Coprocessor register write.

On this Device, the Virtual Peripheral Port is mapped to the same base address and size of the normal peripheral port. Although possible, the user should not enable the virtual peripheral port because the virtual port supports fewer (3 versus 15) outstanding writes, and enabling it will impact performance.

Interrupt outputs: FPIXcm, FPUFCm, FPOFCm, FPDZCm, FPIDcm, and FPIOcm from R5F are not connected. Consequently, the only way to check the status of the cumulative exception status flags is by reading the FPSCR register.

5.5.30 RAT

5.5.30.1 RAT Integration Details

5.5.30.1.1 RAT Source IDs

Each RAT (Region Address Translation) instance is assigned a unique 16-bit RAT Source ID Value to identify the transaction source of any exception which may occur.

The following table shows the RAT source ID mapping associated with the EXCEPTION_LOGGING_HEADER0[23-8] SRC_ID field for each RAT module.

Module Instance	Source ID Value (Decimal)
MCU_ARMSS0_CPU0	2
MCU_ARMSS0_CPU1	3
R5FSS0_CORE0	4
R5FSS0_CORE1	5
R5FSS1_CORE0	6
R5FSS1_CORE1	7
R5FSS2_CORE0	80

Module Instance	Source ID Value (Decimal)
R5FSS2_CORE1	81

5.5.31 RTI

Instance	WKUP Domain	MCU Domain	Main Domain
MCU_RTI[1:0]		√	
R5FSS[33:28,19:15,7:0]			√

5.5.31.1 RTI Unsupported Features

The RTI module features listed below are not supported by the integration on this Device:

- Analog watchdog timer
- External clock supervision
- Periodic interrupt / DMA events

Only the Digital Windowed Watchdog function of the RTI should be used.

5.5.31.2 RTI Integration Details

The Main domain instances of the RTI module are intended to function as a Digital Windowed Watchdog for the CPU core that they are associated with in [Table 5-191](#). It is not intended to use an RTI that is provisioned for a particular CPU core with a different CPU core.

Table 5-191. RTI Integration

RTI Instance	Associated CPU
RTI0	A72SS0_CORE0
RTI1	A72SS0_CORE1
RTI2	A72SS0_CORE2
RTI3	A72SS0_CORE3

6.2 Quad-A72 MPU Subsystem

This section describes the Quad-A72 Microprocessor Unit (MPU) Subsystem (A72SS) in the device.

6.2.1 A72SS Overview

6.2.1.1 A72SS Introduction

The device implements two Quad-core Arm® Cortex®-A72 MPU, which is integrated inside the Compute Cluster, along with other modules. The Cortex-A72 cores are general-purpose processors that can be used for running customer applications.

The A72SS is built around the Arm Cortex-A72 MPCore (A72 cluster), which is provided by Arm and configured by TI. It is based on the symmetric multiprocessor (SMP) architecture, and thus it delivers high performance and optimal power management and debug capabilities.

The A72 processor is a multi-issue out-of-order superscalar execution engine with integrated L1 instruction and data caches, compatible with Armv8-A architecture. The Armv8-A architecture brings a number of new features. These include 64-bit data processing, extended virtual addressing and 64-bit general purpose registers.

The A72 processor features an in-order, 8-stage, dual-issue pipeline, and improved integer, Arm Neon™, Floating-Point Unit (FPU) and memory performance. It supports two execution states: AArch32 and AArch64. The AArch64 state gives the A72 CPU its ability to execute 64-bit applications, while the AArch32 state allows the processor to execute existing Armv7-A applications.

For more details on the Compute Cluster and its internal architecture, see *Compute Cluster*.

6.2.1.2 A72SS Features

Each Quad-A72 Cluster in the A72SS supports the following key features:

- Arm Quad-A72 Cluster (Cortex-A72 MPCore) level features:
 - A72 CPU
 - Full Armv8-A architecture compliance
 - AArch32 and AArch64 execution states
 - AArch32 for full backward compatibility with Armv7
 - AArch64 for 64b support and new architectural features
 - All exception levels EL0-3
 - A32 instruction set (previously Arm instruction set)
 - T32 instruction set (previously Thumb instruction set)
 - A64 instruction set
 - Advanced SIMD and floating point extensions (Neon)
 - Armv8 cryptography extensions
 - Superscalar, variable length, out-of-order pipeline
 - Dynamic branch prediction with Branch Target Buffer (BTB) and Global History Buffer (GHB) RAMs, return stack, and indirect predictor
 - A72 L1/L2 cache memory and MMU
 - 48-entry, fully associative, L1 instruction TLB with native support for 4KB, 64KB, and 1MB page sizes
 - 32-entry, fully associative, L1 data TLB with support for 4KB, 64KB, and 1MB page sizes
 - 4-way, set associative, unified 1K entry L2 TLB per processor
 - 48KB L1 Instruction Cache per processor with parity protection
 - 32KB L1 Data Cache per processor with ECC protection
 - 2MB Shared L2 Cache with ECC protection
 - Arm GICv3 architecture
 - Generic timers
 - Debug
 - Arm CoreSight™ architecture
 - Embedded Trace Macrocell (ETM)
 - Performance Monitor Unit (PMUv3 architecture)
- TI A72SS subsystem level features:
 - 512-bit wide, asynchronous VBUSM.C master interface

- AXI2VBUSM_MASTER bridge
- Cache pre-warming via use of ACP port
- Timebase input interfaces
 - 64-bit graycoded global time
 - 48-bit graycoded debug time
- 32-bit VBUSP slave interface for debug (internally converted to APB)
- 32-bit ATB output port for debug/trace
- Interface with Arm GIC-500 interrupt controller
- Support for ECC on internal RAMs via ECC aggregators
- SoC level features:
 - Supports the SoC multi-core cache coherency architecture
 - Dedicated A72SS clocking (Arm PLL) for full flexibility in performance trade-offs
 - Advanced power management with fine-grained control of individual A72 CPU power domains, coarse grained cluster-level power management, and low-power standby modes (WFI/WFE modes)
 - Dedicated RTI windowed watchdog timer per core

6.2.2 A72SS Functional Description

6.2.2.1 A72SS Block Diagram

Figure 6-2 shows the block diagram of the A72SS subsystem.

Figure 6-2. A72SS Block Diagram

6.2.2.2 A72SS A72 Cluster

The A72 cluster is provided by Arm and configured by TI. Table 6-2 summarizes the configuration of the A72 cluster for this device.

Table 6-2. A72 Cluster Configuration

Parameter	Value
Core type	A72 ⁽¹⁾
Number of cores	2
Bus width	512
L1 instruction cache size	48K
L1 data cache size	32K
L2 cache size	2MB
ECC protection for L2 cache	Included
ECC/parity protection for CPU cache	Included
Advanced SIMD and Floating Point Extension	Included
Cryptography extension	Included
L2 FEQ size	28

(1) The A72 core revision used in this device is r1p0.

6.2.2.3 A72SS Interfaces and Async Bridges

The A72SS has the following main interfaces:

- 512-bit wide VBUSM.C master interface

- Supported by AXI2VBUSM_MASTER Bridge, which performs the following primary functions (among others):
 - Provides an asynchronous voltage domain crossing boundary for the AXI ACE master and ACP slave ports
 - Provides protocol conversion between AXI ACE (128-bit) and CBA VBUSM.C (512-bit)
 - Provides support for cache pre-warming
- 64-bit graycoded system input time
 - Graycode value provided by Global Timebase Counter (GTC)
 - Dedicated decoder (64-bit input) for graycode-to-binary conversion
- 48-bit graycoded debug input time
 - Graycode value provided by GTC
 - Dedicated decoder (48-bit input) for graycode-to-binary conversion
- 32-bit VBUSP slave interface for configuration of ECC aggregators
- 32-bit VBUSP slave interface for debug
 - Supported by VBUSP2APB Bridge, which performs VBUSP-to-APB conversion (for controlling the Arm A72 Cluster internal debug logic)
- 32-bit ATB output port for debug/trace
 - Supported by ATB Bridge, which performs clock and voltage level conversion on the combined ATB interface
 - Connected to the Debug Subsystem
- Cross Trigger Interface (CTI) for debug
 - Connected to the Debug Subsystem
- Interface(s) with Arm GIC-500 Interrupt Controller
 - Supported by GIC AXI Streaming Bridge, which performs clock and voltage level conversion on the AXI streaming protocol
 - Interrupts (PPIs) from Arm A72 Cluster to GIC-500
 - Interrupts (IRQ, FIQ, VIRQ, VFIQ) from GIC-500 to Arm A72 Cluster
- Power/clock interface(s)
 - Dedicated PLL for each Arm A72 Cluster
 - Dedicated LPSC for each Arm A72 Cluster, and also for each A72 core

6.2.2.4 A72SS Interrupts

6.2.2.4.1 A72SS Interrupt Inputs

The A72 CPU receives interrupts at its inputs (IRQ, FIQ, VIRQ, VFIQ) via the dedicated Arm GIC-500 Interrupt Controller which is integrated inside the Compute Cluster and is tightly-coupled to the A72. The GIC-500 supports both A72 cores in the system. The GIC-500 is compliant to the Arm GICv3 specification and supports four types of interrupts:

- *Software Generated Interrupts (SGI)*
 - There are 16 SGIs (ID0-ID15)
 - These are inter-processor interrupts
- *Private Peripheral Interrupts (PPI)*
 - There are 16 PPIs (ID16-ID31)
 - These are wired interrupts dedicated to a specific CPU
 - Many are reserved to specific functions via convention
- *Shared Peripheral Interrupts (SPIs)*
 - There are 960 SPIs (ID32-ID991)
 - These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GIC-500
- *Locality-Specific Peripheral Interrupts (LPI)*
 - There are 57344 LPIs
 - These interrupts are used for message-based interrupts from a peripheral

The mapping of PPIs and SPIs to the GIC-500 interrupt inputs can be found in TBD.

Note

For a brief list of features supported by the GIC-500 module, see *Generic Interrupt Controller (GIC)*.
For detailed description of the GIC-500 module, see the *Arm® CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

6.2.2.4.2 A72SS Interrupt Outputs

Table 6-3 lists the interrupts generated by the A72SS

Table 6-3. A72SS Interrupt Outputs

TI Interrupt Name ⁽¹⁾	Arm Interrupt Name	Interrupt Description
A72 Core Interrupts (PPIs)⁽²⁾		
A72SS0_VCPUMNTIRQy_0	nVCPUMNTIRQ	This interrupt indicates that a virtual CPU interface on the corresponding core needs serviced. This interrupt is serviced by software switching to the virtual CPU and finding what specific service needs done.
A72SS0_CNTHPIRQy_0	nCNTHPIRQ	This interrupt indicates a physical timer event at the EL2 (hypervisor) exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL2 and service accordingly.
A72SS0_CNTPNSIRQy_0	nCNTPNSIRQ	This interrupt indicates a physical timer event at the EL1 non-secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 non-secure and service accordingly.
A72SS0_CNTPSIRQy_0	nCNTPSIRQ	This interrupt indicates a physical timer event at the EL1 secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 secure and service accordingly.
A72SS0_CNTVIRQy_0	nCNTVIRQ	This interrupt indicates a virtual timer event. Service of this interrupt is dependent on what the timer was set for. Software should take exception and service accordingly.
A72SS0_PMIIRQy_0	nPMIIRQ	This interrupt is generated by the Performance Monitor Unit (PMU). The PMU can generate an interrupt based on several conditions, depending on programming. Software should take exception and query the PMU as to the cause of the interrupt, and act accordingly.
A72SS0_COMMIRQy_0	nCOMMIRQ	Communications channel receive or transmit interrupt
A72SS0_CTIIRQy_0	CTIIRQ	Cross Trigger Interface (CTI) interrupt
A72 Cluster Interrupts		
A72SS0_EXTERRIRQ_0	nEXTERRIRQ	This error indicates that an error has occurred on the memory bus. It is considered an external abort (or asynchronous error), because it cannot be attributed to a specific instruction. Depending on the system, software may try to recover, or reset the system.
A72SS0_INTERRIRQ_0	nINTERRIRQ	This error indicates an unrecoverable error in the cache system (L1 or L2 data RAM, L2 tag RAM, or SCU L1 duplicate tag RAM). It is considered an external abort (or asynchronous error), because it cannot be attributed to a specific instruction. Depending on the system, software can try to recover, or reset.

(1) In this column, y is the A72 core index (0 or 1)

(2) These are *per core* interrupts

Note

The mapping of these interrupts in the system is summarized in *A72SS Integration*, and can also be found in *Interrupts*.

For more detailed description of these interrupts and their handling, see the *Arm® Cortex®-A72 MPCore Processor Technical Reference Manual*.

6.2.2.5 A72SS Power Management, Clocking and Reset

6.2.2.5.1 A72SS Power Management

The A72 cluster and each A72 CPU reside in a separate power domain, as follows:

- PD14 (PD_A72_CLUSTER_0): Power domain of A72 cluster
- PD15 (PD_A72_0): Power domain of A72SS0_CORE0
- PD16 (PD_A72_1): Power domain of A72SS0_CORE1
- PDxx (PD_A72_2): Power domain of A72SS0_CORE2
- PDxx (PD_A72_3): Power domain of A72SS0_CORE3

There is a dedicated Local Power Sleep Controller (LPSC) for the A72 cluster and for each A72 core, as well. The LPSC assignment is as follows:

- LPSC78 (LPSC_A72_CLUSTER_0): Dedicated for A72 cluster
- LPSC80 (LPSC_A72_0): Dedicated for A72SS0_CORE0
- LPSC81 (LPSC_A72_1): Dedicated for A72SS0_CORE1
- LPSCxx (LPSC_A72_2): Dedicated for A72SS0_CORE2
- LPSCxx (LPSC_A72_3): Dedicated for A72SS0_CORE3

For more details on these LPSCs, including power-up/down sequences, see *Power*.

6.2.2.5.2 A72SS Clocking

There is a dedicated PLL for the A72 cluster: cluster_0: PLL8 (ARM0 PLL), cluster_1: PLL9 (ARM1 PLL). For more details on this PLL, see *Clocking*.

6.2.2.6 A72SS Debug Support

The A72SS supports the standard Arm CoreSight debug architecture. Details on Arm debug can be found *On-chip Debug*, and the relevant Arm specifications.

6.2.2.7 A72SS Timestamps

The A72SS has two timebase input interfaces:

- 64-bit global timestamp: Used for synchronizing the Arm internal timers. This is done via the Arm CNTVALUEB[63:0] bus
- 48-bit debug timestamp: Can be embedded in Arm trace streams at periodic and strategic locations, allowing the temporal relationship of different trace sources to be determined

Both of them are fed by the Global Timebase Counter (GTC), which provides a 64-bit graycode value. The MPU includes two graycode decoders (for global time and debug time, respectively), which take the asynchronous graycoded times, synchronize them to the appropriate clock, and convert them to binary time, as required by Arm.

Note

Both graycode decoders are 64-bit but the one dedicated to debug time has a 48-bit input (the upper 16 bits are tied to 0).

For more details on the GTC, see *Global Timebase Counter (GTC)*.

6.2.2.8 A72SS Watchdog

The A72SS does not have an integrated watchdog timer. Instead, this feature is provided externally by the Real Time Interrupt (RTI) module, which implements a windowed watchdog timer capable of issuing warm reset to the SoC, when necessary.

There are two RTI modules in the MAIN domain that are assigned to the A72 cores:

- RTI0 used as windowed watchdog for A72SS0_CORE0
- RTI1 used as windowed watchdog for A72SS0_CORE1

For more details on the RTI windowed watchdog feature, see *Real Time Interrupt Module (RTI)*.

6.2.2.9 A72SS Internal Diagnostics

The A72SS integrates three ECC aggregators for internal diagnostics and to stimulate errors in associated RAMs for ECC testing purposes:

- A72SS0_CORE0_ECC_AGGR: ECC aggregator for A72SS0_CORE0 level

- A72SS0_CORE1_ECC_AGGR: ECC aggregator for A72SS0_CORE1 level
- A72SS0_CLUSTER_ECC_AGGR: ECC aggregator for A72_CLUSTER (L2) level

6.2.2.9.1 A72SS ECC Aggregators During Low Power States

When a CPU core is in WFI/WFE, the corresponding CPU ECC aggregator MMR region is not accessible and will return error status. Similarly, when L2 is in WFI, the L2 ECC aggregator MMR region is not accessible and will return error status.

6.2.2.9.2 A72SS CBASS Diagnostics

A72SS0_CORE0_ECC_AGGR integrates all the SVBUS slave endpoints for A72SS0_CORE0.

Table 6-4. A72SS0_CORE0_ECC_AGGR RAM ID Mapping for Interface Diagnostics

Endpoint	Memory ID	Controller
A72SS0_CORE0	24	EDC controller for A72SS0_CORE0_ECC_AGGR

A72SS0_CORE1_ECC_AGGR integrates all the SVBUS slave endpoints for A72SS0_CORE1.

Table 6-5. A72SS0_CORE1_ECC_AGGR RAM ID Mapping for Interface Diagnostics

Endpoint	Memory ID	Controller
A72SS0_CORE1	24	EDC controller for A72SS0_CORE1_ECC_AGGR

A72SS0_CORE2_ECC_AGGR integrates all the SVBUS slave endpoints for A72SS0_CORE2.

Table 6-6. A72SS0_CORE2_ECC_AGGR RAM ID Mapping for Interface Diagnostics

Endpoint	Memory ID	Controller
A72SS0_CORE2	24	EDC controller for A72SS0_CORE2_ECC_AGGR

A72SS0_CORE3_ECC_AGGR integrates all the SVBUS slave endpoints for A72SS0_CORE3.

Table 6-7. A72SS0_CORE3_ECC_AGGR RAM ID Mapping for Interface Diagnostics

Endpoint	Memory ID	Controller

A72SS0_CLUSTER_ECC_AGGR integrates all the SVBUS slave endpoints for CBASS and cluster.

Table 6-8. A72SS0_CLUSTER_ECC_AGGR RAM ID Mapping for Interface Diagnostics

Endpoint	Memory ID	Controller
A72SS0_CLUSTER	32	EDC controller for A72SS0_CLUSTER_ECC_AGGR
	33-41	Internal bridges

6.2.2.9.3 A72SS SRAM Diagnostics

The A72 cluster natively supports ECC/parity protection on some of its internal SRAMs. However, error injection for the memories is not natively supported by the A72 cluster. Instead, this capability is added at A72SS level via ECC aggregator. This is a valuable TI addition to the Arm native implementation.

Table 6-9 shows the A72SS SRAM ECC support details.

Table 6-9. A72SS SRAM ECC Support

A72 RAM	ARM Native Support	TI Error Injection Support
L1 I-Cache Data RAM	Parity protection	Single error injection ⁽¹⁾
L1 I-Cache Tag RAM	Parity protection	Single error injection ⁽¹⁾
L1 I-Cache BTB RAM	No support	N/A
L1 I-Cache GHB RAM	No support	N/A
L1 I-Cache IP RAM	No support	N/A
L1 D-Cache Data RAM	ECC	Single and double error injection ⁽¹⁾
L1 D-Cache Tag RAM	ECC	Single and double error injection ⁽¹⁾

Table 6-9. A72SS SRAM ECC Support (continued)

A72 RAM	ARM Native Support	TI Error Injection Support
L1 PF PHT RAM	No support	N/A
L2 TLB RAM	Parity	Single error injection ⁽¹⁾
L2 Snoop Tag RAM	ECC	Single and double error injection ⁽²⁾
L2 Tag RAM	ECC	Single and double error injection ⁽²⁾
L2 Data RAM	ECC	Single and double error injection ⁽²⁾
L2 Dirty RAM	ECC	Single and double error injection ⁽²⁾
L2 Inclusion PLRU RAM	ECC	Single and double error injection ⁽²⁾

(1) Supported by A72SS0_CORE0/1/2/3_ECC_AGGR

(2) Supported by A72SS0_CLUSTER_ECC_AGGR

6.2.2.9.4 A72SS SRAM ECC Aggregator Configurations

There are several schemas of memory protection employed inside of the processors. [Table 6-10](#) and [Table 6-11](#) describe the schema and arrangement. This describes what bits are protected, how they are protected, the behavior when an error is detected and what bits can be disturbed for ECC testing purposes. This also lists the RAM_ID associated with each memory to the corresponding ECC aggregator.

The key for the protection schemes is as follows:

- Parity: Parity bit(s) to protect data
- ECC: Error Correction Code to protect data
- SECEDED: Single Error Correction, Double Error Detection

Table 6-10. A72SSx_CORE0/1/2/3_ECC_AGGR Mapping

Memory	Protection	Parity/ECC Granularity	RAM Arrangement	RAM_ID	Notes
L1 I-Cache Data	Parity	1 parity bit / 16 bits of Instruction data	[71] – Parity of all odd bits of [63:32] and [67] [70] – Parity of all even bits of [63:32] and [66] [69] – Parity of all odd bits of [31:0] and [65] [68] – Parity of all even bits of [31:0] and [64]	0-5	Parity error invalidates the offending cache line, force a fetch from the L2 cache on the next access. No aborts are generated, location of error is repored in the A72 CPUMERR register.
L1 I-Cache Tag	Parity	2 parity bits / 36 bits tag entry	[107] – Parity of all odd bits of [104:72] [71] – Parity of all odd bits of [68:36] [35] – Parity of all odd bits of [32:0] [106] – Parity of all even bits of [104:72] [70] – Parity of all even bits of [68:36] [34] – Parity of all even bits of [32:0] [105], [69], [33] – Valid bit [104:72], [68:36], [32:0] – Tag	6-7	Parity error invalidates the offending cache line, force a fetch from the L2 cache on the next access. No aborts are generated, location of error is repored in the A72 CPUMERR register.
L1 D-cache Data	ECC SECEDED	32-bit word	[155:149] – ECC [148:117] – Data [116:110] – ECC [109:78] – Data [77:71] – ECC [70:39] – Data [38:32] – ECC [31:0] – Data	8-15	Single bit errors are corrected in the background and the line is removed from the cache as part of the correction process. No exception or interrupt is generated, but the A72 MERR register is updated to indicate a non-fatal error. Double bit errors are detected and an imprecise data abort is triggered and the line is evicted from the cache.

Table 6-10. A72SSx_CORE0/1/2/3_ECC_AGGR Mapping (continued)

Memory	Protection	Parity/ECC Granularity	RAM Arrangement	RAM_ID	Notes
L1 D-Cache Tag	ECC SECEDED	Tag for a single cache line	[39:33] – ECC for [32:2] Tag and [1:0] State	16-19	Single bit errors are corrected in the background and the line is removed from the cache as part of the correction process. No exception or interrupt is generated, but the A72 MERR register is updated to indicate a nonfatal error. Double bit errors are detected and an imprecise data abort is triggered and the line is evicted from the cache.
L2 TLB	Parity		[129] – Parity Bit [128:0] – TLB data	20-23	Error detection results in entry invalidated, new pagewalk to refetch.

Table 6-11. A72SSx_CLUSTER_ECC_AGGR Mapping

Memory	Protection	RAM Arrangement	RAM_ID	Notes
L2 Tag	ECC SECEDED	Odd way: [77:71] – ECC for [70:41] Tag and [40:39] State Even Way: [38:32] – ECC for [31:2] Tag and [1:0] State	12-27	Accesses resulting in an L2 cache hit, where a single-bit error is detected on the data array, the L2 memory system supports in-line ECC correction. Uncorrected data is forwarded to the requesting unit, and in parallel, the ECC circuitry checks for accuracy. If a single-bit error is detected, any uncorrected data returned within two cycles before the error indicator must be discarded.
L2 Data	ECC SECEDED	[143:128] – ECC [127:0] - Data	4-11	Accesses resulting in an L2 cache hit, where a single-bit error is detected on the Data array, the L2 memory system supports in-line ECC correction. Uncorrected data is forwarded to the requesting unit, and in parallel, the ECC circuitry checks for accuracy. If a single-bit error is detected, any uncorrected data returned within two cycles before the error indicator must be discarded.
L2 Snoop Tag RAM	ECC SECEDED	[79:73] – ECC for [72:42] Tag and [41:40] State [39:33] – ECC for [32:2] Tag and [1:0] State	0-3	For single-bit ECC errors detected, the request is flushed from the L2 pipeline and is forced to reissue. The tag bank where the single-bit error occurred, performs a read-modify-write sequence to correct the single-bit error in the array. The request is then reissued.
L2 Inclusion PLRU RAM	ECC SECEDED	[38:32] – ECC for [30:16] PLRU and [15:0] Inclusion	30-31	For single-bit ECC errors detected, the request is flushed from the L2 pipeline and is forced to reissue. The tag bank where the single-bit error occurred, performs a read-modify-write sequence to correct the single-bit error in the array. The request is then reissued.

Table 6-11. A72SSx_CLUSTER_ECC_AGGR Mapping (continued)

Memory	Protection	RAM Arrangement	RAM_ID	Notes
L2 Dirty RAM	ECC SECDED	[47:44] – ECC [43:40] – Page Attribute [39:37] – ECC [36] – Dirty bit [35:32] – ECC [31:28] – Page Attribute [27:25] – ECC [24] – Dirty bit [23:20] – ECC [19:16] – Page Attribute [15:13] – ECC [12] – Dirty bit [11:8] – ECC [7:4] – Page Attribute [3:1] – ECC [0] – Dirty bit	28-29	For single-bit ECC errors detected, the request is flushed from the L2 pipeline and is forced to reissue. The tag bank where the single-bit error occurred, performs a read-modify-write sequence to correct the single-bit error in the array. The request is then reissued.

6.2.2.10 A72SS Boot

For Armv8 cores such as A72, two boot modes are supported: legacy 32-bit address boot mode, and 64-bit address boot mode. The selection is asserted before the A72 core is out of reset and is based on the configuration of the following Compute Cluster register:

- CC_CP_CONFIG_0[3-0] AARCH bit field

When the A72 core is configured for a 32-bit address boot mode, the boot vector is fixed at address 0x0000_0000, which corresponds to the start address of the 2KB boot RAM (PSRAM2KECC0_RAM).

When the A72 core is configured for a 64-bit address boot mode, the boot vector is determined by the RVBARADDRx tie-off signal, which is configured via associated Compute Cluster registers:

- For A72SS0_CORE0: CC_RST_VEC_LO_CP0_0 and CC_RST_VEC_HI_CP0_0
- For A72SS0_CORE1: CC_RST_VEC_LO_CP1_0 and CC_RST_VEC_HI_CP1_0

The Compute Cluster RVBARADDRx setting is latched into the A72 RVBAR register, where reset is applied. Once reset is released, the A72 RVBAR register becomes read-only and the latched value is used as a boot vector location.

Table 6-12 summarizes the A72 boot mode specifics.

Table 6-12. A72 Boot Mode Specifics

32-bit Address Boot Mode	64-bit Address Boot Mode
Boot vector is part of vector table	Boot vector is not part of vector table
Boot vector has a fixed address: 0x0000_0000. It corresponds to the 2KB boot RAM (PSRAM2KECC0_RAM)	Boot vector is determined by RVBARADDRx[39:2] tie-off setting per core. ⁽¹⁾
Location of the vector table is fixed by default (0x0000_0000)	No default location of vector table
No need to program A72 VBAR register if vector table stays at the default address	Each A72 core boot code must program VBAR_ELn core registers to initialize its location of the vector tables for the various Armv8 exception levels
Vector table is 32B	Vector table is 128B
Vector table location can be reprogrammed after boot	Vector table location is unknown until it is programmed after reset

- (1) Although the associated Compute Cluster register provides support for a 50-bit wide reset base vector, the actual support is for a 40-bit reset base vector per SoC restriction.

6.2.2.11 A72SS IPC with Other CPUs

The A72 cores can communicate with other device cores (R5F MCU, C7x DSP, etc) by supporting interrupt generation to and from these cores. The interprocessor communication (IPC) interrupts are assigned in the corresponding Control Module memory-mapped registers (MMRs) called IPC_SETx / IPC_CLRx. For more information, see *Control Module (CTRL_MMR)*.

6.3 Dual-R5F MCU Subsystem

This chapter describes the dual-R5F microcontroller unit subsystem (R5FSS) in the device.

6.3.1 R5FSS Overview

The R5FSS is a dual-core implementation of the Arm® Cortex®-R5F processor configured for split/lock operation. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm CoreSight™ debug and trace architecture, integrated vectored interrupt manager (VIM), ECC aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

6.3.1.1 R5FSS Features

Each R5FSS supports the following features:

- Dual-core Arm Cortex-R5F
 - Core revision: r1p3
 - Armv7-R profile
 - Split/lock operation
 - Split mode: Two independently operating cores (asymmetric multi processing, no coherence)
 - Lock (lockstep) mode: One main operating core with the other operating in lockstep
 - Boot-time configurable to be in split or lock mode
 - L1 memory system
 - 32KB instruction cache
 - 4x8KB ways
 - SECDED ECC protected per 64 bits
 - 32KB data cache
 - 4x8KB ways
 - SECDED ECC protected per 32 bits
 - 64KB tightly-coupled memory (TCM) per CPU in split mode
 - SECDED ECC protected per 32 bits
 - Readable/writable from system
 - Split into A and B banks (with B further splitting into B0 and B1 interleaved banks)
 - 32KB TCMA (ATCM)
 - 16KB TCMB0 (B0TCM)
 - 16KB TCMB1 (B1TCM)
 - 128KB of TCM for CPU0 in lock mode
 - Low interrupt latency with restartable instructions
 - Non-maskable interrupt (NMI)
 - Full-precision floating point (VFPv3)
 - 16 region memory protection unit (MPU)
 - 8 breakpoints
 - 8 watchpoints
 - Dynamic branch prediction with global history buffer and 4-entry return stack
 - CoreSight debug access port (DAP)
 - CoreSight embedded trace macrocell (ETM-R5) interface
 - Performance monitoring unit (PMU)
- Interfaces
 - 64-bit VBUSM master pair (1 read, 1 write) for L3 memory accesses (per core)
 - 64-bit VBUSM slave for TCM access (per core)
 - Also allows access to cache for debug purposes
 - 32-bit VBUSM master pair (1 read, 1 write) for peripheral access
 - Supported for R5FSS0 ; not supported for MCU_R5FSS0
 - 32-bit VBUSP master for peripheral access (per core)
 - 32-bit VBUSP slave configuration port (per core)
 - 32-bit VBUSP slave debug port
 - Allows access to all R5FSS internal debug logic
- Synchronous clock domain crossing on all interfaces

- Interfaces can run at an integer division of the core frequency
- Error detection logic (in lockstep mode only)
- 32-bit to 48-bit region-based address translation (RAT) on memory access masters
 - 16 regions
 - Base address + size
 - Must be size aligned
- Integrated vectored interrupt manager (VIM)
 - 512 interrupts per core
 - Only interrupts connected to R5F core 0 are available in lock mode
 - Each interrupt programmable as either IRQ or FIQ
 - Each interrupt has a programmable enable mask
 - Each interrupt has a programmable 4-bit priority
 - Priority interrupt supported
 - Vectored interrupt interface
 - Compatible with R5F VIC port
 - Programmable 32-bit vector address per interrupt
 - Address is SECEDED error protected
 - Default vector addresses provided on DED
 - Split or lockstep capable
 - Software interrupt generation
- Integrated ECC aggregators
 - Support for error injection to all supported ECC memory blocks to test ECC functionality (add-on function from TI)
 - One ECC aggregator per core to cover all RAMs and caches associated with that core
- Standard Arm CoreSight debug and trace architecture at the R5FSS level
 - Cross triggering: Supported by cross trigger interface (CTI) (per CPU) and cross trigger matrix (CTM) components
 - Processor trace: Supported by embedded trace macrocell (ETM) (per CPU) and advanced trace bus (ATB) funnel components
- Boot
 - From ROM or external memory
 - From TCM

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

6.3.1.2 R5FSS Ports

Table 6-13. R5FSS Clocks and Resets

Module Clock Input	Description
Clocks	
R5FSS_CORE0_FCLK	R5FSS_CORE0 functional clock
R5FSS_CORE0_ICLK	R5FSS_CORE0 interface clock
R5FSS_CORE1_FCLK	R5FSS_CORE1 functional clock
R5FSS_CORE1_ICLK	R5FSS_CORE1 interface clock
Resets	
Module Reset Input	
R5FSS_CORE0_RST	R5FSS_CORE0 main reset
R5FSS_CORE0_DBG_RST	R5FSS_CORE0 debug reset (APB excluded)
R5FSS_CORE1_RST	R5FSS_CORE1 main reset
R5FSS_CORE1_DBG_RST	R5FSS_CORE1 debug reset (APB excluded)

Table 6-14. R5FSS Hardware Requests

Module Interrupt Signal	Description	Type
R5FSS_CORE0 Interrupts		
R5FSS_CORE0_PMU_0	R5FSS_CORE0 performance monitor interrupt	Level
R5FSS_CORE0_VALIRQ_0	R5FSS_CORE0 validation IRQ interrupt	Level
R5FSS_CORE0_VALFIQ_0	R5FSS_CORE0 validation FIQ interrupt	Level
R5FSS_CORE0_CTI_0	R5FSS_CORE0 cross trigger interrupt	Level
R5FSS_COMMON0_COMMRX_LEVEL_0_0	R5FSS_CORE0 DTRRX full interrupt	Level
R5FSS_COMMON0_COMMTX_LEVEL_0_0	R5FSS_CORE0 DTRTX empty interrupt	Level
R5FSS_CORE0_ECC_CORRECTED_LEVEL_0	R5FSS_CORE0 SEC ECC interrupt	Level
R5FSS_CORE0_ECC_UNCORRECTED_LEVEL_0	R5FSS_CORE0 DED ECC interrupt	Level
R5FSS_CORE0_EXP_INTR_0	R5FSS_CORE0 RAT exception interrupt	Level
R5FSS_COMMON0_ECC_SE_TO_ESM_0_0	R5FSS_CORE0 ECC single-bit error interrupt (cache and TCM RAMs)	Level
R5FSS_COMMON0_ECC_DE_TO_ESM_0_0	R5FSS_CORE0 ECC double-bit error interrupt (cache and TCM RAMs)	Level
R5FSS_CORE1 Interrupts		
R5FSS_CORE1_PMU_0	R5FSS_CORE1 performance monitor interrupt	Level
R5FSS_CORE1_VALIRQ_0	R5FSS_CORE1 validation IRQ interrupt	Level
R5FSS_CORE1_VALFIQ_0	R5FSS_CORE1 validation FIQ interrupt	Level
R5FSS_CORE1_CTI_0	R5FSS_CORE1 cross trigger interrupt	Level
R5FSS_COMMON0_COMMRX_LEVEL_1_0	R5FSS_CORE1 DTRRX full interrupt	Level
R5FSS_COMMON0_COMMTX_LEVEL_1_0	R5FSS_CORE1 DTRTX empty interrupt	Level
R5FSS_CORE1_ECC_CORRECTED_LEVEL_0	R5FSS_CORE1 SEC ECC interrupt	Level
R5FSS_CORE1_ECC_UNCORRECTED_LEVEL_0	R5FSS_CORE1 DED ECC interrupt	Level
R5FSS_CORE1_EXP_INTR_0	R5FSS_CORE1 RAT exception interrupt	Level
R5FSS_COMMON0_ECC_SE_TO_ESM_1_0	R5FSS_CORE1 ECC single-bit error interrupt (cache and TCM RAMs)	Level
R5FSS_COMMON0_ECC_DE_TO_ESM_1_0	R5FSS_CORE1 ECC double-bit error interrupt (cache and TCM RAMs)	Level
R5FSS_CCMR5 Interrupts		
R5FSS_COMMON0_SELFTEST_ERR_PULSE_0	R5FSS self test failure interrupt	Pulse
R5FSS_COMMON0_COMPARE_ERR_PULSE_0	R5FSS CPU bus compare failure interrupt	Pulse
R5FSS_COMMON0_BUS_MONITOR_ERR_PULSE_0	R5FSS inactivity monitor failure interrupt	Pulse
R5FSS_COMMON0_VIM_COMPARE_ERR_PULSE_0	R5FSS VIM bus compare failure interrupt	Pulse
R5FSS_CCM_COMPARE_STAT_PULSE_INTR_0	R5FSS CCMR5 in self test or split mode interrupt	Pulse
R5FSS_ESM Interrupts		
R5FSS_ECC_DE_TO_ESM_0	R5FSS_CORE0 ESM Interrupt for double bit errors	Level
R5FSS_ECC_DE_TO_ESM_1	R5FSS_CORE1 ESM Interrupt for double bit errors	Level
R5FSS_ECC_SE_TO_ESM_0	R5FSS_CORE0 ESM Interrupt for single bit errors	Level
R5FSS_ECC_SE_TO_ESM_1	R5FSS_CORE1 ESM Interrupt for single bit errors	Level

6.3.2 R5FSS Functional Description

6.3.2.1 R5FSS Block Diagram

Figure 6-3 shows the R5FSS block diagram.

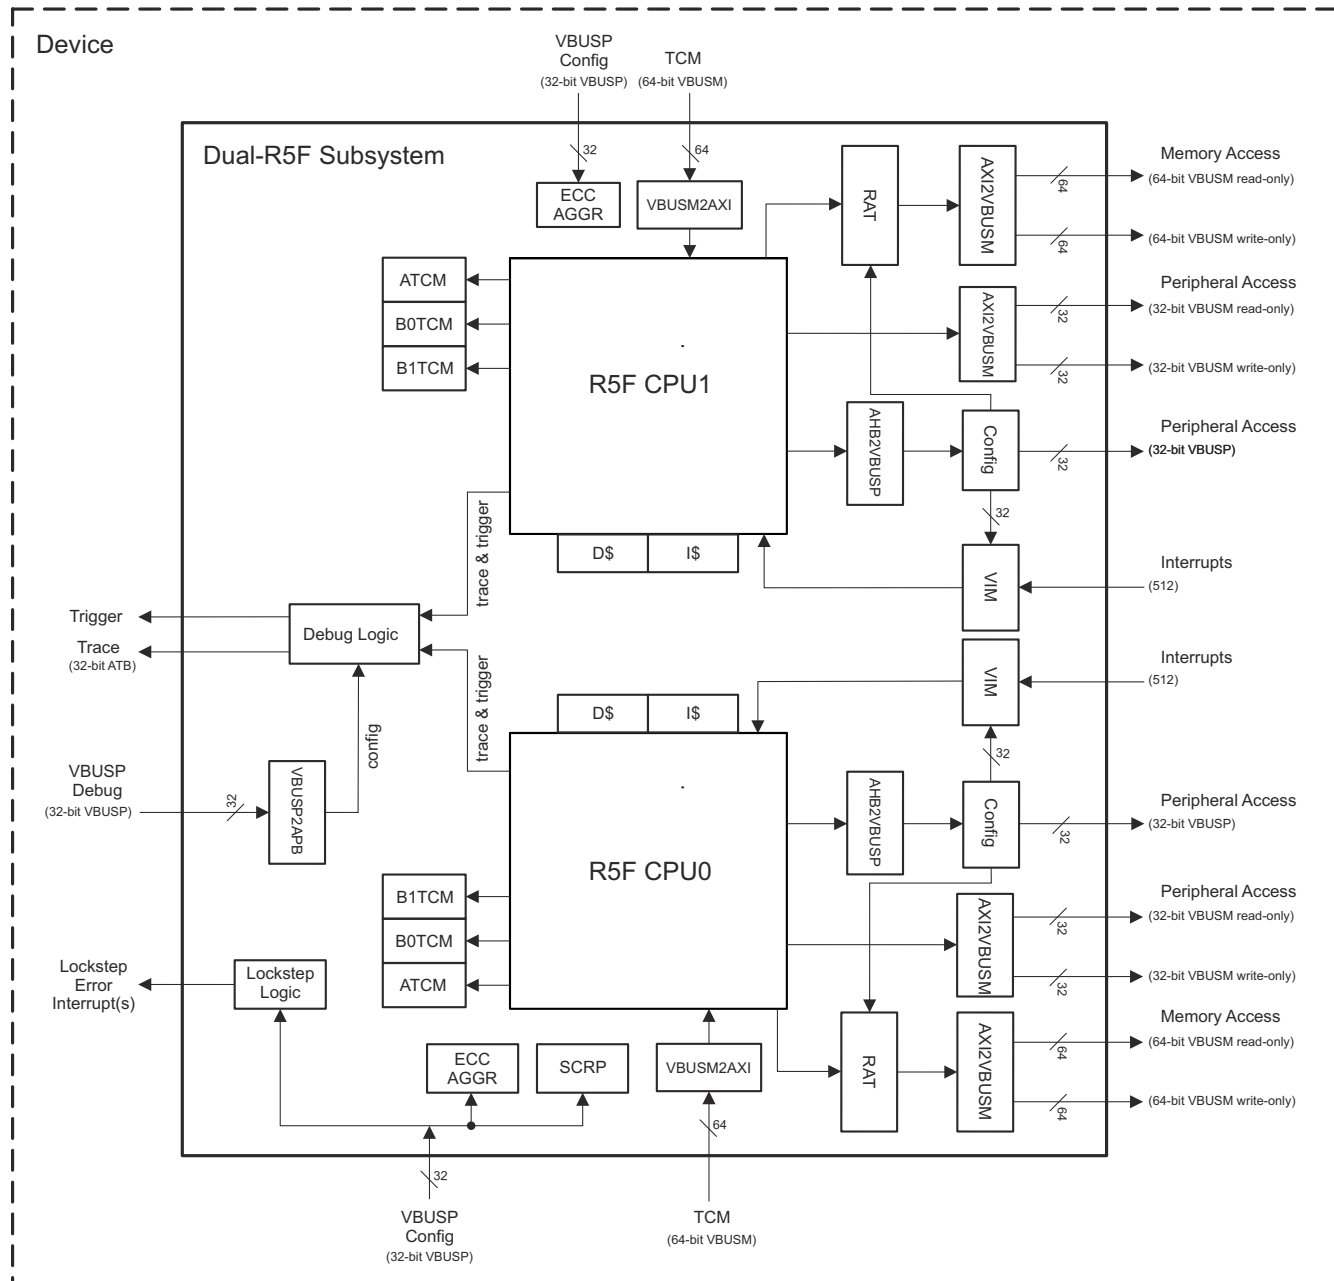

Figure 6-3. R5FSS Block Diagram

6.3.2.2 R5FSS Cortex-R5F Core

The Cortex-R5F is a processor from Arm, which is based on the Armv7-R profile. Each R5FSS implements two R5F cores, CPU0 and CPU1, each with their own RAMs and interfaces. While in reset, they can be bootstrapped to work in one of two modes: split or lockstep.

In split mode, each R5F core works completely independent from the other (asymmetric multi-processing, or AMP). Each core uses its own RAMs and interfaces, with no coherence between the two cores. The only restriction is that CPU0 must be in a higher power/reset state than CPU1. For instance, CPU1 cannot be out of reset if CPU0 is not.

In lock mode, the core logic from CPU1 is used as redundant logic to check for errors in CPU0. Comparison logic automatically checks the redundant logic against the primary logic and flags any errors. The CPU1 interfaces are not used in this mode. In previous generations of R5FSS, the CPU1 TCMs were unused in lock mode. In this generation of R5FSS, for more efficient use of available memories, the CPU1 TCMs are stacked on CPU0 TCMs in lock mode and are accessible only by CPU0 and CPU0 TCM interface. The TCM size for CPU0 is essentially doubled in lock mode (128KB).

For more detailed description of this processor, see the *Arm Cortex-R5 Technical Reference Manual*. A brief list of features supported by the R5F processor in this device is given in [Section 6.3.1.1, R5FSS Features](#).

6.3.2.2.1 L1 Caches

The R5F has a Harvard cache architecture, which means it has an independent L1 instruction cache (32KB) and L1 data cache (32KB). The instruction cache is protected by SECDED ECC per 64 bits. The data cache is protected by SECDED ECC per 32 bits.

6.3.2.2.2 Tightly-Coupled Memories (TCMs)

The R5F has two tightly-coupled memories (TCMs), ATCM and BTCM. The BTCM is further broken down into two interleaved banks, B0TCM and B1TCM.

TCMs are low-latency, tightly integrated memories for the R5F to use. Either TCM can be used for any combination of instruction and/or data. TCM performance is equal to performance on instructions/data that are in cache. However, TCMs have some additional advantages over cache. TCMs can be loaded with instructions that do not cache well (such as ISRs) or preloaded with code by an external source, before that code is needed, to save cache miss time. TCMs are also a good place for blocks of data for intense processing. They can be loaded (or pre-loaded by an external source) before the data is needed, saving cache miss time. The data can then be directly accessed by an external source, instead of needing to do cache evicts.

As mentioned, TCMs can be accessed (either read or written) by an external source over the TCM VBUSM slave interface. This allows instructions or data to be preloaded, or for data to be read out after the R5F has processed it. The VBUSM slave has a lower priority to accessing TCMs than the R5F but care must be taken to keep an external source from reading or writing TCM data that the R5F is working on. This handshaking is external to any of the R5FSS hardware.

TCMs are protected by ECC per 32 bits. For this to work, ECC must be enabled before data is written in to the TCMs (either externally or from the R5F). ECC is enabled via the following R5F system control bits: ACTLR.ATCMPCEN, ACTLR.B0TCMPCEN, and ACTLR.B1TCMPCEN, respectively.

Whether or not the TCMs are enabled is controlled by the ENABLE bit in the corresponding ATCM/BTCM region register. The default (reset) value of this bit is determined by the CPU_n_INITRAMA and CPU_n_INITRAMB bootstraps, respectively. Both ATCM and BTCM are configured for a size of 32KB in this device. Note that the BTCM size is the total of both B0TCM and B1TCM (16KB each).

If a TCM is not enabled, then it does not appear in the R5F memory view, but it can be accessed by an external source. If a TCM is enabled, then its place in the R5F memory map is determined by a combination of bootstrap signal and system register. If the CPU_n_LOCZRAMA bootstrap signal is high, then the initial base address of ATCM is 0x0000_0000 and the initial address of BTCM is 20'h41010. If the CPU_n_LOCZRAMA bootstrap signal is low, then the initial base address of BTCM is 0x0000_0000 and the initial base address of ATCM is 20'h41010.

Note

This base address of 0x41010 for ATCM/BTCM based on the CPU_n_LOCZRAMA bootstrap only affects the R5F's memory view. The SoC will see the ATCM/BTCM based on the TCM slave interface regions, as defined in [Section 6.3.2.3.2](#). The base address of either TCM may be overwritten via the ATCM or BTCM region register. Care must be taken not to move the base address of a TCM when it may be being accessed.

It is possible to preload a TCM with instructions and boot from it. For more details, see [Section 6.3.2.11, R5FSS Boot Options](#).

6.3.2.2.3 R5FSS Special Signals

The following tables list some R5FSS features associated with special signals. Note that in lockstep mode only those for CPU0 apply.

Table 6-15. MCU_R5FSS0 Special Features

Feature	Comment
Cluster affinity group ID	R5F cluster 0 (ID = 0x0)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MCU_SEC_MMR register setting. Defaults to Arm mode
Split or lockstep mode 0 = Split mode 1 = Lockstep mode	Controlled via MCU_SEC_MMR register setting. Defaults to a value defined by eFuse
CPU _n execution halt when coming out of reset (CPU _n _HALT)	Controlled via MCU_SEC_MMR register setting. Defaults to halted state
CPU _n exception vectors base address	Controlled via MCU_SEC_MMR register setting. Defaults to ROM address 0x0000_41810_0000
CPU _n VIM base address	0x40F8_0000
CPU _n RAT base address	0x40F9_0000
CPU _n RAT accesses ID	0x2 (CPU0); 0x3 (CPU1)
CPU _n ATCM enable at reset (CPU _n _INITRAMA)	Controlled via MCU_SEC_MMR register setting. Defaults to disabled state
CPU _n BTCM enable at reset (CPU _n _INITRAMB)	Controlled via MCU_SEC_MMR register setting. Defaults to enabled state
CPU _n A/BTCM reset base address indicator (CPU _n _LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MCU_SEC_MMR register setting. Defaults to 1
CPU _n non-maskable fast interrupts enable	Controlled via MCU_SEC_MMR register setting. Defaults to disabled state
CPU _n VBUSM peripheral port enabled at reset	VBUSM port not used
CPU _n VBUSP peripheral port enable at reset	Enabled
CPU _n VBUSP peripheral port base address	Mapped to 0x0_4000_0000 MCU peripheral base address
CPU _n VBUSP peripheral port size	16MB for MCUS peripheral (0x0_4000_0000 to 0x0_40FF_FFFF)
CPU _n VBUSM normal peripheral port base address	VBUSM port not used
CPU _n VBUSM normal peripheral port size	VBUSM port not used
CPU _n VBUSM virtual peripheral port base address	VBUSM port not used
CPU _n VBUSM virtual peripheral port size	VBUSM port not used
CPU _n clock stopped indication	Status logged into MCU_SEC_MMR register bit
CPU _n WFI state	Status logged into MCU_SEC_MMR register bit
CPU _n WFE state	Status logged into MCU_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MCU_SEC_MMR register setting. Defaults to 0

Table 6-16. R5FSS0 Special Features

Feature	Comment
Cluster affinity group ID	R5F Cluster 1 (ID = 0x1)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
Split or lockstep mode 0 = Split mode 1 = Lockstep mode	Controlled via MAIN_SEC_MMR register setting. Defaults to a value defined by eFuse
CPU _n execution halt when coming out of reset (CPU _n _HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state

Table 6-16. R5FSS0 Special Features (continued)

Feature	Comment
CPU _n exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPU _n VIM base address	0x0FF8_0000
CPU _n RAT base address	0x0FF9_0000
CPU _n RAT accesses ID	0x4 (CPU0); 0x5 (CPU1)
CPU _n ATCM enable at reset (CPU _n _INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU _n BTCM enable at reset (CPU _n _INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPU _n A/BTCM reset base address indicator (CPU _n _LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPU _n non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU _n VBUSM peripheral port enabled at reset	Enabled
CPU _n VBUSP peripheral port enable at reset	Enabled
CPU _n VBUSP peripheral port base address	Mapped to 0x0_0F80_0000 for low latency MAIN peripherals
CPU _n VBUSP peripheral port size	8MB for MAIN peripherals (0x0_0F80_0000 to 0x0_0FFF_FFFF)
CPU _n VBUSM normal peripheral port base address	Mapped to 0x0200_0000 for MAIN peripherals
CPU _n VBUSM normal peripheral port size	32MB for MAIN peripherals (0x0_0200_0000 to 0x0_03FF_FFFF)
CPU _n VBUSM virtual peripheral port base address	Mapped to 0x0200_0000 for MAIN peripherals
CPU _n VBUSM virtual peripheral port size	32MB for MAIN peripherals (0x0_0200_0000 to 0x0_03FF_FFFF)
CPU _n clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPU _n WFI state	Status logged into MAIN_SEC_MMR register bit
CPU _n WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

6.3.2.3 R5FSS Interfaces

6.3.2.3.1 R5FSS Master Interfaces

The R5FSS has several master interfaces per core:

- 64-bit VBUSM master pair (1 read – “RMST”, 1 write – “WMST”) for L3 memory accesses; this is the main memory interface
 - Includes region-based address translation (RAT)
- 32-bit VBUSM master pair (1 read – “PRMST”, 1 write – “PWMST”) for peripheral access
 - Enabled at reset
 - Supported for R5FSS0 ; not supported for MCU_R5FSS0
- 32-bit VBUSP master “PMST” for peripheral access
 - Includes logic that provides the R5F CPU with a private access to VIM and RAT
 - Enabled at reset

6.3.2.3.2 R5FSS Slave Interfaces

The R5FSS has several slave interfaces that define its internal memory space:

- 32-bit VBUSP configuration slave (per core)
 - Region [0]: ECC aggregator block
 - Region [1]: Lockstep comparator block (CCMR5); this region is only applicable to CORE0
- 64-bit TCM slave (per core)
 - Region [0]: ATCM
 - Region [1]: BTCM

- Region [2]: Instruction cache RAMs
- Region [3]: Data cache RAMs
- 32-bit VBUSP debug slave
 - Provides access to all R5FSS internal debug logic

Regions [0] and [1] of the TCM slave interface provide direct access to the TCM RAMs. Access to the RAMs is arbitrated with access from the R5F's L1 memory system. Excessive access while the R5F is also attempting access will degrade performance.

Regions [2] and [3] of the TCM slave interface provide access to the cache RAMs for testing purposes. Access to the cache RAMs can only be done while the caches are disabled and should only be done for test purposes.

In addition to the slave interfaces, there are peripherals (RAT and VIM) that are only accessible by the R5F. The R5F has an access to these modules via the VBUSP peripheral interface.

6.3.2.4 R5FSS Power, Clocking and Reset

6.3.2.4.1 R5FSS Power

The following R5FSS power considerations should be noted:

- R5FSS has a single power domain for all its internal logic
- When operating in split mode, CPU0 must be in a higher power/reset state than CPU1.

For more details on R5FSS power management, including power-up and power-down sequences, see *Power*.

6.3.2.4.2 R5FSS Clocking

The R5FSS has four clock inputs:

- CPU0_CLK: This is the clock for CPU0 logic
- CPU1_CLK: This is the clock for CPU1 logic
- CPU0_ICLK: This is the clock for CPU0 interfaces
- CPU1_ICLK: This is the clock for CPU1 interfaces

CPU0_CLK and CPU1_CLK are the clocks for all of the internal CPU logic. They are provided separately so that:

- In split mode, CPU1's clock may be turned off, while CPU0 is still in active mode
- In lock mode, they are sourced separately

CPU0_ICLK and CPU1_ICLK are the clocks for all of the interfaces for their associated CPU (for example: VBUSM and VBUSP bridges, exception generation, debug and trace logic). They are provided separately so that CPU1_ICLK can be gated if CPU1 is in a lower power state, while CPU0 is ON, or when in lock mode.

The interface clock is an integer ratio of the CPU clock. See *R5FSS Integration*.

6.3.2.4.2.1 Changing MCU_R5FSS0 CPU Clock Frequency

For each MCU_R5FSS0 CPU, the interface clock is an integer ratio of the CPU0 clock. The exact core to interface clock ratio is configured via associated Control Module register:

- CTRLMMR_MCU_R5_CORE0_CLKSEL for both MCU_R5FSS0 cores

The interface clock has a fixed frequency, so this register is essentially used to select the CPU clock frequency. Due to some design limitation, the core frequency switch for the MCU_R5FSS0 may cause clock misalignment. To avoid this this clock misalignment, the below software sequence should be implemented by a core other than MCU_R5FSS0_CORE0 or MCU_R5FSS0_CORE1 when changing the CPU clock frequency:

1. Power down MCU_R5FSS0
2. Change the core to interface ratio by modifying the associated CTRL_MMR register
3. Power up MCU_R5FSS0 and follow the bring up sequence based on split or lockstep mode

Note that the sequence above is a static configuration change and any context in the MCU_R5FSS0 will be not be preserved. There is no dynamic clock reconfiguration available.

6.3.2.4.3 R5FSS Reset

The R5FSS has four reset inputs:

- CPU0_RST: This is the reset for the non-debug logic of CPU0
- CPU0_DBG_RST: This resets the CPU0 debug logic, excluding the APB interface
- CPU1_RST: This is the reset for the non-debug logic of CPU1
- CPU1_DBG_RST: This resets the CPU1 debug logic, excluding the APB interface

In addition to the reset signals, there are two halt signals:

- CPU0_HALT
- CPU1_HALT

These halt signals keep the CPUs from fetching instructions when they come out of reset. The main use is to have the CPUs halted until the TCMs are loaded (when booting from TCM), though halt could be used for any other purpose.

6.3.2.5 R5FSS Lockstep Error Detection Logic

When bootstrapped to lockstep mode, there is a logic that compares the outputs of the two cores. Whenever an error is detected, an interrupt is asserted. A logic is also included to test the comparison logic.

In lockstep mode, the logic from CPU1 is used to check CPU0. CPU1's RAMs and L1 memory system are not used. Instead, all inputs to CPU0 are copied, delayed by two cycles, and fed into CPU1's logic. All outputs from CPU0 are copied, delayed by two cycles, and compared to the outputs of CPU1.

The lockstep error detection logic in the R5FSS is implemented via the CPU compare module (CCMR5). The CCMR5 performs two main functions:

- CPU output compare: Compares the core compare bus outputs of the two R5F processor cores in lockstep mode
- Inactivity monitoring: This is to detect any transaction initiated by the diagnostic R5F core (CPU1) in lockstep mode. The diagnostic core is expected *not* to initiate any transaction in lockstep mode

6.3.2.5.1 CPU Output Compare Block

To implement a lockstep CPU cluster, a diagnostic checker block is included. The diagnostic checker block compares the CPU compare outputs on every cycle. A difference in the CPU output signals is indicated by an error signal.

As the CPUs are working with a two-cycle phase difference, there should be no compare errors generated when the CPUs are reset two cycles apart. For the various CPU interfaces, the comparison will start on the first valid transaction on key control signals.

Note

While R5 is in lockstep and CCM is active, debug using external debugger is not supported.

6.3.2.5.1.1 Operating Modes

The CPU compare block can run in one out of four operating modes:

- Compare active block
- Self test
- Error forcing
- Self test error forcing

To select an operating mode for the CPU compare block, a dedicated key must be written to the key register R5FSS_CCMKEYR1. R5FSS_CCMSR1 is the status register associated with this block.

Table 6-17 provides details on the operating modes of the CPU compare block.

Table 6-17. CPU Compare Block Operating Modes

Mode	Key ⁽¹⁾	Self Test Error Signal	Compare Error Signal	CMPE1 ⁽²⁾	STC1 ⁽³⁾	STET1 ⁽⁴⁾	STE1 ⁽⁵⁾
Compare block active	0000	Enabled	Enabled	Enabled	Disabled	Disabled	Disabled
Self test	0110	Enabled	Disabled	Disabled	Enabled	Enabled	Enabled
Error forcing	1001	Error	Error	Disabled	Disabled	Disabled	Disabled

Table 6-17. CPU Compare Block Operating Modes (continued)

Mode	Key ⁽¹⁾	Self Test Error Signal	Compare Error Signal	CMPE1 ⁽²⁾	STC1 ⁽³⁾	STET1 ⁽⁴⁾	STE1 ⁽⁵⁾
Self test error forcing	1111	Error	Enabled	Enabled	Disabled	Disabled	Disabled

- (1) R5FSS_CCMKEYR1[3:0] MKEY1 bit field
(2) R5FSS_CCMSR1[16] CMPE1: Compare error flag
(3) R5FSS_CCMSR1[8] STC1: Self test complete flag
(4) R5FSS_CCMSR1[1] STET1: Self test error type flag
(5) R5FSS_CCMSR1[0] STE1: Self test error flag

6.3.2.5.1.2 Compare Block Active Mode

In compare block active mode, the output signals of both CPUs are compared, and any difference in the outputs is indicated by the compare error signal. Additionally, as indicated in [Table 6-17](#), the self test error signal is also asserted.

Note

The self test error signal is shared by both the CCMR5's CPU compare and inactivity monitor blocks.

Note

Not all flops inside the R5F CPU(s) are initialized at reset. To avoid an erroneous CCMR5 compare error, the application software needs to ensure that the CPU registers of both CPUs are initialized with the same values before the registers are used. This is to ensure that the programmer's model CPU registers of both CPU are initialized properly.

6.3.2.5.1.3 Self Test Mode

In self test mode, the CCMR5 compare block is checked for faults by applying internally generated series of test patterns. During self test, the core compare disabled signal is deactivated. If a fault on the CCMR5 module gets detected, a self test error is generated.

When self test mode is entered, the CCMR5 module will generate predetermined test patterns to look for any hardware faults inside it. If a fault is detected, then a self test error flag (STE1) is set, a self test error signal is asserted, and the self test is terminated immediately after entering compare mismatch mode. If no fault is found during self test, the self test complete flag (STC1) will be set. The user needs to poll the R5FSS_CCMSR1 status register to find out the self test status. In both cases – self test terminated and self test completed – the CCMR5 will remain in self test mode and will be idle, and therefore the R5FSS_CCMKEYR1 key register will show the self test key until the mode is switched by writing another key to this register. During the self test operation, the compare error signal output is inactive, irrespective of the compare result. When switched out of self test mode, the core compare disabled signal is de-asserted.

There are two types of patterns generated by CCMR5 during self test mode: compare match test, and compare mismatch test. The CCMR5 first generates compare match test patterns followed by compare mismatch test patterns. During self test, each test pattern is applied on CPU output signal ports of the CCMR5's compare block and clocked for one cycle.

Self test of CPU output compare logic is done with respect to CPU clock. As mentioned, self test error is indicated by the self test error signal. Whether the self test failed during compare match test or compare mismatch test is indicated by the self test error type flag (STET1) in the R5FSS_CCMSR1 status register. When the block's self test is completed, the corresponding self test complete flag (STC1) is set.

Note

During self test, both CPUs can execute normally, but the compare logic will not be checking any CPU signals. Also, during self test, only the compare unit logic is tested. The self test is not interruptible.

6.3.2.5.1.4 Compare Match Test

During compare match test, there are four different test patterns generated to stimulate the hardware. An identical vector is applied to both input ports (CPU0 and CPU1 output signals, which are inputs to the CCMR5 block) at the same time expecting a compare match. These patterns cause the self test logic to exercise every CPU output signal. This test can be independently enabled by programming the CCMR5 registers. If the compare unit produces a compare mismatch then the self test error flag is set and the self test error signal is generated. If an error is detected during compare match, then CCMR5 enters compare mismatch mode before terminating the test.

The four test patterns are:

- All 0's on both CPUs
- All 1's on both CPUs
- 0xA's on both CPUs
- 0x5's on both CPUs

These four test patterns will take four clock cycles to complete.

Table 6-18 illustrates the compare match test sequence. The core compare disabled signal is asserted on entry and de-asserted when complete.

Table 6-18. Compare Match Test Sequence

CPU0 Signal Position									CPU1 Signal Position									Cycle
n:8	7	6	5	4	3	2	1	0	n:8	7	6	5	4	3	2	1	0	
0x5	0	1	0	1	0	1	0	1	0x5	0	1	0	1	0	1	0	1	0
0xA	1	0	1	0	1	0	1	0	0xA	1	0	1	0	1	0	1	0	1
0's	0	0	0	0	0	0	0	0	0's	0	0	0	0	0	0	0	0	2
1's	1	1	1	1	1	1	1	1	1's	1	1	1	1	1	1	1	1	3

6.3.2.5.1.5 Compare Mismatch Test

In compare mismatch test, the number of test patterns is equal to two times the number of CPU output signals to compare in compare mode active. The core compare disabled signal is asserted on entry and de-asserted when complete. An 'all-ones' vector is applied to the CCMR5's CPU0 input port and the same pattern is also applied to the CCMR5's CPU1 input port but with one bit flipped starting from signal position 0. The un-equal vector should cause the CCMR5 module to expect a compare mismatch at signal position 0. Note that a mismatch is an expected good result, while a match will indicate hardware fault. When a fault is detected, which means that a compare match is produced by the compare logic, the self test error flag is set and the self test error signal is asserted.

The above compare mismatch test algorithm repeats itself again in a domino fashion with next signal position flipped, while forcing all other signals to logic level '1'. This process is repeated until every single signal position is verified on both CPU signal ports.

The compare mismatch test is terminated if a compare match is detected and the module becomes idle. The compare mismatch test ensures that the compare unit is able to detect a mismatch on every CPU signal being compared.

Table 6-19 illustrates the compare mismatch test sequence.

Table 6-19. Compare Mismatch Test Sequence

CPU0 Signal Position										CPU1 Signal Position										Cycle
n	...	7	6	5	4	3	2	1	0	n	...	7	6	5	4	3	2	1	0	
1	1's	1	1	1	1	1	1	1	1	1	1's	1	1	1	1	1	1	1	0	0
1	1's	1	1	1	1	1	1	1	1	1	1's	1	1	1	1	1	1	0	1	1
1	1's	1	1	1	1	1	1	1	1	1	1's	1	1	1	1	0	1	1	1	2

6.3.2.5.1.6 Error Forcing Mode

In error forcing mode, a test pattern is applied to the CPU related inputs of the compare logic to force an error at the compare error signal of the compare unit. The core compare disabled signal is asserted on entry and de-asserted when complete.

This mode is enabled by writing the dedicated key in the R5FSS_CCMKEYR1 key register (see [Table 6-17](#)). The error signal is generated by asserting the CPU compare error signal.

Error forcing mode is similar to the compare mismatch test operation of self test mode, in which an un-equal vector is injected into the CCMR5 CPU signal ports. Instead of setting a self test error flag and asserting self test error signal, the error forcing mode forces the compare mismatch to set the compare error flag (CMPE1) and assert the compare error signal.

Only one hardcoded test pattern is applied into CCMR5 during error forcing mode. A repeated 0x5 pattern is applied to CPU0 signal port, while a repeated 0xA pattern is applied to the CPU1 signal port. The error forcing mode takes one cycle to complete. Hence, the failing signature is presented for one clock cycle and the mode is automatically switched to lockstep mode and the R5FSS_CCMKEYR1 key register will show the lockstep key (0000). During this cycle the CPUs are not compared. The user should expect to receive the error signal from CCMR5 module once the error forcing mode is entered. If no error signal is set, then a hardware fault is present.

6.3.2.5.1.7 Self Test Error Forcing Mode

In self test error forcing mode, an error is forced at the self test error signal. The compare unit is still running in lockstep mode and the key is switched to lockstep after one clock cycle. The core compare disabled signal is asserted on entry and de-asserted when complete.

6.3.2.5.2 Inactivity Monitor Block

Another function of the CCMR5 module is to monitor the inputs of bus matrix coming from the diagnostic R5F core (CPU1) in lockstep mode, to detect any transaction initiated by diagnostic core. Output signals from the diagnostic core, which indicate a valid transaction on a master interface, are compared against their clamped values. If any signal value is different from its clamped value, an error signal is generated.

[Table 6-20](#) shows the R5F diagnostic core output signals, which are being monitored to detect any activity in the processor bus.

Table 6-20. Inactivity Monitor Block Signals

Signal Name	Interface	Description	Clamp Value
AWVALIDM1	L2 AXI Master	Indicates write address and control are valid	0
ARVALIDM1	L2 AXI Master	Indicates read address and control are valid	0
AWVALIDP1	AXI PP ⁽¹⁾	Indicates write address and control are valid	0
ARVALIDP1	AXI PP ⁽¹⁾	Indicates read address and control are valid	0
HTRANSP1[1:0]	AHB PP	Indicates the type of transfer – idle (00), busy (01), non-sequential (10), sequential (11)	0
BVALIDS1	AXI Slave	Indicates valid write response is available	0

Table 6-20. Inactivity Monitor Block Signals (continued)

Signal Name	Interface	Description	Clamp Value
RVALIDS1	AXI Slave	Indicates Read Data Channel Address and Control are valid	0
ATCEN01	ATCM	Enable for ATCM lower word	0
ATCEN11	ATCM	Enable for ATCM upper word	0
B0TCEN01	B0TCM	Enable for B0TCM lower word	0
B0TCEN11	B0TCM	Enable for B0TCM upper word	0
B1TCEN01	B1TCM	Enable for B1TCM lower word	0
B1TCEN11	B1TCM	Enable for B1TCM upper word	0

(1) Not supported for MCU_R5FSS0

More details on these signals can be found in the *Arm Cortex-R5 Technical Reference Manual*.

The error response in case of a detected transaction is indicated by the bus monitor error signal.

6.3.2.5.2.1 Operating Modes

The inactivity monitor block can run in one out of four operating modes:

- Compare active block
- Self test
- Error forcing
- Self test error forcing

To select an operating mode for the inactivity monitor block, a dedicated key must be written to the key register R5FSS_CCMKEYR3. R5FSS_CCMSR3 is the status register associated with this block.

Table 6-21 provides details on the operating modes of the inactivity monitor block.

Table 6-21. Inactivity Monitor Block Operating Modes

Mode	Key ⁽¹⁾	Self Test Error Signal	Compare Error Signal ⁽²⁾	CMPE3 ⁽³⁾	STC3 ⁽⁴⁾	STET3 ⁽⁵⁾	STE3 ⁽⁶⁾
Compare block active	0000	Enabled	Enabled	Enabled	Disabled	Disabled	Disabled
Self test	0110	Enabled	Disabled	Disabled	Enabled	Enabled	Enabled
Error forcing	1001	Error	Error	Disabled	Disabled	Disabled	Disabled
Self test error forcing	1111	Error	Enabled	Enabled	Disabled	Disabled	Disabled

(1) R5FSS_CCMKEYR3[3:0] MKEY3 bit field

(2) Corresponds to bus monitor error signal for inactivity monitoring

(3) R5FSS_CCMSR3[16] CMPE3: Compare error (bus monitor error) flag

(4) R5FSS_CCMSR3[8] STC3: Self test complete flag

(5) R5FSS_CCMSR3[1] STET3: Self test error type flag

(6) R5FSS_CCMSR3[0] STE3: Self test error flag

6.3.2.5.2.2 Compare Block Active Mode

In compare block active mode, the output signals of CPU1 (after clamping) are compared against their clamped values, and a mismatch is indicated by the bus monitor error signal. Additionally, as indicated in Table 6-21, the self test error signal is also asserted.

Note

The self test error signal is shared by both the CCMR5's CPU compare and inactivity monitor blocks.

6.3.2.5.2.3 Self Test Mode

Inactivity monitor has a self test feature and self test is done by applying a predetermined set of internally generated test patterns on the Inactivity Monitor inputs. For the fault detection, the comparison is done against the clamped values. The generated patterns are same as output compare block test patterns, but they are applied on every HCLK cycles. Any fault detected is indicated by the self test error signal. If no fault is found during self test, the self test complete flag (STC3) will be set. The user needs to poll the R5FSS_CCMSR3

status register to find out the self test status. In both cases – self test terminated and self test completed – inactivity monitor will remain in self test mode and will be idle, and therefore the R5FSS_CCMKEYR3 key register will show the self test key until the mode is switched by writing another key to this register.

Note

Bus monitor error is disabled during self test mode.

Two types of test patterns are applied for inactivity monitor self test:

- Compare match pattern
- Compare mismatch pattern

Self test takes 16 cycles to complete. Self test error is indicated by the self test error signal. Whether the self test failed during compare match test or compare mismatch test is indicated by the self test error type flag (STET3) in the R5FSS_CCMSR3 status register. When the block's self test is completed, the corresponding self test complete flag (STC3) is set.

6.3.2.5.2.4 Compare Match Test

In compare match test, patterns are applied such that no compare error is generated. Because the comparison is done against the clamped values, and all compared signals are clamped to zero, only one test pattern is applicable for compare match test. A pattern of 'all-zeros' is applied for compare match test. If a compare mismatch is found, then self test error flag (STE3) is set and self test error is asserted. If an error is detected during compare match, then CCMR5 enters compare mismatch mode before terminating the test. If no mismatch is found, compare mismatch test is done next.

6.3.2.5.2.5 Compare Mismatch Test

In compare mismatch test, a series of un-equal test patterns are applied on inactivity monitor inputs. Un-equal vectors are expected to generate a compare mismatch and a compare match indicates a fault. If a compare match is found, self test error flag is set and a self test error is indicated. Self test is terminated as well. If all patterns are generating mismatch, self test complete flag (STC3) is set.

Table 6-22 shows the patterns used for compare mismatch test.

Table 6-22. Inactivity Monitor Compare Mismatch Patterns

Inactivity Monitor Compare Mismatch Patterns												Cycle
11	10	9	8	7	6	5	4	3	2	1	0	
0	0	0	0	0	0	0	0	0	0	0	1	0
0	0	0	0	0	0	0	0	0	0	1	0	1
0	0	0	0	0	0	0	0	0	1	0	0	2
0	0	0	0	0	0	0	0	1	0	0	0	3
0	0	0	0	0	0	0	1	0	0	0	0	4
0	0	0	0	0	0	1	0	0	0	0	0	5
0	0	0	0	0	1	0	0	0	0	0	0	6
0	0	0	0	1	0	0	0	0	0	0	0	7
0	0	0	1	0	0	0	0	0	0	0	0	8
0	0	1	0	0	0	0	0	0	0	0	0	9
0	1	0	0	0	0	0	0	0	0	0	0	10
1	0	0	0	0	0	0	0	0	0	0	0	11

6.3.2.5.2.6 Error Forcing Mode

In error forcing mode, a test pattern is applied to inactivity monitor inputs of the compare logic to force an error at the compare error signal of the compare unit. Only one hardcoded test pattern of 'all-ones' is applied into CCMR5 during error forcing mode. The error forcing mode takes one cycle to complete. Hence, the failing signature is presented for one clock cycle and the mode is automatically switched to lockstep mode and the

R5FSS_CCMKEYR3 key register will show the lockstep key (0000). During this cycle the bus monitoring is disabled.

6.3.2.5.2.7 Self Test Error Forcing Mode

In self test error forcing mode, an error is forced at the self test error signal. The compare unit is still running in lockstep mode and the key is switched to lockstep after one clock cycle.

6.3.2.5.3 Polarity Inversion Logic

As already mentioned, there is logic (implemented via XOR) to test the comparison logic itself. The CCMR5 block can be configured to be in self test to check the integrity of the final XOR error generation logic, and can be switched back to functional compare mode after self test completion. To ensure that switching back to functional mode has happened, user can program CCMR5 polarity control register (R5FSS_CCMPCNTRL) to invert the polarity of eight CPU output signals, which will cause a CPU compare error generation. The eight signals that are chosen to be able to control the polarity are: AWVALIDMm, RVALIDSm, ATCEN0m, B0TCEN0m, BITCWEm, IRQACKm, AWVALIDPm, HWRITEP. See the *Arm Cortex-R5 Technical Reference Manual* for details on these signals.

The XOR inversion is placed between the two back-to-back delay flops of CPU1 outputs. Note that the XOR inversion logic is a diagnostic feature. If user does not observe a CPU compare error generation after programming the R5FSS_CCMPCNTRL[7:0] POL_INV inversion bits, this means that:

1. All eight signals of the inversion logics (XOR) are faulty and CPU compare error signal is not asserted. This is a very difficult case to hit but theoretically it could happen if a hard fault gets accumulated over times on these polarity inversion XOR gates; OR
2. The CCMR5 block has not switched back to functional mode yet

User can perform self test again to identify whether the issue is #1 or #2. If the second self test passes that means the issue is #1.

6.3.2.6 R5FSS Vectored Interrupt Manager (VIM)

6.3.2.6.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU(s). It can be used in either split or lockstep configuration. In split, it has two independent interrupt cores, one per CPU. In lockstep, CPU1 acts as a diagnostic on CPU0; only CPU0's outputs are used but all outputs are compared to CPU1 to provide diagnostic coverage.

The VIM module supports the following features:

- 512 interrupt inputs per R5F core
- Each interrupt has its own 4-bit programmable priority
 - Defined via the R5FSS_VIM_PRI_INT_j register
 - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
 - Interrupt enable is done via the R5FSS_VIM_INTR_EN_SET_j register
 - Interrupt disable is done via the R5FSS_VIM_INTR_EN_CLR_j register
- Each interrupt can be programmed as either an IRQ or FIQ
 - Defined via the R5FSS_VIM_INTMAP_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
 - Defined via the R5FSS_VIM_VEC_INT_j register
 - Protected with SECDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
 - Compatible with R5F VIC port
- Default vector provided when a double-bit error is detected
- Split or lockstep capable
 - In lockstep mode, only interrupts connected to VIM interrupt core 0 are available
- Software interrupt generation

6.3.2.6.2 VIM Interrupt Inputs

The VIM supports 512 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the two R5F cores can be found in *Interrupt Sources*.

6.3.2.6.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- **CoreN_IRQn**: This is a normal interrupt for core N (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the R5FSS_VIM_INTMAP_j register) and is enabled (via the R5FSS_VIM_INTR_EN_SET_j register), then it will cause an IRQ to assert
- **CoreN_FIQn**: This is a fast (or non-maskable) interrupt for core N (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

6.3.2.6.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (R5FSS_VIM_VEC_INT_j). Hence, the interrupt vector table is organized in 512 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

Note

The lower two bits of the 32-bit interrupt vector are always 0s.

Figure 6-4 shows the VIM RAM interrupt vector map.

VIM RAM Address Space	VIM RAM Entries
Base Address + 0h	Interrupt 0 Vector
Base Address + 4h	Interrupt 1 Vector
Base Address + 8h	Interrupt 2 Vector
Base Address + 7F8h	Interrupt 510 Vector
Base Address + 7FCh	Interrupt 511 Vector

Figure 6-4. VIM RAM Interrupt Vector Map

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. See [Table 6-23](#) for the VIM RAM ID in the ECC aggregator map.

6.3.2.6.5 VIM Interrupt Prioritization

Each interrupt has a priority number assigned to it (set using the R5FSS_VIM_PRI_INT_j register). Legal values are 0 to 15, where 0 is the highest priority and 15 is the lowest priority. The highest priority interrupt is the

pending interrupt with the smallest priority number. If two pending interrupts have the same priority, the interrupt lowest numerically (0 through maximum number of interrupts) is prioritized. IRQs and FIQs are prioritized separately.

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the R5FSS_VIM_FIQVEC register; IRQ: reading the R5FSS_VIM_IRQVEC register, or the *coreN_IRQACK* going high), then the interrupt is loaded into the corresponding active register (R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to the R5FSS_VIM_FIQVEC register, or R5FSS_VIM_IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. The CPU may or may not service the higher priority interrupt. If the CPU switches this interrupt to active (by reading the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register, or (or *coreN_IRQACK* going high for an IRQ), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by writing to the R5FSS_VIM_FIQVEC / R5FSS_VIM_IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the R5FSS_VIM_ACTFIQ / R5FSS_VIM_ACTIRQ register, so that software may continue where it left off. Note that the R5FSS_VIM_IRQVEC / R5FSS_VIM_FIQVEC address registers are not repopulated with the old vector as it is assumed that the ISR is picking back up where it left off. Only the interrupt number and priority are restored to the R5FSS_VIM_ACTIRQ / R5FSS_VIM_ACTFIQ registers. If software needs the vector again, it will have to read it by using the interrupt number.

6.3.2.6.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the R5FSS_VIM_DEDVEC register is used to provide the default vector for the *coreN_IRQADDRV* signal, the R5FSS_VIM_IRQVEC register, and the R5FSS_VIM_FIQVEC register. The R5FSS_VIM_DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
 - a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt. This makes it possible for a higher priority interrupt to supercede the handling of the error.

Control and reporting are done by the R5FSS ECC aggregator.

6.3.2.6.7 VIM Lockstep Mode

In lockstep mode, CPU1 is used as a diagnostic for CPU0. In this mode, only the interrupt inputs for CPU0 are used. Besides to CPU0, these interrupt inputs are also internally routed to CPU1 (through the level-sync / edge-detect logic dedicated to CPU1, and additionally through some delay circuits). The outputs from both VIM interrupt cores are then sent to the R5FSS CCMR5 module through dedicated compare buses (with CPU0's outputs delayed). The CCMR5 module is responsible for comparing the two sets of output signals and for reporting any mismatches by generating a VIM bus compare interrupt.

Note

In lockstep mode, only the VIM RAM dedicated to CPU0 is used, so software *must not* do anything with the ECC interface on the VIM RAM dedicated to CPU1.

6.3.2.6.8 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

6.3.2.6.9 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in [Section 6.3.2.6.9.1](#), but the procedures in [Section 6.3.2.6.9.2](#) or [Section 6.3.2.6.9.3](#) (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

For FIQs, it is recommended to use the procedure in [Section 6.3.2.6.9.4](#), but the procedure in [Section 6.3.2.6.9.5](#) may be used as an alternative.

Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

6.3.2.6.9.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
 - a. CPU asserts `coreN_IRQACK` high
 - b. VIM asserts `coreN_IRQADDRV` to indicate that the `coreN_IRQADDR` bus is stable with the correct vector address
 - c. CPU reads `coreN_IRQADDR`, jumps to that address, and de-asserts `coreN_IRQACK` low
 - d. VIM de-asserts `coreN_IRQn` and `coreN_IRQADDRV`, VIM masks (discards) all IRQs with the same or lower priority
 - e. VIM loads the value from the `R5FSS_VIM_PRIIRQ[9:0]` NUM bit field (which corresponds to the vector address) into the `R5FSS_VIM_ACTIRQ[9:0]` NUM bit field, which causes the `R5FSS_VIM_ACTIRQ[31]` VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the `R5FSS_VIM_ACTIRQ[9:0]` NUM bit field to determine number, and reading the appropriate bit in the `R5FSS_VIM_INTTYPE_j` register to determine type)
 - a. Pulse
 - i. Clear the status by writing a '1' to the appropriate bit in the `R5FSS_VIM_IRQSTS_j` register, or `R5FSS_VIM_STS_j` register
 - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
 - b. Level
 - i. Clear the interrupt at the source
 - ii. Clear the status by writing a '1' to the appropriate bit in the `R5FSS_VIM_IRQSTS_j` register, or `R5FSS_VIM_STS_j` register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the `R5FSS_VIM_IRQVEC` register
 - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt

- b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

6.3.2.6.9.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the R5FSS_VIM_IRQVEC register and jump to that address to service the ISR
 - a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN_IRQn* will re-assert, allowing priority interruption of an interrupt
 - b. Reading this register will cause the value from the R5FSS_VIM_PRIIRQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_ACTIRQ[9:0] NUM bit field, and the R5FSS_VIM_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
 - a. Pulse
 - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
 - ii. Clear the interrupt at the source
 - b. Level
 - i. Clear the interrupt at the source
 - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
4. Write any value to the R5FSS_VIM_IRQVEC register
 - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
 - b. This will also clear the R5FSS_VIM_ACTIRQ[31] VALID bit

6.3.2.6.9.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the R5FSS_VIM_IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, priority masking will not work if route 1b is used (see below) as the hardware prioritization may not match the software prioritization scheme. In this case, software would be responsible for doing all priority operations.

1. Determine which interrupt to service
 - a. Read the R5FSS_VIM_PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
 - b. Optionally read the R5FSS_VIM_IRQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_IRQSTS_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Read the R5FSS_VIM_IRQVEC register
 - a. Note that this step can be done any time before step 4
 - b. Value is ignored
4. Depending on whether the original source of the interrupt was a pulse or a level
 - a. Pulse
 - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
 - ii. Clear the interrupt at the source.
 - b. Level
 - i. Clear the interrupt at the source
 - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_IRQSTS_j register
5. Write any value to the R5FSS_VIM_IRQVEC register

6.3.2.6.9.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the R5FSS_VIM_FIQVEC register and jump to that address to service the ISR

- a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN_FIQn* will re-assert, allowing priority interruption of an interrupt.
- b. Reading this register will cause the value from the R5FSS_VIM_PRIFIQ[9:0] NUM bit field to be loaded into the R5FSS_VIM_ACTFIQ[9:0] NUM bit field, and the R5FSS_VIM_ACTFIQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS_VIM_ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS_VIM_INTTYPE_j register to determine type)
 - a. Pulse
 - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
 - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
 - b. Level
 - i. Clear the interrupt at the source
 - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS_VIM_FIQVEC register
 - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
 - b. This will also clear the R5FSS_VIM_ACTFIQ[31] VALID bit

6.3.2.6.9.5 Servicing FIQ (Alternative)

If a user does not want to use the R5FSS_VIM_FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS_VIM_FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
 - a. Read the R5FSS_VIM_FIQVEC register to determine which interrupt is the highest priority FIQ currently asserted, OR
 - b. Optionally read the R5FSS_VIM_FIQGSTS register to determine which groups have IRQs pending, then read the R5FSS_VIM_FIQSTS_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
 - a. Pulse
 - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register
 - ii. Clear the interrupt at the source.
 - b. Level
 - i. Clear the interrupt at the source
 - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS_VIM_STS_j register, or R5FSS_VIM_FIQSTS_j register.

6.3.2.7 R5FSS Region Address Translation (RAT)

6.3.2.7.1 RAT Overview

The R5F is a 32-bit processor, which means it can only access 4GB of directly addressable memory. The SoC is a 64-bit virtual (48-bit physical) address system. The R5FSS integrates a standard region-based address translation (RAT) unit (per core) to allow some of its address space to be remapped into the 64-bit world.

The RAT has 16 regions, with each region having dedicated MMRs that define its attributes:

- Base address of the region, defined via R5FSS_RAT_BASE_j[31:0] BASE
- Size of the region, defined via R5FSS_RAT_CTRL_j[5:0] SIZE

- Translated base address, defined via R5FSS_RAT_TRANS_U_j[15-0] UPPER and R5FSS_RAT_TRANS_L_j[31-0] LOWER

Regions can have any base address and size, as long as the base address is size aligned. The maximum region size is 4GB.

Note

The RAT does not provide any logic for checking if base address is size aligned, so it is software's responsibility to ensure that. Regions that are not aligned may have unpredictable results.

6.3.2.7.2 RAT Operation

The RAT works by translating a 32-bit input address into a 48-bit output address. Any input transaction that starts inside of a programmed region will have its address translated, if the region is enabled. Any disabled region is ignored from the translation lookup.

The input addresses are compared against all the enabled regions in parallel. The region size defines how many of the lowest address bits are included in the region space, starting from a 1B space to a 4GB space. Then the upper bits not part of the region are used for the lookup and comparison, matching those bits of the input addresses against the region base address. The region matches when it is enabled and the compare matches. The first region that matches has the output address set with the region's translated base address upper bits. The lower bits that are part of the region size are copied from the input address to the output address. If there are no region matches then the input address is copied to the output address entirely.

Note

Multiple region definitions must not overlap in their covered address space. The RAT does not check for this, so it is software's responsibility to take care of it. Overlapping regions may have unpredictable results.

Here is an example of a region-based address translation, assuming that region [0] is programmed as follows:

- Region [0] base address = 0x1234_5XXX
- Region [0] size = 4KB
- Region [0] translation upper address = 0x0000_ABCD
- Region [0] translation lower address = 0x5432_1XXX

If a transaction comes in with the address 0x1234_5678, then the output transaction will have the address 0x0000_ABCD_5432_1678.

6.3.2.7.3 RAT Error Logging

The RAT does not provide any protection against transactions that cross region boundaries, that is, start inside of a region and end outside of it, or start outside of a region and end inside of it. If a boundary crossing transaction is detected, then the transaction will be flagged as an error (exception) and a log will be made. The log consists of a series of MMRs that captures the details of the transaction, including the input address that caused the error. The RAT module can capture one error before it is cleared by software. Here is the list of exception logging registers:

- Control:
 - R5FSS_RAT_EXCEPTION_LOGGING_CONTROL
- Header:
 - R5FSS_RAT_EXCEPTION_LOGGING_HEADER0
 - R5FSS_RAT_EXCEPTION_LOGGING_HEADER1
- Data:
 - R5FSS_RAT_EXCEPTION_LOGGING_DATA0
 - R5FSS_RAT_EXCEPTION_LOGGING_DATA1
 - R5FSS_RAT_EXCEPTION_LOGGING_DATA2
 - R5FSS_RAT_EXCEPTION_LOGGING_DATA3

The log also produces an interrupt. To clear the log, software must either read the final error logging register, or manually clear the interrupt status bit. This will clear the error status, and not the actual log MMRs, but it does allow the next error to be captured into the log MMRs. If the status is not cleared and additional errors are detected, they are not logged.

The error reports use the value from a dedicated bootstrap (see [Section 6.3.2.2.3](#)) as the value for the R5FSS_RAT_EXCEPTION_LOGGING_HEADER0[23-8] SRC_ID field.

6.3.2.7.4 RAT Protection

As mentioned, the RAT module does not provide any protection by itself. The intention is that RAT is used in conjunction with memory protection unit (MPU) and system firewalls for protection. It is recommended that one or more RAT regions are directly mapped to an MPU region to provide 'MMU-like' behavior.

6.3.2.8 R5FSS ECC Support

The R5F provides native ECC and parity support on all related memories, generating and checking the redundancy automatically. The methods for checking and reporting errors are available in the *Arm Cortex-R5 Technical Reference Manual*.

The R5FSS adds the capability of testing this logic by allowing errors (single and double bit) to be injected into memories (for testing purposes) via an ECC aggregator (per core). Note that because the R5FSS ECC aggregator is only used in error-injection mode, it only supports a subset of the generic ECC aggregator functionality in the device.

For a detailed description of the generic ECC aggregator functionality, see [Section 12.10.6, ECC Aggregator](#). For register descriptions of R5FSS CPU0 and CPU1 ECC aggregators, see *ECC Registers*.

[Table 6-23](#) provides the RAM ID for each core. This is needed for bit field [10-0] ECC_VECTOR in the corresponding R5FSS_CPU0_VECTOR / R5FSS_CPU1_VECTOR register.

Table 6-23. RAM ID Map for ECC Aggregator (Per Core)

RAM ID	Memory Name
0	CPU0/1 ITAG RAM0
1	CPU0/1 ITAG RAM1
2	CPU0/1 ITAG RAM2
3	CPU0/1 ITAG RAM3
4	CPU0/1 IDATA BANK0
5	CPU0/1 IDATA BANK1
6	CPU0/1 IDATA BANK2
7	CPU0/1 IDATA BANK3
8	CPU0/1 DTAG RAM0
9	CPU0/1 DTAG RAM1
10	CPU0/1 DTAG RAM2
11	CPU0/1 DTAG RAM3
12	CPU0/1 DDIRTY RAM
13	CPU0/1 DDATA RAM0
14	CPU0/1 DDATA RAM1
15	CPU0/1 DDATA RAM2
16	CPU0/1 DDATA RAM3
17	CPU0/1 DDATA RAM4
18	CPU0/1 DDATA RAM5
19	CPU0/1 DDATA RAM6
20	CPU0/1 DDATA RAM7
21	CPU0/1 ATCM BANK0
22	CPU0/1 ATCM BANK1

Table 6-23. RAM ID Map for ECC Aggregator (Per Core) (continued)

RAM ID	Memory Name
23	CPU0/1 B0TCM BANK0
24	CPU0/1 B0TCM BANK1
25	CPU0/1 B1TCM BANK0
26	CPU0/1 B1TCM BANK1
27	CPU0/1 VIM RAM

6.3.2.9 R5FSS Memory View

The memory view of each R5F (that is, the memory map as seen by each R5F) is a function of several things:

- Exception vector bootstrap: The R5F exception table (including boot vector) is always 32 bytes at address 0x00000000 as seen by the R5F. If not booting from a TCM, then boot is done over the main memory interface. The exception vector bootstrap is under software control, which allows these 32 bytes at address 0x00000000 to be remapped somewhere else in the SoC memory map.
- TCM locations: TCMs can be enabled or disabled and located at different places in the memory map, depending on bootstrap configuration. For more details, see [Table 6-15](#), and [Section 6.3.2.2.2](#).
- Peripheral interface locations: The R5F natively supports three interfaces for peripheral access. Each can be enabled/disabled and located based on bootstrap configuration. Note that the VBUSP peripheral interface must be enabled in order to use RAT and VIM.
- RAT base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- VIM base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- RAT programming: The RAT can take regions of memory accessible by the main memory interface and map them to different addresses.

The combination of the above determines what the R5F sees where in the memory map, and over what interface different transactions come out. Every transaction that does not directly address a TCM or a peripheral interface comes over the main memory interface. Transactions on the main memory interface can be further remapped with the RAT.

See *Memory Map*, for the complete R5F memory view for this device.

6.3.2.10 R5FSS Debug and Trace

The R5FSS supports standard Arm CoreSight debug and trace architecture. For more details, see the *On-chip Debug* chapter.

6.3.2.11 R5FSS Boot Options

There are two methods of booting the R5F, or rather, two methods of placing the exception vectors (of which the boot vector is one).

The first method is to have the exception vectors external to the R5F. The user can place the exception vectors at the address indicated by the exception vector bootstrap and then program the boot vector there. When the processor exits reset, it will fetch the boot vector from this location.

The second method is to boot from a TCM. To do this, software should take the following steps:

1. Assert the correct bootstraps
 - a. To boot from ATCM, set CPUUn_INITRAMA (or CPUUn_INITRAMB to boot from BTCM)
 - b. Assert CPUUn_LOCZRAMA properly for the desired TCM
2. Assert CPUUn_HALT
3. Release the CPU from reset
4. Load the desired code into the TCM via the TCM slave port
 - a. Exception vectors should be located at address 0x00000000 of the TCM
5. De-assert CPUUn_HALT

6.3.2.12 R5FSS Core Memory ECC Events

The R5F core generates several events as part of event bus that can be monitored by the PMU for debugging. The memory ECC related events from the event bus are exported to ESM for monitoring.

There are four ECC interrupts to the ESM that aggregate different categories of ECC events – CPU0 single error, CPU0 multi error, CPU1 single error, and CPU1 multi error events. Each ECC event has a 2-bit event bus counter associated with it. Everytime an event occurs, the counter is incremented by 1 till it reaches the max value of 3. The interrupt is asserted if the bus counter of any event associated with the interrupt is non-zero.

Each event bus counter has a MMR decrement control to decrement the counter by 1. So, for example, if a counter value is 2, the MMR to decrement the counter would need to be written 2 times to decrement the counter to 0. The reason decrement control has been added instead of clear control is if a new error occurs between the time the status register is read and the clear MMR is written, the new error would be lost. Write-to-decrement ensures that this does not happen.

When all event bus counters of an associated interrupt are zero, the interrupt is cleared. It takes three clock cycles for the event bus counter to be decremented once the write to the decrement control MMR presents itself at the R5FSS boundary.

Since each of the four ECC interrupts have single bit control to set the interrupt but multiple bits for clearing it, note that once an interrupt is set using the R5FSS_EVNT_BUS_ESM_SET register, it can be cleared by setting all the bits of the R5FSS_EVNT_BUS_ESM_CLR register that correspond to that particular interrupt. For example, if bit [0] of the R5FSS_EVNT_BUS_ESM_SET register is set, it can be cleared by setting bits [7-0] of the R5FSS_EVNT_BUS_ESM_CLR register to clear the interrupt.

The R5F core event bus only signals event when it is enabled. Non-invasive or invasive debug mode needs to be enabled to enable the PMU counters.

The export of the events to the event bus can be enabled by setting the X bit in the Performance Monitor Control Register of the R5F core. For more details, refer to *Arm R5 TRM*.

Table 6-24. R5FSS Event Bus Single-Bit Error Events

Event Bus Bit #	Description	Associated Status Register
22	Instruction cache tag RAM parity or correctable ECC error	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[1:0] EVNT_BUS0 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[1:0] EVNT_BUS0
23	Instruction cache data RAM parity or correctable ECC error	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[3:2] EVNT_BUS1 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[3:2] EVNT_BUS1
24	Data cache tag or dirty RAM parity error or correctable ECC error, from data-side or ACP	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[5:4] EVNT_BUS2 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[5:4] EVNT_BUS2
25	Data cache data RAM parity error or correctable ECC error	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[7:6] EVNT_BUS3 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[7:6] EVNT_BUS3
40	ATCM single-bit ECC error	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[9:8] EVNT_BUS4 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[9:8] EVNT_BUS4
41	B0TCM single-bit ECC error	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[11:10] EVNT_BUS5 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[11:10] EVNT_BUS5
42	B1TCM single-bit ECC error	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[13:12] EVNT_BUS6 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[13:12] EVNT_BUS6
43	TCM correctable ECC error reported by load/store unit	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[15:14] EVNT_BUS7 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[15:14] EVNT_BUS7
44	TCM correctable ECC error reported by prefetch unit	R5FSS_CPU0_EVNT_BUS_SB_ERR_CNT_STATUS[17:16] EVNT_BUS8 R5FSS_CPU1_EVNT_BUS_SB_ERR_CNT_STATUS[17:16] EVNT_BUS8

Table 6-25. R5FSS Event Bus Multi-Bit Error Events

Event Bus Bit #	Description	Associated Status Register
26	TCM fatal ECC error reported from the prefetch unit	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[1:0] EVNT_BUS0 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[1:0] EVNT_BUS0
27	TCM fatal ECC error reported from the load/store unit	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[3:2] EVNT_BUS1 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[3:2] EVNT_BUS1

Table 6-25. R5FSS Event Bus Multi-Bit Error Events (continued)

Event Bus Bit #	Description	Associated Status Register
33	Data cache data RAM fatal ECC error	R5FSS_CPU0_EVNT_BUS_MB_ERR_CNT_STATUS[5:4] EVNT_BUS2 R5FSS_CPU1_EVNT_BUS_MB_ERR_CNT_STATUS[5:4] EVNT_BUS2

6.3.3 R5FSS_VIM Registers

Table 6-27 lists the memory-mapped registers for the R5FSS_VIM module. All register offset addresses not listed in Table 6-27 should be considered as reserved locations and the register contents should not be modified.

Table 6-26. R5FSS_VIM Instances

Instance	Base Address
MCU_R5FSS_VIC_CFG	40F8 0000h ⁽¹⁾
R5FSS_VIC_CFG	0FF8 0000h ⁽²⁾

- (1) MCU_R5FSS0 private memory-mapped register space. This region is only accessible by its associated R5F core; it is not accessible by any other SoC master. The base address is the same for each CPU view inside MCU_R5FSS0.
- (2) R5FSS0/1/2 private memory-mapped register space. This region is only accessible by its associated R5F core; it is not accessible by any other SoC master. The base address is the same for each CPU view inside R5FSS0/1/2.

6.3.3.1 R5FSS_VIM_PID Register (Offset = 0h) [reset = 60900001h]

R5FSS_VIM_PID is shown in [Figure 6-5](#) and described in [Table 6-30](#).

Return to [Table 6-27](#).

This register contains the major and minor revisions for the module.

Table 6-29. R5FSS_VIM_PID Instances

Table 6-70. R5FSS_VIM_VEC_INT_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	VAL	R/W	0h	These are the upper 30 bits of the 32-bit vector address associated with interrupt Q. It is the address that will be reflected in the R5FSS_VIM_IRQVEC or R5FSS_VIM_FIQVEC and the VECADDR output when interrupt Q is the active interrupt. Internally, these values are kept in a RAM. The FIQ and IRQ state machines have priority access to this RAM. Writes to this register will be piped internally, but further writes to the MMR interface may be stalled until this write has a chance to complete in the RAM. The new vector address will not take effect until this write completes to the RAM. In order to tell if this write has completed, software may read this register back. That read will not be able to complete unless the write has landed. Reads to this register will stall the MMR interface until the read is able to be completed at the RAM.
1-0	RESERVED	R	0h	Reserved. Read as 0. The lower 2 bits of the 32-bit vector address are always 0. (Vector addresses must be 32-bit aligned.)

6.4 C71x DSP Subsystem

This section describes the C71x Digital Signal Processor Subsystem (C71SS) in the device.

6.4.1 C71SS Overview

The TMS320C71x is the next-generation fixed and floating-point DSP platform. The C71x DSP is a new core in the Texas Instruments' DSP family. The C71x DSP supports vector signal processing, providing significant lift in DSP processing power over a broad range of general signal processing tasks in comparison to the C6x DSP family. In addition, the C71x provides several specialized functions which accelerate targeted functions by more than 30 times. Besides expanding vector processing capabilities, the new C71x core also incorporates advanced techniques to improve control code efficiency and ease of programming such as branch prediction, protected pipeline, precise exception and virtual memory management.

The C71x builds on the C6x's legacy but it is not binary compatible with any previous C6x DSPs. Many of the C71x architecture features are new and unique. The C71x is designed as a platform with these characteristics:

- True 64-bit machine with 64-bit memory addressing (64-bit virtual memory addressing, 40-bit physical addressing) and single-cycle 64-bit base arithmetic operations
- Achieves 4 to 32 times DSP processing capacity compared to C66x
- Preserves out-of-the-box performance parity for C code which has been optimized for C66x with a few exceptions
- Provides a direct software migration path from C66x
- Provides direct architecture support for accelerating OpenCL

Note

The C71SS is also referred to as C71x CorePac.

Figure 6-26 shows an overview of the C71SS.

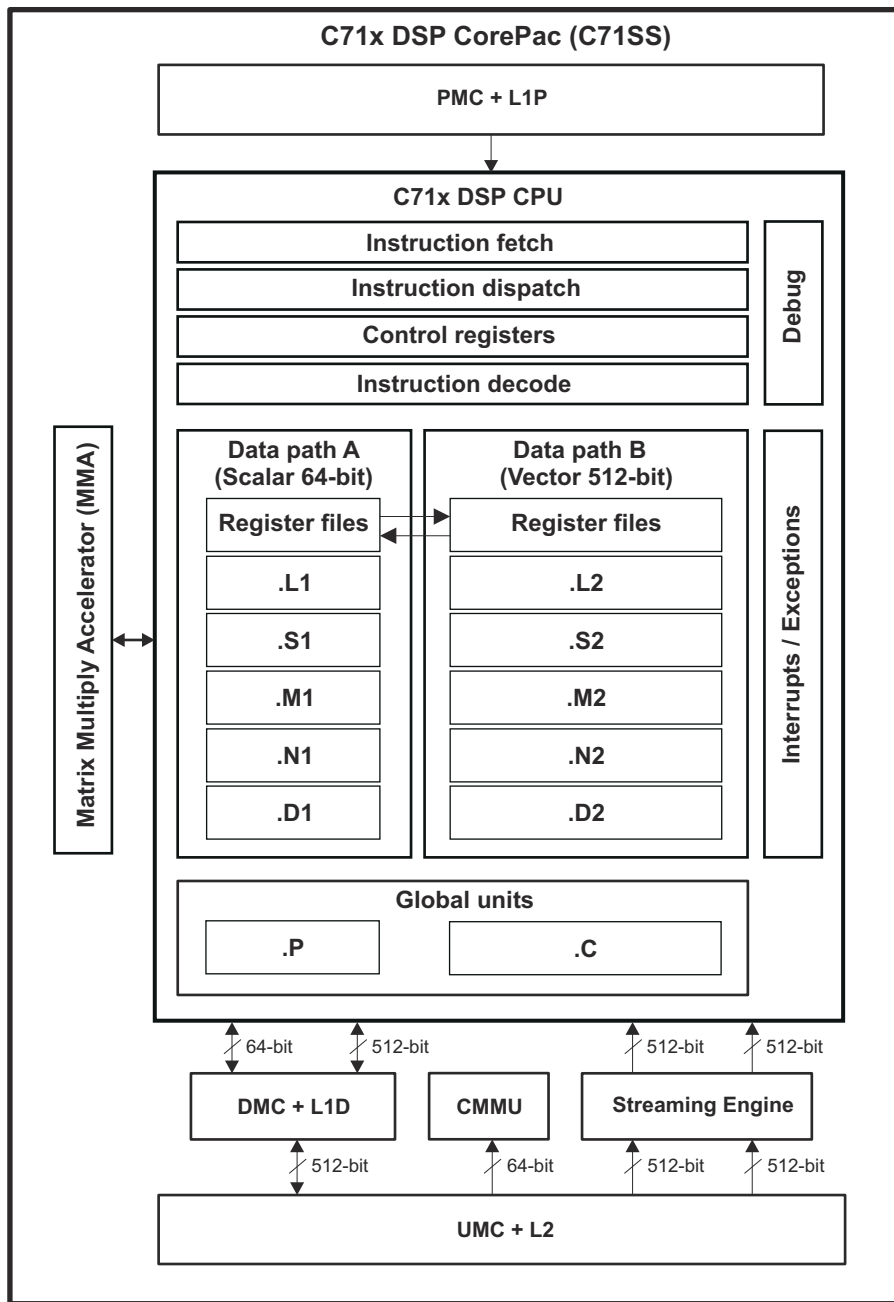

Figure 6-26. C71SS Overview

6.4.1.1 C71SS Features

The C71SS (C71x CorePac) supports the following key features:

- Hierarchical cache memory system
 - Level 1 (L1):
 - L1 program memory controller (PMC) with associated L1 program memory (L1P)
 - L1 data memory controller (DMC) with associated L1 data memory (L1D), either L1 data cache or L1 scratch memory
 - Level 2 (L2):
 - L2 unified memory controller (UMC) with associated L2 memory, either L2 cache or L2 scratch memory
- Streaming engine (SE)
- CorePac memory management unit (CMMU), fully compliant with Armv8-A memory architecture
- Power/clock/reset management unit

- ECC/parity support
 - ECC protection of L2 memory and L1D memory
 - Parity protection of L1P memory
- PBIST and LBIST support
- Cluster Level Event Controller (CLEC) CPU interface
- C71x debug subsystem
- Extended configuration register (ECR) interface for register access (instead of MMR)

6.4.2 C71SS Functional Description

Note

This chapter provides only a brief description of C71SS supported features. Full description of C71x DSP functionality is provided in standalone TI documentation.

6.4.2.1 C71x DSP CPU

The C71x CPU is a true 64-bit core which provides the following key features:

- Instruction fetch unit
- Instruction dispatch unit, advanced instruction packing
- Instruction decode unit
- CPU dual datapath
 - One 64-bit scalar side (side A) and one 512-bit vector side (side B)
 - Side A includes the following functional units
 - Four main scalar processing units (.L1, .S1, .M1, .N1) capable of operating on up to 64-bit wide data
 - Two units (.D1, .D2) for address calculations, enabling parallel load/store operations
 - The following operations can be executed at the same time in a single clock cycle
 - One non-aligned 64-bit load or store operation
 - Two 64-bit arithmetic/logical operations (non-multiply arithmetic instructions)
 - One 128-bit multiply operation
 - Side B includes the following functional units
 - Five main vector processing units (.L2, .S2, .M2, .N2, .C) capable of operating on up to 512-bit wide vector data
 - A predication processing unit (.P) for vector predication
 - The following vector operations can be executed at the same time in a single clock cycle
 - One non-aligned 512-bit load or store operation
 - Two 512-bit arithmetic/logical operations (non-multiply arithmetic instructions)
 - One 1024-bit multiply operation
 - One 512-bit correlation operation or regular arithmetic operation
 - One vector predicate manipulation operation
 - Vector side B can perform up to 128×16-bit fixed-point multiply-accumulate (MAC), 4.0 times the MAC capacity compared to C66x
 - Vector side B can perform up to 80 single precision FLOPs/cycle or 32 double precision FLOPs/cycle, 5.0 times the floating point compared to C66x
 - The C71x CPU can load or store in parallel 64 bits and 512 bits of data per clock cycle, more than four times the bandwidth compared to C66x. In addition, a novel streaming data interface can read an additional 1024 bits of data per clock cycle, providing a total of 12 times more bandwidth compared to the C66x
 - Large set of machine registers:
 - Up to 16×512-bit global vector registers
 - Up to 16×64-bit global scalar registers
 - Local registers
 - Register file cross paths
 - Two cross paths, 64-bit each
 - Allow functional units from one data path to access a 64-bit operand from the opposite side global register file
 - The cross paths can not access the local register files directly
- CPU control logic
 - Support for two security states
 - Secure state: CPU can access both secure and non-secure space
 - Non-secure state: CPU can only access non-secure space, and cannot access secure space
 - Support for six privilege and execution levels for security and virtualization support with banked control registers for full isolation and protection

- Secure root supervisor
- Secure root user
- Non-secure root supervisor
- Non-secure root user
- Non-secure guest supervisor
- Non-secure guest user
- Pipeline can operate in both unprotected and protected modes
 - Unprotected mode: Traditional C6x VLIW DSP operating mode with exposed instruction delay slots
 - Protected mode: Control code execution mode where instructions delay slots are not exposed
- Scoreboarding mechanism to help hide memory system stalls and to allow the compiler to generate more efficient control codes
- Supports recoverable interrupts and internal precise exception
 - No need to disable interrupts during multiple assignment code. In-flight results in multiple-assignment code are recorded by pipeline capture queues. These queues allow all programs to be interrupted at any arbitrary cycle, even during software pipelined loops, and then to be restarted correctly upon return from the interrupt or exception handler
 - Pipeline capture queues may be unloaded and reloaded, allowing the OS to swap out tasks regardless of whether the task was operating in protected or unprotected pipeline mode
 - Programmable event priority, hardware automatic event mask based on priority levels
 - Hardware performs automatic stacking at even handler entry and automatic unstacking at event exiting
- Nested loop counters (NLC): Hardware mechanism to facilitate low-overhead loop collapsing by providing the computations associated with nested loop counters and predicates, avoid the needs of using explicit instructions
- Test, debug, and interrupt logic
- Enhanced instruction set architecture (ISA)
 - Single-cycle 64-bit arithmetic, logical, and shift instructions
 - Improvements to load/store instructions
 - Endian aware vector load instructions
 - Unpacking load / packing store instructions
 - Vector load/store with element reversal
 - Vector load with data duplications
 - Specialized instructions to speed up key benchmarks
 - Horizontal MAX/MIN search acceleration instructions
 - Horizontal ADD, SUB instructions
 - Dedicated FIR instructions
 - Sliding window sum of absolute differences (SAD)
 - Maskable complex dot products
 - Circular comparison instructions to accelerate Viterbi
 - New and improved atomic instructions to replace LL/SC/CL combination
 - Increases orthogonality between 32-bit, 64-bit, and vector operations compared to C66x
 - Supports binlog instruction for vision algorithms
 - Specialized instructions only allowed to execute at required privilege level and secure state
- C71x OpenCL features
 - Full compliance with IEEE 754 floating point standard
 - Support subnormal numbers
 - DVM support
 - Support fencing for uTLB transactions

The matrix multiply accelerator (MMA) is included as a special functional unit in the C71x CorePac and is tightly coupled to CPU operation.

6.4.2.2 C71x DSP Matrix Multiply Accelerator

The matrix multiply accelerator (MMA) provides the following key features:

- Support for fully connected layer using matrix multiply with arbitrary dimension
- Support for convolution layer using 2D convolution with matrix multiply with read panel
- Support for ReLU non-linearity layer OTF

- Support for high utilization (>85%) for typical convolutional neural network (CNN), such as AlexNet, ResNet, and others
- Ability to support any CNN network topologies limited only by memory size and bandwidth
- Coupled with C71x CPU using DSP chassis for data formatting
- MMA and C71x CPU are on a shared power domain
 - MMA cannot be independently powered off or clock gated at LPSC level (although it has extensive clock gating within the IP)

6.4.2.3 C71x DSP Cache Memory System

The C71x CorePac implements a hierarchical cache memory system with the following levels:

- Level 1 (L1):
 - L1 program memory controller (PMC) with associated L1 program memory (L1P)
 - L1 data memory controller (DMC) with associated L1 data memory (L1D)
- Level 2 (L2):
 - L2 unified memory controller (UMC) with associated L2 memory

6.4.2.3.1 C71x DSP L1 Program Memory

The L1P cache controller supports a fixed cache size of 32KB. The purpose of the L1P cache is to maximize performance of the code execution. L1P cache is necessary to facilitate fetching program code at a fast clock rate in order to maintain a large system memory. The cache is responsible for hiding the latency associated with executing code from the slower system memory.

The L1P memory system provides the following key features:

- L1 program memory controller (PMC) with 32KB L1P memory, all cache (no support for L1P SRAM)
- L1P cache
 - 4-way set associative
 - 64-byte line size
 - Virtually indexed, virtually tagged (48-bit virtual address)
 - Auto-prefetching on L1P misses from L2
- Prefetch and branch prediction
- ECC SECDED support
- Software initiated coherence operations
 - Single cycle invalidate with support for three modes: all cache lines, only user cache lines, only supervisor cache lines
- Virtual memory
 - Virtual-to-physical addressing on misses
 - Micro-TLB (uTLB) to handle address translation and for code protection
- Extended control register (ECR) access
 - L1P ECR registers are not memory mapped and instead are mapped to a MOVC CPU instruction

6.4.2.3.2 C71x DSP L1 Data Memory

The L1D includes a non-blocking cache controller, which has a main cache and a small fully associative victim cache. Main cache is read-allocate and supports write-back and write-through. Victim cache services read and write hit directly with no performance overhead as main cache.

The purpose of the L1D memory/cache is to maximize performance of the data processing. The cache is necessary to facilitate reading and writing data at the full CPU clock rate, while still having a large system memory. It is the cache's responsibility to hide much of the latency associated with reading from and writing to the slower system memory. The L1D memory includes two logical sections:

- L1D partition 0: Can support 32KB (max) / 8KB (min) of cache. Cache may only reside in partition 0. A cache size of 0KB is not supported, which means that disabling L1D cache functionality is not possible
- L1D partition 1: Can support 40KB (max) / 16KB (min) of SRAM (may include LUT and histogram)

Note

The minimum cache size (8KB) can only be achieved via L1DMODE register programming.

The L1D memory system provides the following key features:

- L1 data memory controller (DMC) with 48KB L1D memory, configurable as cache and/or SRAM
- L1D partition 0 (cache/SRAM) + L1D partition 1 (SRAM only)
- L1D cache
 - 32KB cache (max), configurable down to 8KB cache (min)
 - Dual datapath (DP0 + DP1) support
 - Direct-mapped (1-way set-associative) main cache
 - 128-byte cache line size
 - Read-allocate cache
 - Support for both write-back and write-through modes
 - Support for victim cache
 - 16 cache lines, fully associative
 - Physically indexed, physically tagged (40-bit physical address)
 - Support for speculative loads
 - Hit under miss
 - Posted write miss support
 - Write merging on all outstanding write transactions inside L1D
- L1D SRAM
 - 16KB (min), configurable up to 40KB (max)
 - Accessible from CPU or DMA
- Lookup table (LUT) and histogram
 - LUT
 - Up to 4 sets of look up tables can be specified simultaneously
 - Supports interpolation mode
 - Indices are unsigned values at 32-bit lanes of the source register
 - Look up table elements can be signed or unsigned, bytes, half-words or words
 - Histogram
 - Up to 4 sets of histograms can be specified simultaneously
 - Supports regular and weighted histogram operations
 - Indices are unsigned values at 32-bit lanes of the source register
 - Histogram weights are at 32-bit lanes of the source register
 - Histogram weights can only be signed bytes or signed half-words
 - Histogram bin data saturates to the minimum or maximum values of its data bin type
- Bandwidth
 - 1024-bit data throughput
 - 16×64-bit banks
- ECC SECDED support
- Coherence
 - Full MESI support
 - Support for global cache coherence operations
 - Snoops and cache maintenance operation support from L2
 - Snoops for L2 SRAM, MSMC SRAM and external (DDR) addresses
- Virtual memory support
 - Support for wider (40-bit) physical address
- ECR access
 - L1D ECR registers are not memory mapped and instead are mapped to a MOVC CPU instruction

6.4.2.3.3 C71x DSP L2 Memory

The L2 memory system provides the following key features:

- L2 unified memory controller (UMC) with 512KB L2 memory, configurable as cache and/or SRAM

- L2 cache
 - 8-way set-associative
 - 128-byte cache line size
 - Write-allocate cache
 - Support for both write-back and write-through modes
 - Physically indexed, physically tagged (40-bit physical address)
 - Supports 2×64-byte streams from one streaming engine
 - External MMR and MDMA accesses on an unified interface to MSMC
 - Caches MMU page tables
 - Cache pre-warming from SE and/or MSMC
- L2 SRAM
 - Security firewall on L2 SRAM accesses
 - DMA access to L2 SRAM on merged MSMC I/F
- Bandwidth
 - 2048-bit data throughput (see [Section 6.4.2.4, C71x DSP Streaming Engine](#))
 - 4×512-bit banks, with 2 virtual banks each
- ECC SECDED support
- Coherence
 - Full MESI support
 - Support for global coherence operations
 - Snoops for L2 SRAM, MSMC SRAM and external (DDR) addresses
 - User coherence commands from SE
 - Full coherence between L1D cache, SE, L2 SRAM, MSMC SRAM and DDR
- ECR access
 - L2 ECR registers are not memory mapped and instead are mapped to a MOVC CPU instruction

6.4.2.4 C71x DSP Streaming Engine

The streaming engine (SE) supports the following key features:

- Provides a flexible, high bandwidth mechanism for reading large quantities of data into C71x CPU
- Supplies two 512-bit data streams (S0, S1) directly from L2 to the vector units
- Provides two stream address generators, supporting the two data streams
 - Flexible multi-dimensional address calculators
 - Provide offset addresses for load and store instructions
- Supports element promotion, decimation, duplication, transpose loads, predication
- LEZR feature can be enabled to return N number of zero vectors to CPU after selected dimension ends. LEZR and transposed mode are not supported together. LEZR is still supported when transposed mode is disabled..
- Provides 6D addressing
 - Access patterns up to 6D can be programmed ahead
 - 6D data is presented as 512-bit vector per cycle
- Communicates with L2 memory controller for requests beyond L2 (MSMC, DDR)
- Coherent with L1D data at stream open/close boundaries
- ECC SECDED support

The SE can sustain 1024-bits/cycle total bandwidth (512 bits/cycle on each of two streams) to the DSP CPU. When combined with its 512-bit/cycle vector load unit and 512-bit/cycle store unit, the DSP CPU can access 2048 bits/cycle of data.

6.4.2.5 C71x DSP CorePac Memory Management Unit

The CorePac Memory Management Unit (CMMU) extends the C71x architecture with support for address translation, access permission and protections and memory attributes determination and checking. It is implemented per C71x cluster as a two-level TLB structure. The CMMU works with the C71x L1 caches, stream buffers in each processor and CorePac memory system of CorePac cluster to translate virtual addresses to physical addresses, controls tablewalk hardware that accesses translation tables in main memory. The CMMU enables fine-grained memory system control through a set of virtual-to-physical address mappings and memory

attributes held in the L1 level micro translation look-aside buffer (uTLB) and CorePac cluster level translation look-aside buffers (TLBs).

The CMMU provides the following key features:

- Supports AArch32 LPAE and AArch64 page table format
 - Programmable levels of page table translation
 - 4KB, 16KB, 64KB translation granules
- Supports multiple page sizes: 4KB, 16KB, 64KB, 2MB, 32MB, 512MB, 1GB, 16GB
- Supports both hardware and software managed table walks
- Hierarchical Table Lookaside Buffer (TLB) caching page entries, intermediate page walk pointers for optimum address translation performance
 - Micro-TLB (uTLB) as first level TLB
 - 16-entry fully associative dual interface L1 data uTLB
 - 8-entry fully associative L1 instruction uTLB
 - CorePac (L2) TLB as second level TLB
 - 512-entry 4-way associative TLB cache, caching both instruction and data page translations with virtual-to-physical address mapping
 - Intermediate table walk caches to reduce memory access during multi-level page walk
 - Allows caching and sharing of intermediate table walks and page tables in the system cache hierarchy
- Security extensions that facilitate the development of secure applications
- Soft-error protection on all RAM and data storage structures

6.4.2.6 C71x DSP ECC Support

[Table 6-71](#) provides the RAM ID for the C71x DSP ECC aggregator.

Table 6-71. RAM ID Map for C71x DSP ECC Aggregator

RAM ID	Endpoint
0	C71x Corepac
1	CBASS P2P
2	CBASS SCR
3	CBASS SCR
4	Reserved
5	Reserved
6	UMC pipe 0
7	UMC pipe 0
8	UMC pipe 1
9	UMC pipe 1
10	UMC pipe 2

16	SE, stream 0
17	SE, stream 1
18	PMC

6.4.2.7 C71x DSP Boot Configuration

In this device, the C71x boots from system memory instead of booting from ROM. A 1KB boot RAM (PSRAM1KECC) is used to store boot vectors for the C71x CPU.

6.4.2.8 C71x DSP Power-Up/Down Sequences

The power-up and power-down sequences for the C71SS can be found in *Power*.

6.4.2.9 C71x DSP Interrupt Control

The cluster level event controller (CLEC) serves the role of an interrupt controller for the C71x DSP. For more details, see *Interrupts*.

6.5 Graphics Accelerator (GPU)

This chapter describes the integration of the Graphics Processing Unit (GPU) subsystem in the device.

6.5.1 GPU Overview

The Graphics Processing Unit (GPU) accelerates 3-dimensional (3D), 2-dimensional (2D) graphics, and compute applications.

The GPU is based on the PowerVR® BXS 4-64 MC1 core from Imagination Technologies.

6.5.2 Features Supported

- Base architecture, fully compliant with the following APIs:
 - OpenGL ES 3.2
 - OpenCL 1.2 EP
 - Vulkan 1.2
- Tile-based deferred rendering architecture for 3D graphics workloads, with concurrent processing of multiple tiles
- Support for DRM security
- Support for GPU virtualization
 - Up to 8 virtual GPUs
 - Separate IRQ for each OSID
- Multi-threaded Unified Shading Cluster (USC) engine incorporating pixel shader, vertex shader and GP-GPU (compute shader) functionality
- USC incorporates an ALU architecture with high SIMD efficiency
- Fully virtualized memory addressing (up to 64 GB address space), supporting unified memory architecture
- Fine-grained task switching, workload balancing and power management
- Advanced DMA driven operation for minimum host CPU interaction
- 256KB System Level Cache (SLC)
- Specialized Texture Cache Unit (TCU)
- Compressed Texture Decoding
- Lossless data compression (PVRGC) - The PowerVR's geometry compression, which is performed in the Geometry Processing phase of the 3D graphics workload.
- Dedicated RISC-V processor for firmware execution
- Separate power island for the firmware processor for low latency power domain transitions
- On-Chip Performance, Power and Statistics Registers.
- Resolution Support
 - Frame buffer max size = 8K × 8K
 - Texture max size = 8K × 8K
- Anti-aliasing
 - Maximum 4× multisampling
- Performance
 - Floating Point Operations (F32) - 64 operations per clock
 - Floating Point Operations (F16) - 128 operations per clock
 - Texture performance - 4 texels per clock (@32 BPP)
 - Pixel performance - 4 pixel(s) per clock (@32 BPP)
 - Geometry Performance - 0.25 triangles per clock
 - Max performance
 - ~50 GFLOPS, 4 GTex/s or 4 GPix/s @ 800MHz

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

6.6 Video Accelerator

The following sections describe the video accelerator details for the device.

6.6.1 Introduction

The Video Accelerator is a 4K codec that supports both HEVC and H.264/AVC video formats. It provides high performance encode and decode capability up to 8bit 4K@60fps with a single-core architecture.

The Video Accelerator can encode and/or decode any resolution up to 8192 x 4320. It guarantees real-time performance for encoding/decoding 4K 60fps based on its sophisticated, latency tolerant hardware architecture. The Video Accelerator is highly optimized for memory bandwidth loading and excellent power management.

The Video Accelerator contains a 32-bit processor called V-CPU, which is responsible for parsing bitstream syntax in decoder or encoding bitstream syntax in encoder from sequence to slice header unit, pre-scanning slice data, controlling the underlying video hardware blocks called V-CORE. The V-CPU also communicates with host CPU through host register interface. The V-CORE performs actual processing of coded slice data: entropy decoding, inverse scan, inverse transform/quantization, motion compensation, and loop filtering in decoder and motion estimation, intra prediction, RDO, and entropy coding in encoder. This software and hardware combined architecture can provide flexibility and high throughput at the same time.

6.6.2 Features

6.6.2.1 Performance

H.265/HEVC Encoder

- Capable of encoding HEVC Main and Main Still Picture Profile @ L5.1 High tier
 - Maximum resolution: 8192x8192
 - The maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
 - Minimum resolution: 256x128
 - Constraints
 - A picture width shall be multiple of 8.
 - A picture height shall be multiple of 8.

Table 6-72. HEVC Encoder Performance

PicWidth	PicHeight	MHz/60fps 160Mbps
3840	2160	500

H.264/AVC Encoder

- Capable of encoding Baseline/Constrained Baseline/Main/High Profiles Level @ L5.2
 - Maximum resolution: 8192x8192
 - The maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
 - Minimum resolution: 256x128
 - Constraints
 - A picture width shall be multiple of 8.
 - A picture height shall be multiple of 8.

Table 6-73. H.264/AVC Encoder Performance

PicWidth	PicHeight	MHz/60fps 72Mbps
3840	2160	500

H.265/HEVC Decoder

- Capable of decoding HEVC Main and Main Still Picture Profile @ L5.1 High tier
 - Maximum resolution: 8192x4320
 - The Maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
 - Minimum resolution: 8x8

Table 6-74. H.265/HEVC Decoder Performance

PicWidth	PicHeight	MHz/60fps 160Mbps
3840	2160	450.00

H.264/AVC Decoder

- Capable of decoding Baseline/Constrained Baseline/Main/High Profiles @ L5.2
 - Maximum resolution: 8192x4320
 - The Maximum resolution means the largest image size that the hardware can process with. Performance is not considered in this term.
 - Minimum resolution: 32x32

Table 6-75. H.264/AVC Decoder Performance

PicWidth	PicHeight	MHz/60fps 72Mbps
3840	2160	450.00

6.6.2.2 Codec Related Features

H.265/HEVC Encoder

- Fully compatible with ISO/IEC 23008-2 high efficiency video coding main profile
- I/P slices
- CTU64
 - Supportable prediction unit (PU) size: 32 x 32, 16 x 16, 8 x 8
 - Supportable transform unit (TU) size: 32 x 32 to 4 x 4
- Parallel tools
 - Wavefront parallel processing (WPP) encoding with a single slice
 - Multi slice: Independent slice segment and dependent slice segment
- High performance offline CABAC encoding
- Motion estimation
 - 1/4-pel precision motion vectors
 - Search range [±128H, ±64V] with an adaptive search center
 - Two reference frames for P-slice
 - Long-term reference for P picture
- Custom tuning tools
 - Custom Lambda map and lambda table
 - Custom mode decision
 - Fully programmable user scaling list
- In-loop filter
 - Deblocking filter
 - Sample adaptive offset (SAO)
 - Loop filtering across slices
- Strong intra smoothing on/off
- Transform skip
- Lossless coding
- Picture/CTU/subCTU level of rate control
- Region of interest (ROI) encoding with custom QP map
- 3DNR
- Adaptive intra refresh (AIR) for error resilience
- Support for YUV420 video format
- Support for YUV422 video format (only encoder)

H.264/AVC Encoder

- Compatible with the ITU-T recommendation H.264 specification. All coding tools in the baseline, constrained baseline, main, and high profiles are supported.
 - With a few exceptions:
 - Interlaced coding tools are not supported.
 - FMO/ASO tool of H.264 is not supported.
- 16 x 16, 8 x 8 and 4 x 4 block sizes are supported and configurable.
- Motion estimation
 - 1/4-pel accuracy motion estimation with programmable search range up to [±64, ±48]
 - One reference frame for P-slice
- Intra prediction
 - Luma 4 x 4 Mode: 9 modes
 - Luma 8 x 8 Mode: 9 modes
 - Luma 16 x 16 Mode: 4 modes (vertical, horizon, DC, plane)
 - Chroma mode: 3 modes (vertical, horizon, DC)
- Custom tuning tools
 - User-defined mode (skip, intra) map
 - User-defined QP map
 - Lambda tuning for custom mode decision
 - Fully programmable user scaling list
- In-loop deblocking filter
- CABAC/CAVLC support
- Error resilience tools:
 - Cyclic intra refresh (CIR)
 - Multi-slice structure
- A frame level and MB level of rate control
- Region of interest (ROI) encoding with custom QP map
- Support for YUV420 video format
- Support for YUV422 video format (only encoder)

H.265/HEVC decoder

- Fully compatible with ISO/IEC 23008-2 high efficiency video coding main/MSP (main still picture) profile. All coding tools in the profile are supported.
- I/P/B slices
 - All intra-prediction modes
 - All inter-prediction modes
- Variable CTU size: 64 x 64 to 16 x 16
 - Variable prediction unit (PU) size: 64 x 64 to 4 x 4
 - Variable transform unit (TU) size: 32 x 32 to 4 x 4
- Advanced motion vector prediction (AMVP) and merge mode
- A quarter motion compensation with 8 tap filters
- Uniform reconstruction quantization (URQ)
- Parallel coding tools
 - Multi tile
 - Wavefront parallel processing (WPP)-encoded bitstream support
 - Multi slice: Independent slice segment and dependent slice segment
- High performance CABAC decoding
- In-loop deblocking filtering
- Sample adaptive offset (SAO)
- Loop filtering across slice/tile boundaries
- Data reporting to the external host
- Robust error concealment
- Sequence change detection
- Support for YUV420 video format

H.264/AVC Decoder

- Fully compatible with the ITU-T recommendation H.264 specification. All coding tools in the baseline/constrained baseline/main/high profile are supported.
 - With a few exceptions:
 - Interlaced coding tools are not supported.
 - FMO/ASO tool of H.264 is not supported.
- Variable block size (16 x 16, 16 x 8, 8 x 16, 8 x 8, 8 x 4, 4 x 8 and 4 x 4)
- CABAC/CAVLC support
- In-loop deblocking filter
- Error detection, concealment and error resilience tools
- Support for YUV420 video format

6.6.2.3 Non-Codec Related Features

Rotation and mirroring

The Video Accelerator supports 8 modes of rotation and mirroring. The PRP block can do rotations of the source picture in 90, 180, or 270 degrees and vertical or horizontal flip before starting to encode the operation.

Bit-depth and chroma format conversion

The PRP block is responsible for source format conversion in the encoder IP. 422 (planar/semi-planar) to 420 conversion can be made before encoding operation.

Frame buffer compression

To overcome bandwidth suffering and at the same time to ensure real-time encode/decode performance, TI has carefully designed lossless, great access patterned frame buffer compression technology and employed it into the WAVE IP series. WAVE521CL achieves significant reduction in bandwidth while sustaining fast processing capability.

Long Burst Write

The Video Accelerator includes burst write back (BWB) module that enables 128-byte burst write access to external memory for better bus utilization. It collects a group of short write requests from loop filter block in 128-byte unit and sends it out to the external memory more efficiently. BWB works for an external Display module or other post processing module that needs to read decoded frames in raster scan order.

The FBC/FBD block also writes or reads 128-byte burst length of compressed frame data from/to the external memory.

3DNR

The Video Accelerator employs temporal noise reduction technology, also called 3DNR (3D noise reduction), for better quality of image under low light. Video noise appears easily in a low light level. It is an important issue in surveillance camera because images are captured often under dark conditions or indoors, which can make identification difficult.

The Video Accelerator can detect and filter noise for each color component Y, Cb, and Cr of a frame. This achieves both good video quality and enhancement of coding efficiency. Noise reduction is done while encoding. Therefore, additional read/write bandwidth is not required.

Note

3DNR is supported in the H.265/HEVC encoder only.

Latency tolerance

The Video Accelerator can afford to reach real time performance under memory access latency if the number of cycles per CTU retains less than 500 cycles. The Video Accelerator is designed to be less sensitive to pipeline delay, especially at a peak bitrate, which might eventually incur performance drop. With use of decoupling techniques and inter-pipe queues, it can hide this sort of delay and deliver high performance at any situation.

Subframe synchronization

The Video Accelerator supports subframe synchronization for low latency coding. By receiving dedicated subframe-ready signals from the image process unit (IPU) or by setting host interface registers from host CPU, the Video Accelerator can start encoding process as early as the minimum set of raw video data is ready.

Programmability

The Video Accelerator embeds the 32-bit CPU and 16-bit DSP dedicated to bitstream processing and their video hardware control. Host interface registers and interrupts are provided for communication between a host processor and the Video Accelerator.

Low Power Consumption

The Video Accelerator can ensure ultra-low power operation by gating the clock sources for some internal hardware blocks in an idle state.

Trick mode

The Video Accelerator supports trick mode such as fast/slow forward playback and fast/slow reverse playback for video applications. By seeking an intra random access point (IRAP) picture as entry points of bitstream, the Video Accelerator can skip non-IRAP pictures and start decoding from an IRAP picture or decode a thumbnail of a picture.

Frame-based processing

V-CPU processor operates video operation on a frame by frame basis. While frame operation is running, there is no need for communication between the host processor and the Video Accelerator. This is the key feature for promising the lowest burden to host processor for video operations.

By issuing a picture processing, the host application can perform its own operations until it receives an interrupt from the Video Accelerator informing of the completion of picture processing.

Handling multi-instances

The Video Accelerator supports multiple instances, which can be helpful for multi-channel encoder and/or decoder applications. To support this multi-instance operation, the Video Accelerator uses an internal context parameter set for each instance. While creating a new instance and starting picture processing, a set of these context parameters is created and updated automatically in the Video Accelerator. Because of this internal context management scheme, different encoder and/or decoder tasks running on the host processor can control Video Accelerator operations independently with their own instances.

When creating a new instance, an application task will get a new handle specifying an instance if a new handle is available on the Video Accelerator. All of the following operations for the given application task could be separately handled on the Video Accelerator by using this task-specific handle. Because the Video Accelerator can only perform one picture processing task at a time, each application task should check whether the Video Accelerator is ready or not before starting a new picture operation. By calling a function for closing a certain instance, the application can easily terminate a single task of video operation on the Video Accelerator.

6.6.3 Block Diagram

Figure 6-27 shows the hierarchical architecture of the Video Accelerator and external bus interfaces.

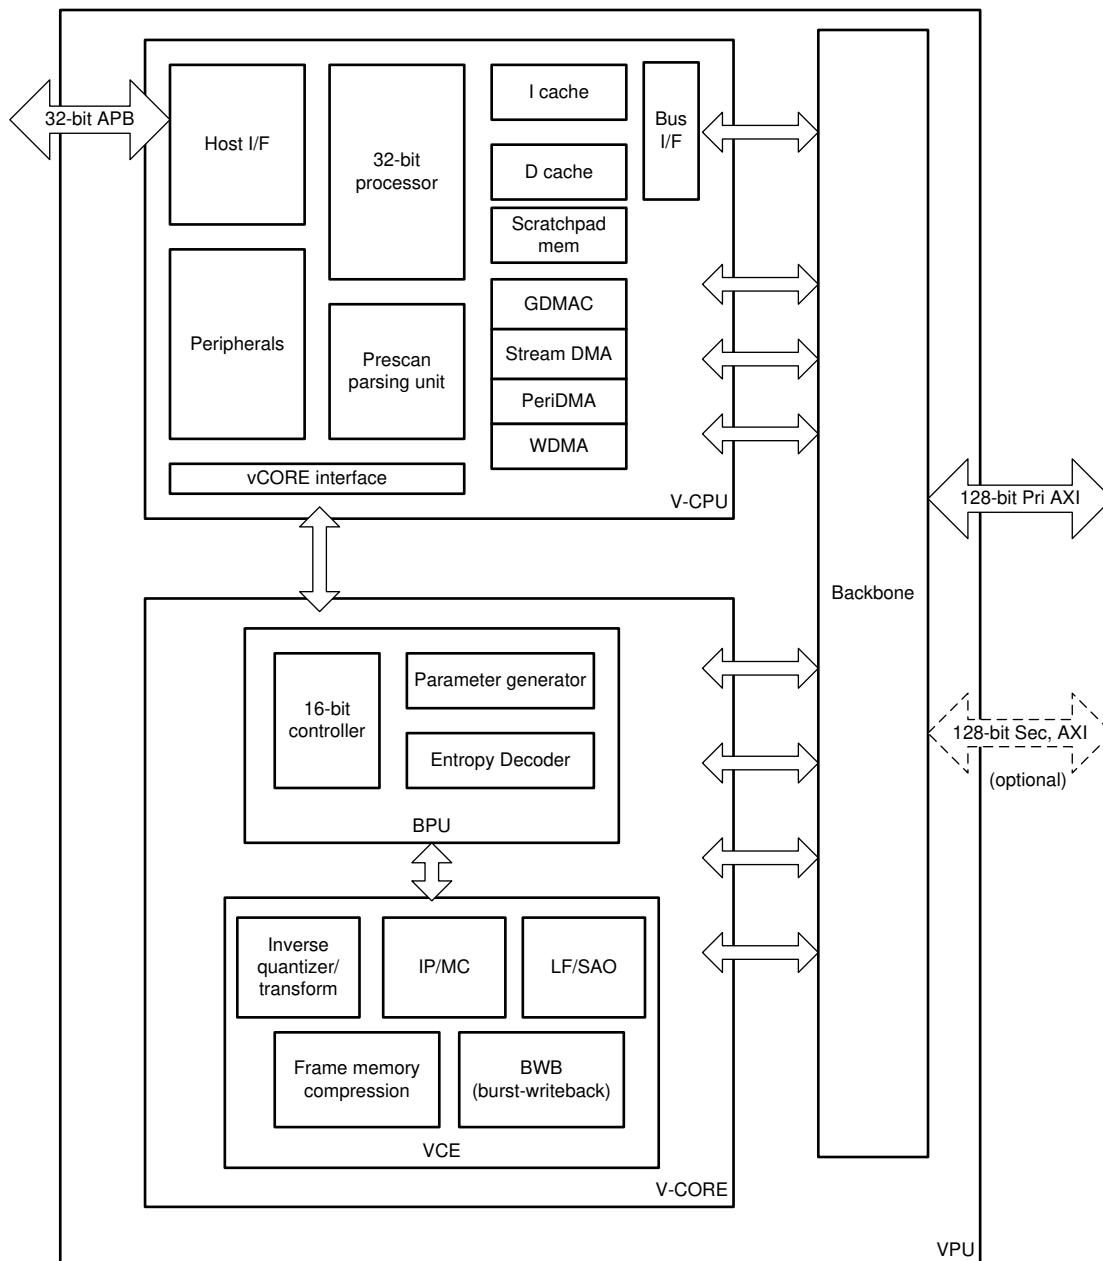

Figure 6-27. Video Accelerator Block Diagram

The Video Accelerator is built on a layer structure for efficient video processing. It is composed of two main parts, V-CPU and V-CORE. V-CPU is a 32-bit processor where the Video Accelerator L1 driver software is running. It mainly encodes and decodes a high-level syntax of bitstream - SPS/PPS/SH, and communicates with the host processor, such as receiving a picture level command from the host processor or sending the result of video task through the 32-bit AMBA3 APB bus. V-CPU can also parse necessary parameters and give necessary slice/tile-level information to the underlying V-CORE hardware.

Particularly in case of an HEVC decoder, V-CPU uses a virtual wavefront parallel processing (VWPP) scheme to balance processing load among V-CORES and to simplify its operation. During the VWPP, V-CPU parses bitstream and extracts some data from bitstream such as CABAC context, QP, and start address for each row and tile. After that, V-CPU reorders the data to meet the WPP processing sequence and dispatches them to the appropriate V-CORES.

V-CORE can encode and decode a slice unit of data. It consists of a 16-bit DSP called a bit processor unit (BPU) and a group of video codec hardware blocks called a video codec engine (VCE).

- BPU is responsible for packing and parsing of coded slice data, CTU/CU/PU/TU-level parameter derivation, and finally passing slice data over to the VCE. To speed up entropy encoding/decoding, some hardware accelerators are included in the BPU.
- On the other hand, VCE is an actual hardware core executing a series of decoding process - encoding and decoding process - motion estimation, intra-prediction, RDO, and entropy coding with their hardwired logics, motion compensation, inverse-transformation/quantization, and loop filter with their hardwired logics. HEVC and H.264/AVC decoders share most of the internal VCE memories and full logics in certain VCE blocks like intra-prediction for small gate count.

They are doing these tasks with CTU-based pipelines and FIFO queues to ensure real-time speed and performance. When it comes to system connection as shown in the [Figure 6-27](#), there is one 32-bit AMBA3 APB interface connecting to the host processor, and there are two 128-bit AMBA3 AXI bus interfaces connecting to the external memory controller for reading and writing picture data and temporal data.

- Primary AXI: AXI interface to read or write work data and coded picture (bitstream), decoded picture data and so forth.
- Secondary AXI (optional): On-chip-SRAM connected AXI interface to read or write temporal buffer required for V-CORE operation. This is an optional interface that can be used to alleviate bandwidth usage.

6.7 Vision Pre-processing Accelerator (VPAC)

This chapter describes the Vision Pre-processing Accelerator (VPAC) in the device.

6.7.1 VPAC Overview

The Vision Pre-processing Accelerator (VPAC) subsystem is a set of common vision primitive functions, performing pixel data processing tasks, such as: color processing and enhancement, noise filtering, wide dynamic range (WDR) processing, lens distortion correction, pixel remap for de-warping, on-the-fly scale generation, on-the-fly pyramid generation. The VPAC offloads these common tasks from the main SoC processors (ARM, DSP, etc.), so these CPUs can be utilized for differentiated high-level algorithms. The VPAC is designed to support multiple cameras by working in time-multiplexing mode. The VPAC also includes an imaging pipe, which can be integrated on-the-fly with external camera sensor, as well as does memory-to-memory (M2M) processing on pixel data.

Figure 6-28 provides an overview of the VPAC subsystem.

Figure 6-28. VPAC Overview

6.7.1.1 VPAC Features

The VPAC includes the following processing and infrastructure sub-modules:

- Vision Imaging Sub-System (VISS). The vision imaging pipe does image processing on raw data which includes Wide Dynamic Range (WDR) merge, Defect Pixel Correction (DPC), Lens Shading Correction (LSC), Global/Local Brightness and Contrast Enhancement (GLBCE), demosaicing, color conversion, and Edge Enhancement (EE). It can operate on sensor data either on-the-fly or in memory-to-memory mode. The VISS provides the following main features:
 - Performance is up to 1 pixel/cycle
 - Up to 16-bit input RAW formats (8b, 12b, 14b, 16b)
 - Support for concurrent 12-bit and 8-bit YUV output
 - Support for generic 2x2 RAW format (Bayer, RCCB, RCCC etc.)
 - Support for other color spaces:
 - RGB output
 - Support for color saturation and gray scale for HSV/HSL, etc.
 - Support for multiple WDR/HDR formats:
 - Combined Companded format (up to 16-bit companded)
 - Separated Exposures – up to 3 frame Motion Adaptive HDR Merge
 - Staggered HDR
 - Digital Lateral Overlap (DLO)
 - Support of statistics for Auto-Exposure/Auto-White-Balance or Auto-Focus (configurable option to select either AE/AWB or AF)
 - Support for Flexible CFA for generating multi-plane output for any 2x2 RAW format sensor configuration.
 - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
 - Can generate up to 4 independent color planes
 - Support for up to 3 directions per color plane
 - Adaptive threshold based on intensity measure
 - Support for multiple color format output generation
 - Supports traditional 12-bit YUV output
 - Supports RGB output (8-bit only)
 - Supports saturation outputs (8 bits only)
 - Supports Grayscale/Luma/IR/Clear output
 - Global/Local Brightness and Contrast Enhancement module
 - Spatial Noise Filter (NSF4V)
 - Supports raw input image in generic 2x2 color pattern format including Bayer pattern
 - Supports 16-bit raw input image
 - Spatially adaptive noise level threshold
 - Configurable soft or hard thresholding

- Supports elliptical lens shading gain adjustment of adaptive noise threshold with 2 sets of independent settings
- White Balance gain
- Signal level detection with flexible cross-color-channel or independent averaging
- Option to bypass visual enhancement functions (NSF4V and GLBCE)
- Edge Enhancement (EE)
 - Enhance the visual quality of the image (Luma only)
 - Edge enhancer filter and the edge sharpener filter can be combined by configuration
 - Option to bypass visual enhancement functions (CAC, NSF4V, and GLBCE)
- Lens Distortion Correction (LDC) block. The LDC engine is YUV domain processor designed to perform perspective and geometric transforms. This can be used for creating several effects, including but not limited to:
 - Lens Distortion Correction, including Fish Eye Lenses
 - Epipolar rectification for Stereo
 - Generic perspective transforms for rotation scaling or Augmented Reality like effects

The output of the LDC block can be sent to external memory (DDR) or sent to other VPAC sub-module (Scalar, Noise filter) for further pre-processing via local shared memory (SL2). The LDC block provides the following main features:

- Performance up to 1 cycle/pixel (bilinear) and 2 cycles/pixel (bicubic)
- Autonomous memory-to-memory operation
- Tile based processing
- Generic mesh based distortion model to correct multiple distortion types
- Perspective warp transformation for perspective correction; affine transform is a subset of perspective warp and supports scaling and rotation
- Supported formats (see [Section 6.7.2.9](#)):
- Supports up to 8192 x 8192 image dimension
- Pixel Interpolation
 - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
 - Bilinear interpolation mode to offer double throughput
- Supports variable block size frame processing (9 regions)
- Multi-Scalar (MSC) block. The MSC block reads data from memory (DDR or on-chip) to shared memory (SL2) and generates up to 10 scaled outputs from a given input with various scaling ratios (between 1x and x0.25). The output of the MSC block can be sent to external memory (DDR) from the local shared memory (SL2), or can be further noise filtered using the VPAC Noise Filter (NF) block. The MSC supports two independent threads (scalars), which combined can generate up to max 10 scales. The MSC block provides the following main features:
 - Multi-scaling capable: 10 simultaneous scaled outputs from 1 or 2 input planes; up to 2 simultaneous processing thread with total of 10 scaled output with 1 to N and 1 to M configurations (where N+M <=10)
 - Each scaling engine can be configured to perform Pyramid or inter-octave scale generation
 - Scaling ratio supported: 1x ~ x/4 (with 1x scaling, MSC can perform a 3~5-tap generic separable convolution filtering)
 - 5-tap separable filter kernel implementation
 - Programmable kernel sizes for vertical/horizontal filter (3, 4, or 5)
 - Poly phase implementation with support of 64 or 32 phases
 - 4 sets of 5-tap x 32 phase coefficients (two can be combined to support 5-tap x 64 phase coefficients and one of set can hold additional 5-tap customer filter coefficients for non-resizing filter)
 - 2 additional sets of 5-tap Gaussian filter coefficients (single-phase) dedicated for Pyramid (Octave) generation
 - Coefficients in 10-bit (S10Q8 format - signed value of 10 bits with 8-bit fraction)
 - Separate initial horizontal and vertical phase programming option
 - Support for two planes of data processing
 - Data in a plane can be uniform (for example, Y plane) or interleaved (Cb/Cr interleaved)
 - 8-bit or 12-bit component data
 - Output data rate is dependent on downscaling ratio
 - Programmable input and output ROI (or clipping) for each scaler

- On-the-fly (OTF) or memory-to-memory (M2M) operation with line buffers in SL2 (frame resolution support is not constrained by MSC line buffer)
- Noise Filter (NF). The NF block reads data from memory (DDR or on-chip) to shared memory (SL2) and does Bilateral filtering to remove noise. The output of the NF block can be sent to external memory (DDR) from shared memory (SL2) or can be further re-sized using the MSC block. The NF block provides the following main features:
 - Support for bilateral and general filtering
 - Supports filter size up to 5x5
 - Supports true 2D bilateral filtering
 - Supports filter size up to 5x5 of programmable static weights
 - LUT based bilateral weights generation (8-bit for weight)
 - Supported formats: one plane (interleaved plane and non-interleaved) YUV 420, 12-bit
 - Performance up to 1 pixel/cycle
- Hardware Thread Scheduler (HTS). The HTS block used for inter-processor communication among various VPAC sub-modules (VISS, LDC, Scalar, and NF) and with the local DMA Engine (UTC). The HTS block provides the following main features:
 - Scheduling the HWA threads and associated tasks
 - Enables rate-controlled task execution
 - Support running several independent threads asynchronously in the sub-system
 - Debug functions:
 - Halting HWA threads at logical task boundary
 - Handling pipeline suspend and subsequent abort by software intervention
- Shared Level 2 (SL2) memory. The SL2 is used as intermediate storage for Hardware Accelerator (HWA) to exchange data across VPAC sub-modules (that is, VISS, LDC, , and NF) and from DDR/System Memory. VPAC supports Realtime and Non-Realtime processing threads simultaneously.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

6.7.2 VPAC Subsystem Level

This section covers VPAC subsystem-level details.

6.7.2.1 VPAC Subsystem Block Diagram

The VPAC subsystem includes imaging pipe to do image processing on raw pixels (bayer, RCCC, etc.). The VPAC subsystem loads pixel data either from memory (for example, DDR or on-chip memory), or captured from camera sensor (via external module on SoC level), and applies many vision primitive functions such as image processing, scaling to generate image pyramids, noise filtering, correcting lens distortion, applying perspective transformation for stereo rectification, etc. Optionally, the VPAC subsystem can also do dynamic range management on received image data. The output image processed data generated by the VPAC subsystem is written into memory (for example, DDR or on-chip). The VPAC subsystem supports software managed and HTS controlled flexible load/store of data using K3 DMA infrastructure sub-modules.

Figure 6-29. VPAC Subsystem Block Diagram

The VPAC subsystem includes the following image processing hardware accelerators (HWAs) and infrastructure blocks:

- Vision Imaging Subsystem (VISS). The VISS does on-the-fly (OTF) processing on raw pixels captured from camera sensor. It also does memory to memory processing for data captured from other sources of its parallel port or video port. The VISS uses VPAC infrastructure modules (HTS, DRU/UTC, interrupt aggregator, etc.) for flow and data management. For more information on the VISS operation and the sub-modules integrated inside, see Section *VPAC Vision Imaging Subsystem (VISS)*. The VISS consists of following Hardware Accelerators (HWA):
 - RAW Front End (RFE) block: The RFE block does RAW pixel (that is, Bayer, RCCC, RGBW, etc.) processing on captured image data from sensor. The processed data is later passed on to the NSF4V block, or otherwise it is passed onto the Flexible Color Processing (FCP) block for demosaicing and color conversion. The RFE includes also the H3A block, which supports the control loops for auto focus (AF), auto white balance (AWB) and auto exposure (AE) by computing image statistics.

- Noise Filter Engine (NSF4v): The NSF4v is a spatial, 3-level wavelet based noise filter engine, supporting generic 2x2 sensor. It receives data from the RFE block and sends it to the GLBCE module.
- Global Local Brightness Contrast Enhancement (GLBCE) module: The GLBCE module is used for dynamic range control within image for visual quality. If a contrast enhancement on the input image is required for visual quality, the RFE output is processed by the NSF4v and GLBCE blocks and then passed onto the FCP block. Otherwise, if contrast enhancement is not required, the NSF4v and GLBCE blocks can be bypassed, and the RFE output is directly provided to the FCP block.
- Flexible Color Processing (FCP) block: The FCP block receives data from GLBCE and does demosaicing and color conversion. The output of the color processing is sent to the internal EE (Edge Enhancer) block, if it is enabled, before being output to VPAC shared memory. Otherwise, the FCP output data is directly sent to VPAC shared memory to be written into external memory for further vision processing by programmable processors (that is, DSP or Arm), or other vision hardware accelerators at SoC level.
- Load/Store Engine (LSE): The LSE is an infrastructure block, which provides the following functions:
 - Receives data, captured through MIPI CSI-2 image sensor (by external module at SoC level), for on-the-fly image processing to reduce DDR bandwidth and latency. LSE also provides horizontal and vertical blanking cycles to allow core data path to settle at proper boundary of line and frame.
 - Provides access to VPAC SL2 memory for loading/storing data. Loaded data from SL2 are passed on to unpacker function of LSE for RFE. Packed data after FCP/H3A processing is written into SL2.
 - Event control. HTS events are generated at line level. These events are routed to RFE to start the processing. For each consumed line HTS needs *task done* indication. For some initial lines consumed, there would not be any valid data output. Similarly, H3A generated data will be at paxel/window height number of lines.
- Lens Distortion Correction (LDC) module. The LDC module deals with lens geometric distortion issues in the camera system. The distortion can be common optical distortions, such as barrel distortion, pin-cushion distortion, or fisheye distortion. Correction is not limited to just these types of distortions. The LDC module consists of a Back Mapping block (which gives coordinates of the distorted image as a function of coordinates of the undistorted output image), a delta_x/delta_y offset table, frame buffer interface, buffer, an interpolation block, and SL2 interface. The frame buffer is external to the LDC module, and is usually in an off-chip SDRAM. The LDC module uses the common VPAC infrastructure modules (HTS, DRU/UTC, interrupt aggregator, etc.) for flow and data management, except for loading input data for which it has its own DMA engine. For more details on the LDC operation, see Section *VPAC Lens Distortion Correction (LDC)*.
- Multi-Scaler (MSC) module. The MSC consists of 10 programmable resizers performing multi-thread/multi-scaling operations (2-input to N-outputs, and 2-input to M-outputs, where N+M is 10 or less). Each processing thread of MSC reads its input plane data from the SL2 circular line buffer, performs multi-scaling operations (ratios between X and 0.25X) on the same input, and writes out results to SL2 circular line buffers. In case of on-the-fly operation, the source data is generated from another VPAC HWA. In case of memory-to-memory operation, the source data is read from the external memory. Data transfers from/to SL2 to/from external memory (or another HWA) are handled by the VPAC DMA controller (DRU/UTC), with transfer request events coming from the VPAC HTS module. The MSC module uses the VPAC infrastructure modules (HTS, DRU/UTC, interrupt aggregator, etc.) for flow and data management. For more details on the the MSC operation, see Section *VPAC Subsystem Multi-Scaler (MSC)*.
- Noise-filter (NF). The NF module reads data from memory (that is, DDR or on-chip) to the shared memory (SL2) and does bilateral filtering to remove noise. The output of the NF block can be sent to external memory (that is, DDR) from the shared memory (SL2) or can be further re-sized using the MSC module. The NF module supports two modes of filtering: bilateral filtering mode (where the overall weights are 8-bit unsigned weights computed based on center pixels), and generic filtering mode (where all weights are 9-bit signed value read LUT). The NF module uses the VPAC infrastructure modules (HTS, DRU/UTC, interrupt aggregator, etc.) for flow and data management. For more details on the NF operation, see Section *VPAC Noise Filter (NF)*.
- Hardware Thread Scheduler (HTS). The HTS module is a messaging layer for low-overhead synchronization of the parallel computing tasks and DMA transfers, and is independent from the host processor. It allows autonomous frame level processing for the VPAC subsystem. The HTS module defines various aspects of synchronization and data sharing between the VPAC HWAs. With regards to producer and consumer dependencies, the HTS module ensures that a task starts only when input data and adequate space to write out data is available. In addition to this, it also takes care of pipe-up, debug, abort and interrupt management

aspects related to the VPAC HWAs. For more details on the HTS operation, see Section *VPAC Hardware Thread Scheduler (HTS)*.

- Common shared level 2 (SL2) memory. The SL2 memory subsystem implements a full crossbar interconnect, and serves as input/output scratch memory for the VPAC HWAs.
- The SCR acts like a 256-bit data routing interconnect within the VPAC subsystem, and is used to route UTC traffic onto SL2 memory or for external (system level) access.
- Counter, Timer and System Event Trace (CTSET) module. The CTSET module provides event tracing capabilities for debug purposes.
- ECC Aggregator. The ECC Aggregator modules provide a mechanism to control and monitor certain internal ECC RAMs via Single Error Correction (SEC) and Double Error Detection (DED) functions.

6.7.2.1.1 Notes on VISS RFE H3A Usage

The H3A module supports the control loops for auto focus (AF), auto white balance (AWB) and auto exposure (AE) by computing image statistics. The statistics are typically used by the host CPU to adjust the various parameters for processing the image data. The H3A module comprises two sub modules: the AF and AE/AWB. The H3A module, which is integrated inside RFE module of VISS, can be configured to produce either AE/AWB or AF statistics in a single run. Data generated is stored into a separate SL2 memory buffer by writes of 32-Byte data in a single burst. There is support of only one H3A output channel between LSE and HTS.

The H3A output data is a single dimensional data and the amount of data produced depends on number of windows/pixel in a frame, various functional modes and corner cases of multiple of 8 windows/pixels in a row, finishing row level statistics at 32-Byte boundary, etc. [Table 6-76](#) shows the size of data produced, depending on H3A configuration.

Table 6-76. VPAC Subsystem H3A Output Data Size

Register Settings		Number of Bytes	Special care
AF H3A_PCR[0] AF_EN = '1'	Vertical AF disabled H3A_PCR[20] AF_VF_EN = '0'	48 Bytes/pixel	If paxel_no_x odd, add 16B per row to make it 32B multiple per row.
	Vertical AF enabled H3A_PCR[20] AF_VF_EN = '1'	64 Bytes/pixel	None
AE and AWB H3A_PCR[16] AEW_EN = '1'	Sum of square H3A_AEW_CFG[9-8] AEFMT = '0'	34 Bytes/window	(+16B) After 8 windows (+16B) At end of row, but no end of windows, if H3A size at Row != 32B
	Min/Max H3A_AEW_CFG[9-8] AEFMT = '1'	34 Bytes/window	(+16B) Num of windows %8 !=0 (+16B) At end of windows, if H3A size at end of windows != 32B
	Sum only H3A_AEW_CFG[9-8] AEFMT = '2'	18 Bytes/window	

The parameters of H3A output buffer need to be configured via VISS LSE register settings. Some special considerations include:

- Configure the H3A line size to be more or equal to maximum H3A data produced in a row. That is, VISS_LSE_BUF_ATTR[15-6] H3A_LN_SIZE $\geq \text{ceil}((\# \text{ of output bytes per H3A paxel/window row})/64)$
- The H3A output data is 1-dimensional in the external storage (DDR or on-chip memory). For ease of synchronization, this 1-D data is converted into multiple of H3A line data. The TR (transfer request) written to transfer H3A data from SL2 to external storage must make sure to configure offset such that data get stored as if 1-D continuous data.
- Configure the minimum VISS_LSE_BUF_ATTR[24-16] CBUF_SIZE = 3, to take care of corner cases.

6.7.2.2 VPAC Subsystem Clocks

Each block within the VPAC subsystem receives its own clocking signal:

- MAIN_CLK is the operation clock for all infrastructure modules, such as UTC/DRU, HTS, ECC Aggregator, INTD, etc.
- VISS0_CLK is the operation clock for the VISS and its sub-modules
- LDC0_CLK is the operation clock for the LDC module

- MSC_CLK is the operation clock for the MSC module
- NF_CLK is the operation clock for the NF module

For more details on the source of each clock at SoC level, see *VPAC Integration*.

6.7.2.3 VPAC Subsystem Resets

Each block within the VPAC subsystem can be reset through its own HW reset signal:

- MAIN_RST is the reset for all infrastructure modules, such as UTC/DRU, HTS, ECC Aggregator, etc.
- VISS0_RST is the reset for the VISS and its sub-modules
- LDC0_RST is the reset for the LDC module
- MSC_RST is the reset for the MSC module
- NF_RST is the reset for the NF module

For more details on the source of each reset signal at SoC level, see *VPAC Integration*.

6.7.2.4 VPAC Subsystem Interrupts

The VPAC subsystem outputs six physical system interrupt lines: VPAC_LEVEL_0_INTR through VPAC_LEVEL_5_INTR. For more information on how the interrupt lines are connected at SoC level, see *VPAC Integration*. The interrupt aggregation within the VPAC subsystem is done using the internal INTD module. Each interrupt line can be mapped to the same list of source interrupt events generated by the modules within the VPAC subsystem.

[Table 6-77](#) shows the INTD interrupt control registers for each VPAC interrupt line. Each interrupt line has a separate set of registers for level and pulse input event types. Each bit in a register corresponds to a particular interrupt event. For more details on the mapping of interrupt events to INTD register bits, see [Table-XXX](#) further below.

- The ENABLE registers enable the mapping of the internal VPAC interrupt events, generated by a module within the VPAC subsystem, to the VPAC output system interrupt lines. Writing a '1' in a register bit position allows the corresponding module interrupt event to trigger the respective system interrupt. Writing a '0' in the same bit position blocks the module interrupt event from triggering the system interrupt.
- The ENABLE_CLR registers disables the mapping of the internal VPAC interrupt events to the VPAC output system interrupt lines.
- The STATUS registers are used to capture which VPAC sub-module interrupt events, that have been mapped to a system interrupt, are active and pending. This status is used when multiple module interrupts are grouped into a single system interrupt, so the software can read the status register to determine exactly which module interrupt has caused the system interrupt.
 - For level interrupts, the status is based on the active level of the module interrupt input, and when the input is inactive then the status is inactive as well.
 - For pulsed interrupts, the status is set upon the pulse and reflects a pending status and software must clear the pending status since the module does not indicate the inactive status (unlike a level interrupt, which does).
- The STATUS_CLR registers allows software to clear the pending status of interrupt events. This register is only valid and functional for pulsed interrupts and has no effect for level interrupts.

Table 6-77. VPAC Subsystem Interrupt Control Registers

Output System Interrupt Line	Input Interrupt Event Type	Interrupt Enable Registers	Interrupt Clear Registers	Interrupt Status Registers	Interrupt Status Clear Registers
VPAC_LEV_EL_0_INTR	Level	VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_0_0 through VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_0_7	VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_0_0 through VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_0_7	VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_0_0 through VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_0_7	VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_0_0 through VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_0_7
	Pulse	VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_0_0 through VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_0_7	VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_0_0 through VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_0_7	VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_0_0 through VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_0_7	VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_0_0 through VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_0_7
VPAC_LEV_EL_1_INTR	Level	VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_1_0 through VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_1_7	VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_1_0 through VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_1_7	VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_1_0 through VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_1_7	VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_1_0 through VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_1_7
	Pulse	VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_1_0 through VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_1_7	VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_1_0 through VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_1_7	VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_1_0 through VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_1_7	VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_1_0 through VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_1_7
VPAC_LEV_EL_2_INTR	Level	VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_2_0 through VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_2_7	VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_2_0 through VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_2_7	VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_2_0 through VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_2_7	VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_2_0 through VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_2_7
	Pulse	VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_2_0 through VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_2_7	VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_2_0 through VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_2_7	VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_2_0 through VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_2_7	VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_2_0 through VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_2_7
VPAC_LEV_EL_3_INTR	Level	VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_3_0 through VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_3_7	VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_3_0 through VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_3_7	VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_3_0 through VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_3_7	VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_3_0 through VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_3_7
	Pulse	VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_3_0 through VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_3_7	VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_3_0 through VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_3_7	VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_3_0 through VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_3_7	VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_3_0 through VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_3_7
VPAC_LEV_EL_4_INTR	Level	VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_4_0 through VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_4_7	VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_4_0 through VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_4_7	VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_4_0 through VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_4_7	VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_4_0 through VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_4_7
	Pulse	VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_4_0 through VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_4_7	VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_4_0 through VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_4_7	VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_4_0 through VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_4_7	VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_4_0 through VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_4_7

Table 6-77. VPAC Subsystem Interrupt Control Registers (continued)

Output System Interrupt Line	Input Interrupt Event Type	Interrupt Enable Registers	Interrupt Clear Registers	Interrupt Status Registers	Interrupt Status Clear Registers
VPAC_LEVEL_5_INTR	Level	VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_5_0 through VPAC_INTD_ENABLE_REG_LEVEL_VPAC_OUT_5_7	VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_5_0 through VPAC_INTD_ENABLE_CLR_REG_LEVEL_VPAC_OUT_5_7	VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_5_0 through VPAC_INTD_STATUS_REG_LEVEL_VPAC_OUT_5_7	VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_5_0 through VPAC_INTD_STATUS_CLR_REG_LEVEL_VPAC_OUT_5_7
	Pulse	VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_5_0 through VPAC_INTD_ENABLE_REG_PULSE_VPAC_OUT_5_7	VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_5_0 through VPAC_INTD_ENABLE_CLR_REG_PULSE_VPAC_OUT_5_7	VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_5_0 through VPAC_INTD_STATUS_REG_PULSE_VPAC_OUT_5_7	VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_5_0 through VPAC_INTD_STATUS_CLR_REG_PULSE_VPAC_OUT_5_7

The VISS interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_0 through VPAC_INTD_xxx_VPAC_OUT_5_0 registers. [Table 6-78](#) provides more details on the VISS interrupt events. All VISS interrupts are single pulse event signals.

Table 6-78. VPAC Subsystem VISS Interrupt Events

Register Bit	Interrupt Event Name	Description
0	RAWFE_CFG_ERR_INTR	Config read or write memory access occurred during functional operation and likely corrupted functional operation. VISS merges all config error sources from RawFE and refer to RawFE spec for the entire error source list.
1	RAWFE_AEW_PULSE_INTR	H3A AEW interrupt.
2	RAWFE_AF_PULSE_INTR	H3A AF interrupt.
3	RAWFE_H3A_PULSE_INTR	H3A interrupt.
4	RAWFE_H3A_BUF_OVRFLOW_PULSE_INTR	H3A output buffer overflow.
5	NSF4V_LINEMEM_CFG_ERR_INTR	VBUSP diagnostic read access of , while NSF data using RAM for functional purpose.
6	NSF4V_HBLANK_ERR_INTR	Horizontal Blanking too short between lines.
7	NSF4V_VBLANK_ERR_INTR	Vertical Blanking too short between frames.
8	GLBCE_CFG_ERR_INTR	Either non-shadowed registers written or static memories are accessed during active window.
9	GLBCE_FILT_START_INTR	GLBCE started filtering. This interrupt is issued at the rising edge of filtering signal.
10	GLBCE_FILT_DONE_INTR	GLBCE ended filtering. This interrupt is issued at the falling edge of filtering signal.
11	GLBCE_HSYNC_ERR_INTR	Generated when delayed HS/HE signals doesn't match with derived signals from GLBCE core.
12	GLBCE_VSYNC_ERR_INTR	Generated when delayed VS/VE signals doesn't match with derived signals from GLBCE core.
13	GLBCE_VP_ERR_INTR	This interrupt is issued, if there is a data input while filtering is high.
14	FCFA_CFG_ERR_INTR	Either non-shadowed registers written or line memories are accessed during active window.
15	FCC_CFG_ERR_INTR	Configuration access to registers/memories has corrupted functional operation. Configuration read or write memory access occurred during functional operation. Merged independent error sources at VISS. Refer to Section <i>VISS Flexible Color Processing (FCP)</i> for all sources.
16	FCC_OUTIF_OVF_ERR_INTR	FIFO overflow on FIFO for Y12 LSE I/F. Merged all FCC output overflow error sources at VISS. Refer to Section <i>VISS Flexible Color Processing (FCP)</i> for all sources.

Table 6-78. VPAC Subsystem VISS Interrupt Events (continued)

Register Bit	Interrupt Event Name	Description
17	FCC_HIST_READ_ERR_INTR	Host was not able to read the entire histogram mem between VS-VE window (triggered when the first access to histogram has been performed but the last has not been performed).
18	EE_CFG_ERR	Cinfiguration happened to EE regions causing corruption during frame processing.
19	EE_SYNCOVF_ERR	EE horizontal synchronization FIFO overflow interrupt.
20	LSE_FR_DONE_EVT_INTR	LSE frame done interrupt.
21	LSE_SL2_RD_ERR_INTR	Set whenever there is an error response on VBUSM read command for any input channel.
22	LSE_SL2_WR_ERR_INTR	Set whenever there is an error response on VBUSM write command for any output channel.
23	LSE_CAL_VP_ERR_INTR	Set whenever one of the following input frame errors is detected at VPORT_INPUT.
24	LSE_OUT_FR_START_EVT_INTR	Ouput Frame Start (from VISS top level).

The LDC interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_1 through VPAC_INTD_xxx_VPAC_OUT_5_1 registers. [Table 6-79](#) provides more details on the LDC interrupt events. All LDC interrupts are single pulse event signals.

Table 6-79. VPAC Subsystem LDC Interrupt Events

Register Bit	Interrupt Event Name	Description
0	LDC_PIX_IBLK_OUTOFBOUND_INTR	Back mapped pixel co-ordinate goes out of the pre-computed input pixel bounding box.
1	LDC_MESH_IBLK_OUTOFBOUND_INTR	Block mesh co-ordinate goes out of the pre-computed mesh bounding box.
2	LDC_PIX_IBLK_MEMOVF_INTR	Input Pixel block memory overflow.
3	LDC_MESH_IBLK_MEMOVF_INTR	Mesh block memory overflow.
4	LDC_IFR_OUTOFBOUND_INTR	Back mapped input co-ordinate goes out of input frame range.
5	LDC_INT_SZOVF_INTR	Affine and perspective transform precision overflow error.
6	LDC_FR_DONE_EVT_INTR	Frame done LDC.
7	LDC_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.
8	LDC_VBUSM_RD_ERR_INTR	Error on Input VBUSM Read interface.

The MSC interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_2 through VPAC_INTD_xxx_VPAC_OUT_5_2 registers. [Table 6-80](#) provides more details on the MSC interrupt events. All MSC interrupts are single pulse event signals.

Table 6-80. VPAC Subsystem MSC Interrupt Events

Register Bit	Interrupt Event Name	Description
0	MSC_LSE_FR_DONE_EVT_0_INTR	Frame done MSC processing thread 0.
1	MSC_LSE_FR_DONE_EVT_1_INTR	Frame done MSC processing thread 1.
2	MSC_LSE_SL2_RD_ERR_INTR	Error on SL2 VBSUM Read interface.
3	MSC_LSE_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.

The NF interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_2 through VPAC_INTD_xxx_VPAC_OUT_5_2 registers. [Table 6-81](#) provides more details on the NF interrupt events. All NF interrupts are single pulse event signals.

Table 6-81. VPAC Subsystem NF Interrupt Events

Register Bit	Interrupt Event Name	Description
8	NF_FR_DONE_INTR	Frame done NF.
9	NF_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.

Table 6-81. VPAC Subsystem NF Interrupt Events (continued)

Register Bit	Interrupt Event Name	Description
10	NF_SL2_RD_ERR_INTR	Error on SL2 VBSUM Read interface.

The HTS interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_3 through VPAC_INTD_xxx_VPAC_OUT_5_3 registers. [Table 6-82](#) provides more details on the HTS interrupt events. All HTS interrupts are single pulse event signals, save for the SPARE_PEND_xxx interrupts, which can be both single pulse events and level events.

Table 6-82. VPAC Subsystem HTS Interrupt Events

Register Bit	Interrupt Event Name	Description
0	PIPE_DONE_0	Pipeline 0 done.
1	PIPE_DONE_1	Pipeline 1 done.
2	PIPE_DONE_2	Pipeline 2 done.
3	PIPE_DONE_3	Pipeline 3 done.
4	PIPE_DONE_4	Pipeline 4 done.
5	PIPE_DONE_5	Pipeline 5 done.
6	PIPE_DONE_6	Pipeline 6 done.
7	TDONE	HWA0 thread done.
8	RESERVED	Reserved.
9	TDONE	HWA2 thread done.
10	RESERVED	Reserved.
11	TDONE	HWA4 thread done.
12	TDONE	HWA5 thread done.
13	TDONE	HWA6 thread done.
14	SPARE_DEC_0	Spare 0 scheduler decrement pulse (ehost mode).
15	SPARE_DEC_1	Spare 1 scheduler decrement pulse (ehost mode).
16	SPARE_PEND_0_PULSE	Spare 0 scheduler pend assertion (ehost mode).
17	SPARE_PEND_0_LEVEL	Spare 0 scheduler pend assertion (ehost mode).
18	SPARE_PEND_1_PULSE	Spare 1 scheduler pend assertion (ehost mode).
19	SPARE_PEND_1_LEVEL	Spare 1 scheduler pend assertion (ehost mode).
20	WATCHDOGTIMER_ERR_0	Watchdog Timeout Error for HWA0.
21	RESERVED	Reserved.
22	WATCHDOGTIMER_ERR_2	Watchdog Timeout Error for HWA2.
23	RESERVED	Reserved.
24	WATCHDOGTIMER_ERR_4	Watchdog Timeout Error for HWA4.
25	WATCHDOGTIMER_ERR_5	Watchdog Timeout Error for HWA5.
26	WATCHDOGTIMER_ERR_6	Watchdog Timeout Error for HWA6.

The UTC interrupt events indicating TR complete are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_4 through VPAC_INTD_xxx_VPAC_OUT_5_4 registers for UTC0, and VPAC_INTD_xxx_VPAC_OUT_0_5 through VPAC_INTD_xxx_VPAC_OUT_5_5 plus VPAC_INTD_xxx_VPAC_OUT_0_6 through VPAC_INTD_xxx_VPAC_OUT_5_6 registers for UTC1. [Table 6-83](#) provides more details on the UTC TR complete interrupt events. All UTC TR complete interrupts are single pulse event signals.

Table 6-83. VPAC Subsystem UTC TR Complete Interrupt Events

Register Bit	Interrupt Event Name	Description
31-0	UTC0_COMPLETE_INTR[31:0]	TR complete interrupt.
31-0 plus 31-0	UTC1_COMPLETE_INTR[63:0]	TR complete interrupt.

The UTC interrupt events indicating error are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_7 through VPAC_INTD_xxx_VPAC_OUT_5_7 registers for both UTC0 and UTC1. [Table 6-84](#) provides more details on the UTC error interrupt events. All UTC error interrupts are single pulse event signals.

Table 6-84. VPAC Subsystem UTC Error Interrupt Events

Register Bit	Interrupt Event Name	Description
0	UTC0_ERR	UTC0 error.
1	UTC1_ERR	UTC1 error.
2	UTC0_PROT_ERR_INTR	UTC0 protocol violation.
3	UTC1_PROT_ERR_INTR	UTC1 protocol violation.

The CTSET interrupt events are mapped to register bits within the VPAC_INTD_xxx_VPAC_OUT_0_7 through VPAC_INTD_xxx_VPAC_OUT_5_7 registers. [Table 6-85](#) provides more details on the CTSET events. All CTSET error interrupts are single pulse event signals.

Table 6-85. VPAC Subsystem CTSET Interrupt Events

Register Bit	Interrupt Event Name	Description
4	CTM_PULSE_INTR	Counter Timer Module (CTM) pulse interrupt.

6.7.2.5 VPAC Subsystem SL2 Memory Infrastructure

The SL2 memory subsystem implements an interconnect

The SL2 memory does not implement ECC, as it contains mostly pixel data.

6.7.2.6 VPAC Subsystem DMA Infrastructure

Two UTC instances are used inside the VPAC subsystem. UTC0 deals with real time (RT) transfer, and UTC1 is used for non-realtime (NRT) transfer. Both UTC0 and UTC1 data transfer channels are used for DMA transfers in and out of the VPAC SL2 memory. All 32 channels of the UTC0 are mapped on *channel_number* = [95:64] and are recommended to be used for real time data transfer only. All 64 channels of UTC1 are mapped on *channel_number* = [63:0] and are recommended to be used for all other DMA transfer needs of the VPAC subsystem.

All data movement transactions at VPAC subsystem boundary are multiples of aligned 128-byte transfers.

6.7.2.7 VPAC Subsystem Data Routing Interconnect

The data routing is based on a system address of the SL2 memory. This is a 256-bit interconnect. The LDC read interface directly connects to AC internal CBASS.

The SL2 master port of this interconnect implements a 512-bit width adaptor. In other words, the write accesses to the SL2 master port accumulate two consecutive 256 bits data phases, pack them to form a 512 bits word and then write it into SL2 memory. The read accesses on this port, on the other hand, are split into two 256 bits data phases before being sent to the requestor port.

The data routing interconnect has four masters on both VPAC SL2 side and on the external VBUSM side.

6.7.2.8 VPAC Subsystem Pipeline Flow Control and Messaging

The VPAC subsystem can run up to 5 independent pipelines using the VPAC HWAs and UTC. These pipelines are completely independent from each other and their input output data management is handled by the HTS module. The thread management is flexible and supports different top level settings of resolution, frame rate, DDR data buffer address, etc.

The VPAC HTS module is used to implement the thread management and control triggering of processing threads within the VPAC subsystem. It is used to manage message transfer and control between VPAC and external host (that is, SoC level processor). HTS can also be used to handle writing LDC block data into the SoC level MSMC (L3 SRAM) and create block to row data for the VPAC MSC and NF processing without going through the external DDR memory.

The mapping of VPAC HWAs to HTS scheduler is shown in [Table 6-86](#). Note that each HWA and spare scheduler has a spare socket on its consumer and producer side (not mentioned in below table) for future expansion. For more details, see Section *VPAC Hardware Thread Scheduler (HTS)*.

Table 6-86. VPAC Subsystem HTS Mapping

HTS scheduler	VPAC HWA
HWA0	VISS0
HWA1	Reserved
HWA2	LDC0
HWA3	Reserved
HWA4	MSC0
HWA5	MSC1
HWA6	NF
HWA7	N/A
HWA8	N/A
DMA0-4	VISS0 [c0,c1,c2,x,x]
DMA8-10	Reserved
DMA32	MSC0 [c0]
DMA40	MSC1 [c0]
DMA48	NF [c0]
DMA56-59	N/A
DMA64-67	N/A
DMA240-245	VISS0 [p0,p1,p2,p3,p4,p5]
DMA256-261	Reserved
DMA272-275	LDC0 [p0,p1,p2,p3]
DMA288-291	Reserved
DMA304-313	MSC0 [p0] / MSC1 [p0],
	MSC0 [p1] / MSC1 [p1],
	...
	MSC0 [p9] / MSC1 [p9],
DMA336	NF [p0]
DMA352-355	N/A
DMA368-371	N/A

6.7.2.8.1 VISS Node Scheduler

The VISS node scheduler comprises 3 consumer sockets and 6 producer sockets. On consumer side, it is only connected to the DMA producer scheduler. On producer socket, it is only connected to the DMA consumer scheduler.

The consumer sockets are mapped to:

1. Exposure #0 for WDR merge (DMA)
2. Exposure #1 for WDR merge (DMA)
3. Exposure #2 for WDR merge (DMA)

The producer sockets are mapped to the following output buffers:

1. Y12 (DMA)
2. UV12 (DMA)
3. Y8 (DMA)
4. UV8 (DMA)
5. S8 (DMA)
6. H3A (DMA)

Pipeline #n (n = 0, ..., 6 configurable) is mapped to this scheduler. When a scheduler is enabled, the DMA producer scheduler triggers UTC data loading from DDR memory into the SL2 memory. Once data is available inside the SL2 memory, the VISS scheduler starts a VISS thread. Prior to starting a VISS thread, the buffer availability to write output data is checked. These consumer and producer sockets can optionally be disabled depending on the usecase.

To enable streaming data support, this scheduler node supports a streaming feature. That is, the scheduler does not go into idle state after the end of the pipe, rather it transitions to initialization state to save host intervention between frame in OTF (on-the-fly) mode.

6.7.2.8.2 LDC Node Scheduler

The LDC node scheduler comprises 0 consumer sockets and 7 producer sockets. On consumer side, the LDC uses its own read DMA engine to fetch input data directly into internal buffer of LDC. On producer socket, it can be connected to 5 different consumers.

The producer sockets are mapped to the following output buffers:

1. Luma(#1) -> Pattern Adapter -> DMA
2. Chroma(#1) -> Pattern Adapter -> DMA
3. Luma(#2) -> Pattern Adapter -> DMA
4. Chroma(#2) -> Pattern Adapter -> DMA
5. Luma/Chroma -> Pattern Adapter -> MSC0
6. Luma/Chroma -> Pattern Adapter -> MSC1
7. Luma/Chroma -> Pattern Adapter -> NF

Pipeline #n (n = 0, ..., 6 configurable) is mapped to this scheduler. When a scheduler is enabled, the LDC read DMA engine loads required input data into the LDC memory. Prior to starting a LDC thread, the output buffer availability is checked to write output data. These producer sockets can optionally be disabled depending on the usecase.

To support on-the-fly MSC and NF operation after LDC, a pattern adapter is used to convert blocks into lines. Although produced data count is only two, the produced data count is still included, along with pattern adapter pair for unique end consumers.

On-the-fly support for LDC -> MSC / LDC -> NF connection can be achieved via the SL2 memory (if space is available) or via the SoC level MSMC SRAM. Both flows are supported using the HTS scheduler.

6.7.2.8.3 MSC Node Scheduler

The MSC supports two independent threads. For this reason, two MSC schedulers are used. Each MSC node scheduler comprises consumer socket and 10 producer sockets. On consumer side, it is either connected to the DMA producer scheduler or the LDC output. On producer socket, it is to the DMA consumer scheduler.

The consumer socket is mapped to:

1. Scalar data from DDR / LDC output

The producer sockets are mapped to the following output buffers:

1. MSC0-0
2. MSC0-1
3. MSC0-2
4. MSC0-3
5. MSC0-4
6. MSC0-5
7. MSC0-6
8. MSC0-7
9. MSC0-8
10. MSC0-9

Pipeline #n (n = 0, ..., 6 configurable) is mapped to this scheduler. When a scheduler is enabled, the DMA producer scheduler triggers UTC data loading from the DDR memory into SL2 memory. Once data is available inside the SL2 meory, the MSC scheduler starts a MSC thread. Prior to starting a MSC thread, the buffer

availability to write output data is checked. These consumer and producer sockets can optionally be disabled depending on the usecase.

For both MSC threads, two schedulers are used in VPAC subsystem. Since the MSC core can output maximum 10 scaled outputs (combining MSC0 and MSC1), this fact is utilized in optimizing the DMA consumer sockets and DMA channels required. The need of DMA channels is mutually orthogonal in inverted order, that is, (MSC0-0 and MSC1-9), (MSC0-1 and MSC1-8), etc. are mapped to the same DMA channel. When the MSC needs to run in the same pipeline as LDC, then pipeline number must be same as of the LDC. The consumer socket needs to be connected to the LDC output (p0).

6.7.2.8.4 NF Node Scheduler

The NF node scheduler comprises 1 consumer socket and 1 producer socket. On consumer side, it is either connected to the DMA producer scheduler or the LDC output. On producer socket, it is only connected to the DMA consumer scheduler.

The consumer socket is mapped to:

1. NF input data from DDR / LDC producer socket (p1)

The producer sockets are mapped to the following output buffer:

1. NF output

Pipeline #n (n = 0, ..., 6 configurable) is mapped to this scheduler. When a scheduler is enabled, the DMA producer scheduler triggers UTC data loading from the DDR memory into SL2 memory. Once data is available inside the SL2 memory, the NF scheduler starts a NF thread. Prior to starting a NF thread, the buffer availability to write output data is checked.

When the NF needs to run in the same pipeline as LDC, then the pipeline number must be same as of the LDC. The consumer socket needs to be connected to the LDC output (p1).

6.7.2.8.5 Spare Scheduler

There are up to spare schedulers in each HTS instance. The key features of each spare scheduler are as follows:

- Store LDC data into L3 memory (SoC level MSMC SRAM) and grow line buffer for next trigger to MSC/NF through spare schedulers.
- Help in inserting any external host through spare schedulers.
- Capability to trigger DMA and include pattern adapters to support block/line conversion control.
- Spare scheduler 0/1 : Inserting external host
- Spare scheduler 2...7 : Managing growing block to line buffer inside MSMC (L3 SRAM)

6.7.2.9 VPAC Subsystem Data Formats Support

summarizes the data formats supported in VPAC Subsystem.

6.7.2.10 VPAC Subsystem Debug Features

The VPAC subsystem is a combination of multiple asynchronous pipelines running concurrently. The Counter, Timer and System Event Trace (CTSET) module within the VPAC subsystem provides the following main features:

- Monitoring up to 255 VPAC events.
- ATB interface compliant trace packets (synchronous to VPAC clock domain).
- Counter (count=8) and Timer (count=4).
- All debug events can be configured to be either selected for trace packet, timer or counter features.
- In one of the combination, debug events can be selected to for timer event out to be used to generate external CTI compliant trigger.

For more information on the CTSET module operation, see Chapter *On-Chip Debug*.

[Table 6-87](#) lists the VPAC subsystem events that are mapped on the CTSET module.

Table 6-87. VPAC Subsystem CTSET Event List

Index	Event Name	HWA	Event Type	Event Description
0	viss_err	VISS0	pulse	VISS Related Error message (config, ovf, sync, blank, access, vp) ⁽¹⁾
1	rawfe_h3a_pulse_intr	VISS0	pulse	H3A interrupt
2	rawfe_dbg_ctl_vs_event	VISS0	pulse	Verticle start in the beginning of the RAWFE pipeline
3	rawfe_dbg_ctl_ve_event	VISS0	pulse	Verticle end in the beginning of the RAWFE pipeline
4	rawfe_dbg_ctl_hs_event	VISS0	pulse	Horizontal start in the beginning of the RAWFE pipeline
5	rawfe_dbg_ctl_he_event	VISS0	pulse	Horizaontal end in the beginning of the RAWFE pipeline
6	rawfe_dbg_ctl_lse_slv_stall_event	VISS0	pulse	RAWFE is stalling lse slave interface due to FCP or MTC stall
7	rawfe_dbg_ctl_lse_mst_stall_event	VISS0	pulse	H3A master interface to LSE is stalled
8	rawfe_dbg_ctl_lse_intf_stall_event	VISS0	pulse	Within a frame (VS to VE at RFE i/p) LSE is not sending data to RFE
9	rawfe_dbg_ctl_x_y_match_event	VISS0	pulse	X,Y pixel position has reached the start of RAWFE pipeline
10	rawfe_dbg_ctl_dpc_otf_corr_event	VISS0	pulse	DPC OTF corrected a pixel position
11	rawfe_dbg_ctl_pipe_adv_event	VISS0	pulse	Active pipeline advancement
12	nsf4v_in_hs_event	VISS0	pulse	Start of Active Line at NSF4V input
13	nsf4v_in_vs_event	VISS0	pulse	Start of Active Frame at NSF4V input
14	nsf4v_in_he_event	VISS0	pulse	End of Active Line at NSF4V output
15	nsf4v_in_ve_event	VISS0	pulse	End of Active Frame at NSF4V output
16	glbce_filt_start_intr	VISS0	pulse	GLBCE filtering start (generated at the rising edge of filtering signal)
17	glbce_filt_done_intr	VISS0	pulse	GLBCE filtering done (generated at falling edge of filtering signal)
18	glbce_sol_event	VISS0	pulse	Start of Active Line at GLBCE input
19	glbce_sof_event	VISS0	pulse	Start of Active Frame at GLBCE input
20	glbce_eol_event	VISS0	pulse	End of Active Line at GLBCE output
21	glbce_eof_event	VISS0	pulse	End of Active Frame at GLBCE output
22	fcfa_sol_event	VISS0	pulse	Start of line processing for CFA input
23	fcfa_sof_event	VISS0	pulse	Start of frame processing for CFA input
24	fcc_stall_event	VISS0	pulse	Stall has occurred on any one of the output LSE interfaces
25	fcc_eol_if_y12_event	VISS0	pulse	End of line on Y12 LSE I/f (only generated for valid lines)
26	fcc_eof_if_y12_event	VISS0	pulse	End of frame on Y12 LSE I/f
27	fcc_eol_if_uv12_event	VISS0	pulse	End of line on UV12 LSE I/f (only generated for valid lines)
28	fcc_eof_if_uv12_event	VISS0	pulse	End of frame on UV12 LSE I/f
29	fcc_eol_if_y8r8_event	VISS0	pulse	End of line on Y8R8 LSE I/f (only generated for valid lines)
30	fcc_eof_if_y8r8_event	VISS0	pulse	End of frame on Y8R8 LSE I/f
31	fcc_eol_if_c8g8_event	VISS0	pulse	End of line on C8G8 LSE I/f (only generated for valid lines)
32	fcc_eof_if_c8g8_event	VISS0	pulse	End of frame on C8G8 LSE I/f
33	fcc_eol_if_s8b8_event	VISS0	pulse	End of line on S8B8 LSE I/f (only generated for valid lines)
34	fcc_eof_if_s8b8_event	VISS0	pulse	End of frame on S8B8 LSE I/f
35	fcc_flexcc_eop_event	VISS0	pulse	End of processing (EOP) for FlexCC

Table 6-87. VPAC Subsystem CTSET Event List (continued)

The VPAC subsystem also supports halting an execution pipeline using external or user halt request. Halting a pipeline is achieved by not granting thread start to HWA. Once halted, VPAC waits for an external sync trigger or config resume to restart execution. VISS, MSC and NF modules halt at line boundary, and LDC halts at block boundary.

The VPAC subsystem supports generic debug capability/features and ARM cross trigger interface for debug triggers:

- Halting the HWA threads on debug request input at logical trigger boundary.
- Continue/restart VPAC from halted state (step/continue) based on external sync trigger and HTS_DBG_CNTL register.
- Debug compliant dbg_attn output after processing external halt request and when VPAC halts debug enabled pipelines.
- CTI (Cross Trigger Interface) compliant out halted trigger after processing external halt request and reaching halted state of VPAC.
- Stalling all pipelines of VPAC (with configurable option to disable impact of debug features on a pipeline).
- Indicate to Host through readable debug_rdy bit in HTS to indicate readiness of HWA resource in case of halted (dbgattn asserted)

The VPAC subsystem debug capability supported is as captured in the HTS_DBG_CAP register. Ext_halt, ext_sync, hwa_halted are CTI (Cross Trigger Interface) mapped async trigger interface (refer to the async protocol of trigger interface in the ARM® CoreSight™ Architecture Specification).

The VISS module, when used in OTF mode, must not be included as debuggable module within VPAC. VISS must be disabled (HTS: debug pipeline disable) to respond to halt request, otherwise behavior is undefined. The VISS module, when used in memory to memory mode, can be halted. But VISS LUTs must not be read during halted state, as it can corrupt the design pipeline.

6.7.2.11 VPAC Subsystem Internal Diagnostic Features

The internal diagnostic features for the VPAC subsystem in HW are as follows:

1. SECCDED/ECC:
 - ECC on all LUT memories and ECC on control lines of interconnects
 - No ECC on Pixel Buffers, or memories containing predictors, motion vectors or disparity data
 - No ECC on Interconnect data
2. Supports PBIST interfaces for all memories (for periodic runtime memory).
3. Supports logic BIST to detect permanent fault.
4. Parallel Signature Analyzer (PSA) based signature generation for all data outputs for faster BIST on Logic and MMRs. The PSA is 32-bit CRC based.
5. Watchdog Timers (per HW processing threads) to detect hang condition (will raise interrupt to external host).
6. K3 compliant diagnostic MMRs to log fault addresses and/or error/hang reason.
7. Supports external host access to all of its MMR space and critical memories while suspended due to error.
8. Enables firewalling on all access into SL2 and config space through NAVSS. The default configuration path is point-2-point connection from MCU R5F, so it does not need firewalling.

6.7.2.11.1 Parallel Signature Analysis (PSA)

The VPAC subsystem supports generating CRC signature on each output channel. The LSE module inside a HWA, implements a CRC signature capture mechanism, wherein it samples pixel (except H3A where it is fixed 32-bit) from each valid transfer from HWA core to LSE for each output channel. This CRC signature updates stop at end of frame and signature is available for reference comparison.

The VISS, NF and MSC modules are line based, hence in CRC signature calculation it is needed to scan frame in raster order (left to right and top to bottom). LDC being 2D block based processing needs different mechanism to compute signature. For LDC, pixels are scanned in raster order within block (left to right and from top to bottom), then blocks are scanned in raster order inside region and enabled regions are scanned in raster order within frame.

6.7.2.12 VPAC Subsystem Security Features

The VPAC subsystem implements region based firewall on slave endpoints within config CBASS and SL2 CBASS. Both CBASS is driven by independent DMSC FW interface from SoC level. All internal masters on SL2 SCR are configured with ISC. [Figure 6-30](#) provides FW/ISC summary.

Module	Interconnect	Security component	Parameter	Endpoints	FW_ID(dec)	FW/ISC/QoS config address offset(hex)	privID reset value(dec)
VPAC	SCRIP	Region FW	2 region	ECC AGG	6048	0

6.7.2.13 VPAC Subsystem Programmer's Guide

6.7.2.13.1 Initialization Sequence

The VPAC subsystem implements 6 configurable pipelines. A pipeline is a combination of several input DMA channels, compute logic and output DMA channels. Few possible configurations for a pipeline are provided in [Table 6-88](#). Each accelerator DMA connection (consumer or producer) is fixed, if enabled. These pipelines will operate independent of each other and their numbering can be configured differently, but supported combination remains the same. One accelerator thread cannot be part of two pipelines simultaneously (for example combination 6 cannot be combined with 2, 3 and 5).

Table 6-88. VPAC Subsystem Pipeline Options

Pipeline	0	1	2	3	4	5	6	7
UTC-VISS0 IN	Y	N	N	N	N	N	N	N
VISS0	Y	N	N	N	N	N	N	N
UTC-VISS0 OUT	Y	N	N	N	N	N	N	N
LDC0	N	N	Y	N	N	N	Y	Y
UTC-LDC0 OUT	N	N	Y	N	N	N	LDC-Y & UV	LDC-Y & UV
UTC-MSC0 IN	N	N	N	Y	N	N	N	Y
MSC0	N	N	N	Y	N	N	LDC-Y/UV	LDC-Y/UV
UTC-MSC0 OUT	N	N	N	Y	N	N	Y	Y
UTC-MSC1 IN	N	N	N	N	Y	N	N	Y
MSC1	N	N	N	N	Y	N	LDC-Y/UV	LDC-Y/UV
UTC-MSC1 OUT	N	N	N	N	Y	N	Y	Y
UTC-NF IN	N	N	N	N	N	Y	N	Y
NF	N	N	N	N	N	Y	LDC-Y/UV	LDC-Y/UV
UTC-NF OUT	N	N	N	N	N	Y	Y	Y
Spare 0	-	-	-	-	-	-	-	Y
Spare 1	-	-	-	-	-	-	-	Y
Spare 2	-	-	-	-	-	-	-	Y
Spare 3	-	-	-	-	-	-	-	Y

The sequence in Figure 6-31 describes a high level initialization sequence for the VPAC pipelines. The parameters pertaining to frame resolution, input and output dependencies, data movement and algorithm need to be updated for every pipeline.

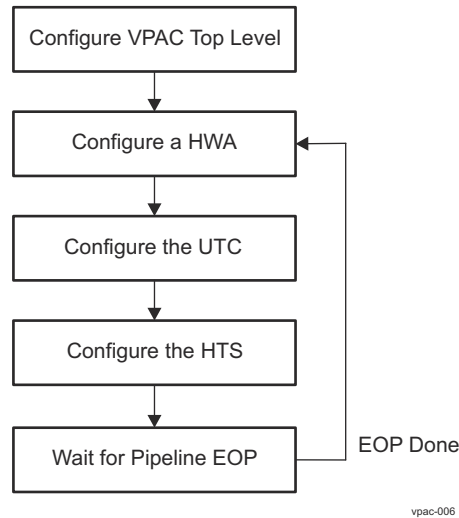

Figure 6-31. VPAC Subsystem Pipeline Processing Initialization Sequence

6.7.2.13.2 VISS Configuration

Refer to Section *VPAC Vision Imaging Subsystem (VISS)* for complete details about its configuration.

The VISS operates in line mode or frame mode:

- Line mode (when VISS_LSE_CFG_LSE[5] IN_CH_SYNC_MODE = 0): Every 'tstart' starts with loading a line and produces a complete line (except due to line delay through VISS pipeline there is no output data for 'tstart' count equals to VISS_LSE_DST_BUF_ATTR0_j[31-25] LOUT_SKIP_INIT register field setting for each channel and no input buffer loading after 'tstart' count goes beyond frame height.
 - Minimum horizontal blanking needs to be configured in LSE (HzlatencyLine)= aggregation of horizontal latency of enabled components: 50(RFE) + 62(GLBCE) + 25 (CFA) + 25(FCC) + 26(EE) + 44(NSF4) ~ for all enabled VISS sub-modules.
- Frame mode, recommended, VISS_LSE_CFG_LSE[5] IN_CH_SYNC_MODE = 0): Every 'tstart' starts with loading a line till 'tstart' count equals to VISS_LSE_DST_BUF_ATTR0_j[31-25] LOUT_SKIP_INIT register field setting for any of the enabled output channels. After this, input line loading is independent from 'tstart' and only output data is synchronized with 'tstart'. Minimum buffer depth on input channels are so chosen to enforce input data availability throughout frame.
 - Minimum horizontal blanking needs to be configured in the LSE module = MAX of horizontal blanking of enabled components:
 - MaxVertBlanking = 2(DPC) + 1(GLBCE) + 3(CFA) + 15(NSFV4)
 - LOUT_SKIP_INIT(S8) = MaxVertBlanking
 - LOUT_SKIP_INIT(Y12) = MaxVertBlanking + 2(EE enabled for Y12)
 - LOUT_SKIP_INIT(UV12) = MaxVertBlanking + 1(420 Chroma)
 - LOUT_SKIP_INIT(Y8) = MaxVertBlanking + 2(EE enabled for Y8)
 - LOUT_SKIP_INIT(UV8) = MaxVertBlanking + 1(420 Chroma)

6.7.2.13.2.1 VISS UTC Configuration

The VISS HWA in a non-streaming mode (memory to memory mode) needs a maximum of 3 input buffers to be loaded by UTC before it can start its processing. The 6 VISS HWA outputs produced need to be stored by UTC into DDR. Refer to chapter *Data Routing Unit (DRU)*, about configuring the UTC for data load and store for VISS processing.

The 3 UTC channels needs to be set up for input data fetch:

- VISS Exposure-0

- VISS Exposure-1
- VISS Exposure-2

The 6 VISS outputs are mapped to independent UDMA channels, as follows:

- VISS-Y-12b
- VISS-UV-12b
- VISS-Y-8b
- VISS-UV-8b
- VISS-S-8b
- VISS-H3A-AE/AF

The UTC channel configuration assumes different channels for each input and output data. SL2 storage needs to allocate minimum ping-pong buffer for each input/output data. Buffer depth is configurable. For each UTC trigger, single line of data is either loaded from DDR or stored into DDR. The HTS module manages start of UTC channels.

6.7.2.13.2.2 VISS HTS Configuration for Line Mode

The HWA0 scheduler in HTS is used for VISS. One example for HTS programming to map VISS on pipeline=0 is as below:

- Assume frame resolution to be 1920x1080 with all components in VISS pipeline enabled, and EE on Y12.
- postLoad = max(LOUT_SKIP_INIT for Y12, LOUT_SKIP_INIT for Y8, LOUT_SKIP_INIT for S8), thr = 1;
- Producer DMA Depth min = Th+1;

```
// HWA0 Scheduler Programming (keep default programming for not included parameters)
HTS->HWA0_wdtimer->wdtimer_en = 1; //Activate WD
HTS->HWA0_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
```

```
// HWA0 consumer and producer control
HTS->HWA0_cons_control->cons0_en = 1; // Enable exp-0 Fetch
HTS->HWA0_cons_control->cons1_en = 1; // Enable exp-1 Fetch
HTS->HWA0_cons_control->cons2_en = 1; // Enable exp-2 Fetch
HTS->HWA0_cons_control->prod0_select = 0; // Fixed to UTC
HTS->HWA0_cons_control->prod1_select = 0; // Fixed to UTC
HTS->HWA0_cons_control->prod2_select = 0; // Fixed to UTC
```

```
HTS->HWA0_prod0_control->prod_en = 1; // Enable Producer socket
HTS->HWA0_prod0_buf_control->depth = 2; // ping-pong buffer
HTS->HWA0_prod0_control->cons_select = 0; // Fixed to UTC
HTS->HWA0_prod1_control->prod_en = 1; // Enable Producer socket
HTS->HWA0_prod1_buf_control->depth = 2; // ping-pong buffer
HTS->HWA0_prod1_control->cons_select = 0; // Fixed to UTC
HTS->HWA0_prod2_control->prod_en = 1; // Enable Producer socket
HTS->HWA0_prod2_buf_control->depth = 2; // ping-pong buffer
HTS->HWA0_prod2_control->cons_select = 0; // Fixed to UTC
HTS->HWA0_prod3_control->prod_en = 1; // Enable Producer socket
HTS->HWA0_prod3_buf_control->depth = 2; // ping-pong buffer
HTS->HWA0_prod3_control->cons_select = 0; // Fixed to UTC
HTS->HWA0_prod4_control->prod_en = 1; // Enable Producer socket
HTS->HWA0_prod4_buf_control->depth = 2; // ping-pong buffer
HTS->HWA0_prod4_control->cons_select = 0; // Fixed to UTC
HTS->HWA0_prod5_control->prod_en = 1; // Enable Producer socket
HTS->HWA0_prod5_buf_control->depth = 2; // ping-pong buffer
HTS->HWA0_prod5_control->cons_select = 0; // Fixed to UTC
```

```
// Exp-0 Fetch
HTS->DMA0_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA0_hop->hop = 1; // Head of the pipe scheduler
HTS->DMA0_hop->hop_thread_count = 1080; // Assuming frame height of 1080
HTS->DMA0_scheduler_control->dma_channel_no = 0; // Assign appropriate UDMA channel
HTS->DMA0_prod0_control->prod_en = 1; // Enable producer socket
HTS->DMA0_prod0_buf_control->depth = 2; // ping-pong
```

```
HTS->DMA0_prod0_count->count_postload = 23; // Additional triggers for vertical blanking to flush
out the VISS.
```

```
// Exp-1 Fetch
HTS->DMA1_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA1_hop->hop = 1; // Head of the pipe scheduler
HTS->DMA1_hop->hop_thread_count = 1080; // Assuming frame height of 1080
HTS->DMA1_scheduler_control->dma_channel_no = 1; // Assign appropriate DMA channel
HTS->DMA1_prod0_control->prod_en = 1; // Enable producer socket
HTS->DMA1_prod0_buf_control->depth = 2; // ping-pong
HTS->DMA1_prod0_count->count_postload = 23; // Additional triggers for vertical blanking to flush
out the VISS.
```

```
// Exp-2 Fetch
HTS->DMA2_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA2_hop->hop = 1; // Head of the pipe scheduler
HTS->DMA2_hop->hop_thread_count = 1080; // Assuming frame height of 1080
HTS->DMA2_scheduler_control->dma_channel_no = 2; // Assign appropriate DMA channel
HTS->DMA2_prod0_control->prod_en = 1; // Enable producer socket
HTS->DMA2_prod0_buf_control->depth = 2; // ping-pong
HTS->DMA2_prod0_count->count_postload = 23; // Additional triggers for vertical blanking to flush
out the VISS.
```

```
// VISS output Y-12
HTS->DMA240_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA240_scheduler_control->dma_channel_no = 3; // Assign appropriate DMA channel
HTS->DMA240_cons0_control->cons_en = 1; // Enable consumer socket
// VISS output UV-12
HTS->DMA241_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA241_scheduler_control->dma_channel_no = 4; // Assign appropriate DMA channel
HTS->DMA241_cons0_control->cons_en = 1; // Enable consumer socket
// VISS output Y-8
HTS->DMA242_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA242_scheduler_control->dma_channel_no = 5; // Assign appropriate DMA channel
HTS->DMA242_cons0_control->cons_en = 1; // Enable consumer socket
// VISS output UV-8
HTS->DMA243_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA243_scheduler_control->dma_channel_no = 6; // Assign appropriate DMA channel
HTS->DMA243_cons0_control->cons_en = 1; // Enable consumer socket
// VISS output S-8
HTS->DMA244_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA244_scheduler_control->dma_channel_no = 7; // Assign appropriate DMA channel
HTS->DMA244_cons0_control->cons_en = 1; // Enable consumer socket
// VISS output H3A-AE
HTS->DMA245_scheduler_control->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA245_scheduler_control->dma_channel_no = 8; // Assign appropriate DMA channel
HTS->DMA245_cons0_control->cons_en = 1; // Enable consumer socket
```

```
// Enable Required Schedulers
HTS->HWA0_scheduler_control->sch_en = 1; //VISS0 Scheduler Enable
HTS->DMA0_scheduler_control->sch_en = 1; //Prod DMA for expo0 Enable
HTS->DMA1_scheduler_control->sch_en = 1; //Prod DMA for expo1 Enable
HTS->DMA1_scheduler_control->sch_en = 1; //Prod DMA for expo2 Enable
HTS->DMA240_scheduler_control->sch_en = 1; //Cons DMA for Y12 Enable
HTS->DMA241_scheduler_control->sch_en = 1; //Cons DMA for UV12 Enable
HTS->DMA242_scheduler_control->sch_en = 1; //Cons DMA for Y8 Enable
HTS->DMA243_scheduler_control->sch_en = 1; //Cons DMA for UV8 Enable
HTS->DMA244_scheduler_control->sch_en = 1; //Cons DMA for S8 Enable
HTS->DMA245_scheduler_control->sch_en = 1; //Cons DMA for H3A Enable
```

```
// Enable Pipeline
HTS-> PIPELINE_CONTROL_0 ->pipe_en = 1; // Enable VISS0 pipeline# 0
```

6.7.2.13.2.3 VISS HTS Configuration for Frame Mode

The HWA0 scheduler in HTS is used for VISS0. The HTS programming is as follows:

- Assume frame resolution to be 1920x1080 with all components in VISS pipeline enabled.
- $Var = \text{ceil}((1024/\text{in_pix_cntsrz} + 808/\text{out_pix_cntsrz} + 8 + \text{HzlatencyLine}) / (\text{Framewidth in pixels} + \text{lse.vp_hblink_cnt}))$;

- $\text{postLoad} = \max(\text{lout_init_skip for Y12}, \text{lout_init_skip for Y8}, \text{lout_init_skip for S8}) + \text{Var};$
- $\text{Th} = \text{Var} + 1;$
- $\text{Producer DMA Depth min} = \text{Th} + 1;$

The rest of the HTS registers configuration remains same as in Line Mode, except for below fields (based on earlier equations):

```
HTS-> dma0_prod0_buf_control.threshold = Var+1;
HTS-> dma0_prod0_buf_control.depth = Var+2;
HTS-> dma0_prod0_count.count_postload = 23+Var;
```

6.7.2.13.3 VISS OTF Configuration

Refer to the programming information within [Section 6.7.2.13.2, VISS Configuration](#), for common details.

The HTS configuration for OTF operation will change as follows:

```
HTS->HWA0_cons_control->cons0_en = 0; // Enable exp-0 Fetch
HTS->HWA0_cons_control->cons1_en = 0; // Enable exp-1 Fetch
HTS->HWA0_cons_control->cons2_en = 0; // Enable exp-2 Fetch
HTS->HWA0_scheduler_control-> strm_en = 1; // streaming input enabled
HTS->DMA0_prod0_control->prod_en = 0
HTS->DMA1_prod0_control->prod_en = 0
HTS->DMA2_prod0_control->prod_en = 0
// Enable Required Schedulers
HTS->DMA0_scheduler_control->sch_en = 0; //Prod DMA for expo0 Enable
HTS->DMA1_scheduler_control->sch_en = 0; //Prod DMA for expo1 Enable
HTS->DMA1_scheduler_control->sch_en = 0; //Prod DMA for expo2 Enable
```

6.7.2.13.4 LDC Configuration (LDC Connected to MSC0, NF and DMA)

In this example configuration, pipeline 2 is used for LDC. The LDC output is stored into DDR, and connected to MSC0 and NF concurrently.

The LDC DMA connection are these: DMA272 (Y12), DMA273 (UV12), DMA274 (Y8), DMA275 (UV8)

The DMA connections for MSC and NF are as follows:

- MSC0: DMA[304:313]
- MSC1: DMA[304:313]
- NF: DMA336

The parameters assumed for this example is: LDC OBW = 32, OBH = 32, Frame width = 1920

For more details on LDC configuration, see [Section VPAC Lens Distortion Correction \(LDC\)](#).

6.7.2.13.4.1 LDC DMA Configuration

The LDC does not need thread management on its input buffer. The LDC uses its own DMA engine to fetch required input data. The LDC needs DMA to write out its output data and needs HTS interface. Refer to chapter *Data Routing Unit (DRU)*, about DMA configuration for data store. Maximum 13 DMA channels need to be set up for writing out output data.

6.7.2.13.4.2 LDC HTS Configuration

The HWA2 scheduler in HTS is used for LDC, the HWA4 is used for MSC0, and HWA6 is used for NF. The HTS programming is as follows:

```
// HWA2/LDC Scheduler Programming (keep default programming for rest of parameters)
HTS->HWA2_wdtimer->wdtimer_en = 1; //Activate WD
HTS->HWA2_scheduler_control->pipeline_num = 2; // Belongs to pipeline 2
```

```
// HWA2/LDC Producer control
HTS->HWA2_prod0_control->prod_en = 1; // Enable Producer socket
HTS->HWA2_prod0_buf_control->depth = 120; // (FW/OBW)*2; ping-pong buffer for 2 rows of 32x32 blocks
HTS->HWA2_prod0_control->cons_select = 0; // Fixed to DMA
HTS->HWA2_prod0_buf_control->threshold = 1; // threshold value
HTS->HWA2_prod0_count-> count_postload=0;
```

```
HTS->HWA2_prod0_count-> count_preload=0;
HTS->HWA2_pa0_control-> pa_ps_maxcount = 32; // OBH
HTS->HWA2_pa0_control-> pa_cs_maxcount = 60; // (FW/OBW)
HTS->HWA2_pa0_control-> pa_buf_cntl = '0'; //
HTS->HWA2_pa0_control-> pa_enable = '1' ;
```

```
// HWA2/LDC Producer control
HTS->HWA2_prod1_control->prod_en = 1; // Enable Producer socket
HTS->HWA2_prod1_buf_control->depth = 2; // ping-pong buffer for chroma blocks
HTS->HWA2_prod1_control->cons_select = 0; // Fixed to DMA
HTS->HWA2_prod1_buf_control->threshold = 1; // threshold value
HTS->HWA2_prod1_count-> count_postload=0;
HTS->HWA2_prod1_count-> count_preload=0;
HTS->HWA2_pa1_control-> pa_enable = '0'; // No pattern adaptation for Chroma
```

```
// HWA2/LDC Producer control
HTS->HWA2_prod4_control->prod_en = 1; // Enable Producer socket
HTS->HWA2_prod4_buf_control->depth = 120; // (FW/OBW)*2; ping-pong buffer for 2 rows of
32x32 blocks
HTS->HWA2_prod4_control->cons_select = 33; // Select MSC0-IN
HTS->HWA2_prod4_buf_control->threshold = 5; // threshold value
HTS->HWA2_prod4_count-> count_postload=2;
HTS->HWA2_prod4_count-> count_preload=2;
HTS->HWA2_pa4_control-> pa_ps_maxcount = 32; // OBH
HTS->HWA2_pa4_control-> pa_cs_maxcount = 60; // (FW/OBW)
HTS->HWA2_pa4_control-> pa_buf_cntl = '1'; // Apply threshold/pos/preload on PA output
HTS->HWA2_pa4_control-> pa_enable = '1';
```

```
// HWA2/LDC Producer control
HTS->HWA2_prod6_control->prod_en = 1; // Enable Producer socket
HTS->HWA2_prod6_buf_control->depth = 120; // (FW/OBW)*2; ping-pong buffer for 2 rows of
32x32 blocks
HTS->HWA2_prod6_control->cons_select = 49; // Select NF-IN
HTS->HWA2_prod6_buf_control->threshold = 5; // threshold value

6.7.2.13.5 Real-time Operating Requirements

SW needs to interfere at frame level for each pipeline.

VPAC subsystem can have a maximum of 6 pipelines at any given time. Refer to Section *VPAC Hardware Thread Scheduler (HTS)*, for further details.

6.7.3 VPAC Vision Imaging Subsystem (VISS)

6.7.3.1 VISS Top Level

This section describes the Vision ISS (VISS) top level details.

6.7.3.1.1 Features Supported

- Performance: up to 1 pixel per clock per HW Instance
- Support for 16 bit input RAW format
- Support for concurrent 12 bit YUV output & 8b YUV output
- Support for multiple RAW formats (e.g. Bayer, RCCC)
- Flexible to handle any 2x2 RAW format
- Enables Support for other color spaces
 - Enables RGB output
 - Support other color spaces e.g. Support for Color saturation and Gray scale for HSV/HSL etc (Hue is not supported)
- Support for multiple WDR /HDR Formats and Up-to 3 exposures merge
- Companded format (12 & 14 bit formats)
- Stagger format of WDR
- Split pixel format of WDR
- Rest of WDR format
- Support of statistics for Auto-Exposure / Auto-white-balance or Auto-Focus (configurable option to select either AE/AWB or AF not both concurrently)
- Advanced Spatial Noise filter with 16-bit support
- Dynamic White balance adaptation
- Histogram on Raw Bayer data
- Support for Flexible CFA for generating multi-plane output for any 2x2 RAW Format sensor configuration
 - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
 - Can generate up to 4 independent color planes
 - Support for up two 3 directions per color plane
 - Adaptive Threshold based on intensity measure
- Support for multiple color format output generation
 - Support traditional 12 bit YUV Output
 - Supports RGB output
 - Supports Saturation outputs (8 bits only)
 - Supports Grayscale/Luma/IR/Clear Output
- Support for flexible output format generation including YUV as well as custom
- Edge enhancement Option to bypass visual enhancement functions (NSF4V and GLBCE) for ADAS vision applications
- Concurrent Human Vision (HV) and Mission Vision(MV) outputs
- Chromatic Abaration Correction

6.7.3.1.2 VISS Block Diagram

The VISS module does on-the-fly processing on raw pixels captured from camera sensor (via CSI RX module). It also does memory to memory processing (via DDR memory) for data captured from other sources at SoC level.

[Figure 6-32](#) is simplified block diagram of VISS top level.

Figure 6-32. VISS Block Diagram

The VISS consists of the following Hardware Accelerators (HWAs):

- RFE (RAW-FE): The RAW Frond End HW block does RAW pixel (that is, Bayer, RCCC, RGBW, etc.) processing on captured image data from sensor and pass-on to NSF4V, GLBCE block, and then to Flexible Color Processing (FCP) HW block for demosaicing and color conversion.
- NSF4V: Spatial Noise Filter supporting generic 2x2 pixel format with 16-bit pixel size. The NSF4V module can be bypassed in the applications where visual enhancement is not desired.

- GLBCE: The GLBCE module is used for dynamic range control within image for visual quality. If contrast enhancement on input image is required for visual quality, the RFE output is processed by the NSF4v and GLBCE blocks. Otherwise, the RFE output is bypassed to FCP.
- FCP: The Flexible Color Processing HW receives data from the GLBCE and does demosaicing and color conversion. The output of FCP is sent to VPAC shared memory to be written into DDR for the rest of the vision processing by programmable processors (for example, DSP or Arm), or other Vision HW blocks (for example, DMPAC).
- LSE: The Load and Store Engine is an infrastructure block, which performs the following functions:
 - CAL video port: The CSI RX module at SoC level receives CSI-2 sensor data, extracts pixels and drives the result data on its video port interface. The video port is mapped onto one of LSE input interfaces for on-the-fly image processing to reduce DDR bandwidth and latency. The LSE also provides horizontal and vertical blanking cycles to allow core data path to settle at proper boundary of line and frame.
 - SL2 memory access: This module supports load/store data from/to SL2 using VBUSM interface. Loaded data from SL2 are passed on to unpacker function of LSE for RFE. Packed data after FCP/H3A processing is written into SL2.
 - Pixel pack/unpack: Source data (512-bit) for RFE processing is loaded from SL2 and passed onto unpacker function for pixel extraction. Extracted pixels are driven on to the video port of RFE. Similarly, the FCP produced pixels are passed through packer function for eventual write into SL2. The H3A generated data is pseudo mapped as pixels of 32-bit for packing purpose and directly driven by the RFE.
 - Event control: The HTS events are generated at line level. These events are routed to LSE to start the processing. For each consumed line, the HTS needs a *task done* indication. For some initial lines of image, there would not be any valid data output. Similarly, the H3A generated data will be at paxel/window height number of lines. For initial lines not producing any valid data, the HTS needs to be indicated with separate mask bits for each output streams. For these initial lines, when there is no valid output due to lines delay inside VISS, the LSE still generates mask output to HTS indicating lack of proper output data.

6.7.3.1.3 VISS Data Flow within VPAC

VISS receives data from sensor through:

- CSI RX video port for OTF processing (Sensor -> CSI RX -> LSE -> RFE -> FCP)
- DMA of VPAC (Sensor -> CAL -> DDR -> VPAC_SL2 -> LSE -> RFE -> FCP)

6.7.3.1.3.1 VISS On-the-fly Processing

The VISS operation is controlled through a single HTS thread. For details of the HTS operation refer to Section *VPAC Hardware Thread Scheduler (HTS)*. The VISS configuration is valid for a single or multiple frame. External-host manages VISS configuration at end of each frame, if required. The HTS controls image processing between lines and handles managing shared memory for VISS inputs/outputs. Sub-frame processing is not natively supported. SW must configure VISS and HTS to start initialization process before enabling sensor capture. After the initialization sequence, the HTS will generate a start trigger to VISS. The generation of the start trigger depends on the availability of H3A data out buffer and FCP data out buffer inside the SL2 memory.

At this stage, the LSE waits for CSI RX video port (VP) to start sending valid pixels. As and when VP data starts streaming in, it is routed to the RFE video port. As RFE and FCP are running in streaming mode, the FCP indicates to LSE about completion of one line of operation. After receiving valid data out, the HTS will trigger for data store into DDR. Each 'thread done' accompanies output mask for all output buffers. Mask bits indicate to HTS about validity of output buffer as for each thread done all output buffers do not need to be produced. The HTS will issue next start after checking all output buffers availability. The streaming data from CSI RX is stallable upto 2KB storage inside VP memory of CSI RX. Any temporary stall can be absorbed, but prolonged stall is buffer overflow inside CSI RX. In VPAC, VISS produced data is transferred using Real Time fabric of NAVSS/MSMC and low predictable latency needs to be guaranteed.

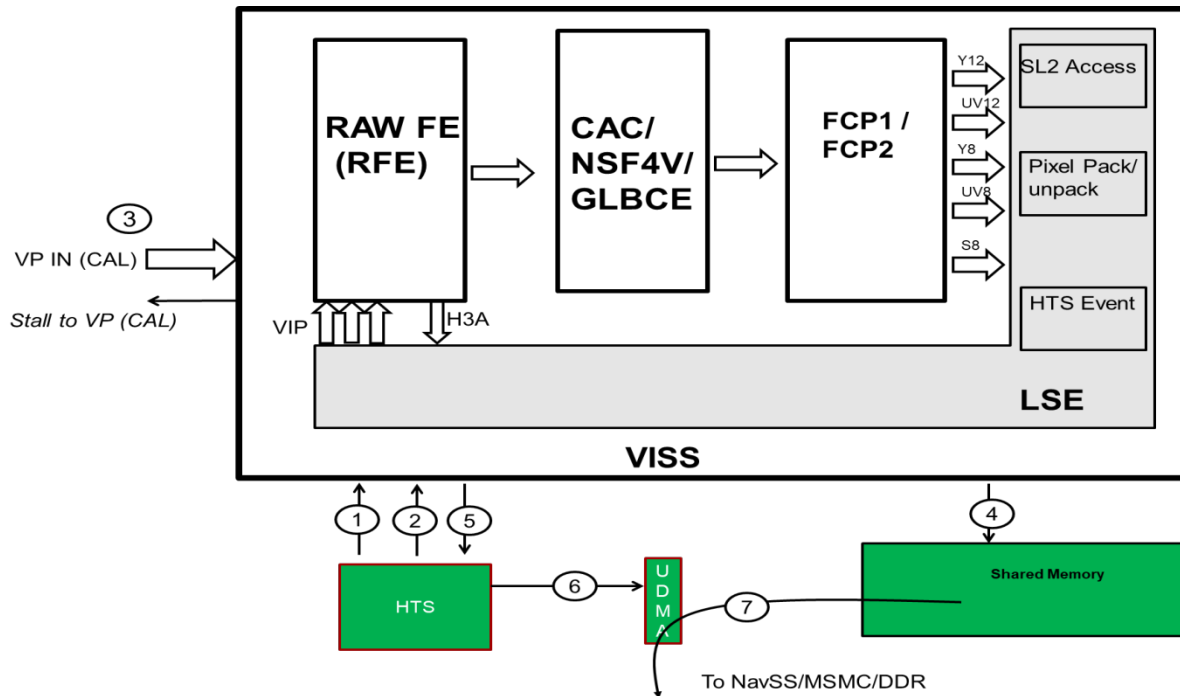

Figure 6-33. VISS On-the-fly Operation

The following OTF operation steps are illustrated in [Figure 6-33](#):

1. *Init* from HTS to initialize VISS.
2. Thread start. Step 1+2 prior to enabling CSI RX + PHY + sensor.
3. Video port data streaming. Unit of operation inside VISS at line level.
4. Output data produced by FCP and H3A at line level. H3A will produce data only at those lines which aligns with paxel_height/window_height.
5. Production of 1 line depends on consumption of 1 line on VP interface. 'Thread done' triggered after completion of 1 processed line write into SL2. In case there is no valid data to be written into SL2, 'thread done' is generated after consumption of 1 line of data from VP. Note: *Horizontal blanking will be configured inside LSE to facilitate writing complete line out of FCP.*
6. HTS triggers DMA to store output buffer from SL2 to DDR.
7. DMA loads data from SL2 and writes into DDR.

The following assumptions are made for the OTF operation described above:

- UDMA write is mapped onto Real Time Thread for guaranteed QoS. Channel done by must be generated after completion of write into DDR. Next thread start depend on availability of minimum one buffer for each output line in SL2. More buffers in SL2 can take care of instantaneous drop in UDMA transfer capacity.
- Cycle gap between HTS done and next start must be minimal. CSI RX VP interface will be stalled whenever LSE input buffer on VP interface reaches near full condition.
- Configurable vertical latency times 'Tstart' generated by HTS to let RFE + NSF4V + GLBCE + FCP flush its internal pipe, even though last line of current frame is already fed into RFE.
- Buffer dependencies:
 - H3A output buffer (AE or AF)
 - FCP output buffer (Y12, YV12, Y8, UV8, S8)

6.7.3.1.3.1.1 Non-WDR or Companded WDR Sensors

VISS is enabled for single input data when either sensor does not support WDR or sensor does on-chip WDR merge and pass on merged data after companding to 12 bit / 14 bits as shown in [Figure 6-34](#).

Figure 6-34. VISS Non-WDR/Companded: High Level

6.7.3.1.3.2 VISS Memory to Memory Processing

CSI RX writes CSI-2 received pixel data into DDR. Once a frame is written, host is triggered to initiate VISS processing. HTS will go through 'init' sequence to initialize VISS and its SL2 pointers. As UDMA is head of pipeline for memory to memory mode of image processing, its scheduler inside HTS needs to be configured for generating "frame height" number of triggers to fetch image lines one by one. This is essential to bring determinism in pipeline as there is no producer for UDMA load thread.

Figure 6-35. VISS Memory to Memory Operation

The following memory to memory operation steps are illustrated in [Figure 6-35](#):

1. CSI-2 stream captured via CSI RX into DDR. This traffic must be routed through Real Time fabric of NAVSS/MSMC. CSI RX capture happens independent of VISS processing.
1. *Init* from HTS to initialize VISS.
2. HTS triggers UDMA to fetch data for processing. There could be max 3 independent input data.
3. UDMA loads the data and stores into SL2.
4. Upon completion of all input buffer loading (at line level) UDMA channel 'done' event triggers VISS thread start (still needs to ensure there are buffer available for writing VISS output data).
5. VISS produces line #N corresponding to loading of line #N + vertical_latency.
6. 'Tdone' triggered to HTS.
7. HTS triggers UDMA for output buffer transfer into DDR.
8. UDMA loads data from SL2 and write into DDR.

The following assumptions are made for the memory to memory operation described above:

- CSI RX write is mapped onto hard real time fabric of NavSS/MSMC.
- Configurable vertical blanking times 'Tstart' generated by HTS to let RFE + NSF4V + GLBCE + FCP flush its internal pipe, eventhough last line of current frame is already fed into RFE.
- Buffer dependencies:
 - RFE input buffer (exp0, exp1, exp2)
 - H3A output Buffer (AE or AF)
 - FCP output Buffer (Y12, UV12, Y8, UV8, S8)

6.7.3.1.4 Concurrent Machine Vision and Human Vision Output

Machine vision (MV) and human vision (HV) output requires different tuning of algorithmic blocks. For HV output, emphasis is on visual appearance while machine vision output requires output close to the original scene. A general machine vision application would not need NSF4V and GLBCE functions. Thus, to support concurrent output generation for MV and HV, a second instance of FCP is added. Raw image processing performed by RFE and CAC are common functions needed by both MV and HV.

When all outputs are generated to one FCP path, it should be done using a legacy FCP1 instance. Though it is not a hard requirement, FCP2 is targeted to be used in machine vision path and legacy FCP1 path is targeted for human vision path. FCP2 can be clock gated (by default) when not required to be used using the `FCP2_CNTL.PIX_CLKEN` register control.

To enable flexible use cases, FCP2 can receive inputs from any IPs prior in the pipe line. This includes RFE, CAC, NSF4V, and GLBCE. Though each instance of FCP generates 5 output channel data, it is mux'ed with flexible combinations (mux control is in the `LSEOUT_MUX_CNTL` register) and 5 output channel data is generated.

6.7.3.1.5 VISS Clocking

The clock frequency requirement for the on-the-fly VISS pipe is 83 MHz to support 2M@30fps with 25% blanking and 10% DMA overhead. Clock frequency to support 4 pipes of 2MP@30fps image processing in memory to memory mode is 300 MHz with 25% system/DMA overhead. In memory to memory image processing, the high performing image pipe will create instantaneous peak bandwidth.

All modules inside VISS has 2 clock inputs:

- Functional clock : Used for all non-data path operation, like configuration logic and non-pixel data interfaces.
- Gated pixel clock : Pixel clock, that is synchronous to the functional clock, but is enabled when input data is available from LSE. All data path operations are done on the pixel clock. All the operations move in streaming fashion till the final output generation.

6.7.3.1.6 VISS Data Formats Support

Table 6-89 lists the data formats supported by VISS. VISS does not support YUV Input. In case of external YUV Sensor, CSI RX directly writes into DDR and the data is subsequently processed by the rest of VPAC.

Table 6-89. VISS Data Formats

Direction	Pixel Width	Pixel Container Width (M2M)	Packing	Video port (OTF)	Comments
VISS Input	RAW12/14/16	16b	No	16b / pixel	1. Companded data/External ISP 2. MSB bits are padded with zeros within fixed width pipeline
	RAW8	8b	Yes	16b / pixel	
	RAW12	12b	Yes	16b / pixel	
VISS Output	YUV420 (12b) NV12	12b	Yes	N/A	
	YUV420 (12b) NV12	16b	No	N/A	
	YUV420 (8b) NV12	8b	Yes	N/A	
	YUV422 (8b) UYVY/YUY2/NV16	8b	Yes	N/A	
	RGB (planar)	8b	Yes	N/A	With RGB output, limited YUV data outputs are available (only 12-bit YUV data is available)
	S8	8bit	Yes	N/A	

6.7.3.1.7 VISS VPORT Interface

The video port (VPORT) interface is used to stream the pixel data from up stream to down stream module. In VISS, the VPORT interface is used to receive data from CSI RX (in streaming mode) and in between VISS sub-modules (RFE -> NSF4V -> GLBCE -> FCP).

The VPORT supports stall signal (VP_STALL) and also either one pixel or 2 pixel data per cycle.

The pixel data (VP_DATA) received on the VPORT is organized in 32 bits as follows:

- VP_DATA[15:0] = pixel (n)
- VP_DATA[31:16] = pixel (n+1). This is ignored, when VPORT_TWO_PIXEL = 0
- MSBs are padded with 0's when less than 16 bits are used.

6.7.3.1.8 VISS Submodule Integration Specifics

6.7.3.1.8.1 LSE Integration

Figure 6-36 captures the channel integration between LSE and rest of VISS submodules. Though diagram shows three input channels between LSE to RFE, 3 channels data is transferred using single VBUSP interface.

Figure 6-36. VISS LSE Channel Integration

The LSE configuration for VISS can be read in VISS_LSE_STATUS_PARAM register fields.

For more information on LSE module operation, see Chapter *Load and Store Engine (LSE)*.

6.7.3.1.8.2 Chromatic Aberration Correction

Figure 6-37 captures the CAC, NSF4V, and GLBCE integration in the VISS pipe line. All CAC, NSF4V, and GLBCE can be enabled or disabled based on use case. By default, all are disabled. General Visual use cases require NSF4V and GLBCE (along with FCP.EE) to be enabled. Low cost lenses with purple fringe artifact require CAC to be enabled.

Figure 6-37. CAC, NSF4V, and GLBCE Integration

6.7.3.1.8.3 Spatial Noise Filter (NSF4V)

Figure 6-37 captures the NSF4V and GLBCE integration in the VISS pipe line. Both NSF4V and GLBCE can be enabled or disabled based on use case. By default, they are disabled. General Visual use cases require NSF4V and GLBCE (along with FCP.EE) to be enabled.

Figure 6-38 captures the RawHistogram and Dynamic White Balance block integration in NSF4V. Both DWB and RawHistogram can be enabled/disabled independent of NSF4V enable. When Histogram is enabled, **minimum frame width must be 128** (required to initialize the histogram memory at the frame start).

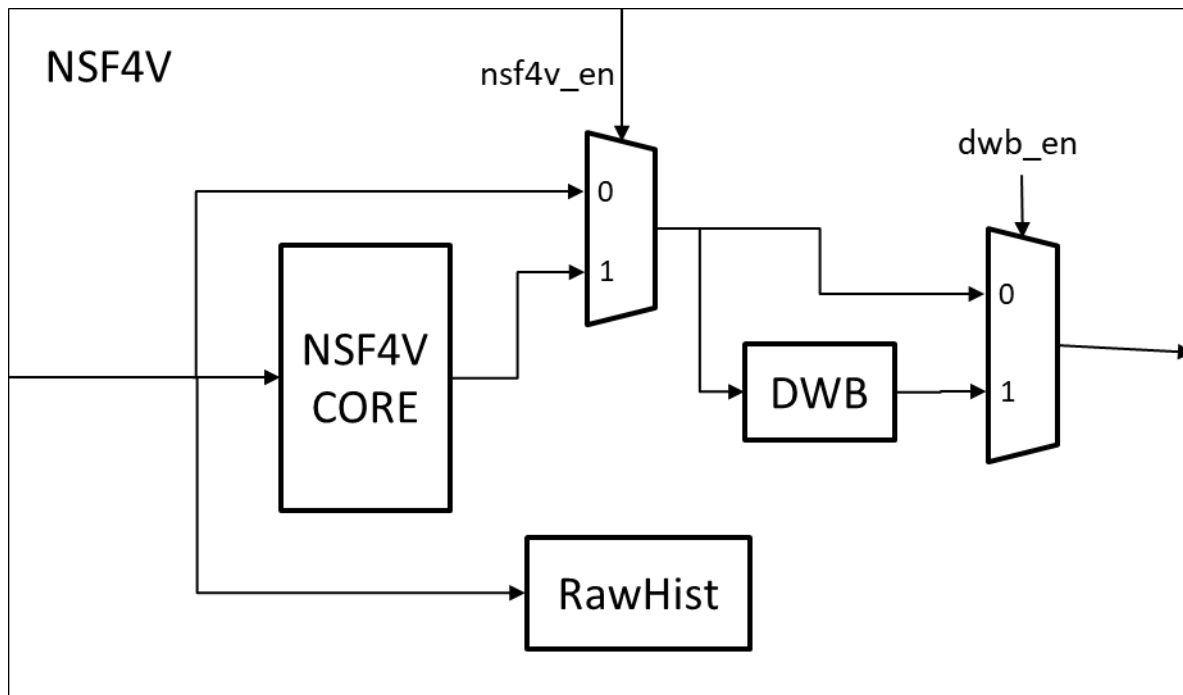

Figure 6-38. RawHistogram and DWB integration in NSF4V

6.7.3.1.8.4 GLBCE Integration

GLBCE is Global/Local Brightness and Contrast Enhancement module.

The GLBCE module supports the following main features:

- One pixel/cycle operation
- Up to 4096 pixels/line (line size)
- Bayer image
- When GLBCE is off, the RFE/NSF4V output is bypassed to FCP

For more information on GLBCE operation, see [Section 6.7.3.5, VISS Global/Local Brightness and Contrast Enhancement \(GLBCE\) Module](#).

6.7.3.1.8.4.1 GLBCE Startup

GLBCE requires approximately 5400 clock pulses after startup before it could receive data on its video port. Therefore, before RFE -> GLBCE -> FCP path could be used after a GLBCE reset, the SW shall use the following sequence to provide those required clock pulses:

- Prior to enabling rest of VISS pipe, configure VISS clock control to allow free running clock to GLBCE.
- Wait for the 'glbce_filtering_done' event. It indicates that GLBCE has received enough PCLK pulses for internal initialization and that it is now ready to receive pixels.
- Configure GLBCE clock to normal mode. Enable the rest of VISS pipeline.

GLBCE has a minimum input restriction of 480x240 pixels. The input frame must be at least this size.

GLBCE LUTs must not be changed during the active frames. They can only be updated in vertical blanking. GLBCE_LUT_FI may be changed frame by frame depending on the GLBCE tuning method. Other LUTs (GLBCE_REV_PERCEPT_LUT_xx, GLBCE_FWD_PERCEPT_LUT_xx, and GLBCE_WDR_GAMMA_LUT_xx) are not expected to be updated dynamically except in very limited case.

6.7.3.1.8.4.2 GLBCE Bypass

When the GLBCE is disabled (by VISS_CNTL[0] GLBCE_EN = 0), any access targeted to GLBCE registers or GLBCE statistics memory will respond with error status, and 'glbce_cfg_err' interrupt will be generated.

6.7.3.1.8.5 Flexible Color Processing (FCP)

Figure 6-39 captures top level overview of FCP. LUT in front on CFA can map 16-bit data to 12-bit when CFA is operating in 12-bit mode. It can also be used to 16b to 16b remap when CFA is operating in 16-bit mode. EE data path is clock gated when EE module is not used. EE has bypass condition (YEE = 0) where data flows thorough it unchanged with the same latency as the enable condition.

Figure 6-39. FCP Top Level Overview

In the CC module, Y12 to Y8 and U12 to UV8 LUTs should be enabled or disabled together (i.e $CFG_2.C8LutEn = CFG_2.C8LutEn$).

Program $EE_CFG_1.Yuv8_cl_align = 1$ while generating interleaved 422 8-bit and $EE_CFG_1.Yuv12_cl_align = 1$ while generating interleaved 422 12-bit output. This function is available even when EE path is not used.

6.7.3.1.9 VISS Stall Handling

VISS can handle momentarily stall condition created due to lack of enough band width.

6.7.3.1.10 VISS Blanking Requirements

Table 6-90 lists some blanking and latency details for VIS submodules.

Table 6-90. VISS Blanking Requirements

IP	Blanking		Latency	
	Vertical (in number of lines)	Horizontal (in pixel clock cycles)	Vertical (in number of lines)	Horizontal (in pixel clock cycles)
RawFE	2 - DPC Enable 0 - DPC Disable	8	2 - DPC Enable 0 - DPC Disable	50
GLBCE	- (1)	5	1	
CFA	1	5	3	
FCC	0	20	1 (2)	25
EE	2	2	2	29
NSF4V	15	28	15	44

(1) GLBCE requires $(1033*7 + 2066*FLOOR(VARIANCEINTENSITY/2,1) + VARIANCESPACE*2066+30)$ cycles for vertical blanking.

(2) In 420 mode, Chroma is vertically downsampled. For the first line, Chroma channel does not generate any dummy VBUSP requests. Hence, 1 line vertical delay is required.

The VARIANCEINTENSITY and VARIANCESPACE parameters (in Table 6-90 notes) affect the sensitivity of the transforms across different parts of the frame. Both parameters can be configured through the GLBCE_VARIANCE register.

In Table 6-90, the vertical blanking/latencies are expressed in number of lines (except for GLBCE), and horizontal blanking/latency is expressed in number of pixel clock cycles.

Horizontal blanking, buffer depth and HTS programming parameters (Threshold and PostLoad) depend on VISS frame mode or line mode of operation (selected via LSE_CFG_LSE[5] IN_CH_SYNC_MODE register field). Frame mode is the recommended mode of operation, and line mode is primarily used for debug purposes.

- Frame mode:
 - LSE input line fetch starts once the previous input line plus horizontal blanking cycle are provided to RFE. Horizontal blanking should meet two requirements:
 - Greater than minimum horizontal blanking of each enabled modules
 - Greater than maximum cycle gap between the last line pixel write on all LSE enabled output channel line ends
 - Horizontal Blanking of 35 is expected to be sufficient for most use cases. Horizontal blanking of 55 should be used, if EE is enabled and any of the CFA outputs is directly written out.
- Line mode:
 - LSE input line fetch start on HTS Tstart
 - Horizontal blanking is addition of all enabled modules horizontal delay (that is, latency)

LSE will automatically generate required vertical blanking until all output channels produce HTS_EOP, and GLBCE processing is complete (when GLBCE is enabled). In the vertical blanking window, LSE generates dummy lines (data = 0x0) following frame width paramter. LSE prematurely ends line w/o HE marker once vertical blanking requirement is met (that is, processing is done and HTS_EOP is generated).

6.7.3.1.11 FCP2 Sync FIFO

The second instance of FCP (referred as FCP2) can receive data from different IPs prior to being in the pipeline. It creates difference in both veritcal and horizontal latency in the pipe line compared to the FCP1 instance. Vertical latency can be handled using the *DST[a]_BUF_ATTR0.lout_skip_init* parameter in the LSE. However, horizontal latency difference in the pipe line needs higher horizontal lanking in frame mode of operation, which can result in reduced efficiency.

To align the VPORT timing at both instances of FCP, SyncFIFO block is added, which delays the FCP2 input VPORT interface by a programmable number of pixel cycles. The delay parameter can be programmed in *FCP2_CNTL.IN_PIPEDLY*. The delay value should be equal to the addition of the horizontal latency of all the IPs included in the FCP1 path but not in FCP2 input. Examples:

- If both FCP1 and FCP2 are getting data from GLBCE then program *FCP2_CNTL.IN_PIPEDLY* = 0
- If FCP2 is getting data from CAC and FCP1 is getting data from GLBCE with NSF4V and DWB enabled, program *FCP2_CNTL.IN_PIPEDLY* = 114 (44 [NSF4V] + 8 [DWB] + 62 [GLBCE])

6.7.3.1.12 VISS Interrupts

The VISS submodules generate the interrupt events described in Section *VPAC Subsystem Interrupts*.

6.7.3.1.12.1 Interrupts Merging

The configuration error interrupts are merged at VISS level. The following list describe the configuration error eventss and the corresponding merged interrupts.

- RAWFE_CFG_ERR_INTR: Generated when configuration interface access the RFE end points, while frame processing is active. Merged interrupts from RFE:
 - lut1_cfg_err_intr
 - lut2_cfg_err_intr
 - lut3_cfg_err_intr
 - wdr_lut_cfg_err_intr
 - dpc_line_cfg_err_intr
 - dpc_lut_cfg_err_intr
 - h3a_lut_cfg_err_intr
 - h3a_line_cfg_err_intr
- GLBCE_CFG_ERR_INTR: Generated when the configuration interface access the GLBCE register region or statastics memory, while frame processing is active. Merged interrupts from GLBCE:
 - glbce_statmem_cfg_err_intr
 - glbce_mmr_cfg_err_intr
- FCFA_CFG_ERR_INTR: Generated when the configuration interface access the CFA register region, or LUT or line memory, while frame processing is active. Merged interrupts from CFA:
 - lut_cfg_err_intr
 - cfa_mmr_err_intr

- cfa_pix_err_intr
- FCC_OUTIF_OVF_ERR_INTR: Generated when any of the FCC output interfaces overflows. Merged interrupts from CC:
 - overflow_if_y12_intr
 - overflow_if_uv12_intr
 - overflow_if_y8r8_intr
 - overflow_if_c8g8_intr
 - overflow_if_s8b8_intr
- FCC_CFG_ERR_INTR: Generated when the configuration interface access FCC register region or its LUTs, while frame processing is active. Merged interrupts from FCC:
 - contrast0_cfg_err_intr
 - contrast1_cfg_err_intr
 - contrast2_cfg_err_intr
 - lut_12to80_cfg_err_intr
 - lut_12to81_cfg_err_intr
 - lut_12to82_cfg_err_intr
- EE_CFG_ERR_INTR: Configuration happened to EE regions causing corruption during frame processing. Merged EE sources are:
 - eelut_cfg_err_intr
 - ee_pix_err_intr
- EE_SYNCOVF_ERR_INTR:
 - ee_hz_align12_intr
 - ee_hz_align8_intr

6.7.3.1.12.2 Handling of Configuration Error Interrupts

Table 6-91 give hints on handling configuration error interrupts.

Table 6-91. VISS Configuration Error Interrupts Handling

Memory	Error Generation Window	HWA-level Register Status Clearing Mechanism
RAWFE		
PWL1_LUT, PWL2_LUT, PWL3_LUT	Config read access during active line OR write access during active frame.	Write '1' to corresponding bit in RAWFE_INT_STAT register.
WDR_LUT		
H3A_LUT		
H3A_ACCM		
H3A_LINE	Config read/write access during active frame at H3A boundary.	
DPC_LUT	Config read/write access during active frame.	
DPC_LINE	Config read access during active line OR write access during active frame.	
LSC Table	Config read/write access during active frame. Active frame in lsc case is VS at pwl to VE at lsc input delayed by 1 cycle.	
NSF4V		
NSF4V_LINE	Config read/write access when datapath is accessing the corresponding memory on the same cycle.	No register status in NSF4V.
GLBCE		
GLBCE non-shadowed registers	Config write access during active frame. Active frame window is from VS_IN to Filter done.	Write '1' to GLBCE_INT_STAT[0] MMR_CFG_ERR register bit.
GLBCE_STAT	Config read/write access during active frame. Active frame window is from VS_IN to Filter done.	Write '1' into GLBCE_INT_STAT[1] STATMEM_CFG_ERR register bit.
GLBCE_LINE	Not mapped to config.	N/A
CFA		
CFA FIR Filter registers	Config write access during active frame.	Write '1' to CFA_INT_STATUS[2] CFA_MMR_ERR register bit.

Table 6-91. VISS Configuration Error Interrupts Handling (continued)

Memory	Error Generation Window	HWA-level Register Status Clearing Mechanism
CFA_LUT	Config read/write access during active frame.	Write '1' into CFA_INT_STATUS[0] LUT_CFG_ERR register bit.
CFA_LINE	Config read/write access during active frame.	Write '1' to CFA_INT_STATUS[1] CFA_PIX_ERR register bit.
FCC		
LUT_CONTRAST	Config access (read/write) occurs during active line when the LUT is enabled.	Write '1' to corresponding bit in FCC_FLEXCC_INT_STATUS register.
HISTOGRAM	Config access has occurred to the first location but not to the last location till the start of next frame implying that full histogram was not read.	
LUT_COLOR	Config access (read/write) occurs during active line when the LUT is enabled.	
CC_LINE	No error generation logic.	N/A
EE		
EE_LINE	Config accesses during active frame.	Write '1' to EE_INT_STATUS[1] EE_PIX_ERR register bit.
LUT	Config accesses during active frame.	Write '1' to EE_INT_STATUS[0] EELUT_CFG_ERR register bit.

6.7.3.1.13 VISS Error Correcting Code (ECC) Support

ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

One or more memories within VISS are ECC protected using an ECC Memory Wrapper which implements Single Error Correction and Double Error Detection (SECDED).

The ECC wrapper provides Single Error Detection and Correction (SED/SEC). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC wrapper also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC wrapper also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

An ECC Aggregator at the VISS level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. It provides a single EOI-handshake based interrupt to the host (for both single and double error detections) and a standard 32-bit VBUSP interface for configuring and querying the various ECC wrappers via their ECC register set.

The following VISS memories are ECC protected:

- GLBCE statistics memory.
- RAWFE non pixel line buffer memories. See Section *VISS RAW Front-End (RAWFE)*, for more information.
- FCP non pixel line buffer memories

For more information on the ECC Aggregator operation, see Section *ECC Aggregator* in Chapter *Safety Modules*.

6.7.3.1.14 VISS Programmer's Guide

6.7.3.1.14.1 VISS Initialization Sequence

VISS initialization is part of any other HWA initialization on VPAC. Prior to starting HWA initialization through HTS, VISS must be configured in below order.

1. Configure RFE registers, GLBCE registers, NSF4V registers and FCP registers:
 - The VISS_CNTL[0] GLBCE_EN register bit needs to be set, in order to configure the GLBCE registers.
2. Select input / output stream properties inside LSE.
3. After reset and prior to enabling LSE, apply the following configuration:

- a. Make sure VISS_CNTL[0] GLBCE_EN bit is '1'.
- b. Enable IRQ for interrupt event 'glbce_filtering_done'.
- c. Set VISS_GLBCECONFIG[0] GLBCE_PCLKFREE register bit to '1'.
- d. Wait for interrupt 'glbce_filtering_done'.
- e. Clear VISS_GLBCECONFIG[0] GLBCE_PCLKFREE register bit.
4. Enable LSE input and output buffer lines.
5. Enable pipeline and schedulers associated with VISS HTS configuration (pipeline enable must happen after enabling all attached schedulers).
6. Enabling HTS will trigger init sequence which will initialize LSE, RFE and FCP. This will also trigger head of pipe for NAVSS UDMA fetch (in case of memory to memory operation). Otherwise, VISS waits for streaming data from CSI RX.
7. After initializing VISS/VPAC, configure and enable CSI RX, CSI RX PHY and camera sensor in order.
8. Once streaming data starts, it will continue till the end of frame. Blanking (set in VISS_LSE_CFG[31-22] VP_HBLNK_CNT register field) must be configured more than VISS blanking needs (see *VISS Blanking Requirements*).
9. Once a complete frame is fully written into DDR, the HTS module comes back to init state and restart from step #6. For some usecase, LSE input/out enables after each frame might be considered as well (step #5).
10. After each 'frame_done', if the configuration needs to be changed, it must be done within vertical blanking period for not shadowed registers (refer to Sections *VISS RAW Front-End (RAWFE)* and *VISS Flexible Color Processing (FCP) Module*, for more details).
11. At any stage, if there is a need to stop the streaming interface, the HTS must first be paused and then aborted, and then reset and re-configure the entire VISS as part of recovery from abort.

6.7.3.1.14.2 VISS Configuration Restrictions

Frame size restriction:

- If GLBCE is enabled in the VISS pipeline, the minimum frame required is 480x240 pixels.
- If GLBCE is disabled in the VISS pipeline, the minimum frame required is 64x16 pixels.
- Frame width and height has to be even.
- Histogram can only be enabled when the frame width is 256 pixels minimum.

LSE H3A channel enabling restriction:

- When the H3A output channel is enabled in LSE, at least one other output channel needs to be enabled.

6.7.3.1.14.3 VISS Real-time Operating Requirements

SW needs to configure UTC/UDMA channel registers for write out buffers.

SW needs to reconfigure RAWFE LSE LUT, if needed, and any other non-shadowed registers during vertical blanking period only. Some control bits would be shadowed, which can be configured during a complete frame.

6.7.3.2 VISS RAW Frond-End (RAWFE)

This section describes the Vision Imaging Sub-system (VISS) RAW Frond-End (RAWFE) module in the device.

6.7.3.2.1 RAWFE Overview

The RAWFE is a set of raw pixel processing functions to enhance the RAW image signal received from the sensor. The key application of the RAWFE is in the ADAS space where in it is used for both analytics as well as visual use cases.

6.7.3.2.1.1 RAWFE Supported Features

Each RAWFE module implements the following features:

- Support for any 2x2 RAW data pattern.
- Support for merge up to 3 separate exposures.
- PWL (piecewise linear) and LUT based de-companding at the front end of each exposure channel
- Support for WDR merge, including 2 exposure merge, 3 exposure merge and 2 exposure hybrid (12 bit and 16 bit) merge.
- Support for companding LUT from 24 bits down to 12 bits.
 - LUTs support higher precision in lower end.
- Support for LUT as well as adaptive Defect Pixel Correction.
- Support for table based lens shading correction.
- Support for 3A statistics
 - Statistics can be generated on independent exposures or merged data after tone map.

6.7.3.2.1.2 RAWFE Not Supported Features

The RAWFE does not support the following features:

- Motion compensated WDR Merge
- Simultaneous statistics using H3A on all 3 exposures
- More than 3 exposures for WDR

6.7.3.2.2 RAWFE Functional Description

6.7.3.2.2.1 RAWFE Functional Operation

The RAWFE processes captured image data from sensor and passes the data to the Flexible Color processing module (FCP) for demosaicing and color conversion.

[Figure 6-40](#) shows a high level conceptual block diagram of the RAWFE module.

The RAWFE consists of the following main components

- **Decompanding block:** This is used to decompand the sensor compressed raw to native bit depth. The same block can be used for tone mapping as well. The decompanding block can take sensor compressed RAW data and can decompand to up to 24 bits.
- **WDR Merge:** Each instance of the WDR merge block can take in 2 independent exposures (up to 16 bits) and generate up to 20 bit data.
- **LSC Block:** The block performs lens shading correction by applying gains stored in a look up memory.
- **DPC:** The block performs defect pixel correction using either LUT based memory or adaptive defect correction.
- **H3A:** The H3A block generates 2 different set of statistics, one for AWB and AE and the other for auto focus.

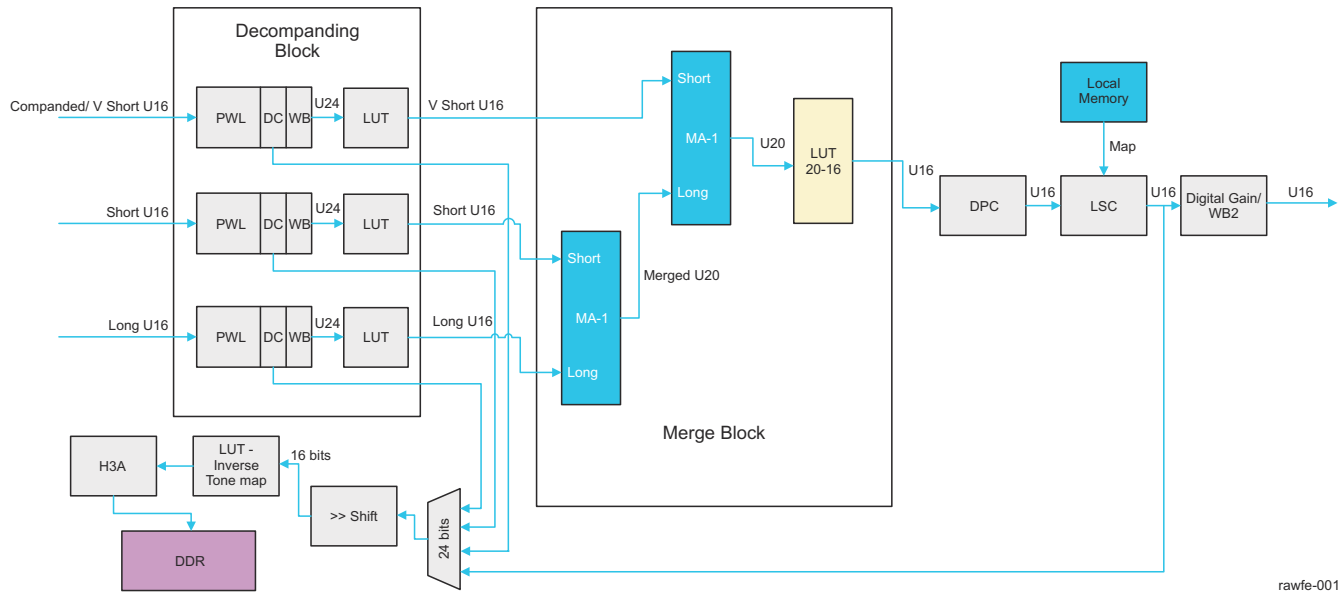

Figure 6-40. RAWFE Block Diagram

6.7.3.2.2.2 RAWFE Integration in VISS

Figure 6-41 show the VISS Block Diagram integrating the RAWFE module.

The VISS Consist of following hardware accelerators

1. RAWFE: The RAWFE block does RAW pixel (e.g. Bayer, Clear Channel) processing on captured image data from sensor and later passes to FCP block for demosaicing and color conversion.
2. FCP (Flexible Color Processing): The FCP receives data from RAWFE and does demosaicing and color conversion. The output of FCP is sent to external memory for vision processing by programmable processors (e.g. DSP or ARM) as well as Vision HW Blocks (e.g. VPAC and DMPAC).
3. GLBCE (Global Local Brightness and Contrast Enhancement): This is local adaptive tone mapping block.

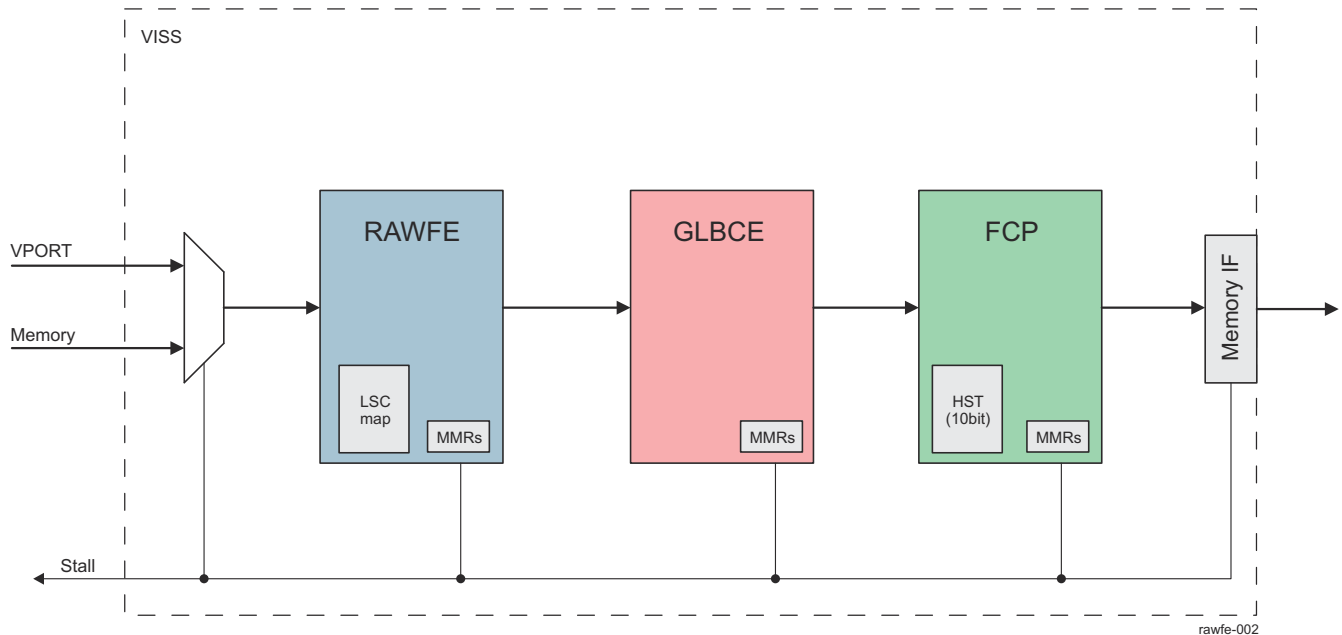

Figure 6-41. RAWFE Integration in the VISS

6.7.3.2.2.3 RAWFE Memory Map

Table 6-92 lists the RAWFE memory mapped RAMs.

Table 6-92. RAWFE Memory Map

Address Offset	Register Space	Size
0x00000	RAWFE registers	
0x00400	H3A registers	
0x00800	V-Short LUT (LUT3-RAM) ⁽¹⁾	639 x16 bits
0x01000	Short LUT (LUT2-RAM) ⁽¹⁾	639 x16 bits
0x01800	Long LUT (LUT1-RAM) ⁽¹⁾	639 x16 bits
0x02000	Merge LUT (WDR_LUT-RAM) ⁽¹⁾	639 x 16 bits
0x02800	H3A LUT (H3a_LUT-RAM) ⁽¹⁾	639 x 10 bits
0x03000	DPC LUT (DPC-RAM) ⁽¹⁾	256x 29 bits
0x08000	LSC LUT(RAM) ⁽¹⁾	19032 Bytes

(1) Partial writes to RAMs are NOT supported. Software must write the full word. This restriction is an artifact of simplifying ECC support.

Most registers in RAWFE MMR space are shadowed. On frame start, the non shadowed registers will update the shadowed registers and used for the remainder of the frame for data processing. The following registers are not shadowed:

- VISS_RAWFE_INT_STAT
- VISS_RAWFE_DBG_STAT1
- VISS_RAWFE_DBG_STAT2
- VISS_RAWFE_DBG_STAT3
- VISS_RAWFE_DBG_STAT4
- VISS_RAWFE_DBG_CTL

H3A has partial shadowing, refer to [Section 6.7.3.2.4.6](#) for details.

LUT3 ram is shadowed. LUT3 and LUT2 will be multiplexed for shadowing capabilities. Software must use a control register to select which lut is to be used during frame. Software must fully configure LUT2 in this case as well.

Note

Accesses to non shadowed registers or rams during active window can cause corruption. During an active phase, non blanking region, any accesses to a ram, read or write, will corrupt the output data. H3a rams, lsc lut, dpc lut rams are exceptions. These rams must be outside the full frame, including horizontal blanking regions, otherwise they will cause corruption. Any write to mmr's that are not shadowed will result in data corruption in non blanking area, the interrupt status and debug registers are exception. Mmr reads to any type of register are ok and will not result in frame output corruption. Interrupt events will be asserted if config accesses corrupt frame data.

6.7.3.2.2.4 RAWFE ECC for RAMs

Table 6-93 lists the RAWFE ECC RAMs

Table 6-93. Table 3: RAM ECC capabilities

Module	# Rams	ECC
PWL LUT1	2	ECC, with single bit correction, including writeback.
PWL LUT2	2	ECC, with single bit correction, including writeback.
PWL LUT3	2	ECC, with single bit correction, including writeback.
WDR LUT	2	ECC, with single bit correction, including writeback.
H3A LUT	2	ECC, with single bit correction, including writeback.
DPC (line buffer)	4	No ecc
LSC LUT	1	ECC, with single bit correction, including writeback.

Table 6-93. Table 3: RAM ECC capabilities (continued)

Module	# Rams	ECC
LSC GAIN	1	ECC, with single bit correction, including writeback.
H3A accum	1	No ecc
H3A line	1	No ecc

6.7.3.2.3 RAWFE Interrupts

The following section lists the RAWFE interrupts

6.7.3.2.3.1 RAWFE CPU Interrupts

Table 6-94 lists the interrupts generated by the RAWFE sub-modules.

Table 6-94. RAWFE Interrupts

Interrupt	Description
LUT1_CFG_ERR	Config access to LUT1 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LUT2_CFG_ERR	Config access to LUT2 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LUT3_CFG_ERR	Config access to LUT3 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if cfg access occurs during active line. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
WDR_LUT_CFG_ERR	Config access to WDR LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
H3A_LUT_CFG_ERR	Config access to H3A LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
H3A_ACCM_CFG_ERR	Config access to H3A accum ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
H3A_LINE_CFG_ERR	Config access to H3A line ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
DPC_LUT_CFG_ERR	Config access to DPC LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
DPC_LINE_CFG_ERR	Config access to DPC line ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LSC_CFG_ERR	Config access to LSC ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame. Active frame in lsc case is VS at pwl to ve at lsc input delayed by 1 cycle.
H3A_AEW	h3a aew interrupt.
H3A_AF	h3a af interrupt
H3A	h3a interrupt
H3A_BUF_OVRFLOW_PULSE_INTR	Generated when an overflow occurs in the H3a output buffer

6.7.3.2.3.2 RAWFE Debug Events

Table 6-95 lists the RAWFE debug events. Debug events are used for hardware debug as well as performance measurement. They are not intended to be used as interrupts where the cpu needs to process them.

Table 6-95. RAWFE Debug events

Event	Description
VS_EVENT	ventricle start in the beginning of the rawfe pipeline
VE_EVENT	ventricle end at the end of the rawfe pipeline
HS_EVENT	horizontal start in the beginning of the rawfe pipeline
HE_EVENT	horizontal end at the end of the rawfe pipeline
LSE_SLAVE_STALL	rawfe is stalling lse slave interface due to ext or mtc stall
LSE_MASTER_STALL	lse master interface is stalled
LSE_INTERFACE_IDLE	within a frame lse is not sending data
X_Y_EVENT_MATCH	x-y pixel position has reached the start of rawfe pipeline
DPC_OTF_CORR_EVENT	dpc otf corrected a pixel position
PIPE_ADV_EVENT	active pipeline advancement

6.7.3.2.3.3 RAWFE Interrupt Handling: High Priority

When a high priority interrupt occurs, the CPU starts shutting down the RAWFE and stopping its usage. The next steps of actions are under software control.

6.7.3.2.3.4 RAWFE Interrupt Handling: Low Priority

When a low priority interrupt occurs, the CPU notices these conditions and maintain statistics of such occurrences. The next steps of actions are under Software control.

6.7.3.2.4 RAWFE Sub-Modules Details

The following sections describe in detail the sub-modules present within the RAWFE module.

6.7.3.2.4.1 RAWFE Decompaning Block

The decompaning block is responsible for decompaning pwl (or LUT) compressed data back to its linear bit width. The decompaning block can generate up to 24 bits of data, however the data needs to be tone mapped down to 16 bits before additional processing can take place. There are 3 instances of the Decompaning block each implementing the same functionality.

The input interface of the decompaning block is 16 bits.

Figure 6-42 shows a high level block diagram of the decompaning block.

rawfe-003

Figure 6-42. RAWFE Decompaning Block Diagram

6.7.3.2.4.1.1 RAWFE Mask & Shift

The mask and shift block is used to mask out any control bits present in the data. The 'Mask' is a 16 bit configuration register which will perform a bit wise 'and' operation on the incoming data. (For example for sensor data with data in 12 bits and 4 bits of control information, the mask value would be programmed to 0xFFFF). The Mask operation is followed by a shift operation. The 'Shift' field is a 3 bit configuration register which can perform a right shift (>>) from 0 to 7 bits.

6.7.3.2.4.1.2 RAWFE Piece Wise Linear Operation

The PWL block is used to apply a piece-wise-linear gain on the incoming pixel data and is generally used to uncompress sensor compressed data. The knee points of the PWL curve should be programmed to correspond with the compression knee points used by the sensor configuration.

The PWL block supports an input size from 8 – 16 bits and can support an output up to 24 bits.

Figure 6-43 depicts a PWL curve applied on incoming data

Figure 6-43. RAWFE PWL Curve implementation

The PWL block implements the following equation assuming the input lies in the nth segment.

$$\text{Out_Pixel} = ((X - \text{ThrX}_n) \times \text{Slope}) + \text{ThrY}_n \quad (2)$$

The figure below shows the PWL block architecture

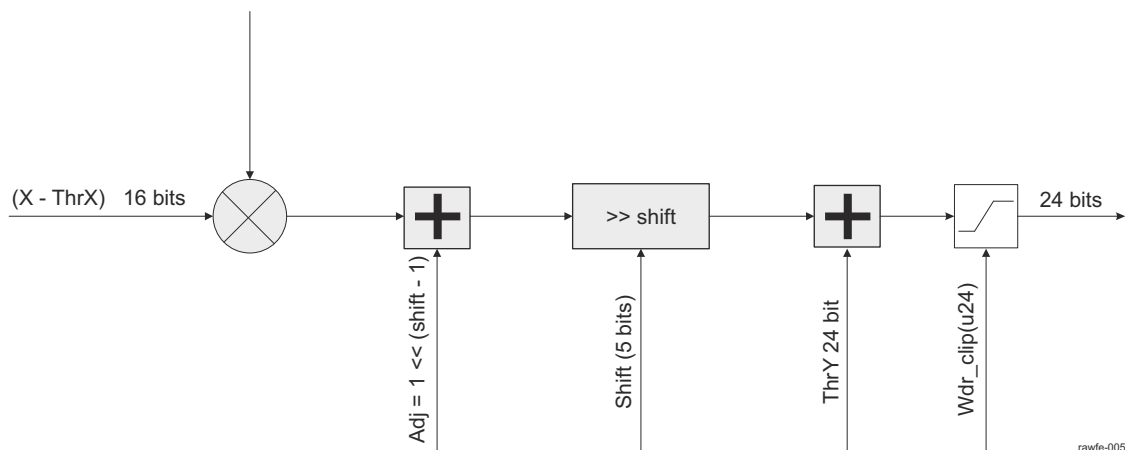

Figure 6-44. RAWFE PWL Block Diagram

The Wdr_clip parameter can be set to clip the output at the desired bit width (typically 20 bits).

6.7.3.2.4.1.3 RAWFE Offset/WB-1 Block

This block is used for applying White balance correction in linear domain as well as for subtracting the DC offset using the signed 24 bit offsets. The functionality is similar to the WB2 block. Note, there is a tap out point to H3A after the offset application, but prior to the gain block. This allows the H3A to receive DC subtracted (but not WB corrected) data.

6.7.3.2.4.1.4 RAWFE LUT Based compression

The LUT based compression is used for addressing multiple use cases.

- The primary function of the LUT is to take the PWL decomposed data (up to 24 bits and after DC subtraction) and compress it using an x^n curve to a bitwidth of 16 bits. This is required since the downstream path is only capable of supporting up to 16 bits of data.

- It can be used to decompand data when the compression curve cannot be addressed using 3 knee points or if the compression is true curve instead of PWL. In this scenario the DC subtraction IP is disabled and the LUT is used to implement both the decompression as well as the DC subtraction functionality.

The LUT compression is modified from the implementation in previous generation ISPs. The previous LUTs had 512 entries leading to a step size of $2^{20}/512 = 2048$. As such there were only 2 LUT points in the critical low range (0-4095) of the image. The LUT implementation is optimized for a 20-bit decompounded data and allows for a step size of 32 in the critical range (lower 12 bits) and a step size of 2048 in the successive ranges.

The Non Linear LUT implementation supports 3 zones for the input range

- For bitWidth < 12 bits, the LUT offers a linear range with a step size of 32. (Only the first 128 locations (plus 129th location for supporting interpolation) are utilized in this mode)
- For bitWidths between 13 and 20: This is the most common operating zone for the LUT. In this mode, the range between 0 and 4k is split in 128 locations with a step size of 32. Beyond 4k range, the step is variable and is set to 2k for the highest bit width of 20 and subsequently reduces by half as the bitwidth is reduced (E.g. 1k for 19 bits etc)
- For bitwidths between 21 and 24: In this operation zone, the first 128 locations are used with a varying step size based on bit width such that the step size is 64 for 21 bits of data and doubles with increase in bitWidth. (E.g. 128 for 22 bits etc). The remaining locations implement a varying step size between 4k (for 21 bits) and 32k (for 24 bits).
 - Example-1: Bitwidth=21 bits:
 - Range 0-8k-> Step size = 64;
 - Range 8k- 2^{21} -> Step Size = 4096
 - Example-2: Bitwidth = 22 bits
 - Range 0 -16k -> Step Size = 128
 - Range 16k - 2^{22} -> Step_Size = 8192
 - Example 3: Bitwidth = 24 bits
 - Range 0 - 64K -> Step Size = 512
 - Range 64K - 2^{24} -> Step Size = 32k

The LUT logic provides a generic table which can support any bit width and can be used in different regions in the RAWFE as well as other modules.

The LUT3 supports shadowing for very short frame only. If the MMR shadow enable is set then the LUT2 is used on the LUT3 data.

6.7.3.2.4.2 RAWFE WDR Merge Block

The merge block supports merging up to 3 exposures to generate a cumulative 20 bit frame.

The merge block is based on 2 instances of the Motion-Adaptive merge block, each of which is independently capable of supporting the merging of 2 exposures (10 – 16 bits each) to a combined bit width of up to 20 bits. In a more generic scenario the merge block should be designed and verified to support the following scenarios

- Merge 2 exposures of 10 bits each to 16 bits
- Merge 2 exposures of 12 bits each to 16 bits
- Merge 2 exposures of 12 bits each to 20 bits
- Merge 2 exposures (12 bit and 16 bit) to 20 bits.
- Merge 2 exposures of 16 bit each to 20 bits.

Using two instances of the motion adaptive merge block provides the functionality to merge up to 3 independent exposures, each of 12 bits, to a combined bitwidth of 20 bits. The block also provides capability to only merge 2 exposures using a combination of mux and clipping blocks.

The merge block comprises of two instances of the motion adaptive merge (MA1/MA2) as well as an LUT based companding block and mux structures to enable different data flow. To keep the design complexity under control some restrictions are applied to the data connectivity on the merge blocks. A key restriction is that for the two exposure merge only the MA-2 block should be used and the MA-2 should be used along with MA-1 for 3 exposure merge. Further the position of the long and short exposures on each block are fixed. [Table 6-96](#)

summarizes some of the possible combinations which can be realized using the logic. (Note, this is not an exhaustive list from a DV perspective).

The MA block when set to bypass/disabled mode, will pass the input stream marked as 'short' (refer to [Figure 6-40](#)) to the output.

Table 6-96. Figure 7:RAWFE Different merge modes

Merge Mode	MA-1	MA-2	LUT
2 Exposures (12 bit) to 20 bit	Bypassed	Merge Long / Short	Use VS and Short Exposures Set to 20-16
2 Exposures (12 bit) to 16 bit	Bypassed	Merge Long /Short	Use VS and Short Exposures Bypassed
2 Exposures (12 bit) to 16 bit with tone mapping	Bypassed	Merge Long /Short	Use VS and Short Exposures Set to 16-16 mode
2 Exposures (12 & 16) to 20 bit	Bypassed	Merge Long /Short	Use VS and Short Exposures Set to 20-16
3 Exposures (12 bit each) to 20 bit	Merge Long and Short	Merge VS / MA-1 output	Use all 3 exposures Set to 20-16
Single exposure companded	Bypass	Bypass	Use VS exposure only Bypassed

6.7.3.2.4.2.1 RAWFE WDR Motion Adaptive Merge (MA1 / MA2)

This section provides the detailed description of the two instances of the motion adaptive merge.

[Figure 6-45](#) shows the high level block diagram of the MA merge block

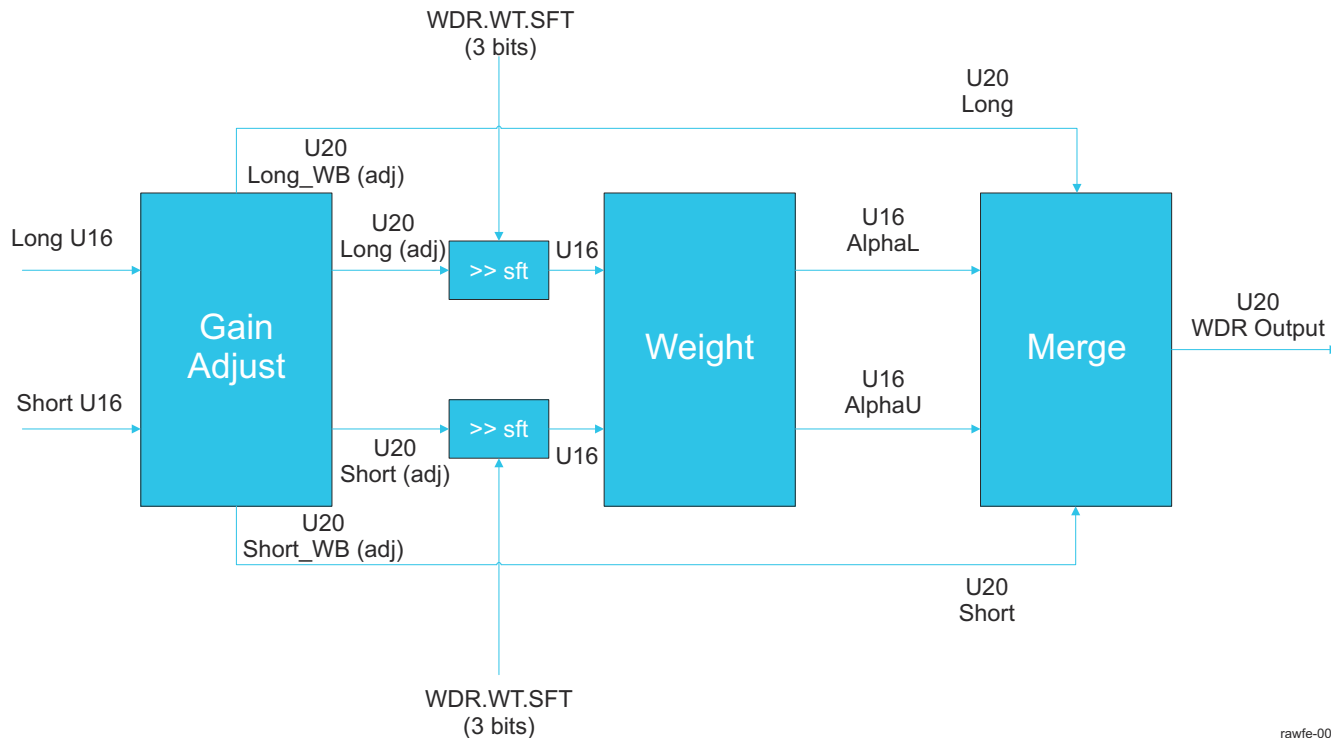

Figure 6-45. RAWFE WDR Motion Adaptive Merge

The MA block receives two inputs each of which can be up to 16 bits. As mentioned earlier, the ordering of the long and the short exposure cannot be changed and should be positioned as it's depicted in the figure above. The MA block consists of 3 main sub-blocks, which are described in the following sub-sections.

6.7.3.2.4.2.2 RAWFE Companding LUT

The companding LUT is used to perform a global tone mapping on the image and reduce the bit depth from 20 bits down to 16 bits. The LUT is implemented as a non uniformly spaced memory, with higher precision in the lower range of the image intensity. The LUT architecture is similar to that used for the decompanding LUT in the previous section.

6.7.3.2.4.3 RAWFE Defective Pixel Correction (DPC) Block

The defect pixel correction (DPC) block is responsible for correcting defective pixels present on the sensor as an artifact of the manufacturing process. The defect pixel detection can either be LUT based or on the fly (OTF – DPC). For LUT based DPC, the defect map is stored in a memory.

Figure 6-46 shows a high level block diagram of the DPC module. The DPC comprises of two different methods of performing the functionality, each of which is highlighted below. The LUT based defect correction mechanism requires the sensor to be calibrated and the defect positioned stored in memory, whereas the Adaptive DPC automatically detects defects and corrects them. If required the LUT DPC and adaptive DPC can be enabled together in sequence.

Figure 6-46. RAWFE DPC Block Diagram

6.7.3.2.4.3.1 RAWFE LUT Based DPC

LUT based defect pixel correction provides the highest level of accuracy since all defects can be identified perfectly without any false positives. The LUT based DPC mechanism however suffers from the limitation that the sensor has to be calibrated (each sample has to be individually calibrated) and that can add cost to the testing and qualification process. Some automotive grade sensor vendors provide the defect pixel locations already in an on chip memory and that can additionally be utilized to program the defect LUT without adding the cost. The LUT size for the DPC is constrained to 256 entries, since it is assume for a sensor of 2 -3 Mpix resolution, 256 entries are more than sufficient. Each entry in the LUT is 29 bits with 13 bits for x coordinate, 13 bits for Y coordinate and 3 bits for the method. Figure 6-47 illustrates the organization of the LUT memory

Figure 6-47. RAWFE DPC LUT Memory Organization

A sample table is provided below for 7 entries. The LUT is specified in left to right and top to down fashion (Raster Scan order). As such design only has to look at the current LUT pointer to be able to determine if the current location is a defect or not.

Table 6-97. Figure 14: RAWFE Sample DPC Table

10	1400	0	
236	1107	1	
236	1200	1	
488	10	1	
488	100	2	
800	138	3	
900	1000	1	
900	1100	3	

The method filed pertains to how the defect pixel is treated once it has been detected. Several possibilities arise including copying from one of the neighbors or using an average of the neighbors. The table below summarizes different methods that can be programmed for treating defect pixels.

Table 6-98. Figure 15:RAWFE LUT DPC Method(s)

Method Value	Functional equivalent
0	Replace with Black or white dot based on config
1	Dout = d4
2	Dout = d5
3	Dout = (d4 + d5)/2
4	Dout = (d2 + d7)/2
5	Dout = d2
6	Dout = d7
7	Dout = ((d2 + d7)/2 + (d4 + d5)/2)/2

The pixel arrangement and numbering convention is depicted in the image below with 'd0' being considered the center pixel.

rawfe-018

Figure 6-48. RAWFE DPC Pixel numbering convention

When the DPC method is set to '0', the output is either a black or a white pixel (depending on a separate configuration register). With this method, the LUT dpc can be used in conjunction with OTF DPC in a way that the LUT programmed defects are almost always identified by the adaptive DPC. This can be used to accurately correct for all known defects and then using adaptive DPC to correct for temperature or other operating condition based defects. (Defect pixels are strongly correlated with analog gain).

6.7.3.2.4.3.2 RAWFE On-The-Fly (OTF) DPC

The LUT based DPC suffers from the drawback that each sensor die has to be calibrated for defects. The calibration process adds cost to the sensor dies, as such the preferred DPC method relies on automatically detecting the defects based on thresholds.

The OTF DPC algorithm detects defective pixels by comparing the current pixel (d0 on the left of the figure below) against its 8 neighboring pixels with the same color (d1 ~ d8 on the left of the figure below). Let's use dmax and dmin to denote the maximum and minimum of d1 ~ d8 respectively. If the current pixel d0 is greater than the sum of dmax and a detection threshold T (i.e., $d0 > dmax + T$) as shown on the right of the figure below, then the current pixel is considered a defect and its value is replaced by dmax. Similarly, if $d0 < dmin - T$, then the current pixel is replaced by dmin.

Figure 6-49. RAWFE OTF DPC

The detection threshold T is made adaptive by calculating the local image intensity and using a programmable look-up-table. The local intensity is approximated by the average of the second largest and the second smallest pixel values among $d1 \sim d8$ ($d_{\max 2}$ and $d_{\min 2}$ respectively in the figure above). With this average value, the threshold T is obtained from the look-up-table with linear interpolation. The look-up-table contains the detection thresholds (U16) at the average values of 0, 512, 1024, 2048, 4096, 8192, 16384, 32768 and the corresponding slope values (S12Q8) for linear interpolation.

6.7.3.2.4.4 RAWFE Lens Shading Correction (LSC) and Digital Gain (DG) Block

The lens shading module corrects for the lens fall off (loss of light) at the corners of the lens. Figure 6-50 shows a sample image of this phenomenon and the corresponding result after treating with LSC operation.

Figure 6-50. RAWFE Before and After LSC

The image on the left shows a block at the center of the lens and a corresponding block at the edge of the lens. Both blocks are equally illuminated, as such should appear equally bright on the image. However, due to lens fall off, the block at the edge appears significantly darker than the block at the center. The image on the right shows the corresponding result after LSC gains have been applied.

This block (2D-LSC) contains lens shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image is conceived to be in Bayer CFA format having a 2x2 color pattern. The gain factor map is stored in internal MEMORY down-sampled, and is accessed and up-sampled by the LSC module to pixel resolution before being applied to the pixel data. The key difference from previous generation LSC is that the gain map is stored internally in the memory instead of relying on DRAM fetch.

The LSC module does not implement any Region of Interest (ROI) functionality and the LSC gain mask is applied on the entire image. Further, only an 8 bit gain is stored in the mask. The gain can be stored in different formats depending on the range. The 8 bits of gain can be used to represent different ranges based on the `lsccfg.GAIN_FORMAT` register as per the table below

- 0 : U8Q8 -> 0 to 0.996
- 1 : U8Q8 +1 -> 1 to 1.996
- 2 : U8Q7 -> 0 to 1.992
- 3 : U8Q7 +1 -> 1 to 2.992
- 4 : U8Q6 -> 0 to 2.984
- 5 : U8Q6 +1 -> 1 to 3.984
- 6 : U8Q5 -> 0 to 6.968
- 7 : U8Q5 +1 -> 1 to 7.968

Note

The offset field is removed from the implementation of the LUT and only the gain field is retained. This is different than previous implementations.

rawfe-021

Figure 6-51. RAWFE LSC block diagram

6.7.3.2.4.1 RAWFE LSC Features Supported

- Gain map is MxN down-sampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {8,16,32,64,128 } independently.
- The size of the internal memory is based on a 2Mpix sensor with 16x32 downscaling ratio. As such the size is approximately 19 Kbytes-(4758 locations with 4 Bytes/location) -> Each entry has gains for all 4 colors. This corresponds to a sensor resolution of 1928 x 1208
- Support 8-bit entry in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0 to shift the range up)

Figure 6-50 illustrates the LSC active region and map up-scaling feature. (The maps are stored independently per color channel)

6.7.3.2.4.4.2 RAWFE LSC Image Framing with Respect to Gain Map Samples

The gain maps are stored MxM downsampled, and needs to be upsampled by LSC hardware before being applied to the image. It is most straightforward for LSC hardware if the gain map grid is aligned with the input image grid. In other words, first pixel corresponds to a source gain map entry, rather than being upsampled through interpolation. Figure 6-52 shows the LSC active region with respect to the gain map grid.

Figure 6-52. RAWFE LSC active region with respect to gain map samples

For an image frame size of W x H (output and input are the same size), gain map being MxN downsampled, it needs $(\text{ceil}(W / M) + 1) \times (\text{ceil}(H / N) + 1) \times 4$ bytes of gain map data in internal memory. (NOTE: $\text{ceil}()$ represents the ceiling function).

The LSC module is designed to work with Bayer CFA data, having R/Gr/Gb/B color pattern. For the purpose of functional description, we assume Red is the starting color, but any other starting color or other 2x2 color pattern can be used by placing color gains in the appropriate order.

Each 2x2 set of samples is stored together in a 32-bit word in internal memory. For R/Gr/Gb/B CFA data and 8x8 downsampled gains, the following order is assumed in the gain map, using conventional (X, Y) coordinate notation (X for horizontal offset and Y for vertical offset):

Line 0: R(0,0) Gr(1,0) Gb(0,1) B(1,1) R(8,0) Gr(9,0) Gb(8,1) B(9,1)...

Line 1: R(0,8) Gr(1,8) Gb(0,9) B(1,9) R(8,8) Gr(9,8) Gb(8,9) B(9,9)...

6.7.3.2.4.5 RAWFE Gain & Offset Block

The gain block allow 2 primary functions

- Allow for digital gain to be applied if the image is too dark even after analog gain and exposure time have been set to the maximum
- Independent gain setting for each color channel in 13 bit format U13Q9 with 9 bits of fraction.
 - Allows a gain value from 0 to 31.996 in steps of 1/256.

The Gain block can be configured to apply an offset on top of the gain. This is to support the log compressed image mode, where in the traditional WB Gain becomes an offset.

6.7.3.2.4.6 RAWFE H3A

6.7.3.2.4.6.1 RAWFE H3A Overview

The H3A module supports the control loops for autofocus, auto white balance, and auto exposure by collecting statistics about the raw image. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus (AF) engine:

The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a 2D block of data referred to as a paxel. The AF engine supports the following features:

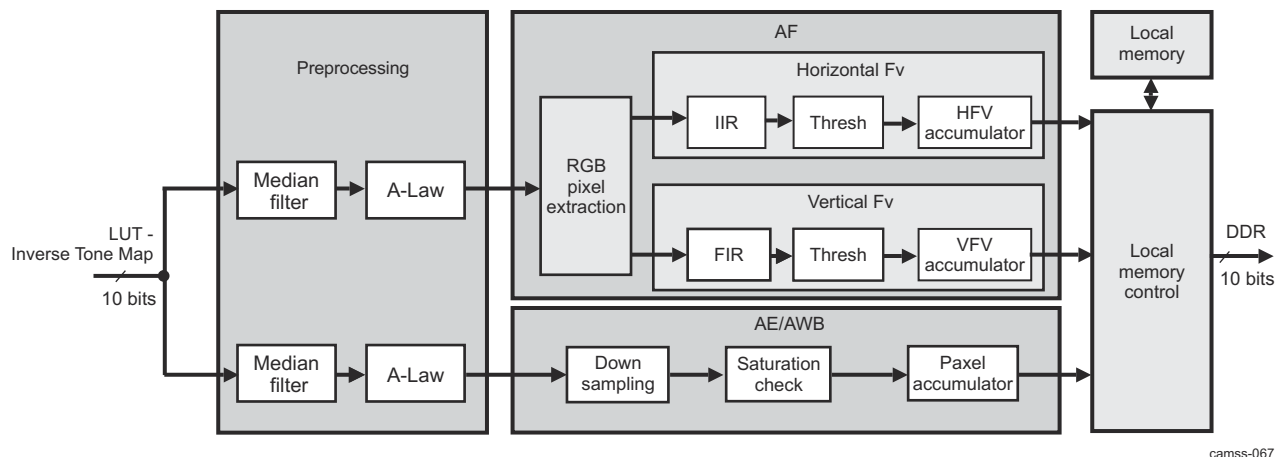

- Peak mode in a paxel: Accumulation of the maximum focus value (FV) of each line in a paxel
- Accumulation mode in a paxel
- Accumulation of horizontal and vertical focus value in a paxel
- Up to 12 paxels in the horizontal direction and up to 12 paxels in the vertical direction with vertical focus
- Up to 36 paxels in the horizontal direction and up to 128 paxels in the vertical direction with horizontal focus only
- Programmable width and height for the paxel/window
- Programmable red, green, and blue position within a 2×2 matrix
- Separate horizontal start for paxel and filtering
- Programmable vertical and horizontal line increments within a paxel
- Horizontal FV uses parallel infinite impulse response (IIR) filters configured in a dual-biquad configuration with individual coefficients (two filters with 11 coefficients each). The filters are intended to compute the sharpness/peaks in the frame on which to focus.
- Vertical FV uses a 5-tap FIR filter with 8-bit coefficients. With horizontal steps each paxel has up to 32 columns to be maintained for vertical FV calculation.
- Auto exposure and auto white balance (AE/AWB) engine:

The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the 2D block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:

- Accumulate clipped pixels along with all nonsaturated pixels in each window per color
- Accumulate the sum of squared pixels in each window per color
- Minimum and maximum pixel values in each window per color
- Support for up to 36 horizontal windows with $\text{sum} + \{ \text{sum_sq or min+max} \}$ output
- Support for up to 56 horizontal windows with sum output
- Support for up to 128 vertical windows
- Programmable width and height for the windows. All windows in the frame are the same size.
- Separate vertical start coordinate and height for a black row of paxels that is different than the remaining color paxels
- Programmable horizontal sampling points in a window
- Programmable vertical sampling points in a window
- Double-buffer for paxel/window accumulation
- H3A data path is 10 bits.
- Maximum input size is 4096 pixels.

6.7.3.2.4.6.2 RAWFE H3A Top-Level Block Diagram

The block diagram in [Figure 6-53](#) shows the process of the AF and AE/AWB data paths through the H3A module.

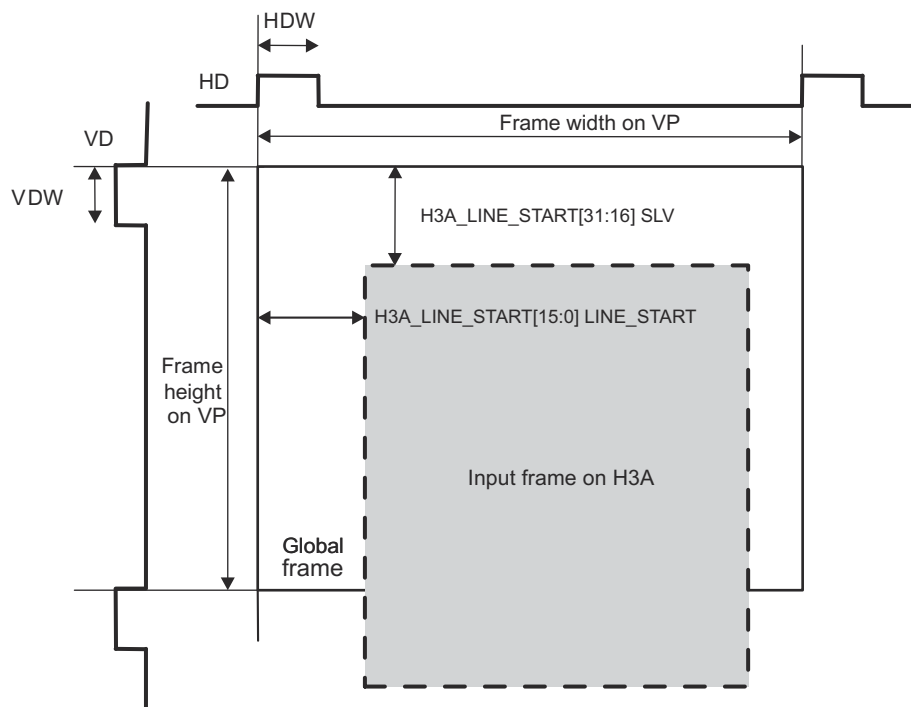

camss-067

Figure 6-53. RAWFE H3A Top-Level Block Diagram

6.7.3.2.4.6.3 RAWFE H3A Line Framing Logic

In certain cases the number of clock cycles between HD pulses is greater than the line buffer included in the H3A. To solve this problem a framing module was added before the line buffer. The framing module uses the VISS_RAWFE_H3A_LINE_START register to find the position of the first pixel to place into the line buffer. All other registers reference this point as the 0 pixel for their start positions. The line size is 4096 pixels. After 4096 clock cycles the framing logic disables the line buffer and waits until the next HD. If the next HD comes before 4096 clock cycles, then the active region ends immediately and the counter waits for the VISS_RAWFE_H3A_LINE_START register count to be reached again. For the vertical position the VISS_RAWFE_H3A_LINE_START[31:16] SLV bit field can be used to determine where the start point of the frame is relative to the rising edge of VD. This logic allows for an active frame to cross VD boundaries and remain in the same frame.

Figure 6-54 shows the RAWFE H3A frame format settings.

camisp-073

Figure 6-54. RAWFE H3A Frame Format Settings

Note

(Frame width on VP) - (VISS_RAWFE_H3A_LINE_START[15:0] LINE_START) must be less than or equal to 4096, because the H3A memory lines are limited to 4096 pixels.

6.7.3.2.4.6.4 RAWFE H3A Optional Preprocessing

The input to the H3A module is 10-bit RAW data from the IPIPEIF. A 10-bit to 8-bit A-Law compression step can be enabled and disabled separately for the AF engine (the VISS_RAWFE_H3A_PCR[1] AF_ALAW_EN bit) and the AE/AWB engine (the VISS_RAWFE_H3A_PCR[17] AEW_ALAW_EN bit). A-Law compression offers added protection against overflowing the accumulators.

If the A-Law table is enabled, the output is 10 bits, with the upper two bits filled with 0.

For the AF process, a horizontal median filter can be enabled and disabled (the VISS_RAWFE_H3A_PCR[2] AF_MED_EN bit) before A-Law compression. This filter is useful for reducing temperature-induced noise. The horizontal median filter calculates the absolute difference between the current pixel (i) and pixel (i - 2), and between the current pixel (i) and pixel (i + 2). If the absolute difference exceeds a threshold, and the sign of the differences is the same, the average of pixel (i - 2) and pixel (i + 2) replaces pixel (i). The threshold of the horizontal median filter can be set in the VISS_RAWFE_H3A_PCR[10:3] MED_TH bit field.

6.7.3.2.4.6.5 RAWFE H3A Autofocus Engine

The AF engine works by extracting each green (Gr or Gb) pixel from the video stream and subtracts a fixed offset of 128 or 512 (depending on whether A-Law is enabled or disabled) from the pixel value. The offset value is then passed through an IIR filter and the absolute value of the filter output is the focus value (FV). Both FV and FV² are produced. The FV and FV² values can be accumulated or the maximum for each line/column can be accumulated. The following sections describe this process in more detail.

6.7.3.2.4.6.5.1 RAWFE H3A Poxel Extraction

From the poxel starting coordinate (the VISS_RAWFE_H3A_AFPAXSTART[27:16] PAXSH and VISS_RAWFE_H3A_AFPAXSTART[11:0] PAXSV bit fields) specifies the starting point of the poxel grid, with respect to first pixel of the input image frame.

The poxel starting coordinate also indicates which color pixels are extracted if VF is enabled (that is, if VISS_RAWFE_H3A_PCR[20] AF_VF_EN = 1). Normally, either Gr or Gb is used for AF, but it is not important to the hardware whether it is red, green, or blue. If VF is not enabled, then the red, green, and blue pixel extraction is controlled by the VISS_RAWFE_H3A_PCR[13:11] RGBPOS bit field to extract the correct colors from the input stream. [Figure 6-55](#) shows the available options for this bit field. The red and blue pixel positions are interchangeable. For each 2 × 2 grid, the green pixels are summed to create a single value. Because of this, the amplitude of the green output contains 2 pixels, while the red and blue outputs each contain 1 pixel.

Figure 6-55. RAWFE H3A Red, Green, and Blue Pixel Extraction Examples

Each paxel is VISS_RAWFE_H3A_AFPAX1[23:16] PAXW × VISS_RAWFE_H3A_AFPAX1[7:0] PAXH (width × height) pixels. Inside each paxel, horizontal FV can skip lines, operating on one every VISS_RAWFE_H3A_AFPAX2[16:13] AFINCV lines. Vertical FV can skip columns, operating on one every VISS_RAWFE_H3A_AFPAX2[20:17] AFINCH columns. Up to 32 columns are supported for each paxel. If floor (PAXW/AFINCH) ≥ 32, only the first 32 designated columns are operated on. Because PAXW, PAXH, AFINCV, and AFINCH are all even numbers, AF always operates on the same green color, Gr or Gb. IIR filters for the horizontal FVs start operation at column VISS_RAWFE_H3A_AFIIRSH[11:0] IIRSH.

Figure 6-56 shows the RAWFE H3A horizontal/vertical fv paxel configuration.

Figure 6-56. RAWFE H3A Horizontal/Vertical FV Poxel Configuration

Note

$(\text{VISS_RAWFE_H3A_AFPAXSTART}[27:16] \text{ PAXSH}) + (\text{VISS_RAWFE_H3A_AFPAX2}[5:0] \text{ PAXHC})$
 $\times (\text{VISS_RAWFE_H3A_AFPAX1}[23:16] \text{ PAXW}) \leq [(\text{Frame width on VP}) -$
 $(\text{VISS_RAWFE_H3A_LINE_START}[15:0] \text{ LINE_START})] \leq 4096$

Table 6-99 lists the bit fields that configure the size and number of paxels.

Table 6-99. RAWFE H3A Poxel Register Field Descriptions

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AFPAX1[23:16] PAXW	8	Poxel width (in pixels)
VISS_RAWFE_H3A_AFPAX1[7:0] PAXH	8	Poxel height (in lines)
VISS_RAWFE_H3A_AFPAX2[5:0] PAXHC	6	Poxel count for horizontal direction
VISS_RAWFE_H3A_AFPAX2[12:6] PAXVC	7	Poxel count for vertical direction
VISS_RAWFE_H3A_AFPAX2[16:13] AFINCV	4	Line increments in a poxel
VISS_RAWFE_H3A_AFPAX2[20:17] AFINCH	4	Column increments in a poxel
VISS_RAWFE_H3A_AFPAXSTART[27:16] PAXSH	12	Poxel start position H
VISS_RAWFE_H3A_AFPAXSTART[11:0] PAXSV	12	Poxel start position V
VISS_RAWFE_H3A_AFIIRSH[11:0] IIRSH	12	IIR filter start position

The H3A AF engine also has an option for an advanced or normal stats collection mode. When 0xCA00 is written to the VISS_RAWFE_H3A_ADVANCED[31:15] ID bit field, then VISS_RAWFE_H3A_ADVANCED[0] AF_MODE can be used to toggle between normal and advanced AF stats collection mode. When the advanced AF stats collection mode is enabled, the ZEROS section of the AF poxel packet is filled with the sum of the maximum FVs, regardless of the color, from HFV_1 and HFV_2.

6.7.3.2.4.6.5.2 RAWFE H3A Horizontal FV Calculator

The FV calculator takes the unsigned red/green/blue extracted data and subtracts 128 or 512 (depending on whether A-Law is enabled) to place the data in the range –128 to 127 or –512 to 511.

After removing the offset, the data is sent through two parallel IIR filters configured in a dual-biquad configuration. Each filter uses a unique set of 11 programmable coefficients. Each coefficient is 12-bits-wide with 6 bits of decimal, S12Q6 (VISS_RAWFE_H3A_AFCOEFO10 to VISS_RAWFE_H3A_AFCOEFO010 for SET0, and VISS_RAWFE_H3A_AFCOEFO110 to VISS_RAWFE_H3A_AFCOEFO1010 for SET1). The filter-shift

registers are cleared on each horizontal line at the position set by the register IIR horizontal start register (the VISS_RAWFE_H3A_AFIIIRSH[11:0] IIRSH bit field). The absolute values of the output (16 bits wide with 4 bits of decimal, U16Q4) of both filters are then sent to the AF accumulator module. Signed clipping is performed during the FV calculation. If the input value is m bits (signed) and the required output value is n bits, clipping transforms the input to between -2^1 and 2^1 . Values lower than -2^1 are set to -2^1 , and values higher than 2^1 are set to 2^1 .

6.7.3.2.4.6.5.3 RAWFE H3A HFV Accumulator

The horizontal focus value (HFV) accumulator takes the output of the horizontal IIR filter and accumulates values for each paxel. The size and number of paxels is configurable by registers.

Table 6-99 lists the register fields that configure the size and number of paxels:

- In peak mode (VISS_RAWFE_H3A_PCR[14] FVMODE = 0x1), the maximum value is accumulated.
- In sum mode (VISS_RAWFE_H3A_PCR[14] FVMODE = 0x0), all HFV_n are accumulated in a paxel.

The following equations detail the calculation for:

- Sum of pixel values used in HFV: The pixel values that are used for filtering and accumulation of HFV are also accumulated in this sum of pixel values.
- HFV_n (HFV_n_peak for peak mode or HFV_n_sum for sum mode)
- HFV_count_n
- HFV_sq_n (HFV_sq_n_peak for peak mode or HFV_sq_n_sum for sum mode)

$n = 1$ or 2 for IIR1 and IIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
for (k=0; k<PAXH) // Loop on paxel rows
{
    rowpeak_n = 0;
    for (l=0; l<PAXW; l++) // Loop on values within a row
    {
        aIIRout_n = ABS(IIRout_n);
        if (aIIRout_n >= threshold_n)
        {
            hfval = aIIRout_n - threshold_n;
            HFV_count_n++;
        }
        else hfval = 0;
        if (hfval > rowpeak_n)
        {
            rowpeak_n = HFV_n;
        }
        HFV_n_sum += hfval;
        HFV_sq_n_sum += (hfval* hfval + RNDADD) >> RNDSHIFT;
    } // Finished looping on values in a row
    HFV_n_peak += rowpeak_n;
    HFV_sq_n_peak += (rowpeak_n * rowpeak_n + RNDADD) >> RNDSHIFT;
}
```

- threshold_n is VISS_RAWFE_H3A_HVF_THR[15:0] HTHR1 and VISS_RAWFE_H3A_HVF_THR[31:16] HTHR2, respectively.
- IIRout_n is the IIRout_1 and IIRout_2 outputs, respectively.
- HFV_count_n and HFV_sq_n are not sent to the DMA interface if VF is disabled.
- RNDADD and RNDSHIFT depend on whether input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.
- If VF is enabled, only the green color channel values are output to the DMA interface.
- In sum mode:
 - HFV_n = HFV_n_sum
 - HFV_sq_n = HFV_sq_n_sum
- In peak mode:
 - HFV_n = HFV_n_peak
 - HFV_sq_n = HFV_sq_n_peak

6.7.3.2.4.6.5.4 RAWFE H3A VFV Calculator

The VFV calculator takes the unsigned extracted data through two FIR filters, each with a set of five coefficients (VCOEF1_x, where x = 0 to 4, in the VISS_RAWFE_H3A_VFV_CFG1 and VISS_RAWFE_H3A_VFV_CFG2 registers for FIR 1, and VCOEF2_x, where x = 0 to 4, in the VISS_RAWFE_H3A_VFV_CFG3 and VISS_RAWFE_H3A_VFV_CFG4 registers). Each coefficient is 8 bits wide with 4 bits of decimal (S8Q4). The filter outcome is downshifted by 4 bits and takes an absolute value to produce a 16-bit unsigned value. This is then sent to threshold VISS_RAWFE_H3A_VFV_CFG2[31:16] VTHR1 for FIR 1, and VISS_RAWFE_H3A_VFV_CFG4[31:16] VTHR2 for FIR 2, and square logic to produce VFV_n and VFV_sq_n.

6.7.3.2.4.6.5.5 RAWFE H3A VFV Accumulator

The VFV accumulator takes the output of the vertical FIR filters and accumulates values for each paxel. The size and number of paxels is configurable by registers.

[Table 6-99](#) lists the bitfields that configure the size and number of paxels.

The following equations detail the calculation for:

- VFV_n
- VFV_count_n
- VFV_sq_n

n = 1 or 2 for FIR1 and FIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
FIR_coef_n = [VCOEFn_0, VCOEFn_1, VCOEFn_2, VCOEFn_3, VCOEFn_4]; /* coefficient values in S8.4
format */
aFIRout_n = (ABS(inner_product(extracted_G, FIR_coef_n)) + 8) >> 4;
if (aFIRout_n >= threshold_n)
{
    VFV_n = aFIRout_n - threshold_n
    VFV_count_n++;
}
else VFV_n = 0;
VFV_sq_n = (VFV_n * VFV_n + RNDADD) >> RNDSHIFT;
```

- threshold_n is VISS_RAWFE_H3A_VFV_CFG2[31:16] VTHR1 and VISS_RAWFE_H3A_VFV_CFG4[31:16] VTHR2, respectively.
- FIRout_n is the FIRout_1 and FIRout_2 outputs, respectively.
- RNDADD and RNDSHIFT depend on whether the input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.

6.7.3.2.4.6.6 RAWFE H3A AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows, and then subsamples each window into 2 × 2 blocks. For each subsampled 2 × 2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2 × 2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

The AE/AWB module has three output format modes, which are set through the VISS_RAWFE_H3A_AEWCFG[9:8] AEFMT bit field:

- Sum of square mode: VISS_RAWFE_H3A_AEWCFG[9:8] AEFMT = 0x0
- Min/max mode: VISS_RAWFE_H3A_AEWCFG[9:8] AEFMT = 0x1
- Sum-only mode: VISS_RAWFE_H3A_AEWCFG[9:8] AEFMT = 0x2

6.7.3.2.4.6.6.1 RAWFE H3A Sub_sampler

The subsampler partitions the frame into windows using the size, count, and starting location parameters shown on the left in [Figure 6-57](#). Each window is further sampled down to a set of 2 × 2 blocks. The horizontal and vertical distances between the start of blocks within a window is programmable using the parameters shown on the right in [Figure 6-57](#).

camisp-072

Figure 6-57. RAWFE H3A AE/AWB Window Configurations

Table 6-100 lists the bit fields that configure the window and block sizes, counts, and starting positions.

Table 6-100. RAWFE H3A AE/AWB Window Register Field Descriptions

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
VISS_RAWFE_H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
VISS_RAWFE_H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
VISS_RAWFE_H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
VISS_RAWFE_H3A_AEWINSTART[11:0] WINSH	12	Window start position H
VISS_RAWFE_H3A_AEWINSTART[27:16] WINSV	12	Window start position V
VISS_RAWFE_H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
VISS_RAWFE_H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples

6.7.3.2.4.6.2 RAWFE H3A Additional Black Row of AE/AWB Windows

In addition to the 128 rows of windows, the AE/AWB module provides support for an additional row of windows for black data. This data may be useful in determining the DC offset noise of the rest of the data. The black row of windows can be before or after the regular rows of windows. The vertical start line for the black row of windows is specified in the VISS_RAWFE_H3A_AEWINBLK[27:16] WINSV bit field, and the height is specified in the VISS_RAWFE_H3A_AEWINBLK[6:0] WINH bit field. The horizontal starting pixel and horizontal width of the black row of windows are the same as for the regular rows of windows.

Figure 6-58 shows a black row of windows before rows of windows.

camisp-075

Figure 6-58. RAWFE H3A Black Row of Windows Before Regular Rows of Windows

Table 6-101 lists the bit fields that configure the window and block sizes, counts, and starting positions.

Table 6-101. RAWFE H3A AE/AWB Window With Additional Black Row Register Field Descriptions

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
VISS_RAWFE_H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
VISS_RAWFE_H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
VISS_RAWFE_H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
VISS_RAWFE_H3A_AEWINSTART[11:0] WINSH	12	Window start position H
VISS_RAWFE_H3A_AEWINSTART[27:16] WINSV	12	Window start position V
VISS_RAWFE_H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
VISS_RAWFE_H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples
VISS_RAWFE_H3A_AEWINBLK[27:16] WINSV	12	Window start position H for single black line
VISS_RAWFE_H3A_AEWINBLK[6:0] WINH	7	Window height (in lines) for single black line

6.7.3.2.4.6.3 RAWFE H3A Saturation Check

The saturation check module compares the data from the subsampler to the value programmed in the VISS_RAWFE_H3A_PCR[31:22] AVE2LMT bit field. This value is the maximum clipping value. If all 4 pixels in the 2 × 2 block are less than the AVE2LMT value, the value of the unsaturated block counter is incremented. There is one unsaturated block counter per window. The unsaturated block counters are later written to memory.

6.7.3.2.4.6.4 RAWFE H3A AE/AWB Accumulators

The output from the saturation check module and the subsampler module are separately accumulated for each pixel in every 2 × 2 pixel block for each window. Therefore, there are eight accumulators per window (one accumulator for each pixel in a 2 × 2 pixel block, times two sets of accumulators: clipped/saturated data and presaturated data). Each of the 4 pixels in the 2 × 2 pixel grid is associated with a color R, Gr, B, Gb); however, the output of these accumulators is referenced by position in the grid, not color.

The accumulators are 16 bits wide, and the accumulated data is 10 bits wide. Therefore, when a window contains more than 64 pixels of the same color, an overflow risk exists. This risk can be reduced by enabling the A-Law conversion in the preprocessing stage. See Section 6.7.3.2.4.6.4 for details.

The AE/AWB module has a shift value for the accumulation of pixel values that is set in the VISS_RAWFE_H3A_AEWCFG[3:0] SUMSHFT bit field.

6.7.3.2.4.6.7 RAWFE H3A DMA Interface

The DMA interface module takes the data from the AF engine and AE/AWB engine and builds packets to be sent to the memory through the BL module.

The data interface has separate start pointers for the AF and AE/AWB engines.

- The starting address for the AF engine is the VISS_RAWFE_H3A_AFBUFST[31:5] AFBUFST bit field.
- The starting address for the AE/AWB engine is the VISS_RAWFE_H3A_AFBUFST[31:5] AEWBUFST bit field.

The DMA interface module continuously loops through this data as it builds the packets. To optimize the transfer sizes, the DMA interface sends out an AF or AE transfer for each row of paxels or windows. This requires that each horizontal row of paxels or windows starts and ends on a 32-byte boundary. If a horizontal row of paxels or windows ends on a non-32 byte boundary, the hardware packs zeroes. The counts for the AEW that occur every eight windows is sent in the row with the eighth consecutive window.

Table 6-102 shows the packet formats for AF with vertical AF enabled.

Table 6-102. RAWFE H3A AF Packet Format With Vertical AF Enabled

Buffer Start 31 Address (Byte Address) VISS_RAWFE_ H3A_AFBUFST	16 15	0

6.7.3.2.4.6.8 RAWFE H3A Events and Status Checking

The AF and AEW engines generate an interrupt event at the end of processing each frame. However, these two interrupts are internally tied together so that only one H3A interrupt signal is generated. If the AF engine and AEW engine do not process the same frame concurrently, this should not be an issue. However, if they do run concurrently, one of two outcomes may occur:

- The H3A interrupt may seem to trigger only once for each frame. This can happen when the processing for the AF and AEW engines finishes at or near the same time. The interrupt service routine (ISR) does not have enough time to clear the interrupt flag for the first interrupt before the second interrupt occurs.
- The H3A interrupt may trigger twice for each frame. This can happen when the AF engine or the AEW engine finishes processing the frame much earlier than the other engine. In this case, the ISR does have enough time to clear the interrupt flag for the first interrupt by the time the second interrupt occurs.

The outcome depends on the difference in location of the last paxel/window in the frame (determines when processing is finished), the frequency of the relative clocks in the system, the occurrence and triggering of other interrupts in the system, and the latencies of the context switching and ISR execution.

The VISS_RAWFE_H3A_PCR[15] BUSYAF and/or VISS_RAWFE_H3A_PCR[18] BUSYAEAWB status bits are set when the start of frame occurs (if the VISS_RAWFE_H3A_PCR[0] AF_EN and/or VISS_RAWFE_H3A_PCR[16] AEW_EN bits are 1 at that time). They are automatically reset to 0 at the end of processing a frame. The VISS_RAWFE_H3A_PCR[15] BUSYAF and/or VISS_RAWFE_H3A_PCR[18] BUSYAEAWB status bits may be polled to determine the end of frame status.

6.7.3.2.4.6.9 RAWFE H3A Interface Mux

The H3A logic also implements an LUT or Shift /clip block. The LUT logic is same as the decompanding LUT in the previous section(s) with some minor modifications. The input bit width to the LUT cannot exceed 16 and the LUT entry size is only 10 bits, since the H3A logic works on 10 bit data.

The logic also implements a shift and clipU10 functionality for converting data from up to 24 bits down to 10. The shift parameter has to be programmed to implement the desired shift value. The shift register programming must ensure that the output of the shift is not greater than 16bits when the LUT is enabled and it should not be greater than 10 bits when the LUT is disabled.

6.7.3.2.4.6.10 RAWFE H3A interface to LSE

The H3A interface to LSE is VBUSP. It uses channel id to indicate data or control information. Please refer to LSE functional spec on control information mapping to channel id bits.

6.7.3.2.4.6.11 RAWFE H3A Erratas

The following hardware restrictions apply and need to be taken care of by software:

1. When AF is enabled software can not use the first or last pixels in the window. Start at position 2 end at line -2.
2. When AEW is enabled software can not use the first pixel in a window. Start at position 2.
3. $(PAXW+1) \% (AFINCH+1) \neq 1$ when VF enabled (PAXW and AFINCH are raw MMR parameters)

6.7.3.2.5 RAWFE Programmer's Guide

6.7.3.2.5.1 RAWFE Core programming details

There are multiple use cases that can be enabled with this module, however broadly the use case are broken in to two categories, one for Companded Data sensors and the other for Separate Exposures sensors. The following fields should be programmed correctly for the IP to function

- PWL Core
- Set slopes and thresholds as per sensor settings only for Companded sensors
- Decompanding LUT
- This LUT is used for global tone map of decompounded data from 24 bits to 16 bits. (This is typically not used for separate exposures sensor)
- Merge Logic
- Program the merge block based on the exposure ratios of the incoming data.
- This block is typically not used for companded sensors.
- LUT after merge should be programmed to tone map from 20 bits down to 16 (Separate exposure sensors only)
- DPC/ LSC
- Set as per tuning parameters for both companded/separate exposures sensors
- H3A LUT and settings
- Use LUT if H3A input comes after LSC. Program LUT to apply inverse global curve.
- Use shift if data is coming from exposures directly.

6.7.3.2.5.2 RAWFE HTS programming details

See *HWA Thread Scheduler* and [Section 6.7.2, VPAC Subsystem](#) for details.

6.7.3.2.5.3 RAWFE Data transfer programming details

See , *UDMA* for details of programming for PARAM Space.

6.7.3.2.5.4 RAWFE Initialization Sequence

See [Section 6.7.2, VPAC Subsystem](#) for details.

6.7.3.2.5.5 RAWFE Real-time Operating Requirements

See [Section 6.7.2, VPAC Subsystem](#) for details.

6.7.3.2.5.6 RAWFE Power up/down Sequence

See [Section 6.7.2](#), *VPAC Subsystem* for details.

6.7.3.3 Chromatic Aberration Correction (CAC) Module

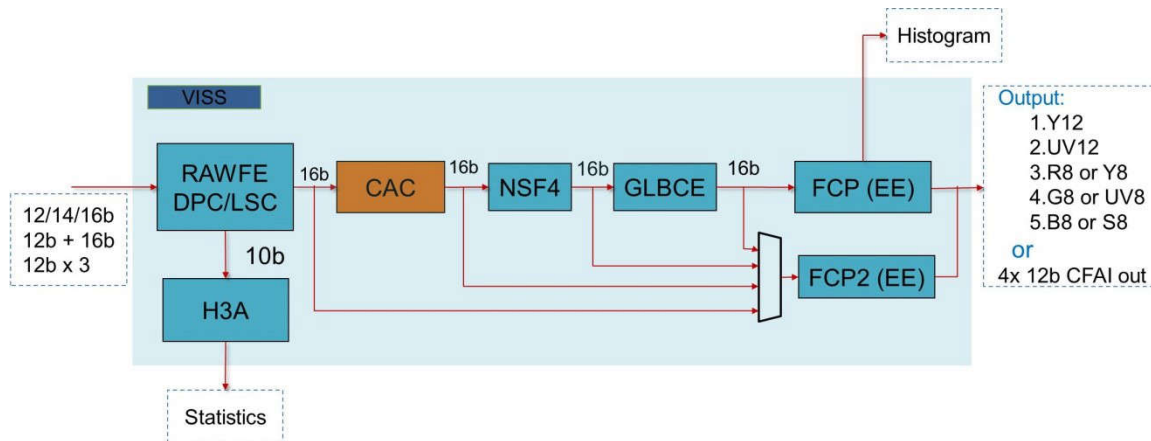

6.7.3.3.1 Overview and Feature List

6.7.3.3.1.1 Features Supported

- Chromatic Aberration Correction (CAC) for Red and Green color in Bayer color formats
- Generic mesh based model for CAC
- LUT to store programmable differential correction with 1/8th pixel precision
- Programmable Block size with each block having 2 LUT entries covering entire frame
 - Intermediate correction values are calculated using bilinear interpolation
- Bi-cubic pixel interpolation on corrected back mapped pixel
- Supports Horizontal Correction in the range of -8.0 to +8.0 and Vertical Correction in the range of -4.0 to +4.0
- Performance: up to 1 Pix/cycle (excluding blanking)
- Streaming based processing architecture targeted to integrate with VISS
- Support 16-bit pixel
- Logic support frame dimension of 8Kx8K. Line memory support is limited to 4K line width

6.7.3.3.2 Functional Description

6.7.3.3.2.1 CAC Integration in VISS

The VISS consist of following hardware accelerators:

- RFE (RAW-FE): The RAW-FRONT HW Block does RAW pixel (e.g. Bayer, RCCC, RGBW etc) processing on captured image data from sensor and pass-on to CAC, NSF4V, GLBCE block, and then to Flexible ColorProc HW block for demosaicing and color conversion.
- CAC (Chromatic Aberration Correction): Captured in this spec.
- NSF4V: Spatial Noise filter supporting generic 2x2 pixel format with 16-bit pixel size. NSF4V IP can be bypassed in the applications where visual enhancement is not desired.
- GLBCE: Iridix7 Ip of Apical is used for dynamic range control within image for visual quality. Iridix Ip is integrated within GLBCE module to adapt its interface with rest of image pipe and integrate its configuration registers. If contrast enhancement on input image is required for visual quality RFE/CAC/NSF4V output is processed by GLBCE block. Otherwise GLBCE is bypassed to FCP.
- FCP (FLEXible COLOR PROCessing): The FLEX-COLOR-PROC HW receives data from GLBCE and does demosaicing and color conversion. The output of COLOR-PROC is sent to VPAC shared memory to be written into DDR for rest of vision processing by programmable processors (e.g. DSP or ARM) or Vision HW Blocks (e.g. VPAC and DMPAC).

6.7.3.3.2.2 Introduction

Chromatic aberration, also known as “color fringing” or “purple fringing”, is a common optical problem that occurs in low quality lens when a lens is either unable to bring all wavelengths of color to the same focal plane (**Longitudinal Chromatic aberration**), and/or when wavelengths of color are focused at different positions in the focal plane (**Lateral Chromatic aberration**) .

Figure 6-59 shows one example of Chromatic Aberration referred as *Lateral Chromatic Aberration* (LCA). In this case, all colors are in focus in the same plane, but the foci are not placed along the optical axis. CAC Hardware accelerator performs *Lateral Chromatic aberration* correction as part of VISS Pipe line.

Figure 6-59. Lateral Chromatic Aberration

6.7.3.3.2.3 Functional Operation

CAC correction requires remapping locations of Red and Blue pixels to align with Green pixel. Green pixel is taken as reference and assumed no correction is needed on Green pixel. Legacy block based correction wouldn't fit into the streaming VISS pipe line and incurs additional bandwidth and latency. CAC HWA is implemented using line based back mapping architecture. Correction involves back-mapping each output pixel to pixel position in the source image, and thus the corrected image is fully populated. As the back mapped pixel locations mostly fall onto fractional coordinates, correction involves bi-cubic interpolation among the nearest available pixels.

As shown in Figure 6-60, CAC consists of Timing control module, 8KB LUT with mesh correction offset table, Mesh LUT bi-linear interpolation block, Pixel interface module, pixel bi-cubic interpolation block and 10 pixel line memories.

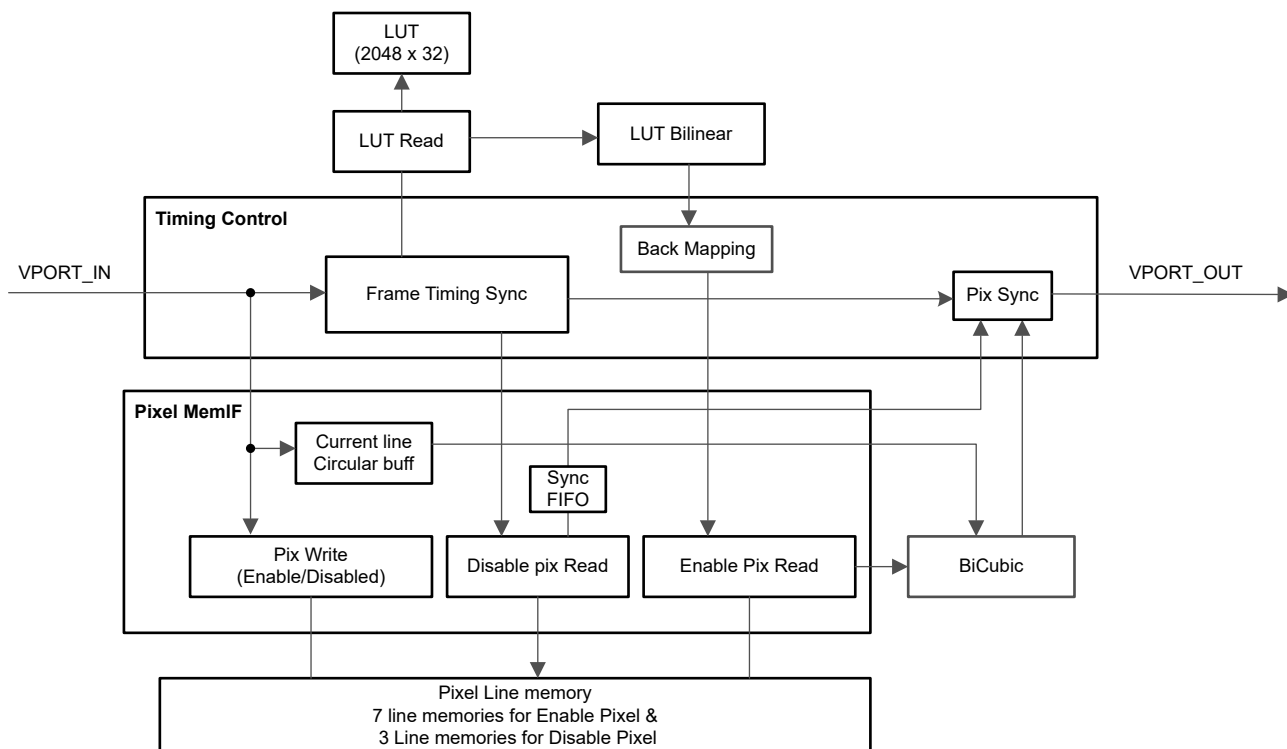

Figure 6-60. CAC Functional Block Diagram

Timing Control module handles all the timing synchronization aspects of CAC. It generates the Output frame co-ordinates, initiates the Mesh LUT operation on receiving 7th input valid line. It also handles timing synchronization between all the blocks in the design.

6.7.3.3.2.3.1 CAC Back Mapping

Offset table defines a ($\square x$, $\square y$) vector for a regular grid of output points. Each grid will define 2 offset vectors one each for EVEN and ODD line(s), defining how far output pixel needs to be moved in either direction. Final pixel location in input source image is used to compute the output pixel. Offset table can have precise definition and can capture rapidly changing offset tables. However it will require a large amount of memory. Since most offset tables are not expected to change rapidly in a small spatial region, CAC uses a subsampled offset table. Grid is down sampled with down-sampling factor in the range of 8 to 128 with increments of 4 in both horizontal and vertical directions. Subsampling factor is set in the register; BLOCKSZ.SIZE This enables reducing the amount of memory required to describe the offset vectors, but requires hardware to interpolate the missing offset vectors. CAC supports bilinear interpolation to interpolate missing offset vectors.

The mapping procedure is described by the following series of equations. Given an output pixel at location (x_0, y_0), we compute the input image pixel location (x_1, y_1).

$$\begin{aligned} ind_x &= \frac{X_o}{Blk_{size}}; f_x = MOD(X_o, Blk_{size}) \\ ind_y &= \frac{Y_o}{Blk_{size}}; f_y = MOD(Y_o, Blk_{size}) \end{aligned}$$

Clip new index to Offset grid boundaries.

$$i_x = CLIP(ind_x, Grid_{HCnt})$$

$$i_y = CLIP(ind_y, Grid_{VCnt})$$

$$\Delta x_p = \frac{\left((blk_{size} - f_y) \cdot T_{x0} + f_y \cdot T_{x1} + \frac{square(blk_{size})}{2} \right)}{square(block_{size})}$$

$$\Delta y_p = \frac{\left((blk_{size} - f_x) \cdot T_{y0} + f_x \cdot T_{y1} + \frac{square(blk_{size})}{2} \right)}{square(blk_{size})}$$

Clip to Horizontally to -8.0 to +8.0 pixel range (-64 to +64 with Q3 precision).

Clip to Vertically to -4.0 to +4.0 pixel range (-32 to +32 with Q3 precision).

Figure 6-61. Back Mapping Procedure Using Offset Table

The input coordinate (x1,y1) refers to final input frame co-ordinates.

6.7.3.3.2.3.1.1 Offset Table Storage Format

The size of the offset table is dependent on the output frame size. The size must be:

$$Table\ Width = CEIL\left(\frac{Frame\ Width}{Blk_{size}}\right) + 1$$

$$Table\ Height = CEIL\left(\frac{Frame\ Height}{Blk_{size}}\right) + 1.$$

The Offset table should be stored with Δx and Δy offsets interleaved and stored in raster order. Each offset is S8Q3, so a table entry is 32-bits, including both Δx and Δy for both Even and Odd line. Each line captures offset for one color either Red or Green.

6.7.3.3.2.3.2 Pixel Interpolation

As the coordinates calculated by the back mapping function are not integer values in most cases, b-cubic interpolation is applied to the back mapped pixels. Interpolation is done on the pixel of same color (either Red or Blue).

Output pixel is interpolated from the 16 pixels in the 4x4 grid around the back mapped location, as shown in Figure 6-62. R_i and B_i indicate integer co-ordinates of back mapped pixels. Bi-cubic interpolation is used first along the horizontal direction, then the vertical direction.

Figure 6-62. Bi-Cubic Interpolation Input Data

6.7.3.3.2.3.3 Bi-cubic Coefficients

The following coefficients are used for bi-cubic operation. Though back-mapped pixel has Q3 precision, there are 16 fractional phases due to Bayer pattern. The filter coefficients should be in S12Q10 format (signed 12-bit with 10 bits of fraction).

Phase	Coefficients (S12Q10)			
0/16	0	1024	0	0
1/16	-28	1014	40	-2
2/16	-49	987	93	-7
3/16	-63	944	158	-15
4/16	-72	888	232	-24
5/16	-76	821	313	-34
6/16	-75	745	399	-45
7/16	-71	663	487	-55
8/16	-64	576	576	-64
9/16	-55	487	663	-71
10/16	-45	399	745	-75
11/16	-34	313	821	-76
12/16	-24	232	888	-72
13/16	-15	158	944	-63

15/16	-2	40	1014	-28

Figure 6-63. Bi-cubic Coefficients

6.7.3.3.2.4 Interrupt Conditions

6.7.3.3.2.4.1 Interrupts

Name	Width	Type	Polarity	Category	Clock	Reset	Description
cac_lut_cfg_err	1	pulse	high	func	func_clk	srstn_mod_g_rs t_n	CAC cac_lut_cfg_err event

A ***cac_lut_cfg_err*** interrupt is generated when configuration access happens on LUT memory while CAC is operating on a valid frame. A valid frame is defined as Input Frame Start (VS_IN) to output frame end (VE_OUT).

6.7.3.3.2.4.2 Debug Events

Table 6-106. Debug Events

Event	Description
cac_in_vs_event	Frame Start Input. Optionally can be enabled by setting DBG_CTL.DBG_EN && DBG_CTL.SOF_EN. Status can be observed in DBG_STAT.SOF.
cac_in_hs_event	Frame Start Input. Optionally can be enabled by setting DBG_CTL.DBG_EN && DBG_CTL.SOL_EN. Status can be observed in DBG_STAT.SOL.
cac_out_ve_event	Frame End Output. Optionally can be enabled by setting DBG_CTL.DBG_EN && DBG_CTL.EOF_EN. Status can be observed in DBG_STAT.EOF.
cac_out_he_event	Line End Output. Optionally can be enabled by setting DBG_CTL.DBG_EN && DBG_CTL.EOL_EN. Status can be observed in DBG_STAT.EOL.

6.7.3.4 VISS Spatial Noise Filter (NSF4V)

6.7.3.4.1 NSF4V Introduction

6.7.3.4.1.1 NSF4V Features

For a list of features supported by the NSF4V module, see Section *VPAC Features*.

Some additional NSF4V parameters include:

- Input image format: any 2x2 raw color pattern
- Frame Width: limited to 4096
- Throughput:
 - 1 pixel in/out per clock

6.7.3.4.2 NSF4V Overview

The advanced noise filter NSF4v decomposes the input image into low-frequency, mid-frequency, and high-frequency bands first and then filter out the noise in frequency domain. NSF4v can adapt its noise filtering strength to local image intensity according to the user programmable noise threshold registers. NSF4 is also able to adjust its strength according to the amount of previously applied lens shading correction gains with a user programmable approximate radial model.

6.7.3.4.2.1 Decomposition Kernel Representation

With combination of just level 1, levels 1+2, and levels 1+2+3, horizontally and vertically, the result feature detection filter kernels are shown in [Figure 6-64](#). Note that all coefficients are powers of 2, and therefore do not require multiplication.

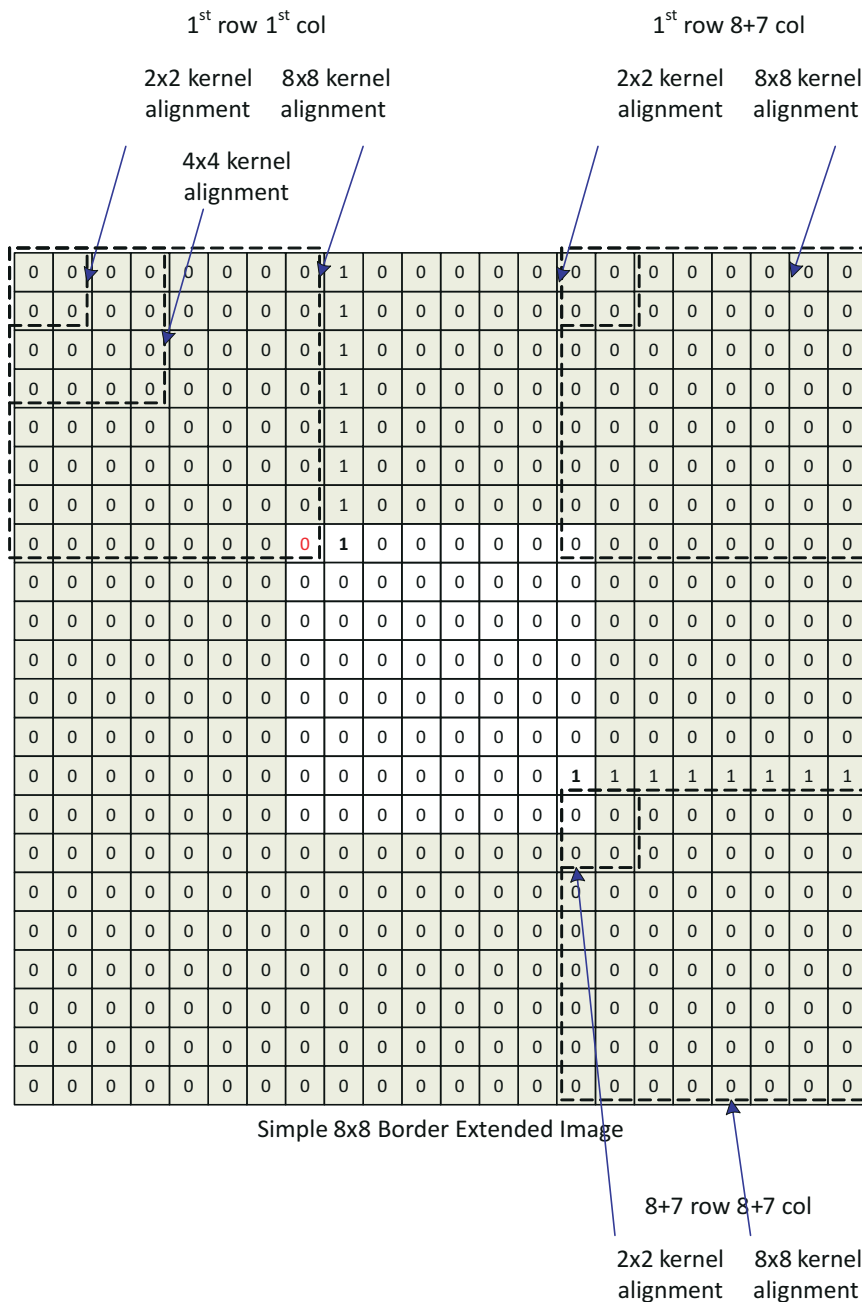

$$\begin{aligned}
 F1 &= \begin{bmatrix} 1 & -1 \\ 1 & -1 \end{bmatrix} /4 \\
 F2 &= \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix} /4 \\
 F3 &= \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} /4 \\
 F4 &= \begin{bmatrix} 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \end{bmatrix} /16 \\
 F5 &= \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 \end{bmatrix} /16 \\
 F6 &= \begin{bmatrix} 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \\ -1 & -1 & 1 & 1 \\ -1 & -1 & 1 & 1 \end{bmatrix} /16 \\
 F7 &= \begin{bmatrix} 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \end{bmatrix} /64 \\
 F8 &= \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \end{bmatrix} /64 \\
 F9 &= \begin{bmatrix} 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \end{bmatrix} /64
 \end{aligned}$$

nsf4v-002

Figure 6-64. NSF4V Kernel Representation for Decomposition Filters

G1...9 are the counter-part reconstruction kernels. Each of G1...9 is a row-wise and column-wise mirror of the counterpart F function.

The kernel representation in [Figure 6-65](#) illustrates a filter alignment.

nsf4v-003

Figure 6-65. NSF4V Kernel Representation Filter Alignment

Figure 6-65 is showing an academic 8x8 pixel image frame which has been border extended on all 4 edges. Superposed onto this border extended frame (shown in dotted lines) is the kernel alignment for all 3 different kernel sizes for each of the three levels:

- Level 1: 2x2 kernel
- Level 2: 4x4 kernel
- Level 3: 8x8 kernel

For each of the 9 different kernels, a matrix of (width + 7) x (height + 7) decomposition values result. All of these result matrixes are exactly aligned.

nsf4v-004

Figure 6-66. NSF4V Example F1 Kernel Result

The kernel alignment is top-left aligned for the first pixel. Which translates in the recursive approach as a X-Y shift. In order to be mathematically aligned in the Recursive approach, the Level 1 output needs to be shifted 6 positions in both the X and Y direction relative to the Level 3 output. Additionally, the Level 2 output needs to be shifted 4 positions in both the X and Y direction relative to the Level 3 output. These shifts are critical such that Level 1, 2, and 3 values are cycle aligned when presented to the thresholding circuit.

One can reach the same conclusion by looking at the figure and thinking about which line delay or which horizontal pipelined pixel position is used in order for the kernels to output their results in the same pipeline cycle.

6.7.3.4.3 NSF4V Lens Shading Correction Compensation

The Lens Shading Correction (LSC) is implemented prior to NSF. This is not an optimal order of operation and therefore an adjustment factor is implemented to compensate for the order of operations. The LSCC (Lens Shading Correction Compensation) first approximates the gain of LSC and calculates both that gain and its inverse. Within the T_n calculation, the inverse gain is applied to the LL2 average, then the T_n is calculated. Last, the result is multiplied by the gain. In this way, the LSC is approximately reversed temporarily in order that T_n is calculated properly.

LSCC calculates the radius (distance) from the center of the image, then uses a programmable curve to look up the gain value.

While calculating the radius, the center on the frame is programmable. Also a correction gain (kh and kv) separately for X and Y are programmable which allows for elliptical shaped lenses. Because the SQRT is such an expensive function, the resulting radius is used in the SQR form and as such has a very large dynamic range. A programmable shift value effectively selects which portion of this dynamic range is to use for the curve lookup.

The curve lookup is a 16 segment curve. The SQR(Radius) is lookup on the X axis and the resulting gain is supplied on the Y axis.

6.7.3.4.4 NSF4V Noise Threshold Adaptation to Local Image Intensity

Figure 6-67 shows the local image intensity to noise threshold T_n mapping via the 12-segment interpolated lookup. Twelve sets of (X, Y, S) , S = slope, are provided per curve, one set per color plane, with the first X coordinate fixed at zero.

Figure 6-67. NSF4V Local Image Intensity to Noise Threshold Piece-wise Linear Function

The slopes should be implemented with signed value, as some image sensors might require higher noise threshold at the low intensity range than high intensity range.

6.7.3.4.5 Delta Features

- Dynamic White Balance
 - Applies white gain calculated based on intensity of neighboring 6 pixels horizontally
 - Intensity is calculated on even pixel but used for that pixel and next odd pixel
 - Gain is calculated from intensity using 8-segment PWL implementation
 - Each 2x2 color component will have independent PWL parameters
- Raw Bayer domain Histogram
 - Convert 16-bit tone mapped to 12-bit log domain using LUT
 - Phase select to enable histogram on up to 2 color channels in 2x2 pattern. If 2 channels are enabled, then they need to be in different lines.
 - Total 128 bins of 22-bits each (step size of 32)
 - Capture the histogram of up to 8 independent programmable non-overlapping regions
 - Histogram output is mapped to MMR space. Data needs to be read once Output frame is completed

6.7.3.5 VISS Global/Local Brightness and Contrast Enhancement (GLBCE) Module

6.7.3.5.1 GLBCE Overview

The Global Local Brightness Contrast Enhancement module performs dynamic range compression or tone mapping of an input image based on a model of the human visual system. It is used to produce most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations.

6.7.3.5.2 GLBCE Interface

Data flow control of GLBCE module is done by PCLK. GLBCE processes the image cycle by cycle, and output the data after certain cycles of latency.

6.7.3.5.3 GLBCE Core

The GLBCE Core is an iridix® core which performs "dynamic range compression" or "tone mapping" on an input image based on a model of the human visual system. It is used in a camera pipeline to produce the most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations. The purpose of the transform is to map the image content from an input source such that it remains fully visible on an output display without loss of content. Note that iridix is specifically designed to preserve color, sharpness and boost contrast of the source image.

The iridix core is based on space-variant or pixel-by-pixel processing algorithms which construct a family of transforms based on the analysis of image content. The algorithms inside iridix are adaptive, meaning that a single set of parameters can be set to process any source image or any video sequence under different lighting conditions.

Iridix generates effective tone curves by analyzing the regions surrounding each pixel. The tone curves generated by iridix are based on an asymmetry curve which is then shaped and controlled by a number of parameters that control the gain limitation weighting towards shadows, mid tones and highlights.

6.7.3.5.3.1 GLBCE Core Key Parameters

[Table 6-107](#) shows the key parameters within the iridix core. It is recommended that all parameters be set statically to their recommended values other than the iridix strength parameter, which should be controlled dynamically with scene content. The calculation of iridix strength is explained in [Section 6.7.3.5.3.2](#).

Table 6-107. GLBCE Core Key Parameters

Parameter	Description
iridix strength	This register sets iridix processing strength.
	0x00: Video data will not be processed at all, and will pass to the output unchanged.
	0xFF: Maximum processing strength.
Variance space	This register affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). If this parameter is set to zero, the sensitivity to small areas is maximized (i.e. the transform becomes more local). When this parameter is set to 0xF, the transform deemphasizes small local details, and the transform becomes more global
Variance intensity	For a high-contrast image with shadows and highlights, a small value will cause iridix to adjust shadows and highlights almost independently. A large variance causes iridix to become progressively more global, meaning that the presence of highlights affects the processing of shadows and vice-versa.
Slope min limit	This register is used to restrict the slope of the tone curve generated by iridix. When this parameter is set to 0x00, the tone curve slope generated by iridix is not limited.
	When this value is set to 0xFF, iridix will not generate a tone curve with a slope less than 3/4. Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-128
Slope max limit	This register is used to restrict the slope of the tone-curve generated by iridix. When this parameter is set to 0xFF, the tone curve slope generated by iridix is not limited.
	When this value is set to 0x00, iridix will not generate a tone-curve with slope greater than 16/15 (48°). Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-160. For noisy images, lower values should be used.
Black level	The value stored in this register will be used as the zero level for iridix processing in all data channels. Data below this value will not be processed and remain unchanged.

Table 6-107. GLBCE Core Key Parameters (continued)

Parameter	Description
White level	The value stored in this register will be used as the white level for iridix processing in all data channels. Data above this value will not be processed and remain unchanged.
Asymmetry LUT	This look-up-table is 33 words, each of which is 16-bits. The asymmetry function is used to balance the iridix effect between the dark and bright regions of the image.
Forward perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is presented to the core, this look-up-table must be used to map the linear data to the perceptual space so that iridix can perform its perceptual functions.
Reverse perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is required from the output of the core, this look-up-table must be used to map the data from the perceptual space back to linear space for further processing in the pipeline.

6.7.3.5.3.2 GLBCE Iridix Strength Calculation

This section describes how the dynamic parameter, iridix strength, is calculated.

Note

Dynamic range of a digital camera can be described as the ratio of maximum light intensity measurable (at pixel saturation), to minimum light intensity measurable (but above read-out noise). This is a very important concept to consider when computing iridix strength, because the gain applied by iridix is also proportional to the visible boost of noise in the image. The maximum gain applied by iridix should be determined by the dynamic range of the camera system. This is governed by the equation presented in this section.

With iridix strength is zero, all tone curves are linear for all images. As iridix strength is increased, the variation between curves in shadows, mid tones and highlights increases, resulting in increasing compression of global dynamic range.

Iridix strength is calculated as follows:

$$\text{iridix strength} = \text{Max} \left(0, \text{Min} \left(\frac{\text{IR_Gain_Target} - 1}{\text{IR_Gain}_{\text{Max}} - 1}, f(\text{analog gain}) \right) \right) * 255$$

glbce-843

Figure 6-68. GLBCE Iridix Strength Formula

Where:

- IR_Gain_Target is the desired iridix gain to be applied to the image. This is calculated from the image's histogram on a per-frame basis by the auto exposure algorithm (in RAWFE H3A module). The histogram is analysed to compute an exposure ratio for the desired global histogram shift. This computed exposure ratio is then used to feed a look-up-table which in turn generates the IR_Gain_Target parameter.
- IR_GainMax is the maximum iridix gain. If the fwd_percep_lut is disabled, then the IR_GainMax should be set to 64, and if the fwd_percep_lut is enabled, then the IR_Gainmax should be set to 16.
- f(analog gain) is a function that determines the maximum iridix strength in relation to noise. f(analog gain) is characterised as follows:

Figure 6-69. GLBCE Iridix f(Analog Gain) Function

f(analog gain) should only be used when the RAWFE is in linear mode. Otherwise, it should be set to 1

6.7.3.5.3.3 GLBCE Iridix Configuration Registers

6.7.3.5.3.3.1 GLBCE Iridix Frame Width

Frame Width is the number of pixels in an active line and is controlled from GLBCE_FRAME_WIDTH[15:0] VAL. Recommended value 2560 (decimal)

6.7.3.5.3.3.2 GLBCE Iridix Frame Height

Frame Height is the number of active lines in a frame and is controlled from GLBCE_FRAME_HEIGHT[15:0] VAL. Recommended value 1920 (decimal)

6.7.3.5.3.3.3 GLBCE Iridix Control 0

This is the main control register for the iridix core is GLBCE_CONTROL0 where GLBCE is enabled/disabled and the type of processing algorithm is selected.

6.7.3.5.3.3.4 GLBCE Iridix Control 1

This register is reserved for debugging purposes. Recommended value 6 (decimal)

6.7.3.5.3.3.5 GLBCE Iridix Strength

GLBCE_STRENGTH_IR[7:0] VAL register sets the processing strength of the iridix core. Recommended value 128 (decimal)

6.7.3.5.3.3.6 GLBCE Iridix Variance

The GLBCE_VARIANCE parameter affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). GLBCE_VARIANCE[7:4] VARIANCEINTENSITY recommended value 12 (decimal). GLBCE_VARIANCE[3:0] VARIANCESPACE recommended value 7 (decimal).

6.7.3.5.3.3.7 GLBCE Iridix Dither

When the number of color gradations of a display device is small (for example 6 bits per color), pixel dithering can make gradients look smother. Dithering of the least significant bits is applied and then these bits can be later truncated. The three least significant bits (D2, D1, D0) of this GLBCE_DITHER register are responsible for the strength of dithering. There are 4 possible levels of dithering. Recommended value 0 (decimal)

6.7.3.5.3.3.8 GLBCE Iridix Amplification Limit

The parameters dark amplification limit and bright amplification limit are used to restrict the luminance space in which iridix can adaptively generate tone curves for each

pixel. GLBCE_LIMIT_AMPL[7:4] BRIGHTAMPLIFICATIONLIMIT recommended value 0 (decimal).
GLBCE_LIMIT_AMPL[3:0] DARKAMPLIFICATIONLIMIT recommended value 0 (decimal).

6.7.3.5.3.3.9 GLBCE Iridix Slope Min and Max

GLBCE_SLOPE_MIN[7:0] SLOPEMINLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 64 (decimal).

GLBCE_SLOPE_MAX[7:0] SLOPEMAXLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 72 (decimal).

6.7.3.5.3.3.10 GLBCE Iridix Black Level

The value stored in the Black Level register GLBCE_BLACK_LEVEL[15:0] VAL will be used as the zero level for iridix processing in all data channels. Data below the Black level will not be processed and remain unchanged. Recommended value 0 (decimal).

6.7.3.5.3.3.11 GLBCE Iridix White Level

The value stored in White Level register GLBCE_WHITE_LEVEL[15:0] VAL will be used as white level for iridix processing in all data channels. Data above White level will not be processed and stay unchanged. Recommended value 65535 (decimal).

6.7.3.5.3.3.12 GLBCE Iridix Asymmetry Function Look-up-table

The Asymmetry function is used to balance the iridix effect between the dark and bright regions of the image. The Asymmetry Function Lookup Table geometry is 33 words, each of which is 16-bits wide.

GLBCE_LUT_FI_00

GLBCE_LUT_FI_01

... repeat until...

GLBCE_LUT_FI_32

Recommended values (decimal):

0:5377:10218:14600:18585:22224:25561:28631:31466:34092:36530:38801:40921:42904

:61429:62322:63176:63995:64781:65535

The C-code for generating the Asymmetry LUT is shown below:

```
#include <math.h>
int AsymmetryTable[33];
void GenerateAsymmetry(int Asymmetry, int SecondPole)
{
    double x = (double(Asymmetry)+1)/257 * 2 - 1;
    int ai = (int)floor(0.5 + 255 * (1- 1/(1000*x*x*x) + x - ((x >= 0)*2)));
    double as = fabs(double(ai) / 255);
    double dp = double(SecondPole) / 255;
    int ii;
    for (ii = 0 ; ii < 33 ; ++ii)
    {
        if(ai >= 0)
        {
            x = double(ii) / 32;
        }
        else
        {
            x = double(32 - ii) / 32;
        }
        int y = (int)floor((dp+(1-dp)*pow((fabs(1-dp-x)/dp), 3)) * (x*(as+1)/(as+x) ) *
            65535.0 + 0.5);
        y = y < 0 ? 0 : y > 65535 ? 65535 : y;

        if (ai < 0)
        {
            y = 65535 - y;
        }
        AsymmetryTable[ii] = y;
    }
}
```

6.7.3.5.3.3.13 GLBCE Iridix Forward and Reverse Perceptual Functions Look-up-tables

The iridix core works in a perceptually uniform space and thus when linear data is presented to the core it needs to be processed with special perceptual functions. These are implemented as two perceptual LUTs namely: Forward Perceptual LUT and Reverse Perceptual LUT. Each LUT is made up of sixty-five 32-bit words.

6.7.3.5.4 GLBCE Embedded Memory

GLBCE needs 2 lines of line memories and 1 set of cache memories.

Table 6-108. GLBCE Memories

Memory Type	Qty	Size	Clock	ECC Supported	Description
DELAY LINE	1	2122 x 64 (GLBCE_LINE_SIZE /2+10)x64	FCLK	No	GLBCE line memory
STATMEM	8 banks	16 bit x 1024	FCLK	Yes	GLBCE Cache memory (computes and stores the statistics from the frame)

6.7.3.5.5 GLBCE General Processing

GLBCE block needs appropriate statistics information to be stored to its cache memory in prior to processing incoming frame. Usually, this takes a two-pass process.

1. GLBCE is configured for input frame-A
2. Frame-A is given to GLBCE
3. GLBCE processes the input frame-A
4. GLBCE generates statistic (statistics-A) data based on frame-A in vertical blanking period
5. (Optional process) statistics-A is read from cache memory and moved to SDRAM
6. GLBCE is configured for input frame-B
7. Frame-B is given to GLBCE
8. GLBCE processes the input frame-B with the statistics-A generated from frame-A
9. GLBCE generates statistics-B based on frame-B in vertical blanking period
10. (Optional process) statistics-B is read from cache memory and moved to SDRAM

Alternatively, GLBCE can process in the following manner

1. Pre-calculated Statistics-C is copied to GLBCE cache memory from SDRAM
2. GLBCE is programmed for input frame-D
3. Frame-D is given to GLBCE
4. GLBCE processes frame-D based on statistics-C
5. GLBCE generates statistics-D based on frame-D in vertical blanking period
6. (Optional process) statistics-D is read from cache memory and moved to SDRAM

In [Section 6.7.3.5.6](#), some examples closer to real world use cases are explained based on the above two processes.

6.7.3.5.6 GLBCE Continuous Frame Processing

This is a very basic case, which does not need transferring statistics between cache memory and SDRAM. The most common example is video capture. In this case, the most straight forward way to run GLBCE, is to generate statistics from N-th frame, and apply it to (N+1)-th frame. The effect from using statistics of different frame should be small if the difference between frames is small. For example, it is expected this does not generate artifact, if the video frame rate is 30fps or larger. Below this rate, the single frame processing programming model explained in [Section 6.7.3.5.7](#) should be considered.

In the case of continuous frame processing, GLBCE is operated in the following manner:

1. GLBCE is programmed for incoming frame
2. Input frame comes in
3. GLBCE processes Input frame based on the statistics from the previous frame
4. GLBCE generates statistics based on the current input frame in the vertical blanking period
5. Repeat Step 1 through 4 as required

For the first frame of a set of sequential frames, Strength parameter should be 0, so GLBCE does not affect the image based on wrong statistics. SW may need to increase the strength value gradually after the first frame.

6.7.3.5.7 GLBCE Single Image Processing

For a single image, GLBCE needs to process the image twice, once for statistics generation, and once for actual GLBCE process.

1. GLBCE is configured for the input image.
2. The image is given to GLBCE. (Output image from GLBCE should be suppressed, for example, by disabling the next module in the path)
3. Statistics is generated in vertical blanking period.
4. The input image is given to GLBCE again. Output image with right GLBCE is generated.

Also, GLBCE can take in small size image in the first pass to reduce processing time.

5. A small size version (IMG-S) of the input image (IMG-IN) is generated.
6. GLBCE is configured for the small size image (IMG-S).
7. The small size image (IMG-S) is given to GLBCE.
8. Statistics for the small size image is generated in vertical blanking period.
9. GLBCE is configured for the original input image (IMG-IN).
10. The original input image (IMG-IN) is given to GLBCE.

6.7.3.6 VISS Flexible Color Processing (FCP) Module

6.7.3.6.1 FCP Overview

The Flexible Color Processing module is responsible for performing CFA Interpolation as well as performing a host of color processing functions for generating different color outputs.

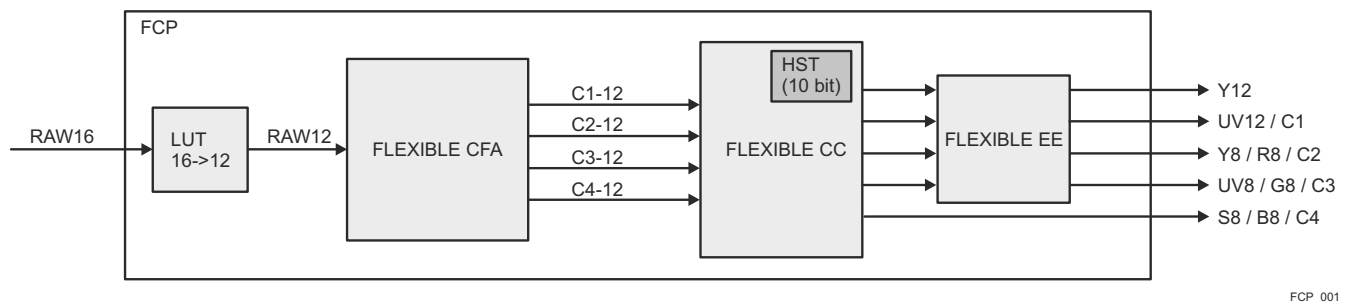

6.7.3.6.1.1 FCP Features Supported

The FCP include the following main features:

- Flexible CFA for generating multi-plane output for any 2x2 raw format sensor configuration.
 - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
 - Can generate up to 4 independent color planes
 - Support for up to 3 directions per color plane
 - Adaptive Threshold based on intensity measure
- Support for multiple color format output generation:
 - Support 12-bit YUV output
 - Supports RGB output
 - Supports Saturation outputs (8 bits only)
 - Supports Grayscale/Luma/IR/Clear output.
- Support for flexible output format generation including YUV as well as RGB, SV, and so forth.
- Single cycle/pixel performance

6.7.3.6.2 FCP Functional Description

The Flexible Color Processor (FCP) receives data from RAW-FE and does demosaicing and color conversion. The output of FCP is sent to external memory.

FCP_001

Figure 6-70. FCP Block Diagram

The FCP consists of the following major sub-blocks for supporting different sensor and output formats:

- LUT based compression: used to reduce the bit width from 16 bits to 12 bits while still preserving the dynamic range.
- Flexible CFA: this block takes in as input any 2x2 raw sensor pattern and is capable of generating up to 4 full resolution color planes.
- Flexible Color Conversion (Flexible CC): this block takes in the output of the Flexible CFA and generates multiple standard as well as custom data formats.
- Flexible Edge Enhancer (Flexible EE): this block can take the output of the Color Conversion and align the Y and UV channels as well as enhance the edges in the luma channel.

6.7.3.6.3 FCP Submodule Details

6.7.3.6.3.1 Flexible CFA / Demosaicing

6.7.3.6.3.1.1 Feature-set

The Flexible CFA include the following main features:

- Support for Flexible CFA for generating multi-plane output for any 2x2 raw format sensor configuration.
 - Supports RCBC, RCCC, Bayer, RGBC as well as other formats.
 - Can generate up to 4 independent color planes.
 - Supports Clear (C) pixel.

- Supports Infrared (IR) pixels.
- Edge aware CFA interpolation.
- Software programmable filter for interpolation up to 4 color channels.
- Support for up to 4 phases and 3 directions per color channel.
- Software controlled algorithm for direction selection.
- Adaptive threshold calculation for direction selection.
- Support of up to 2 sets of programmable mask based gradient selection

6.7.3.6.3.1.2 Block Diagram of Flexible CFA

The Flexible CFA module follows the VPORT (internal) interface for both the input/output to the RAW-FE or Flexible CC module.

6.7.3.6.3.1.2.1 Gradient/Threshold Calculation

The Flexible CFA incorporates 2 sets of gradient and direction selection logic. Typically for symmetric 2x2 patterns like Bayer, only a single set is sufficient; however in sensors wherein one of the channels is working on a different data type, the second set can be used for that channel. An example of such sensors is the RGB-IR sensor, wherein the 2x2 pattern consists of one pixel of each color channel and one pixel of the IR channel. In this case, mixing the gradients and intensity of the color channels with the IR channel could be meaningless.

The gradient selection uses bit masks to select the desired pixel position for calculating the horizontal and the vertical gradient.

Figure 6-71 shows the notation for the bit-mask values. The same notation is used for vertical masks as well and the notation implies that setting a '1' in any field of the bit Mask enables the absolute difference of those 2 pixels to be summed in the gradient calculation.

FCP_007

Figure 6-71. Gradient Bit Masks

Similar masks are also used to calculate the intensity (see Figure 6-72), however instead of taking the absolute difference, the bit masks are used to sum up the pixels in those locations.

FCP_008

Figure 6-72. Intensity Bit Mask

The 4 bit Intensity mask is used to choose which pixels in the 6 rows should be used for creating the intensity sum. The same masks are used for every 2x2 window within the 6x6 buffer. (Thus setting all 4 bits to '1' will be equivalent to summing up the entire 6x6 window.) A programmable shift is then used to bring the intensity down to the 0-16k range. The maximum value of intensity can be $6 \times 6 \times 4k = 144k$, so the maximum value of shift is 4 (divide by 16). The shift value can be programmed to any value between 0 and 4 and should be chosen based on the mask. Note that dependent on the shift value, it's possible that the full range of 0-16k of the intensity may not be reached, hence the adaptive threshold should be programmed accordingly.

The adaptive threshold calculation uses the calculated intensity. For more information, see [Section 6.7.3.6.3.1.2.2, Software Controlled Direction Selection](#).

6.7.3.6.3.1.2.2 Software Controlled Direction Selection

Software can control or guide direction selection at frame or sequence level as shown in Figure 6-73.

FCP_009

Figure 6-73. Software Controlled Direction Selection

Table 6-109 summarizes number of option available to software.

Table 6-109. Summary of HSX Spaces

Mode	Name	Details
0	Horizontal	Dir = 0
1	Vertical	Dir = 1
2	HV	Dir = 2
3	HV_Threshold (Fixed threshold is MMR)	in Dir = 0: $\text{gradH} \geq \text{gradV} + \text{threshold}$ in Dir = 1: $\text{gradV} \geq \text{gradH} + \text{threshold}$ in Dir = 2: Otherwise
4	HV_AdaptiveThreshold	in Dir = 0: $\text{gradH} \geq \text{gradV} + \text{threshold}$ in Dir = 1: $\text{gradV} \geq \text{gradH} + \text{threshold}$ in Dir = 2: Otherwise

For calculation of adaptive threshold, 7 options are used. Each one defines a threshold to be used as a different intensity level as it follows:

- Entry-0 -> Intensity = 0
- Entry-1 -> Intensity = 512
- Entry-2 -> Intensity = 1024
- Entry-3 -> Intensity = 2048
- Entry 4 -> Intensity = 4096
- Entry 5 -> Intensity = 8192
- Entry 6 -> Intensity = 16384

The adaptive threshold can then be calculated as a linear interpolation between 2 successive entries based on the given intensity.

6.7.3.6.3.1.3 Example Filter Coefficients - Green Interpolation

Figure 6-74 shows an example Green filter for Bayer.

Four left thermograms show the directional filter for green interpolation. Combines early cutoff and extended cutoff filters.

While the two on the right shows the non-directional filter. Used when no direction is preferred. Provides reasonable passband in horizontal and vertical directions without extending too far to avoid artifacts.

Note that all phases of same component (for example Green) have identical frequency response but phase shifted based on position.

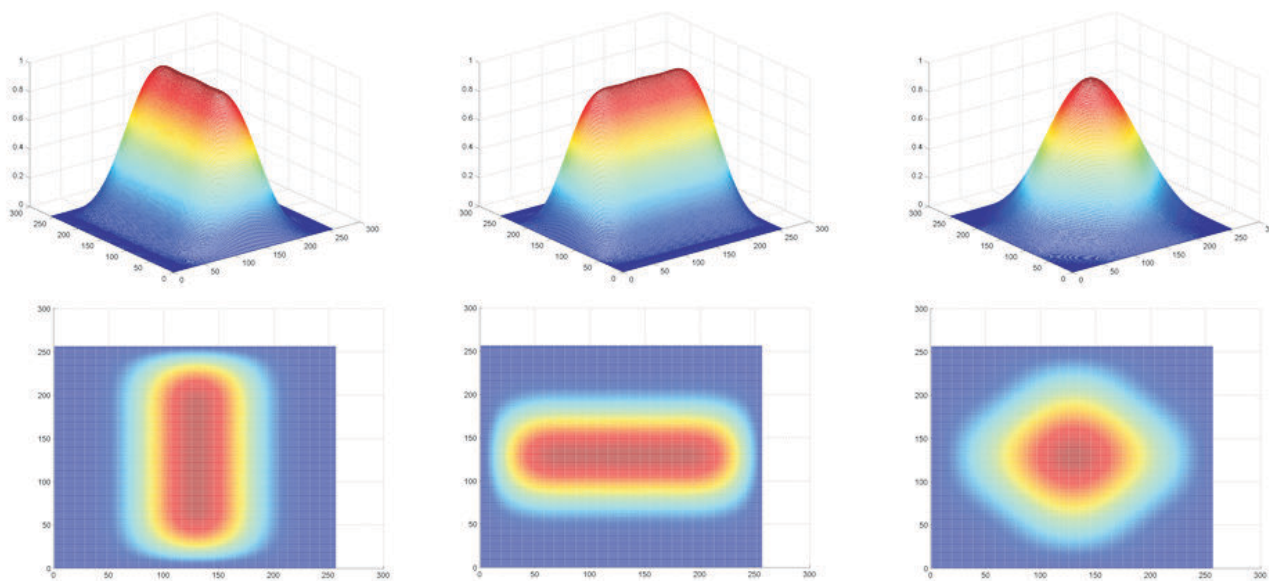

Figure 6-74. Example Green Filter for Bayer

6.7.3.6.3.1.3.1 Example Filter Coefficients - Red/Blue Interpolation

Figure 6-74 shows an example Red/Blue filter for Bayer.

Two left thermograms show the lowpass filter used on red/blue images.

While the four right shows the directional highpass filter used on green image to add additional high frequency content to red/blue images. In non-directional case, these are not used.

Note that all phases of same component (for example Red/Blue) have identical frequency response but phase shifted based on position.

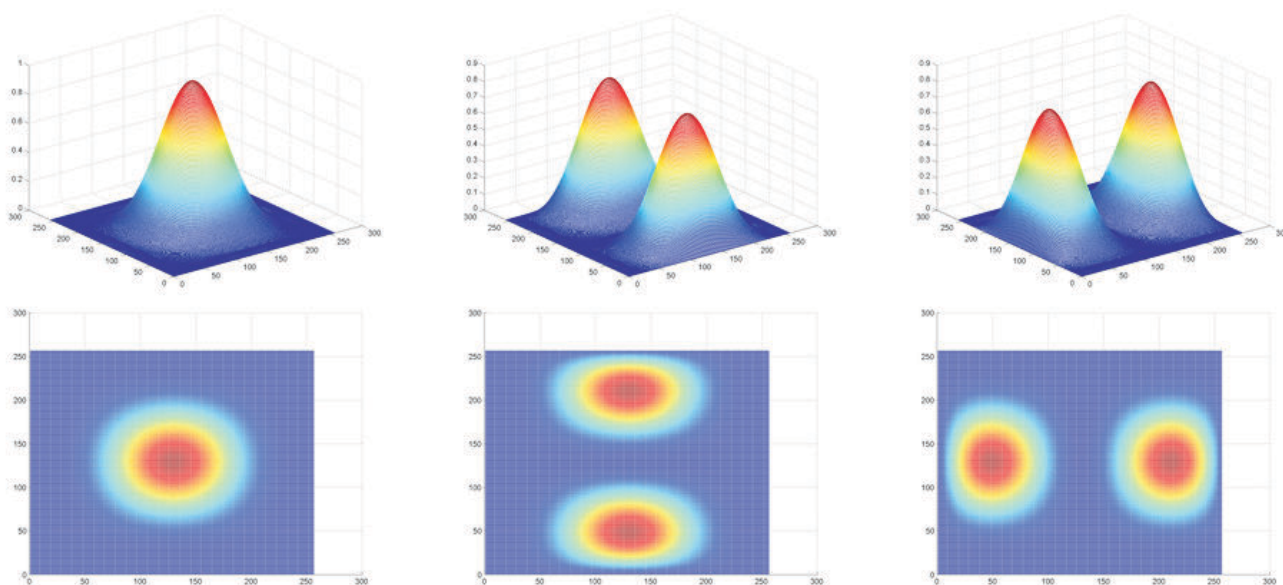

Figure 6-75. Example Red/Blue Filter for Bayer

6.7.3.6.3.1.4 CFA 16-Bit Upgrade

The following changes are done to make the CFA 16 bit compliant:

- Core filter data path is updated to 16 bits
- Gradient block
 - The gradients are normalized by adding a right shift of 4, this retains the range of gradients as the older implementation
 - Gradients are compared with thresholds and wrt each other
- FLXD_Intensity
 - Increased the size of the shift (after intensity calculation) by 1 bit (4 bits now)
 - Refer to the description of SET0_INTENSITY0 (Intensity BitField), (0x1d98)
- FLXD_ThrCalc()
 - No update since intensity remains in the same range as previous implementation

6.7.3.6.3.1.5 FIR Filter Output Scaling

Prior to the final output of the C1-C4 FIR Filter there is a scaling and offset addition.

That is the sum of the selected coefficients (derived from the intensity, gradient logic and controls above) times the pixel values is then sent through a scaling multiplier U14Q8 and then added an offset U16.

6.7.3.6.3.1.6 Decompanding, 24-bit Color Conversion Matrix and Companding Blocks

Figure 6-76 shows the block receives the internal Flex-CFA outputs and allows the pixel data to be decompanded up to 24-bits prior to going through a Color Conversion Matrix and then Companded back to 12-bit for the Flex-CC.

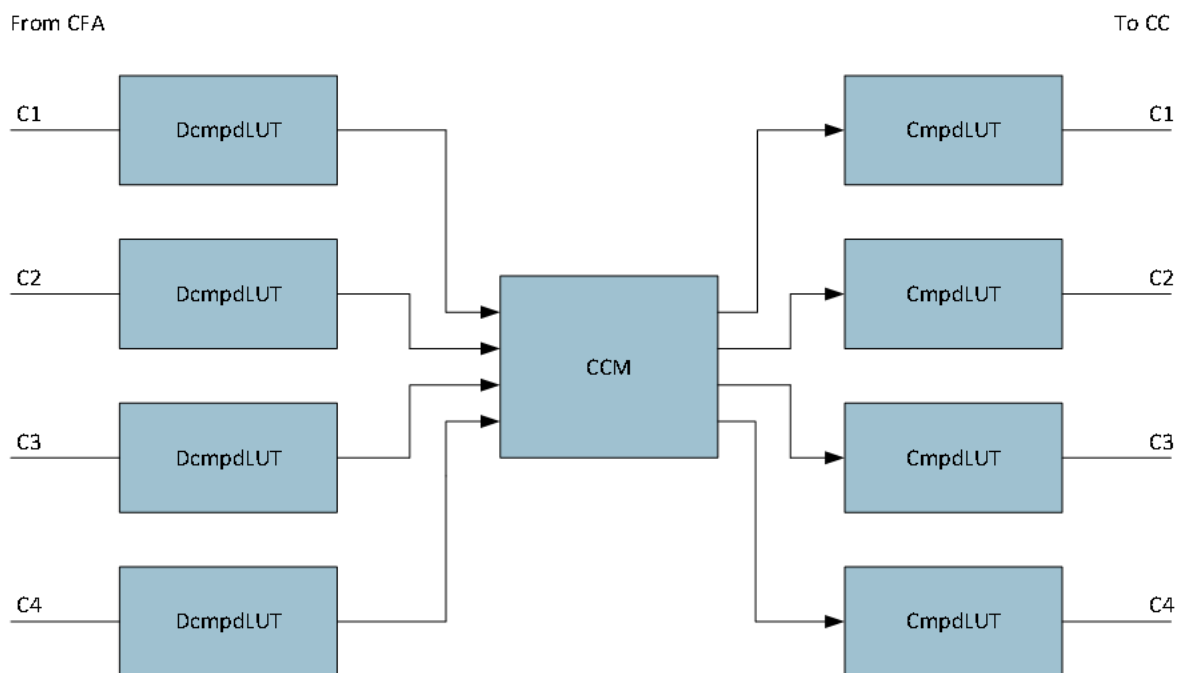

Figure 6-76. Block Diagram

6.7.3.6.3.1.6.1 The DcmpdLUT Block

The DcmpdLUT block can expand the 12- or 16-bit pixel data up to 24 bits for the Color Conversion Matrix block to process. Due to the input bit width being tied to 16, only 609 entries in the DLUT table are used. Normally used when the 16-bit data path is enabled.

6.7.3.6.3.1.6.2 The CCM Block

The CCM block uses the following formula to determine the output data E_x ; the input data C_x is from the DcmpdLUT blocks.

$$E1(x,y)=(W11*C1(x,y))+(W12*C2(x,y))+(W13*C1(x,y))+(W14*C4(x,y))+OFFSET1$$

$$E2(x,y)=(W21*C1(x,y))+(W22*C2(x,y))+(W23*C1(x,y))+(W24*C4(x,y))+OFFSET2$$

$$E3(x,y)=(W31*C1(x,y))+(W32*C2(x,y))+(W33*C1(x,y))+(W34*C4(x,y))+OFFSET3$$

$$E4(x,y)=(W41*C1(x,y))+(W42*C2(x,y))+(W43*C1(x,y))+(W44*C4(x,y))+OFFSET4$$

Where W_{ab} is CCM_OCHb_ICHa register fields. And $OFFSET_c$ is CCM_OCHc_OFFSET register fields.

6.7.3.6.3.1.6.3 The CmpdLUT Block

The CmpdLUT block compresses the selected data from the CCM back to 12-bit pixel data for the CC to process. The input width is controlled by the dandc_com_ctrl.linearbitwidth register setting.

6.7.3.6.3.1.6.4 Controls for the Decompaning, CCM, and Companding Blocks

- dCmpdLutEn - enable decompaning LUT
- LinearBitWidth - bit width at which DLUT, CCM and CLUT Input operations (Can be 16-24 range)
- ccmEn // Enable CCM logic
- cmpdLutEn // enable companding LUT
- CCM Controls with offset
 - Weights (4x4) are S12Q8
 - Offset is 26 bits signed (S26Q24) and can span a range of -2 to +1 for 24 bit data
 - Offsets need to be programmed by the user correctly for the desired LinearBitWidth
 - For instance, if the CCM output is $O_{out0} = W0R0 + W1G0 + W2B0 + 1$ // Offset should be set to 2^{24} if the data is 24 bits or 2^{16} if the data is 16 bits

6.7.3.6.3.1.6.5 Example Use Cases

The addition of these registers enables multiple use cases, not all of which are valid.

Table 6-110 highlights some possible use cases and the following MMR settings.

Table 6-110. Use Cases

	Name	Cfg_1.en16bitmode	LutEn (Legacy LUT)	Dcmpd En	Cmpd En	Linear BitWidth	CCM	Comments
0	Legacy	0	Valid	0	0	12	Valid	Legacy mode but can use an optional CCM
1	Basic 16 bit	1	0	0	0	16	Valid	Enhanced mode which can use a 16 bit CFA, however no companding / decompaning. A CCM may be used. In this usecase the data is shifted down to 12 bits after CCM by the logic automatically

Table 6-110. Use Cases (continued)

	Name	Cfg_1.en16bitmode	LutEn (Legacy LUT)	Dcmpd En	Cmpd En	Linear BitWidth	CCM	Comments
2	Basic 16 bit – inverse tone map (Visual)	1	0	1	0	16	Valid	Similar mode as basic 16 bit, however cmpnding LUT is used to apply an inverse gamma. CCM may be optionally used. This mode is similar to enhanced legacy visual mode but utilizes the new 16 bit CFA
3	20 Bit RCCB analytics	1	0	1	1	20	RCB -> RGB	This is 20 bit RCCB mode. The decompanding LUT maps to 20 bit, linear CCM converts RCB to RGB and then a LOG curve is applied with companding LUT
4	24 Bit RCCB analytics	1	0	1	1	24	RCB -> RGB	This is 20 bit RCCB mode. The decompanding LUT maps to 24 bit, linear CCM converts RCB to RGB and then a LOG curve is applied with companding LUT

6.7.3.6.3.2 Edge Enhancer Module Wrapper (WEE)

Figure 6-77 shows a high level block diagram of the Edge Enhancer (EE) module wrapper. For more information about the Edge Enhancer algorithm, see *Edge Enhancer (EE)*. The wrapper places the Edge Enhancer within the FCP structure along with associated muxes.

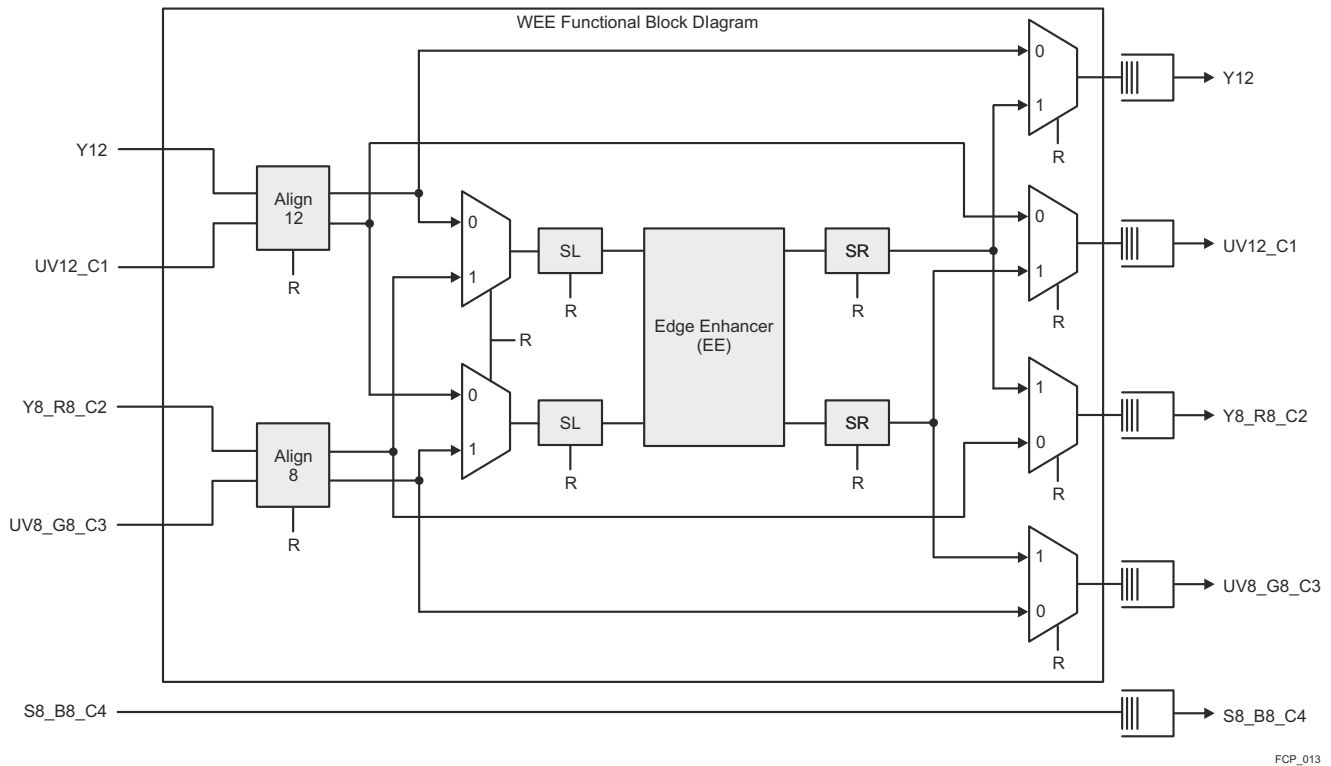

Figure 6-77. Block Diagram of Edge Enhancer Module Wrapper

6.7.3.6.3.2.1 Align 12 Block

The Align 12 block is responsible for aligning the 12-bit Chroma and Luma channels. It supports a missalignment of up to ± 19 pixels. The Align 12 block can be used independently from the EE block so that Y12 and UV12 can be output simultaneously.

6.7.3.6.3.2.2 Align 8 Block

The Align 8 block is responsible for aligning the 8-bit Chroma and Luma channels. It supports a missalignment of up to ± 19 pixels. The Align 8 block can be used independently from the EE block so that Y12 and UV12 can be output simultaneously.

6.7.3.6.3.2.3 Mux Blocks

The six mux blocks muxes one of two frames to the destination port. This is not a simple mux, but it only switches on frame boundaries. This means overlapping frames will not create frame fragments. Frame B is the only one to be forwarded and only after frame A completes. So if the frames overlap, a partial frame may be dropped during the switch. When the output MUX blocks are all bypassing the EE, the EE clock is gated to save power.

6.7.3.6.3.2.4 SL - Shift Left Block

This block shifts the data left by the programmed amount. Changes to the shifted left value only occurs prior to SOF (start-of-frame) received at the block. Which means the shifted amount is not changed during a frame.

6.7.3.6.3.2.5 EE - Edge Enhancer Block

The Edge Enhancer module is used to enhance the visual quality of the image by increasing its sharpness. The module only works on Y (Luma) data and uses a combination of 2D High-Pass Filtering to detect edges and then apply them on the input image.

6.7.3.6.3.2.6 SR - Shift Right Block

This block shifts the data right by the programmed amount. Changes to the shifted right value only occurs prior to SOF received at the block. Which means the shifted amount is not changed during a frame.

6.7.3.6.3.2.7 Edge Enhancer Module Wrapper (WEE) Registers

The WEE control registers are effectively shadowed which means changes take effect at the start-of-frame. The only exception is the WEE muxes which may have frame overlap. This happens if a switch occurs prior to frame B start-of-frame, but frame A is still in transit when the frame B arrives, then the first frame of frame B is dropped. In such case the Mux does not send a fragmented frame due to a mux switch occurring.

6.7.3.6.3.3 Flexible Color Conversion (CC)

Figure 6-78 shows a high level block diagram of the Flexible Color Conversion (CC) module.

Figure 6-78. Flexible CC Block Diagram (Logical View)

The Flexible CC enables multiple use cases and allows different color formats to be generated.

The Flexible CC module follows the VPORT (Internal) Interface for both the input to the Flexible CC module.

6.7.3.6.3.3.1 Interface Mux

The Flexible CC logical block diagram has 5 primary outputs connecting to the LSE modules in the VISS. For more information about LSE modules, see *Load Store Engine (LSE)*. A multiplex scheme is used to connect multiple outputs on to 5 interfaces using the interface Mux. The Flexible CC output can optionally also allow data from Flexible CFA to be tapped out on to one of the primary interfaces. Note that 12-8 LUTs are shared between the RGB generation and the Y/UV 8-bit generation logic.

Figure 6-79 shows the details of the interface mux. There are only 3 LUTs shared in different mode and only 5 concurrent output streams can be activated at any point of time. For 8-bit outputs, the data is stored in the MSB 11-4 bits of the 12-bit bus. Further, the Y12 output is dedicated and not multiplexed with other interface signals.

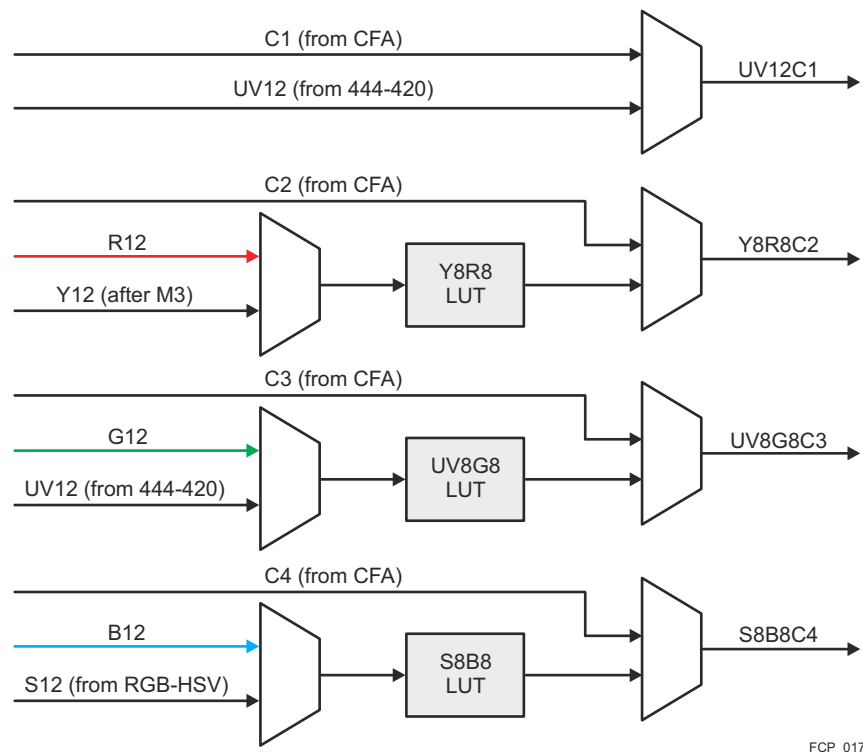

Figure 6-79. Flexible CC Interface Mux

6.7.3.6.3.3.2 Color Conversion (CCM-1)

The Color Conversion (CCM-1) is defined using the mathematical equations from [Figure 6-80](#).

$$\begin{aligned} E1(x, y) &= W11 \times C1(x, y) + W12 \times C2(x, y) + W13 \times C3(x, y) + W14 \times C4(x, y) + Offset_1 \\ E2(x, y) &= W21 \times C1(x, y) + W22 \times C2(x, y) + W23 \times C3(x, y) + W24 \times C4(x, y) + Offset_2 \\ E3(x, y) &= W31 \times C1(x, y) + W32 \times C2(x, y) + W33 \times C3(x, y) + W34 \times C4(x, y) + Offset_3 \end{aligned}$$

Figure 6-80. CCM-1

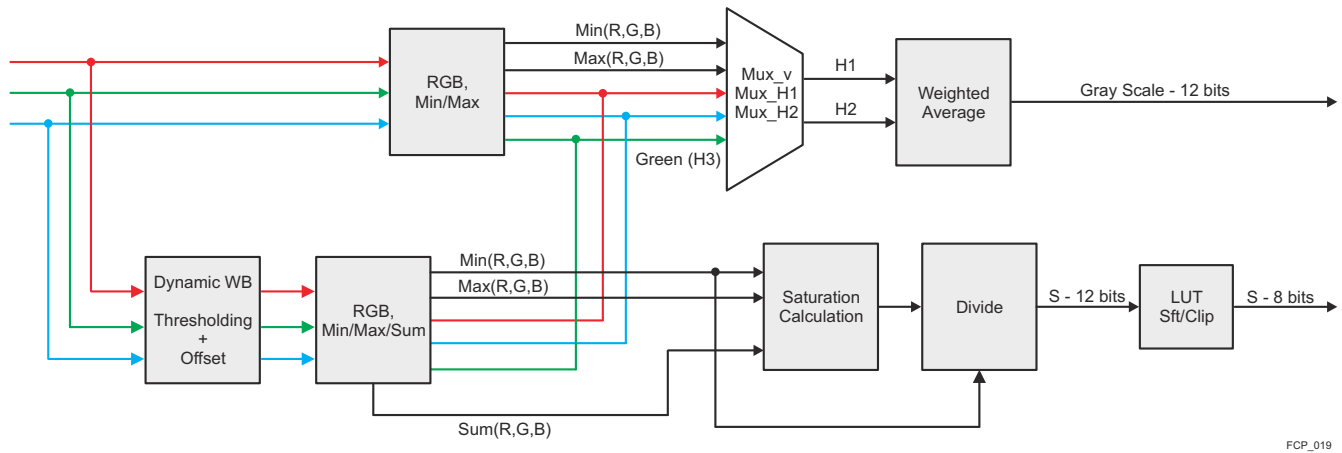

The CCM matrices weights (W^{**}) are 12 bit signed each (S12Q8) representing a range from -8 to +7.996 with 8 bits of fraction. The offsets are 13 bit signed notation (S13Q11) representing a range of -4096 to +4095. The offset is effectively shifted by one (left shifted/ multiplied by 2) before being applied. The effective range of offset is -2 to +1.995 with 11 bits of fraction.

The 4 component CCM allows for a power combination of color format generation to be addressed.

6.7.3.6.3.3.3 RGB to HSX Conversion

The RGB-HSV module is used for converting color spaces and creating custom luminance data plane. This way the 8-bit Saturation and 12-bit Luminance (L or V) plane are generated.

[Figure 6-81](#) shows the block which generates the Luminance / Gray Scale Plane as well as the Saturation (8-bit) plane.

FCP_019

Figure 6-81. S & V Generation

6.7.3.6.3.3.1 Weighted Average Block

The Weighted Average block implements the equation shown on [Figure 6-82](#).

$$GrayScale(x, y) = W1 \times H1(x, y) + W2 \times H2(x, y) + W3 \times H3(x, y) + Offset_1$$

Figure 6-82. Gray Scale Computation

In the equation on [Figure 6-82](#) the Weights (W1*) are 12 bits signed with a range of -8 to +7.9996 in S12Q8 format. The offset is Signed 13 bits in S13Q11 format with a range of -2 to +1.995.

[Figure 6-83](#) depicts the architecture of the Weighted Average block:

FCP_020

Figure 6-83. Weighted Average Block

The mux before the matrix chooses whether the native R/B channels are transmitted or alternatively the Min/Max (RGB) from the Min-Max block are transmitted. Further, the calculation of V can work on either the non-WB corrected data or the WB corrected version. For more information about WB correction, see [Section 6.7.3.6.3.3.2, Saturation Block](#).

The combination of the Min-Max block, the mux and the Weighted Matrix allows any of the Gray Scale calculation as shown in [Table 6-111](#).

Table 6-111. Summary of HSX Spaces

No	Formula	Configuration
Grey scale (HSI)	$(R+G+B) / 3$	H1 = R, H2 = B; Offset_1 = 0; W1 = W2 = W3 = 1/3 = 85;
Gray Scale (HSV)	Max(RGB)	H1 = Max(RGB); H2 = NA Offset_1 = 0; W2/W3 = 0; W1 = 1 (256);
Gey Scale HSL	$(\text{Max}(\text{RGB}) + \text{Min}(\text{RGB})) / 2$	H1 = Max(RGB), H2 = Min(RGB); W1 = W2 = 0.5 (128) Offset_1 = 0; W3 = 0;
		H1 = R, H2 = G; W1 = W3 = 0.25 (64); W2 = 0.5 (128) Offset_1 = 0

Table 6-112. Grey Scale and Saturation Calculation

No	HSI Color Space	HSV Color Space	SHL Color Space	Customer Requirements
Grey Scale Computation	$(R+G+B) / 3$	Max(R,G,B)	$(\text{Max}(\text{R,G,B}) + \text{Min}(\text{R,G,B})) / 2$	$(R+2*G+B) / 3$
Saturation (S) Computation	$1 - (\text{Min}(\text{R,G,B}) / (R+G+B))$	$(\text{Max}(\text{R,G,B}) - \text{Min}(\text{R,G,B})) / \text{Max}(\text{R,G,B})$	$(\text{Max}(\text{R,G,B}) - \text{Min}(\text{R,G,B})) / 255 - \text{Gray value}$	$S = \text{Max}(\text{R,G,B}) - \text{Min}(\text{R,G,B})$
Hue (H) Computation	Complex formula involving (R-G) (R-B) & (G-B)	Division formula livolving (R-G) (R-B) & (G-B)	Complex formula involving all component	Separate output for (R-G) and Yellowness

6.7.3.6.3.3.3.2 Saturation Block

The Saturation block first applies a dynamic white balance offset to correct the saturation plane when the image is in log domain and is used for analytics data flow. Once the WB offset is applied, the saturation calculation proceeds as described below. Note that the White balance offset is only applied if the independent pixel values are below a threshold (VISS_FCP_FCC_RGBHSV_WB_LINLOGTHR_1/2). Further, even the minimum of RGB is compared against a threshold (VISS_FCP_FCC_RGBHSV_WB_LINLOGTHR_2[27-16] SATMINTHR bit field) and the higher of the two is used. The saturation calculation always uses the data with the WB correction applied, however the V calculation can choose between WB corrected or uncorrected data using VISS_FCP_FCC_CFG_1[26] MUXRGBHSV_MUX_V.

Table 6-112 shows the condensed form for the Grey Scale and Saturation calculation. In the Flexible CC the saturation calculation is supported using two modes based on the VISS_FCP_FCC_CFG_2[6] HSVSATMODE bit as follows.

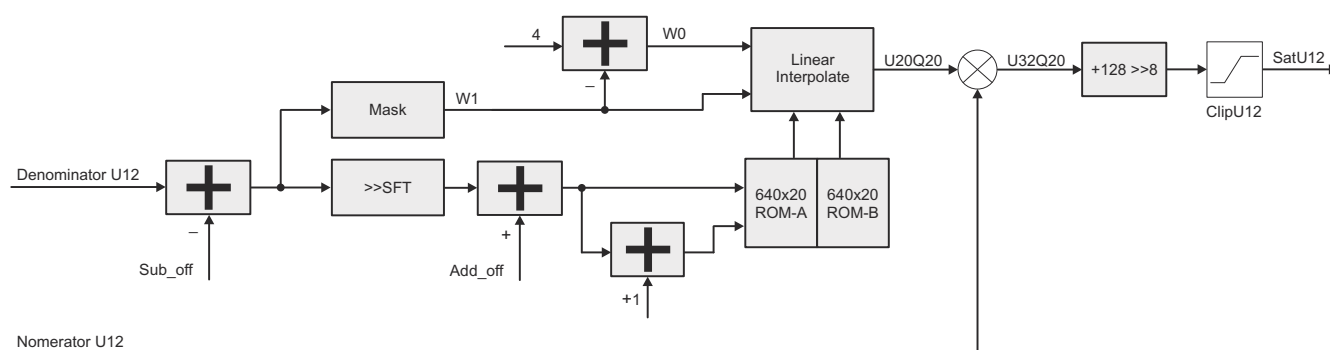

- HSVSATMODE = 0: Max(RGB) - Min(RGB)
- HSVSATMODE = 1: SUM(RGB) - Min(RGB)

Similarly the denominator for the dvision is chosen using the following selection on the VISS_FCP_FCC_CFG_2[5-4] HSVSATDIVMODE bit field.

- HSVSATDIVMODE = 0: No division, denominator = 1
- HSVSATDIVMODE = 1: Max(RGB)
- HSVSATDIVMODE = 2: 4095 – Gray value (computed in [Figure 6-82](#))
- HSVSATDIVMODE = 3: Sum(RGB)

6.7.3.6.3.3.3.3 Division Block

The division operation is implemented to calculate 1/x followed by a multiplication with the value. The input to the LUT is 12-bit unsigned value and the output is 8-bits fraction representing 1/x calculation. The divide LUT is implemented as a non-linear ROM with 1216 (1280 for aligning to 128 size boundary) entries and up to 2 segments to reduce error. Ideally to implement a full ROM for an input space of 12 bits would require 4k entires, however to save space and reduce error, the ROM is partitioned such that it is full resolution for the first 256 entries where the curve is highly non linear, whereas the next 4k - 256 entires have a step size of 4. Each ROM entry has a bit size of 20 bits in U20Q20.

FCP_022

Figure 6-84. Division LUT

These are the parameters that need to be calculated based on the range of the input.

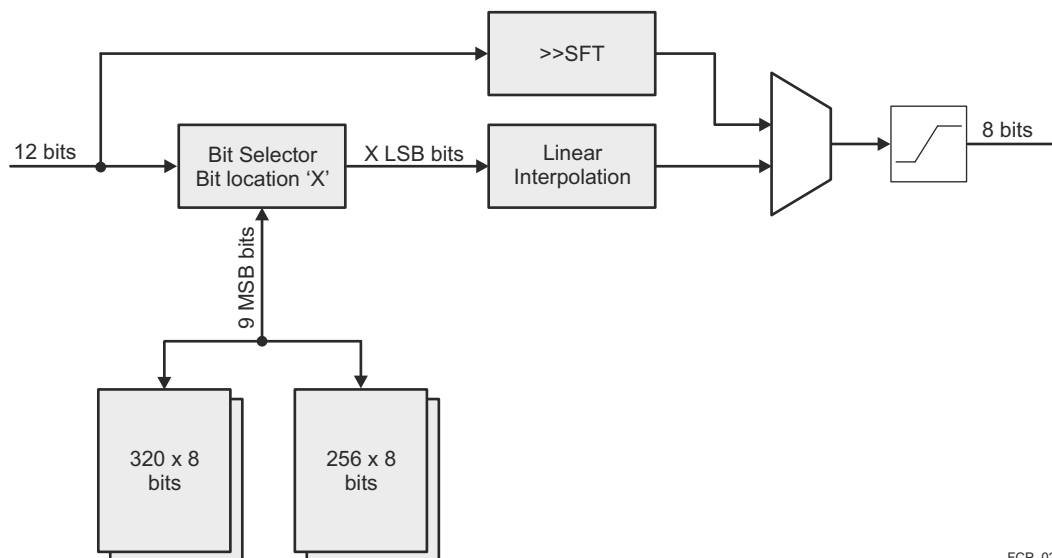

- SFT: '0' if input <256, 2 otherwise
- Mask: '0' if input <256, 4 otherwise
- Add_off: '0' if input <256, 256 otherwise
- Sub_off: '0' if input <256, 256 otherwise

The 'shift' parameter at the end is a configuration register which needs to be programmed. Typical programming value is 8 to generate a result in Q12 format (such that the range is 0 to1). This is usually the case when the denominator is greater than the numerator.

6.7.3.6.3.3.4 LUT Based 12 to 8 Downsampling

In the final step the generated saturation value (12 bit) or the incoming RGB values (12 bit) needs to be scaled down to 8 bits using the linear LUT with 513 entries.

Figure 6-85 is a high level block diagram of the LUT block. It shows the weight calculation for the LUT assuming the incoming data can be of any bit depth between 8 and 12 bits.

FCP_023

Figure 6-85. LUT Based 12-8 Compression

The LUTs are sized to provide 513 locations of data, to enable linear interpolation for all locations. The internal weights are sized as 3 bits since the maximum delta between 2 steps is only $4095/512 = 8$.

Figure 6-86 shows the high level block diagram of the interpolation process. The logic is designed to scale for bit width and can support anything from 8 to 12 bits of input to support different usecases. However, since the

step size is different depending on the input bit width, the bit selection and weight calculation logic is designed to account for that.

A shift operation can be performed instead of LUT to reduce bitwidth from 12 down to 8 bits.

FCP_024

Figure 6-86. Linear Interpolation on LUT

The code below shows the addressing for the LUT as well as the weight calculation logic for supporting multiple bit widths at the input from 8 – 12 bits.

12-8 Bit LUT Curve

```

CASE BIT_SEL
12 (12 bit data): Addr = Inp[3:11]; wt1 = Inp[2:0]
11 (11 bit data): Addr = Inp[2:10]; wt1 = Inp[1:0] & '0'
10 (10 bit data): Addr = Inp[1:9]; wt1 = Inp[0] & '00'
9 (9 bit data): Addr = Inp[0:8]; wt1 = '000'
8 (8 bit data): Addr = Inp[0:7]; wt1 = '000';
//Wt0 is always calculated at 8 - Wt1
Wt0 = 8 - Wt1

```

The input bit width (BIT_SEL) is specified using a dedicated register for generating Y8 output. However for other paths (RGB/UV/Sat) the 8 bit conversion is done using either 12 bits (if data is tapped prior to contrast block) as the bitwidth or the clipping value after contrast block (VISS_FCP_FCC_CFG_2[12:9] CONTRASTBITCLIP, if data is tapped after contrast block).

6.7.3.6.3.3.4 Histogram

The histogram can work on either one of the color components after the CCM-1 or the fourth color component routed directly from the Flexible CFA. The Histogram can also work on internally generated Luma value using simple averaging of RGB components. The Histogram module supports a local memory which can be read by the host processor. The Histogram provides data which can be used by the software to generate tone curves for the Contrast Stretch LUT.

The input to the Histogram module is calculated based on the control MMR as it follows:

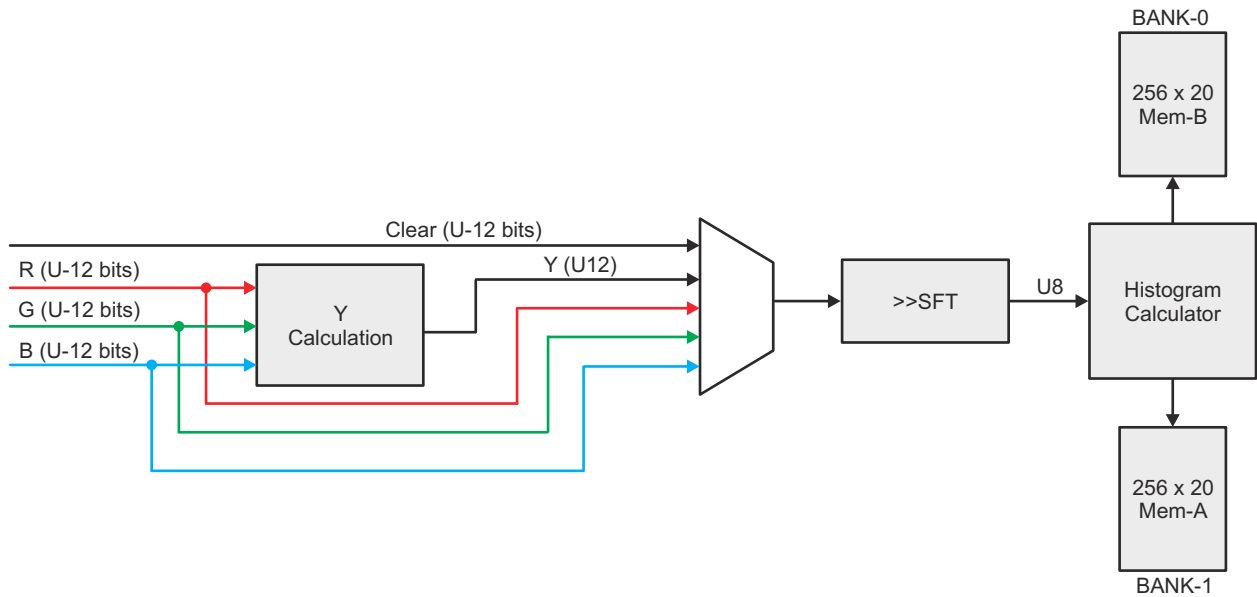

- 0: R
- 1: G
- 2: B
- 3: MuxC1_4
- 4: $(R+2*G+B) / 4$

The histogram module downsamples the image in the horizontal direction by a factor of 2 using simple averaging filter. This ensures that the memory access requirements of the module are limited to 1 read + 1 write access every 2 cycles (1 access/cycle) and thus can be achieved using a simple memory architecture.

The histogram module requires a ping-pong memory which is mapped to the configuration bus. This allows for histogram operation to run in concurrent with the Read operation from the host. For ease of software complexity, both the Ping/Pong memories map to the same address and it is the responsibility of the design to ensure that the muxing logic always take care of the correct access from both the host and the module. To detect error conditions, if the host is not able to read fast enough from the memory, an error interrupt should be generated whenever the host has initiated a read transfer from the first location of the memory but has not initiated a read transfer from the last location of the memory.

The Histogram module has 2 banks of memores each of 256x20 bits which are used in ping pong fashion. The input pixel has to be downshifted to match the bin size. The Histogram module has separate registers for creating an ROI using horizontal/vertical start postions as well as horizontal/vertical size.

Typically the ROI registers (VISS_FCP_FCC_CFG_HIST_1 and VISS_FCP_FCC_CFG_HIST_2) have to be set that at least one line is skipped for histogram calculation. The one line of time can be used by the histogram module to set the value of each of the bins to zero. This also puts a constraint on the histogram ROI to have a minmum width of 256 pixels.

FCP_026

Figure 6-87. Histogram Module

6.7.3.6.3.3.5 Contrast Stretch / Gamma

The logic of the Contrast/Gamma unit is based on the same as that of the 12-8 bit conversion LUTs. There are 3 copies of the logic, one for each color channel. The standard data flow allows for a 12 bit input and 12 bit unsigned output, however different bit width combinations are possible using the select bit of the LUT and the clip value. Each entry of the LUT table is 12 bits.

Figure 6-88 and Figure 6-89 show the block diagram and implementation of linear interpolation for the Contrast Stretch/Gamma module.

FCP_027

Figure 6-88. Contrast Enhancement Module

FCP_028

Figure 6-89. Contrast Enhancement Linera Interpolation

The code below shows the LUT addressing scheme which is similar to the 12-8 bit conversion module. The configurable clip at the end of processing allows for less than 12 bit output to be supported directly from the module.

Contrast Enhancement, LUT Addressing

```
CASE BIT_SEL
0 (12 bit data): Addr = Inp[3:11]; wt1 = Inp[2:0]
1 (11 bit data): Addr = Inp[2:10]; wt1 = Inp[1:0] & '0'
2 (10 bit data): Addr = Inp[1:9]; wt1 = Inp[0] & '00'
3 (9 bit data): Addr = Inp[0:8]; wt1 = '000'
4 (8 bit data): Addr = Inp[0:7]; wt1 = '000';
//wt0 is always calculated at 8 - wt1
wt0 = 8 - wt1
```

6.7.3.6.3.3.6 RGB-YUV Conversion

The RGB-YUV conversion is a matrix based conversion from 12-bit RGB to 12-bit YUV. The output after conversion is YUV444.

The conversion is carried out using the equation on [Figure 6-90](#).

$$Y(x,y) = WRY \times R(x,y) + WGY \times G(x,y) + WBY \times B(x,y) + Offset_1$$

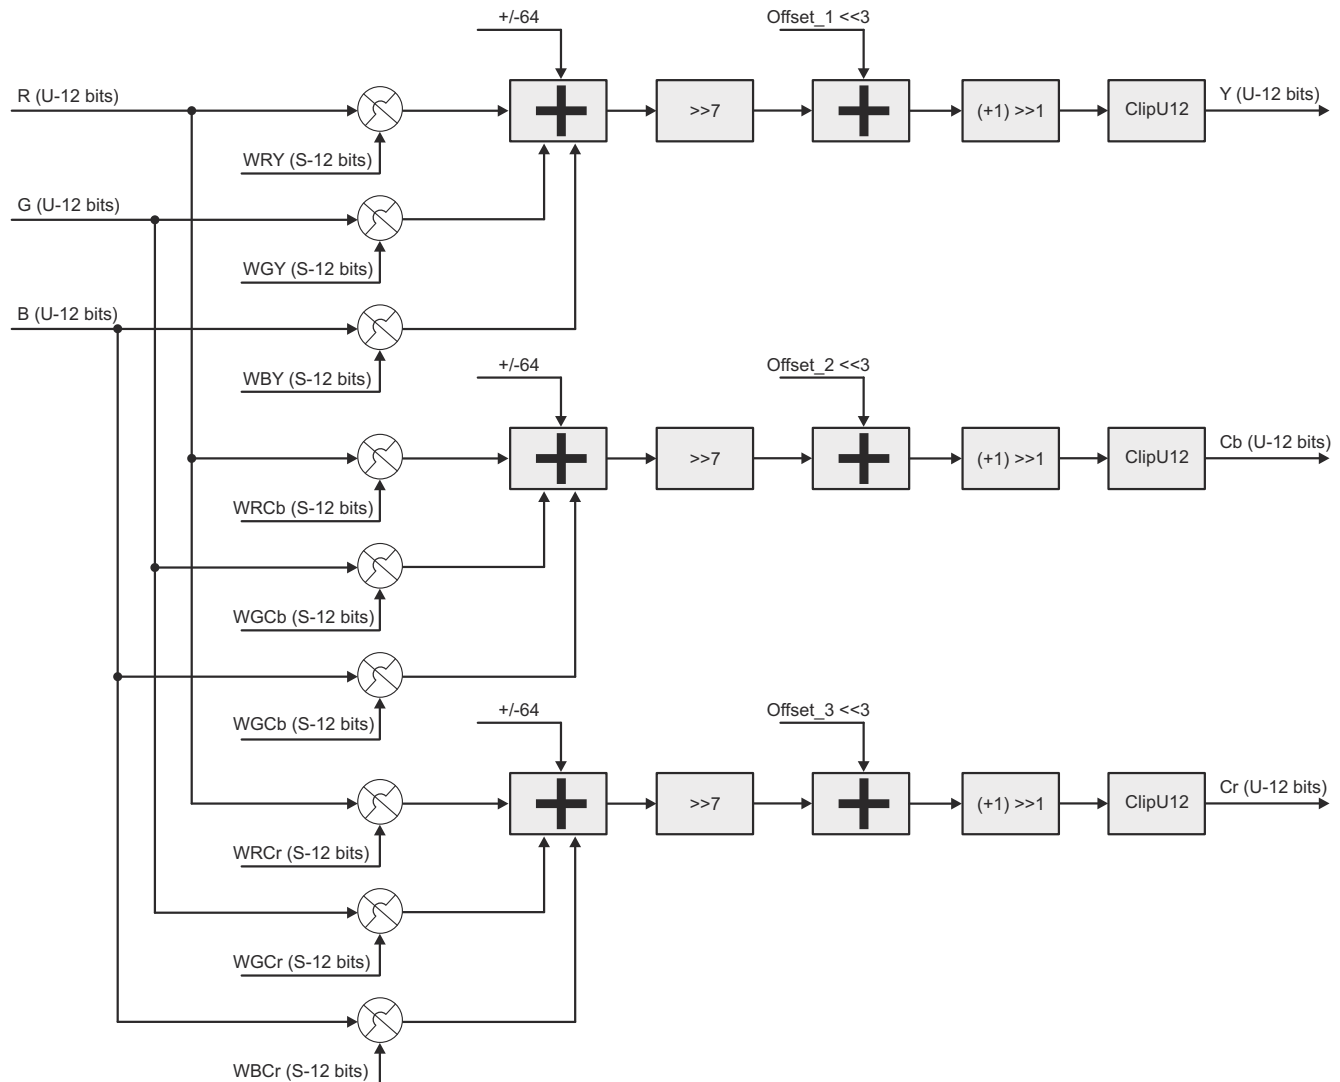

$$Cb(x,y) = WRCb \times R(x,y) + WGCb \times G(x,y) + WBCb \times B(x,y) + Offset_2$$

$$Cr(x,y) = WRCr \times R(x,y) + WGCr \times G(x,y) + WBCr \times B(x,y) + Offset_3$$

Figure 6-90. RGB-to-YUV Conversion

In this equation, the weights are signed 12 bits (S12Q8) with 8 bit of fraction precision, representing a range of -8 to +7.996. The offsets are signed 13 bits.

Figure 6-91 shows the implementation of the RGB to YUV module. The output after conversion is YUV444, as such it is followed by a chroma downsampling stage where in the Chroma resolution is reduced by half in both the horizontal and vertical direction.

FCP_030

Figure 6-91. RGB to YUV

6.7.3.6.3.4 444-422/420 Chroma Down-sampler

This module down-samples the chroma components from 444-420 format; effectively reducing the chroma resolution to 50% in both the horizontal and vertical direction.

The downsampling is performed using a 3 Tap filtering [1 2 1] followed by decimation. The conversion logic generates chroma in co-sited/co-located format in both the horizontal and vertical direction.

Figure 6-92 shows the block diagram of the format conversion module. The Chroma output can be optionally downshifted from 12 bits to 8 bits using the LUT/SFT module. Only one copy of the Horizontal averaging filter is required since there is a decimation step following the filtering. Only even locations of both Cb/Cr are retained while the odd locations are decimated, however from design perspective the Hz Averager module works on Cb on even cycles and Cr on odd cycles.

FCP_031

Figure 6-92. 444 to 420 Module

Additionally another mode of operation is to support planar YUV422 mode. In this case the chroma is only downsampled in the horizontal direction and the vertical averaging/downsampling is disabled.

The mode is referred to pseudo 422 since actual 422 mode requires the data to be interleaved between the Y and the chroma channels. In this case the interleaving of Y & C is handled by LSE whereas the Flexible CC module will only generate Y & Cb/Cr (interleaved) planes separately.

6.7.3.6.3.5 Blanking and Latency

Table 6-113 shows the blanking and latency functions in the FCP module.

Table 6-113. Blanking and Latency

Horizontal Blanking	Vertical Blanking	Horizontal Latency	Vertical Latency
10 cycles	0 line	25 cycles	1 lines – 420 Chroma 0 lines – Other Ch(s)

6.7.3.6.4 FCP Clocking

The FCP module has two clocks - CLK_A and VBUSP_CLK as it follows:

- CLK_A is 60 MHz.
- VBUSP_CLK must be greater than 30 MHz.

6.7.3.6.5 FCP Interrupts

The FCP module has three interrupts, as it follows:

- LUT_CFG_ERR - 16-12 LUT is written during active window
- CFA_PIX_ERR - Access to line memories by CFG during active window
- CFA_MMR_ERR - Non-Shadowed registers are written during active window

There are two additional events:

- SOL_EVENT - Start of line processing for Flexible CFA, triggered when the line enters the Flexible CFA
- SOF_EVENT - Start of frame processing for Flexible CFA, triggered when the frame enters the Flexible CFA

For information about the FCP interrupt events, see Section VISS Top Level Functional Description.

6.7.3.6.6 FCP Programmer's Guide

6.7.3.6.6.1 HWA Core Programming Details

The following fields should be programmed correctly for the FCP module to function.

- Input LUT
 - Use the LUT to reduce the bitwidth of the data to 12 bits so that it can pass through the Flexible CFA pipe.
 - If the GLBCE module is disabled, set the bit width and enable the LUT.
- Flexible CFA
 - Program the Flexible CFA kernels based on the input data pattern. Program only 3 channels for Bayer sensors and up to 4 for other non-standard formats like RGB-IR.
 - Set up the correct thresholds (use only one set for Bayer type sensors and two sets for non-standard formats like RGB-IR).
- Flexible CC
 - Set up the Flexible CC for either visual or analytics data flow.
 - For visual, program the CCM-1 to be used as RGB2RGB and Contrast to be used as Gamma with clip at 10 bits. Only the 8-bit outputs are used and the Y8/C8 data is generated using shift down from 10 to 8 (instead of LUT).
 - For analytics, CCM-1 is programmed depending on sensor input format and the histogram is used to populate the contrast table. 12-bit outputs are used however Y8/C8 can be generated using 12 to 8 LUT based downshifting. The correct Saturation generation parameters should also be set.

6.7.3.6.6.2 HWA HTS Programming Details

For details of programming, see *HWA Thread Scheduler (HTS)* and [Section 6.7.2, VPAC Subsystem](#).

6.7.3.6.6.3 HWA Data Transfer Programming Details

For details of programming for PARAM space, see *Section UDMA Specification*.

6.7.3.6.6.4 Initialization Sequence

6.7.3.7 VISS Edge Enhancer (EE)

This section describes the Edge Enhancer module.

6.7.3.7.1 Edge Enhancer Introduction

The Edge Enhancer module is used to enhance the visual quality of the image by increasing the sharpness of the image. The module only works on Y (Luma) data and uses a combination of 2D HPF (High-Pass Filter) filtering to detect edges and then apply them on the input image.

The Edge Enhancer consists of two separate blocks internally, the edge enhancer filter and the edge sharpener filter. The module can be programmed to either select the output of one of the filters or to use a blend of both.

Figure 6-93 below shows a conceptual block diagram of the edge enhancer filter. The input data is assumed to be a 12 bits/pixel. The EE module is tuned to process 8-bit images (MSB aligned) but has support to process 10-bit and 12-bit images as well.

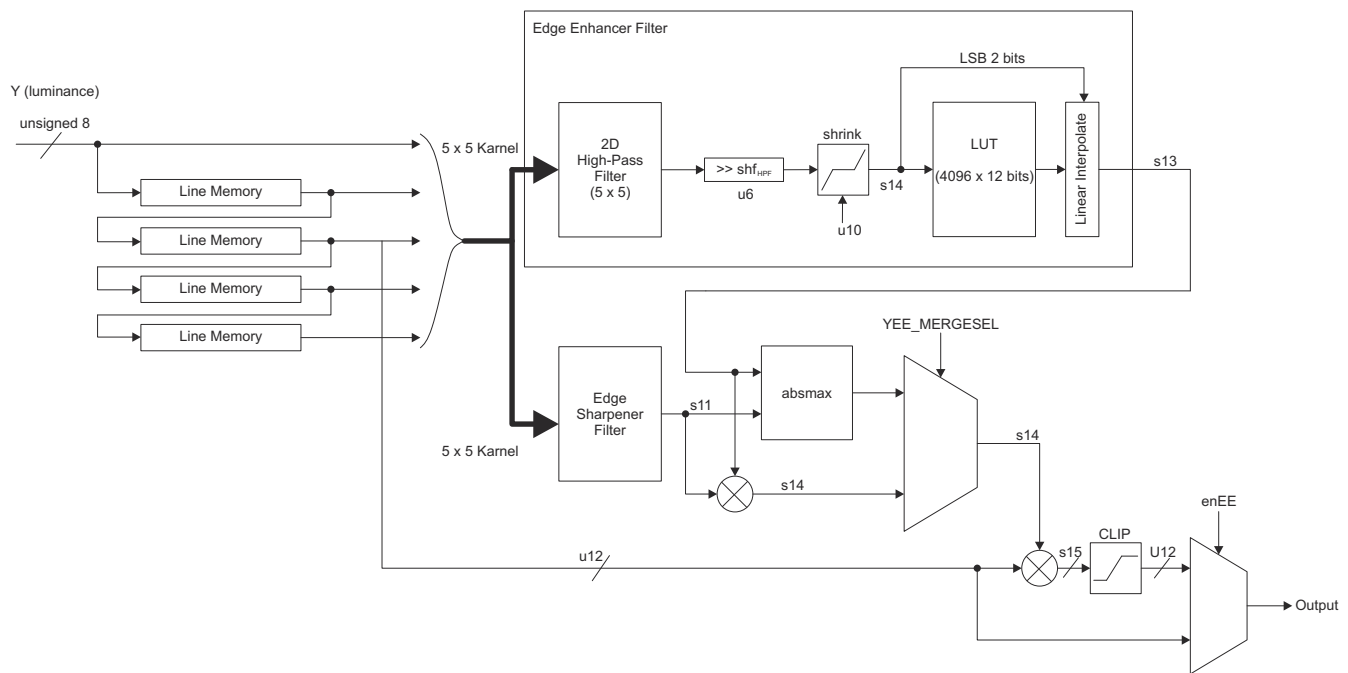

Figure 6-93. Edge Enhancer Block Diagram

6.7.3.7.1.1 Edge Enhancer Filter

The edge enhancer filter works on a 5×5 HPF filter (M) with programmable coefficients. The filter is symmetric as such only 3×3 coefficients are programmable.

Here, M is a 5×5 matrix with programmable coefficients specified by VISS_FCP_EE_YEE_COEF_Ri_Cj (i and j are 0, 1, or 2). The shift value (shf_{HPF}) is specified by VISS_FCP_EE_YEE_SHIFT[5-0] YEE_SHIFT.

$$HPF(h, v) = \left(\sum_{j=-2}^2 \sum_{i=-2}^2 M_{i,j} Y(h+i, v+j) \right) >> shf_{HPF}$$

$$M = \begin{pmatrix} M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,0} & M_{1,0} & M_{0,0} & M_{1,0} & M_{2,0} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \end{pmatrix}$$

Figure 6-94. Edge Enhancer Linear Filter

The HPF value is shrink by a threshold value, $threshold_{HPF}$ ($u6 = 10$), specified by VISS_FCP_EE_YEE_E_THR register, and clipped to signed 14 bits to get the index for the LUT. The MSB 12 bits of the index are used for the LUT address (4k locations) whereas the LSB 2 bits acts as weight to the linear interpolation logic.

$$index = clip(shrink(HPF, threshold_{HPF}), -8k, 8k)$$

$$shrink(x, threshold) = \begin{cases} x + threshold & x < -threshold \\ 0 & -threshold \leq x \leq threshold \\ x - threshold & threshold < x \end{cases}$$

$$clip(x, limit_{LOW}, limit_{HIGH}) = \begin{cases} -limit_{LOW} & x < -limit_{LOW} \\ x & -limit_{LOW} \leq x \leq limit_{HIGH} \\ limit_{HIGH} & limit_{HIGH} < x \end{cases}$$

Figure 6-95. Edge Enhancer Indexing

The edge enhancement intensity is looked up from the LUT, where A is the MSB 12 bits of the index.

$$E_{int} = Interpolate(LUT[A], LUT[A+1])$$

Figure 6-96. Edge Intensity LUT Formula

The 5×5 HPF filter is not fully programmable, rather only the top left quadrant is programmable coefficients. The rest of the kernel is symmetric along the y and the x axis.

Figure 6-97 below depicts how the kernels are implemented, with the kernel locations marked inside the boxes. The green color shows the kernels that are programmable.

Figure 6-97. 5 × 5 HPF Filter

The border conditions are handled by data duplication on each of the borders when the desired pixel goes out of range.

The output of the LUT is the final output of the edge enhancer filter.

6.7.3.7.1.2 Edge Sharpener Filter

Figure 6-98 below shows a high level block diagram of the edge sharpener function.

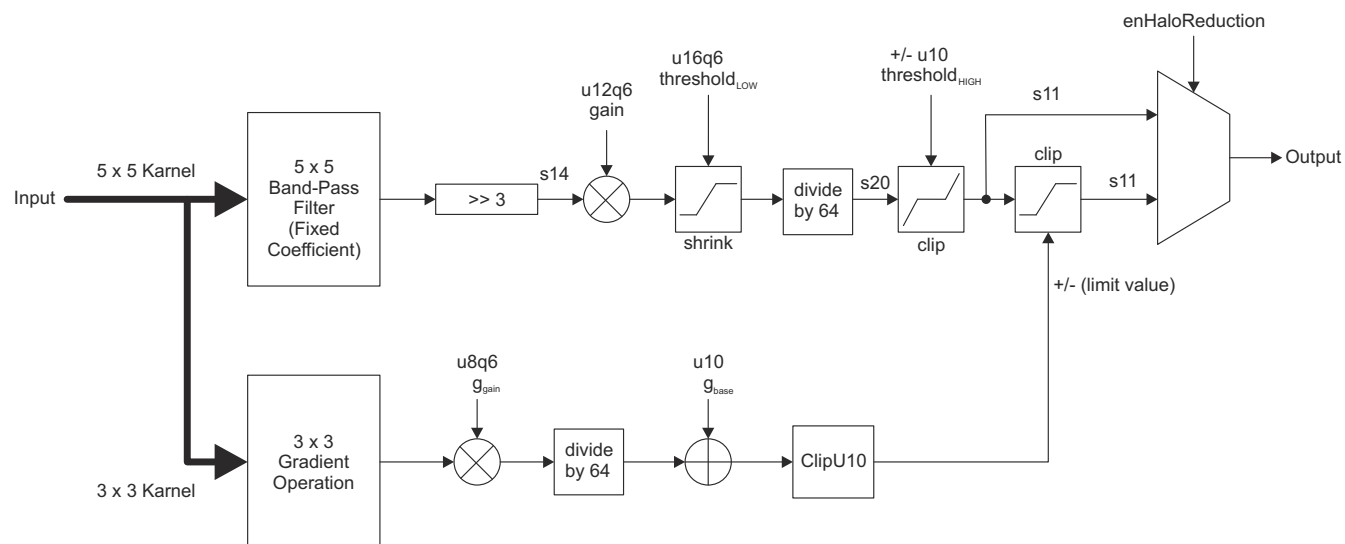

Figure 6-98. Edge Sharpener Function

In edge sharpener filter module, enabled when VISS_FCP_EE_YEE_MERGESEL[0] YEE_MERGESEL = 1, edge clarity is enhanced without producing a halo artifact. In this module, edge intensity is derived by the following 2D linear filter with fixed coefficients shown in Figure 6-99.

$$S_{i,j} = \begin{pmatrix} 0 & -1 & -2 & -1 & 0 \\ -1 & 0 & 2 & 0 & -1 \\ -2 & 2 & 8 & 2 & -2 \\ -1 & 0 & 2 & 0 & -1 \\ 0 & -1 & -2 & -1 & 0 \end{pmatrix}$$

$$sharpness(h,v) = \text{clip} \left(\text{shrink} \left(g \times \left(\sum_{j=-2}^2 \sum_{i=-2}^2 S_{i,j} Y(h+i, v+j) \right) \gg 3 \right), threshold_{LOW} \right) \gg 6, -threshold_{HIGH}, threshold_{HIGH}$$

Figure 6-99. Edge Sharpener Details

The gain (g) and threshold values for shrink/clip function ($threshold_{LOW}$, $threshold_{HIGH}$) are determined by register values (VISS_FCP_EE_YES_E_GAIN, VISS_FCP_EE_YES_E_THR1, VISS_FCP_EE_YES_E_THR2). The precision of g is in U12Q6, $threshold_{LOW}$ is in U16Q6 and that of $threshold_{HIGH}$ is in U10.

This edge intensity is then clipped by a threshold value in the formula shown in [Figure 6-100](#).

$$S_{int} = \begin{cases} \text{clip}(sharpness, -grad, grad) & \text{Halo reduction on} \\ sharpness & \text{Halo reduction off} \end{cases}$$

Figure 6-100. Edge Intensity Clipping Formula

The threshold value ($grad$) is a function of the activity around the target pixel, which is derived from gradient values. Gain (g_{grad}) and offset (g_{base}) are specified by VISS_FCP_EE_YES_G_GAIN and VISS_FCP_EE_YES_G_OFT.

$$grad = g_{grad} (\min(gx_L, gx_R) + \min(gy_T, gy_B)) \gg 6 + g_{base}$$

$$\begin{aligned} gx_L &= abs \left(\sum_{j=-1}^1 \sum_{i=-1}^1 G_{xL}(i,j) \cdot y(h+i, v+j) \right) & G_{xL} &= \frac{1}{4} \begin{pmatrix} 1 & -1 & 0 \\ 2 & -2 & 0 \\ 1 & -1 & 0 \end{pmatrix} \\ gx_R &= abs \left(\sum_{j=-1}^1 \sum_{i=-1}^1 G_{xR}(i,j) \cdot y(h+i, v+j) \right) & G_{xR} &= \frac{1}{4} \begin{pmatrix} 0 & 1 & -1 \\ 0 & 2 & -2 \\ 0 & 1 & -1 \end{pmatrix} \\ gy_T &= abs \left(\sum_{j=-1}^1 \sum_{i=-1}^1 G_{yT}(i,j) \cdot y(h+i, v+j) \right) & G_{yT} &= \frac{1}{4} \begin{pmatrix} 1 & 2 & 1 \\ -1 & -2 & -1 \\ 0 & 0 & 0 \end{pmatrix} \\ gy_B &= abs \left(\sum_{j=-1}^1 \sum_{i=-1}^1 G_{yB}(i,j) \cdot y(h+i, v+j) \right) & G_{yB} &= \frac{1}{4} \begin{pmatrix} 0 & 0 & 0 \\ 1 & 2 & 1 \\ -1 & -2 & -1 \end{pmatrix} \end{aligned}$$

Figure 6-101. Edge Threshold Value Formula

Capping with gradient value prevents overly enhancing edges, and suppresses halo artifacts around edges.

6.7.3.7.1.3 Merge Block

The output from edge enhancer filter and edge sharpener filter are merged with the following function.

$$E_{merge} = \begin{cases} E_{int} + S_{int} & VISS_FCP_EE_YEE_MERGESEL[0]YEE_MERGESEL = 0 \\ \text{absmax}(E_{int}, S_{int}) & VISS_FCP_EE_YEE_MERGESEL[0]YEE_MERGESEL = 1 \end{cases}$$

$$\text{absmax}(x, y) = \begin{cases} x & \text{abs}(y) \leq \text{abs}(x) \\ y & \text{otherwise} \end{cases}$$

Figure 6-102. Edge Enhancer and Sharpener Merger Formula

The E_{merge} value is added to the Y input value to make the final output.

The contribution of each of the filters can be modified. The edge sharpener filter block can be turned off or reduced in strength using the gain fields. The edge enhancer filter block can be disabled using the LUT.

6.7.3.7.2 Edge Enhancer Programming Model

Table 6-114 captures the programming parameters and the programming model of the Edge Enhancer module.

Note

UMQN implies M bits with N bits of fraction and M-N bits of Integer.

For more information, see *Edge Enhancer Registers*.

Table 6-114. Edge Enhancer Programming Parameters

Parameter Name	New Precision	Tuning Methodology
VISS_FCP_EE_EE_CFG_0[12-0] WIDTH	13 bits	Width of the image
VISS_FCP_EE_EE_CFG_0[28-16] HEIGHT	13 bits	Height of the image
VISS_FCP_EE_EE_ENABLE[0] YEE_ENABLE	1	Enable Module
VISS_FCP_EE_YEE_SHIFT[5-0] YEE_SHIFT	U6	-
VISS_FCP_EE_YEE_COEF_R0/1/2_C0/1/2[9-0] YEE_COEF_R0/1/2_C0/1/2	Signed 10	-
VISS_FCP_EE_YEE_E_THR[9-0] YEE_E_THR	U10	Shrink Threshold before LUT, scale by 16×
VISS_FCP_EE_YEE_MERGESEL[0] YEE_MERGESEL	1 bit	Mergesel: Off(0), On(1)
VISS_FCP_EE_YES_E_HAL[0] YES_E_HAL	1 bit	Halo Reduction; Off(0)/On(1)
VISS_FCP_EE_YES_G_GAIN[7-0] YES_G_GAIN	U8Q6	Usually 1.5 times YES_E_GAIN
VISS_FCP_EE_YES_G_OFT[9-0] YES_G_OFT	U10	Scale by 16
VISS_FCP_EE_YES_E_GAIN[11-0] YES_E_GAIN	U12Q6	Same as previous
VISS_FCP_EE_YES_E_THR1[15-0] YES_E_THR1	U16Q6	Scale by 16
VISS_FCP_EE_YES_E_THR2[9-0] YES_E_THR2	U10	Scale by 16

6.7.4 VPAC Lens Distortion Correction (LDC) Module

This section describes the Lens Distortion Correction (LDC) module.

6.7.4.1 LDC Overview

The LDC module deals with lens geometric distortion issues in the camera system. The distortion can be common optical distortions, such as barrel, pin-cushion, or fisheye distortion. LDC is not limited to just these types of distortions. Affine transformation support is also added to support the image and video stabilization application, where multiple images of the same scene need to be aligned. Perspective warp is an extension to affine transform and offers additional capabilities. Perspective transformations can align two images that are captured from different camera viewpoints or locations. This can also be used to rectify the left and right images of a stereo camera to reduce the complexity of a disparity computation. Perspective transformations can also generate new viewpoints.

6.7.4.1.1 LDC Features

- Autonomous memory-to-memory operation
 - Tile based processing
- Generic mesh based distortion model to correct multiple distortion types
- Perspective warp transformation for perspective correction; affine transform is a subset of perspective warp and supports scaling and rotation
- Support multiple input and output YUV data formats:
- Support up to 8192 x 8192 image dimension
- Pixel Interpolation
 - Bi-cubic interpolation for Y and bilinear interpolation for Cb/Cr
 - Bilinear interpolation mode to offer double throughput
- Performance
 - 1 cyc/pixel (bilinear)
 - 2 cyc/pixel (Bi-cubic)
- Support to process either Luma only or Chroma only modes in YUV420 input data format to save bandwidth
- Support for independent block size in multiple regions (up to 9 regions)
- Dual output channels for programmable output pixel size
- ECC support on Mesh Data internal storage memories and width conversion LUTs on dual output channel
- Interface to HTS module for block level synchronization with other IPs
- Circular addressing support for Output Write (for SL2 interface) and Input Read
- Event for Block/Frame completion and Error scenarios

6.7.4.2 LDC Functional Description

6.7.4.2.1 LDC Integration in VPAC

Figure 6-103 shows the LDC integration within the device

The list of hardware blocks in VPAC are as follow:

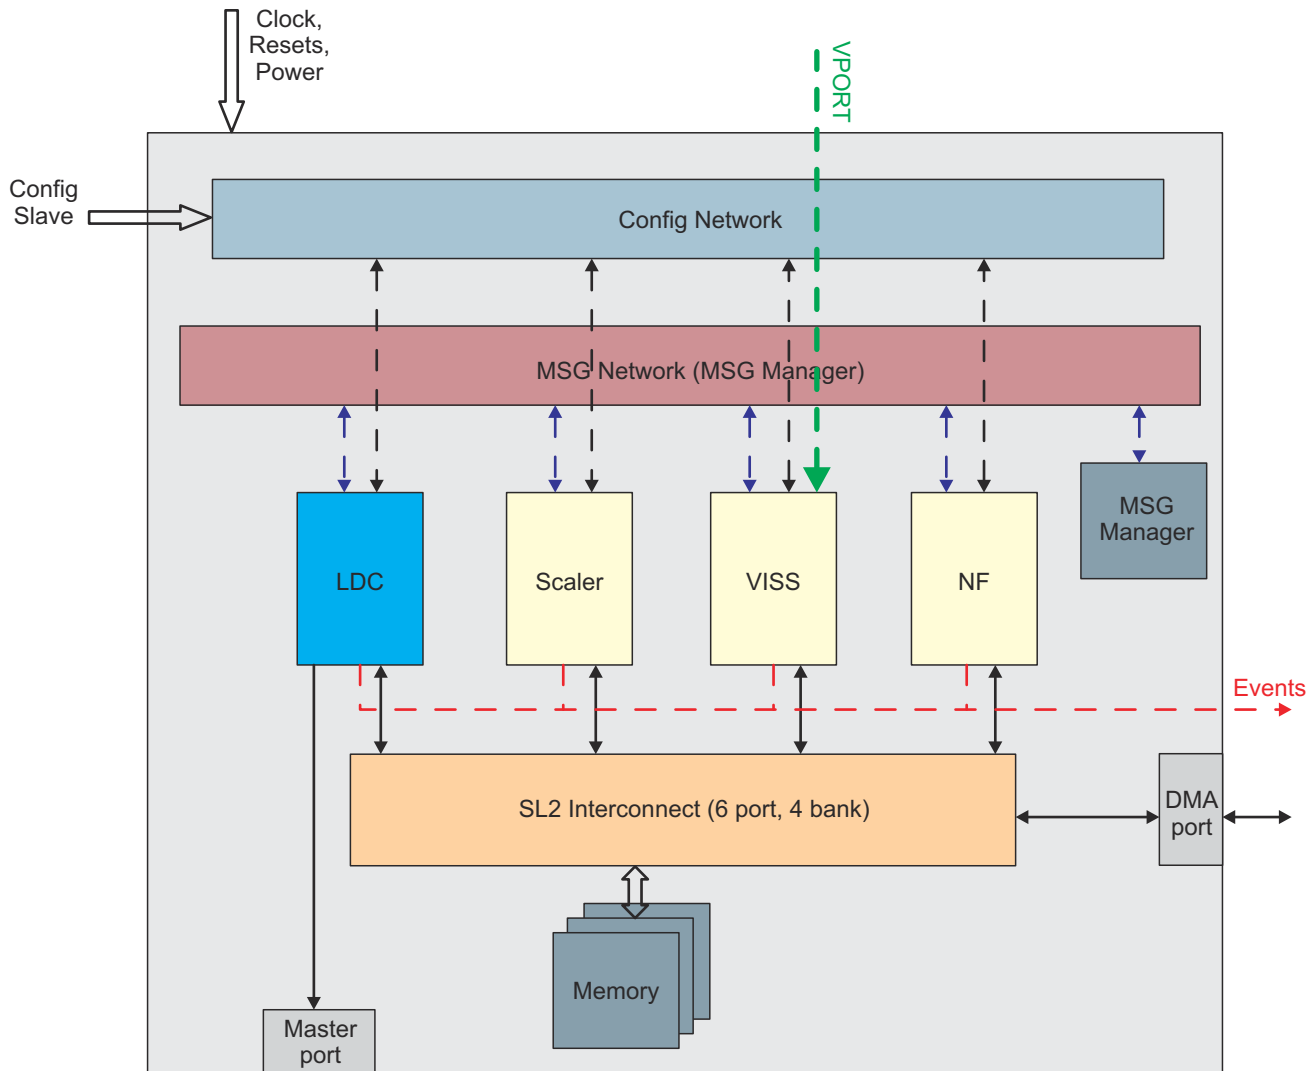

1. LDC (Lens distortion correction): LDC block reads data from memory (e.g. DDR or on-chip) and applies perspective transform as well as correction of lens distortion (including fisheye lenses). The output of LDC block can be sent to external memory (e.g. DDR) or sent to other hardware block (e.g. Scalar, Noise filter) for further pre-processing via local shared memory (SL2).
2. Scalar: Scalar block reads data from shared memory (SL2) and generates up to 10 scaled output from 2 inputs with various scaling ratios (between x and x0.5). The output of Scalar to Shared memory (SL2) can be further noise filtered using NF block or written to DDR.
3. Noise Filter (NF): NF block reads data from memory (e.g. DDR or on-chip) to shared memory (SL2) and does bilateral filtering to remove noise. The output of NF block can be sent to external memory (e.g. DDR) from Shared memory (SL2) or can be further re-sized using Scalar HW.
4. VISS (Vision ISS): There are two instance of on-the-fly processing for sensor related processing in VISS.

The list of infrastructure blocks in VPAC are following as follow:

1. Shared Level 2 (SL2) memory: This is used to exchange data across HW IP block (e.g. LDC, Scalar and NF) as well as to DMA Engine (e.g. UDMA).

2. HTS (Hardware Thread Scheduler): HTS is used for IPC communication among various HW IP Blocks (e.g. LDC, Scaler and NF as well as DMA Engine (e.g. UDMA)). Message Manager shown in Figure 1 is implemented as HTS.

VPAC has dedicated UDMA for DMA transfers except for LDC Read Data. For more top level integration and functional details see [Section 6.7.2](#), *VPAC Subsystem* for details.

ldc-001

Figure 6-103. LDC Integration in VPAC

6.7.4.2.2 LDC Block Diagram

Most digital cameras suffer from some degree of nonlinear geometric distortion. A spatial transformation is required to correct the distortion. In automotive applications, cameras use wide angle lenses, including fisheye lenses to provide 180+° field of view. To visually present the scene to the user in an easy-to-consume representation, these distortions need to be corrected

Back mapping gives coordinates of the distorted image as a function of coordinates of the undistorted output image. Correction involves back-mapping each output pixel to a location in the source distorted image, and thus the corrected image is fully populated. As the distorted pixel locations mostly fall onto fractional coordinates, correction involves interpolation.

As shown in [Figure 6-104](#), the LDC consists of a back mapping block, a x/y offset table, image buffer interface, buffer, an interpolation block, and SL2 interface.

Figure 6-104 is a block diagram of the LDC.

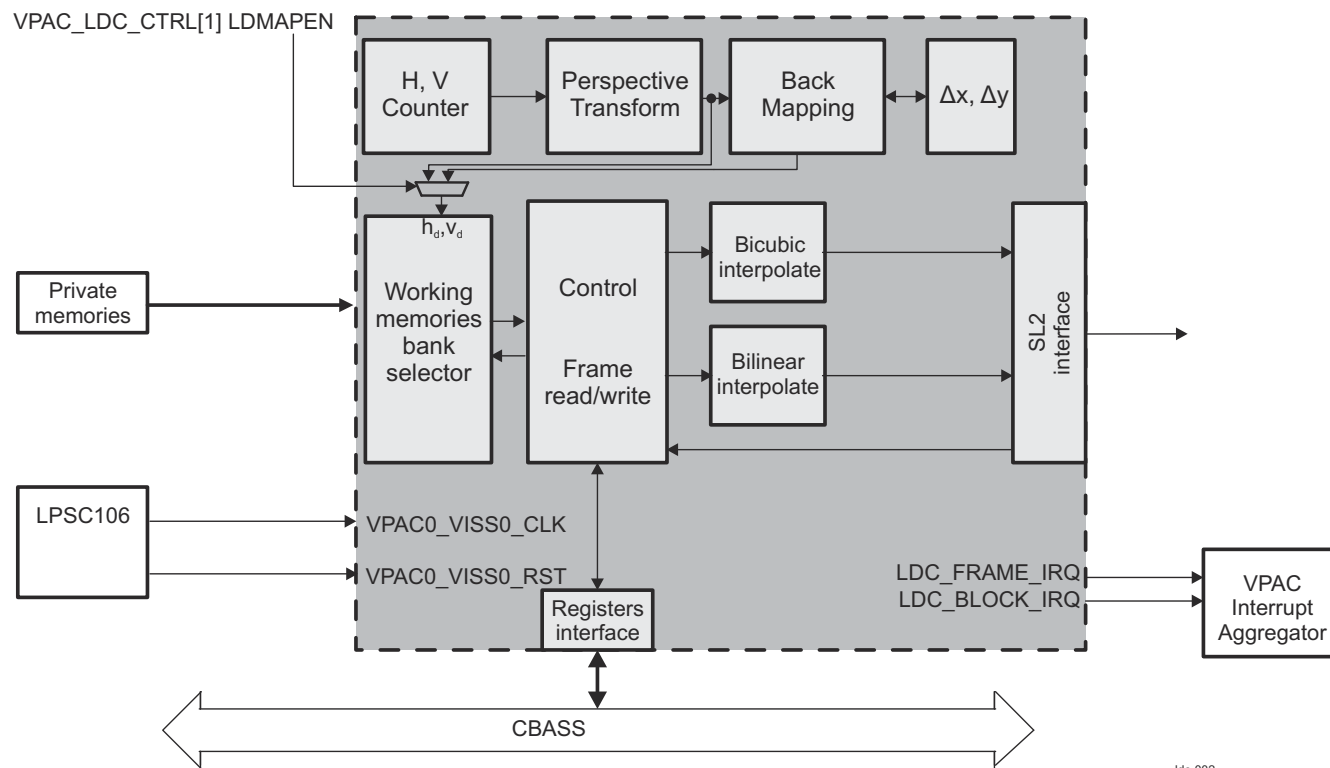

Figure 6-104. LDC Block Diagram

Given the coordinates of the undistorted image, the corresponding coordinates of the distorted image are calculated by combining the output coordinates and the offsets from the offset table. Distorted pixels are read from the image buffer, and buffered for the bilinear interpolation. After the interpolation, corrected image is written back to the SL2 memory.

The LDC processes the image in small two-dimensional (2D) blocks. The software configures appropriate parameters, then initiates the LDC function by writing to an LDC register. The LDC controls the sequencing through 2D blocks, DMA transfers, and computation to process an entire image autonomously. Interrupt, if enabled, is asserted at the completion of the image.

The LDC write is controlled by HTS at block level.

To start the LDC, software must set the VPAC_LDC_CTRL[0] LDC_EN bit to 1. The VPAC_LDC_CTRL[2] BUSY bit is a status that reflects LDC activity.

6.7.4.2.3 LDC Clocks

Complete VPAC LDC operates on single clock (that is, VPAC0_LDC0_CLK). Except the signals that are coming from LPSC, all other LDC sub-block clock domains are synchronous to VPAC0_LDC0_CLK.

6.7.4.2.4 LDC Interrupts

LDC generates interrupt events and these are made available to the VPAC. VPAC implements compatible interrupt function via the interrupt aggregator, see chapter [Section 6.7.2 VPAC Subsystem](#).

All the interrupts are active high and pulsed for one VPAC0_VISS0_CLK cycle. Following interrupts events are generated. Out of these only ECC interrupt should be treated as real interrupt and others are used as events for the interrupt aggregator at VPAC level.

Table 6-115. LDC Interrupt Events

Interrupt Event	Type	Category	Description
PIX_IBLK_OUTOFBOUND	pulse	func	PIX_IBLK_OUTOFBOUND pulse interrupt event

Table 6-115. LDC Interrupt Events (continued)

Interrupt Event	Type	Category	Description
MESH_IBLK_OUTOFBOUND	pulse	func	MESH_IBLK_OUTOFBOUND pulse interrupt event
IFR_OUTOFBOUND	pulse	func	IFR_OUTOFBOUND pulse interrupt event
INT_SZOVF	pulse	func	INT_SZOVF pulse interrupt event
VPAC_LDC_FR_DONE_EVT	pulse	func	LSE frame done event
VPAC_LDC_SL2_WR_ERR	pulse	func	LSE SL2 VBUSM Write Error interrupt event
PIX_IBLK_MEMOVF	pulse	func	Input pixel block internal memory overflow event
MESH_IBLK_MEMOVF	pulse	func	Input mesh block internal memory overflow event
VPAC_LDC_VBUSM_RD_ERR	pulse	func	Error event on VBUSM Read Interface
UNCORR_PULSE	pulse	error	ECC Aggregator uncorrectable error, pulse
UNCORR_LEVEL	level	error	ECC Aggregator uncorrectable error, level

CORR_LEVEL	level	error	ECC Aggregator correctable error, level

6.7.4.2.4.1 LDC Interrupt Events Description

6.7.4.2.4.1.1 PIX_IBLK_OUTOFBOUND

Generated when back mapping of block non-corner pixel co-ordinate goes out of the pre-computed input bounding box (i.e. data required for processing is not available in private pixel storage). This event is generated for the first occurrence of error in each frame. Upon this error, PIX_PAD setting needs to be reviewed. Upon pixel out of bound, pixel co-ordinate will be clipped to the pre-fetched block boundary. Usually no special treatment is required on this error event. Only few pixels are expected to be have this condition..

6.7.4.2.4.1.2 MESH_IBLK_OUTOFBOUND

Generated when mesh data required for non-corner mesh co-ordinate goes out of the pre-computed mesh bounding box (i.e. mesh data required for processing is not available in internal mesh storage). This event is generated for the first occurrence of error in each frame. This error condition is handled inside design by clipping the mesh data location to the pre-fetched block boundary. No special treatment is expected on this error event.

6.7.4.2.4.1.3 IFR_OUTOFBOUND

Generated when back mapped input pixel co-ordinate goes out of valid input frame boundary or co-ordinates post Perspective warping goes out of valid Mesh frame size (Frame size for which mesh data is available). This event is generated for the first occurrence of error in each frame. In the event of error condition, design will clip the co-ordinates to valid frame boundary. It is recommended to review the source of the error to make sure that it is expected.

6.7.4.2.4.1.4 INT_SZOVF

Generated when intermediate variables of affine or perspective transform operation goes above what hardware supports (U16Q3). This event is generated for the first occurrence of error in each frame. In the event of error condition, design will clip the variables the size to what HW supports. Upon this error, Affine and Perspective coefficients need to be reviewed.

6.7.4.2.4.1.5 VPAC_LDC_FR_DONE_EVT

Generated on once complete output frame is written into SL2.

6.7.4.2.4.1.6 VPAC_LDC_SL2_WR_ERR

This event is generated whenever the LDC SL2 Output VBUSM Interface write status is something other than 0 (success).

6.7.4.2.4.1.7 PIX_IBLK_MEMOVF

Generated when input pixel block memory storage requirement is more than internal pixel memory or each side of input block size goes above 1023. This event will be generated once per block in case of error. In the event of error condition, one or more output pixel blocks corruption. Upon this error, Output Block size setting needs to be reviewed.

6.7.4.2.4.1.8 MESH_IBLK_MEMOVF

Generated when Mesh block internal storage requirement is more than internal Mesh memory or either side of input block size goes above 1010. This event will be generated once per block in case of error. In the event of error condition, one or more output pixel blocks corruption. Upon this error, Output Block size or Affine/Pwarp parameters or mesh sub-sampling factor setting needs to be reviewed.

6.7.4.2.4.1.9 VPAC_LDC_VBUSM_RD_ERR

This event is generated whenever the LDC Read VBUSM Interface status is something other than 0 (success).

6.7.4.2.5 LDC Affine Transform

The LDC first performs an affine transform, which can be used for rotations and scaling, as shown in [Figure 6-105](#). The output of the pixel coordinate is used as the input address to the affine transform.

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} a \times \cos(\theta) & a \times \sin(\theta) \\ -a \times \sin(\theta) & a \times \cos(\theta) \end{bmatrix} \begin{bmatrix} h_u \\ v_u \end{bmatrix} + \begin{bmatrix} h_0 - h_0 \times a \times \cos(\theta) - v_0 \times a \times \sin(\theta) \\ v_0 + h_0 \times a \times \cos(\theta) - v_0 \times a \times \sin(\theta) \end{bmatrix}$$

ldc-010

Figure 6-105. LDC Affine Transformation

The mapping from destination coordinate to the source coordinate is expressed as:

$$h_{aff} = a \times h_u + b \times v_u + c$$

$$v_{aff} = d \times h_u + e \times v_u + f$$

This transform allows full rotation, expansion, contraction, and translation. The parameters {a, b, d, e} are in S16Q12 (signed number on 14 bits with 2 bits for integer and 12 bits of fraction) format, and parameters {c, f} are in S16Q3 format (signed number on 16 bits with 13 bits for integer and 3 bits of fraction). These parameters must be set in following bit fields:

- a = VPAC_LDC_AFF_AB[15:0] A
- b = VPAC_LDC_AFF_AB[31:16] B
- c = VPAC_LDC_AFF_CD[15:0] C
- d = VPAC_LDC_AFF_CD[31:16] D
- e = VPAC_LDC_AFF_EF[15:0] E
- f = VPAC_LDC_AFF_EF[31:16] F

6.7.4.2.6 LDC Perspective Transformation

When a camera is viewing a scene from two different positions or when multiple cameras are viewing the scene from different positions, a transformation between the two viewing angles is needed to align the images. Under specific conditions, the class of geometric transformations known as homography, or planar-perspective transformation, will capture the geometric relationship between the images accurately. Common applications of homography transforms are to align (or stitch) multiple frames of the same scene to compute a panoramic output image. A second application is the alignment of planar surfaces in the world. Finally, perspective transforms are also useful in computing depth maps from a stereo image pair. By rectifying the two views, the search to compute disparity between the two views is simplified to a 1-D search problem. The homography is defined by a 3x3 transformation matrix, as in

$$h_{aff} = a * h_u + b * v_u + c \quad (3)$$

$$v_{aff} = d * h_u + e * v_u + f \quad (4)$$

$$z = \max(0, g * h_u + h * v_u + 1) \quad (5)$$

$$h_p = h_{aff} / z \quad (6)$$

$$v_p = v_{aff} / z. \quad (7)$$

The affine transform is a subset of the perspective transformation. By setting $g = h = 0$, $h_p = h_{aff}$ and $v_p = v_{aff}$.

In image alignment applications, the homography matrices are computed by locating corresponding points in the two frames and estimating the matrix parameters to transform the set of points in one frame onto the corresponding points in the second frame. In the stereo rectification application, the matrix is determined (pre-computed) at the calibration step and remains fixed.

When LDC is requested to provide a change in the frame size between the input and output, the affine/perspective parameters must be programmed to implement the coordinate scaling (see for programming details). In the following sections, the mesh table is used to program distortion correction. The table sizes are defined based on the total output frame size.

6.7.4.2.7 LDC Lens Distortion Back Mapping

In YCbCr mode, the offset table defines a (x,y) vector for a regular grid of output points. The grid can be fully sampled or down sampled. A fully sampled grid will define an offset vector for every output pixel, defining exactly where to fetch the input data to compute the output pixel. This is the most precise definition and can capture rapidly changing offset tables. The drawback is that it will require a large amount of memory bandwidth as the LDC engine will be reading offset values for every output pixel. Since most offset tables are not expected to change rapidly in a small spatial region, LDC supports reading a subsampled offset table. Offset tables can be subsampled by powers of two in both horizontal and vertical directions and the subsampling factor is set in the register, VPAC_LDC_MESHTABLE_CFG[2-0] M. This mode conserves memory bandwidth by reducing the amount of data read to describe the offset vectors, but requires more hardware to interpolate the missing offset vectors. LDC supports bilinear interpolation to interpolate missing offset vectors.

The mapping procedure is described by the following series of equations. Given an output pixel at location, we compute the input pixel location.

$$x_c = \text{CLIP}(x_o, 0, 8 \times W - 1), W: \text{Mesh Frame Width} \quad (8)$$

$$y_c = \text{CLIP}(y_o, 0, 8 \times H - 1), H: \text{Mesh Frame Height} \quad (9)$$

$$\text{Mask} = (1 \ll (3+M)) - 1 \quad (10)$$

$$i_{x0} = (x_c \gg (3 + M)), f_x = x_c \& \text{Mask} \quad (11)$$

$$i_{y0} = (y_c \gg (3 + M)), f_y = y_c \& \text{Mask} \quad (12)$$

Clip new locations to previously fetched mesh block boundaries.

$$i_x = \text{CLIP}(i_{x0}, \text{block_startmx}, \text{block_endmx} - 1) \quad (13)$$

$$i_y = \text{CLIP}(i_{y0}, \text{block_startmy}, \text{block_endmy} - 1) \quad (14)$$

$$\begin{aligned} \text{Ofst0} &= \text{READ32}(\text{OfstTable}[i_x, i_y]) \\ \Delta x_0 &= \text{MSB16}(\text{Ofst0}) \\ \Delta y_0 &= \text{LSB16}(\text{Ofst0}) \end{aligned}$$

$$\begin{aligned} \text{Ofst1} &= \text{READ32}(\text{OfstTable}[i_x + 1, i_y]) \\ \Delta x_1 &= \text{MSB16}(\text{Ofst1}) \\ \Delta y_1 &= \text{LSB16}(\text{Ofst1}) \end{aligned}$$

$$\begin{aligned} \text{Ofst2} &= \text{READ32}(\text{OfstTable}[i_x, i_y + 1]) \\ \Delta x_2 &= \text{MSB16}(\text{Ofst2}) \\ \Delta y_2 &= \text{LSB16}(\text{Ofst2}) \end{aligned}$$

$$\begin{aligned} \text{Ofst3} &= \text{READ32}(\text{OfstTable}[i_x + 1, i_y + 1]) \\ \Delta x_3 &= \text{MSB16}(\text{Ofst3}) \\ \Delta y_3 &= \text{LSB16}(\text{Ofst3}) \end{aligned}$$

$$T_{x0} = ((1 \ll (M + 3)) - f_x) \cdot \Delta x_0 + f_x \cdot \Delta x_1$$

$$T_{x1} = ((1 \ll (M + 3)) - f_x) \cdot \Delta x_2 + f_x \cdot \Delta x_3$$

$$T_{y0} = ((1 \ll (M + 3)) - f_y) \cdot \Delta y_0 + f_y \cdot \Delta y_1$$

$$T_{y1} = ((1 \ll (M + 3)) - f_y) \cdot \Delta y_2 + f_y \cdot \Delta y_3$$

$$\Delta x = (((1 \ll (M + 3)) - f_y) \cdot T_{x0} + f_y \cdot T_{x1} + (1 \ll 2M + 5)) \gg (2M + 6)$$

$$\Delta y = (((1 \ll (M + 3)) - f_x) \cdot T_{y0} + f_x \cdot T_{y1} + (1 \ll 2M + 5)) \gg (2M + 6)$$

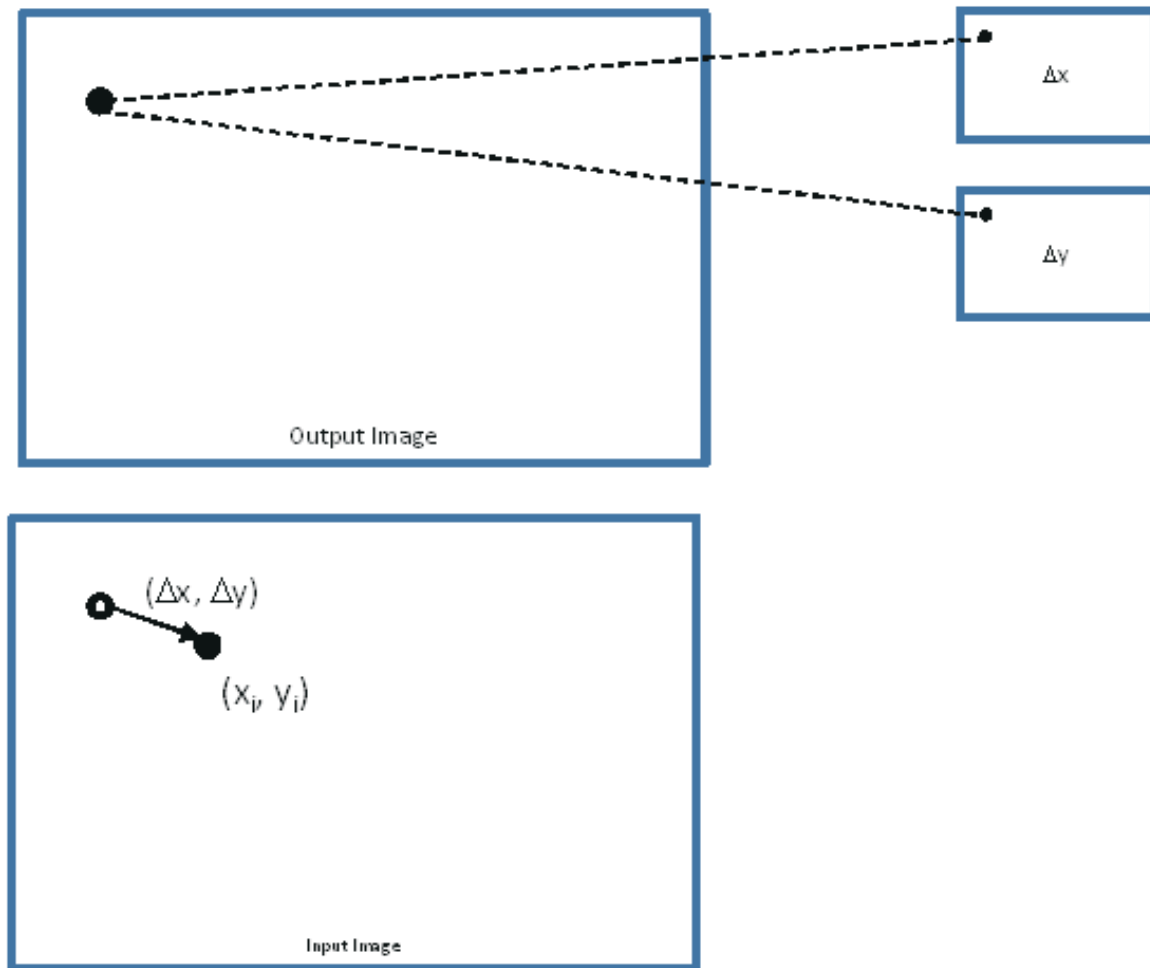

$$\begin{aligned} x_i &= x_o + \Delta x \\ y_i &= y_o + \Delta y \end{aligned}$$

$$\begin{aligned} x_o, y_o &: \text{U16Q3} \\ x_i, y_i &: \text{U16Q3} \\ \Delta x, \Delta y &: \text{S16Q3} \end{aligned}$$

ldc-023

Figure 6-106. LDC Lens Distortion Back Mapping Offset Calculation

Graphically, this procedure is shown in [Figure 6-107](#).

ldc-024

Figure 6-107. LDC Back Mapping Procedure Using Offset Table

The input coordinate (x_i, y_i) refers to final input frame co-ordinates and is used to fetch the appropriate input pixels for interpolation. The interpolation procedure is described in . Before fetching $data(x_i, y_i)$, is clipped to the input frame boundary.

6.7.4.2.7.1 LDC Mesh Table Storage Format

The size of the mesh table is dependent on the Total output frame size. The size must be:

$$\text{Table Width} = \text{CEIL}((\text{Mesh Frame Width})/2^M) + 1 \quad (15)$$

$$\text{Table Height} = \text{CEIL}((\text{Mesh Frame Height})/2^M) + 1. \quad (16)$$

Mesh frame width and height are specified by registers: VPAC_LDC_MESH_FRSZ[13-0] W and VPAC_LDC_MESH_FRSZ[29-16] H. The downsampling factor, M, is specified by register VPAC_LDC_MESHTABLE_CFG[2] M.

The mesh table should be stored with delta(x) and delta(y) offsets interleaved and stored in raster order. Each offset is S16Q3, so a table entry is 32-bits, including both delta(x) and delta(y). The location of the mesh table is configured by registers VPAC_LDC_MESH_BASE_H and VPAC_LDC_MESH_BASE_I. The buffer width (\geq Table Width), is provided by VPAC_LDC_MESH_OFST[15-0] OFST. The mesh table must be aligned on a 16-byte boundary.

6.7.4.2.8 LDC Pixel Interpolation

In UYVY and NV12 mode, the pixel interpolation type can be set to bi-cubic interpolation for best quality or bilinear interpolation for faster performance.

As the coordinates (h_d, v_d) calculated by the back-mapping function are not generally integer values, bi-cubic or bilinear interpolation is applied to the distorted pixels.

Depending on register configuration, bi-cubic or bilinear interpolation is used to interpolate the output Y pixels:

- VPAC_LDC_CFG[6] YINT_TYP = 0, bi-cubic interpolation for Y, bilinear for other components
- VPAC_LDC_CFG[6] YINT_TYP = 1, bi-linear interpolation for all components

In the case of bi-cubic interpolation, the distorted pixel is interpolated from the 16 Y pixels in the 4 x 4 grid around the distorted location, as shown in [Figure 6-108](#). Bi-cubic interpolation is used first along the horizontal direction, then the vertical direction.

Figure 6-108. LDC Bi-cubic Interpolation for Y

If bi-linear interpolation is selected, the distorted pixel is interpolated from the four Y pixels in the 2 x 2 grid around the distorted location, as shown in [Figure 6-109](#).

Figure 6-109. LDC Bi-linear Interpolation for Y

For Cb and Cr components, simple bilinear interpolation is used. Each distorted pixel is interpolated from the four same-color pixels on the 2 x 2 grid around the distorted location. For UYVY data, the Cb/Cr grid is not square, but is 2x wider compared to the height. This is shown in [Figure 6-110](#).

Figure 6-110. LDC Bilinear Interpolation for CB/Cr in UYVY and NV12 Format

6.7.4.2.9 LDC Buffer Management

Nonlinear nature of the Back Mapping suggests 2-D processing to make more efficient use of external memory bandwidth. Since the mapping computation is non-trivial, the hardware requires the software to provide a number of data management parameters to assist hardware with data transfers.

6.7.4.2.9.1 LDC Buffer Management

Once mesh block fetch is completed, final input co-ordinates are calculated by applying back mapping on previously calculated perspective warp corner pixel co-ordinates. Additional padding is applied on top of these back mapped corner co-ordinates based on the interpolation type.

The LDC processes a block of VPAC_LDC_OUT_BLK SZ[7:0] OBW x VPAC_LDC_OUT_BLK SZ[15:8] OBH (output block width by output block height) pixels at a time in a raster-scan order throughout the image. OBW is constrained to be a multiple of a base width, depending on the operating mode. This is described in [Table 6-116](#). OBH should be even. The LDC uses four corners of the output block plus some padding to fetch the input block. Due to extreme scenarios, there will be scenarios where above bounding box calculated by hardware doesn't cover all the input data required to generate particular output block. To cover those cases, software needs to supply additional PixelPad, the amount of padding in input block in all directions. Software must supply OBW, OBH, and VPAC_LDC_OUT_BLK SZ[19:16] PIXPAD, the amount of padding in input pixels. Software must guarantee that, for EVERY output pixel in the OBW x OBH output block, the input pixels required are bounded by back mapping of the four corners plus/minus the padding. More precisely, the input block is determined by:

- $IBX_start = \min(\text{truncate}(\text{distortx}(\text{corner1})), \text{truncate}(\text{distortx}(\text{corner3}))) - \text{HwPad} - \text{PixelPad}$
- $IBX_end = \max(\text{truncate}(\text{distortx}(\text{corner2})), \text{truncate}(\text{distortx}(\text{corner4}))) + \text{HwPad} + \text{PixelPad}$
- $IBY_start = \min(\text{truncate}(\text{distorty}(\text{corner1})), \text{truncate}(\text{distorty}(\text{corner2}))) - \text{HwPad} - \text{PixelPad}$
- $IBY_end = \max(\text{truncate}(\text{distorty}(\text{corner3})), \text{truncate}(\text{distorty}(\text{corner4}))) + \text{HwPad} + \text{PixelPad}$

where corner1, corner2, corner3, and corner4 are upper-left, upper-right, lower-left, and lower-right corners of the OBW x OBH output block, and distortx(.), distorty(.) are X and Y distorted coordinates of the corners. Distorted coordinates computed by the back-mapping process described in [Section 6.7.4.2.7, LDC Lens Distortion Back-Mapping](#). [Figure 6-111](#) shows the input block bound calculation. [Table 6-116](#) lists the OBW requirements.

Figure 6-111. LDC Input Block Bound

Table 6-116. LDC OBW Requirements

Data Format	OBW must be a multiple of
YUV422	8
YUV420	8

Typically for geometric distortion, the LDC_BLOCK[19:16] PIXPAD bit field must be 4 to accommodate neighbor sets for all colors. Software must set the PIXPAD bit field correctly.

OBH and OBW must be large enough for efficient operation of the lens distortion operation. As shown in [Table 6-116](#), OBW is constrained to ensure efficient external memory write. Another constraint is that input block size, $(IBX_end - IBX_start + 1) \times (IBY_end - IBY_start + 1)$, for EVERY input block of the image, must fit the allocated input buffer. These parameters must not be specified pessimistically (OBH, OBW too small, or PixelPad too large). Pessimistic parameter setting degrades performance and incurs unnecessary external memory transfer.

The LDC can process a portion of the image, rather than the entire image. This saves time by letting an image process through multiple software/LDC interactions to correct only a portion of the image (See Multi-pass Frame processing).

An intermediate event, *hts_tdone*, is also provided on completion of each macro block output write. This allows the LDC operation to be pipelined with other tasks. The LDC output write stall after this event, waiting for a pulse on the *hts_tstart* signal to begin writing the next macro block.

6.7.4.2.10 LDC Multi Region with Variable Block size

Distortion in wide angle lenses causes output block size to be very small due to extreme scaling in particular regions of the Image. This could be caused by high field-of-view or viewing position. The range of “Ratio of Output block to input pixel block size” is very high across the frame.

In order to solve this, LDC supports dividing the frame into multiple regions and output block size can be programmed independently for each region. Frame can be divided up to 9 regions. Frame can be divided into maximum of three slices horizontally and maximum of three slices vertically as shown in Figure 6-112. All the regions in a vertical slice share the common horizontal start location and all the regions in a horizontal slice share the common vertical start location. Width of vertical slices can be configured using VPAC_LDC_REGN_W12_SZ[13-0] W1, VPAC_LDC_REGN_W12_SZ[29-16] W2 and PAC_LDC_REGN_W3_SZ[13-0] W3 register fields. Height of horizontal slices can be configured using VPAC_LDC_REGN_H12_SZ[13-0] H1, VPAC_LDC_REGN_H12_SZ[29-16] H2 and VPAC_LDC_REGN_H3_SZ[13-0] H3 register fields.

ldc-026

Figure 6-112. LDC Variable Block Size with Multiple Regions

Hardware will process the each region as independent frame, hence processing of the pixels will in 2D sequence with in the region. Up on completing processing of one region, it will process next region in raster direction.

6.7.4.2.10.1 LDC Region Skip Feature

In surround view use case, some regions of the frame won't be used for stitching of final frame. By programming VPAC_LDC_REGION_CTRL_j[0] ENABLE to low, hardware will skip the processing of particular region.

Note

Hardware has to make sure that FRAME_DONE information to LSE is generated on last pixel of last valid region.

As an example shown in [Figure 6-113](#), Region-5, 7 and 8 are skipped for processing. FRAME_DONE is passed on last pixel of Region-6. Ordering and numbering of the regions will remain the same even in the case of skipping some regions.

Idc-027

Figure 6-113. LDC Region Skipping Example

6.7.4.2.10.2 LDC Support for sub-set of 3x3 regions

HW supports dividing the frame into sub-set of 3x3 regions. Following combinations of regions are supported.

- 3 vertical slices
 - $RW1 = x$, $RW2 = y$ and $RW3 = z$
- 2 vertical slices
 - $RW1 = x$, $RW2 = y$ and $RW3 = 0$
 - Last region width has to be zero
- 1 vertical slice
 - $RW1 = x$, $RW2 = 0$ and $RW3 = 0$
 - Last two regions width has to be zero
- 3 horizontal slices
 - $RH1 = x$, $RH2 = y$ and $RH3 = z$
- 2 horizontal slices
 - $RH1 = x$, $RH2 = y$ and $RH3 = 0$

- Last region height has to be zero
- 1 horizontal slice
 - $RH1 = x$, $RH2 = 0$ and $RH3 = 0$
 - Last two regions height has to be zero

As shown in Figure 6-114, 2x2 region partitioning can be done by programming $RW3=RH3=0$.

Note

Region numbering remains as in 3x3 region partitioning with R3, R6-R8 being null regions.

Idc-028

Figure 6-114. LDC 2x2 Region Partitioning Example

6.7.4.2.10.3 LDC Limitations of Multi Region Scheme

Following features can't be supported when multi region processing is enabled.

- Circular buffer support can't be enabled on Input data fetch
- HTS synchronization can't be enabled on Input data fetch
- LDC can't be joined with other HWAs in the VPAC. LDC output needs to be written to external memory.
- HTS can't make use of multiple BPR buffers available in SL2 circular buffer

6.7.4.2.10.4 LDC Multi Region Block Constrains

- $RW1+RW2+RW3$ must be equal to OFW
- $RH1+RH2+RH3$ must be equal to OFH
- SW to program the LSE buffer Stride, at-least the size of largest output block width among all regions.
- SW to program buffer height at-least twice the maximum block height among all regions

6.7.4.2.11 LDC Multi-pass Frame processing

The LDC can process a portion of the image, rather than the entire image. This saves time by letting an image process through multiple software/LDC interactions to correct only a portion of the image.

An intermediate interrupt can occur after processing each macro block. This lets the LDC operation be pipelined with other tasks.

To process only a portion of the image, the following parameters are required:

- VPAC_LDC_INITXY[12:0] INITX: X coordinate of upper-left corner of output frame
- VPAC_LDC_INITXY[28:16] INITY: Y coordinate of upper-left corner of output frame

- VPAC_LDC_INPUT_FRSZ[13:0] W: Width of output frame
- VPAC_LDC_INPUT_FRSZ[29:16] H: Height of output frame
- FrameBase SDRAM address of upper-left corner of output frame (Y and Cb/Cr base needed in case of YCbCr420)
- FrameOfst SDRAM frame width (in bytes)

Figure 6-115 is an example of multiple-pass processing with middle-of-the-image skipped.

Figure 6-115. LDC Multiple-Pass Correction Example

The LDC does not copy skipped blocks from the input frame to the output frame (necessary task unless output frame = input frame); software must set up and initiate this memory copy.

A note on in-place operation to conserve external memory: Depending on the offset table and configuration parameters, it may not be feasible to point the output image at the input image and have corrected pixels overwriting the source image. Software must determine whether it is feasible to overwrite, and allocate a separate frame buffer when it is not feasible. The LDC does not care if the input and output image pointers coincide, nor does it check any dependency violations.

The starting address of the input frame, corresponding to input coordinate (0, 0), is specified in the LDC_RD_BASE[31:0] RBASE bit field and offset in the LDC_RD_OFST[15:0] ROFST bit field ((Y and Cb/Cr base required for YCbCr4:2:0: LDC_420C_RD_BASE[31:0] RBASE)). The LDC does not clips input block to input frame size if any of the input block falls outside the input frame.

Note

- Any number of input blocks CAN fall partially or totally outside the input frame by assuming coordinates that are outside valid range (negative or exceeding maximum image width defined by the line offset).
- If any output pixel refers to any input pixel outside the input frame, the computed value for that output pixel would be same as neighbor pixel which falls into valid input frame. The other output pixels can still have correct outcomes.

6.7.4.2.12 LDC Input/Output Data Formats

captures valid number of LDC input and output data mode/format combinations.

Output data mode will be same as input data mode except when input data is 422, output data can also be converted to 420.

The following list contains the register fields used to configure data modes and formats:

- Input data mode - VPAC_LDC_CTRL[-3] IP_DATAMODE
- Input data format - VPAC_LDC_CTRL[] IP_DFMT
- Output Luma data format – VPAC_LDC_LSE_BUF_CFG_j (j = 0, 2) PIX_FMT_PW
- Output Chroma data format – VPAC_LDC_LSE_BUF_CFG_j (j = 1, 3) PIX_FMT_PW

The sample grid for YCbCr 422_UYVY is shown in [Figure 6-116](#).

ldc-029

Figure 6-116. LDC Sample Grids for UYVY

UYVY data are stored in 8-bit per color components as shown in [Table 6-117](#).

Table 6-117. LDC UYVY 8-bit Per Color Components

31			0
Y(1)	Cr(0)	Y(0)	Cb(0)

The sample grid for YUV420 NV12 is shown in [Figure 6-117](#).

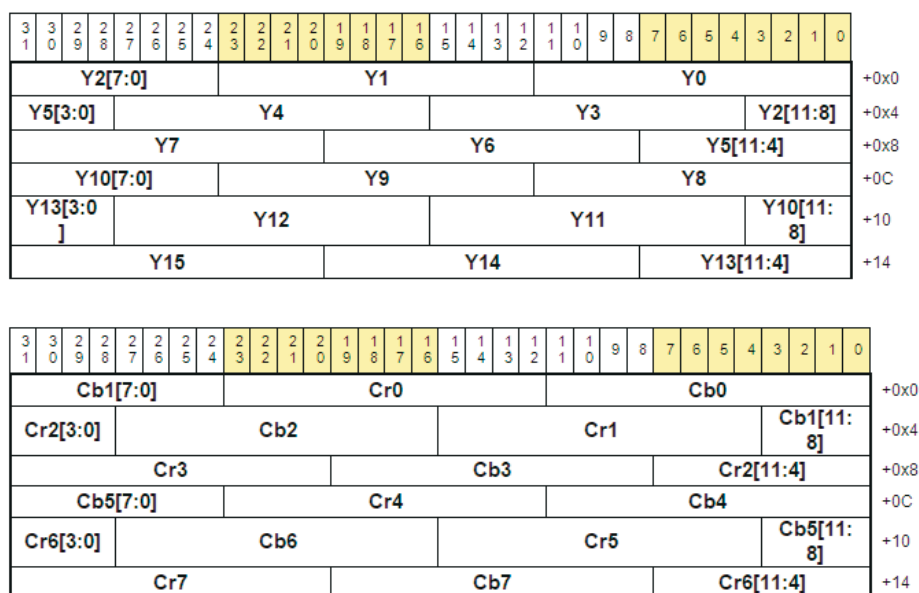

Idc-029

Figure 6-117. LDC Sample Grids for NV12

YCbCr 420 data are stored 8-bit per color components, and in two planes, Y by itself and Cb/Cr interleaved as shown in [Table 6-118](#)

Table 6-118. LDC YCbCr 420 data stored 8-bit per color components

31			0
(Y plane) Y(3)	Y(2)	Y(1)	Y(0)
(Cb/Cr plane) Cr(2)	Cb(2)	Cr(0)	Cb(0)

Idc-031

Figure 6-118. LDC YUV420 (2-plane 12-bit Fully Packed Format)

6.7.4.2.13 LDC YUV422 to YUV420 Conversion

Supporting input YUV422 format enables external sensors providing the YUV data directly. YUV422 to YUV420 conversion is done after pixel interpolation and achieved by dropping odd Chroma lines in the block. This retains the Chroma co-sited relation with Luma as at LDC input.

Idc-032

Figure 6-119. LDC YUV422 to YUV420 Conversion

6.7.4.2.14 Independent Channel Control

Some of the applications require high bit depth (up to 12-bit) for Luma but 8-bit is sufficient for Chroma data. This can be achieved by configuring independent Chroma data format parameter. Independent parameters are enabled by setting `CTRL.CH_CHANCTRL_EN`. This can be enabled when Luma and Chroma are stored in separate buffer (i.e. all the data modes except `422_UYVY` mode).

When `CTRL.CH_CHANCTRL_EN` is high, following parameters will take effect and all parameters should be programmed even if they have same value as Luma counterpart.

- `CTRL.CH_IP_DFMT` – Chroma Data format
- `CH_RD_OFST.OFST` – Chroma buffer Read Offset (aka Stride)
- `CH_RD_OFST.MOD` – Chroma Circular Buffer Height
- `HYBD_CHCBUFF_PARAM` – Chroma Hybrid addressing parameters

Following Input data control parameters are common between Luma and Chroma.

- `CTRL.HYBD_ADDREN` – Input Hybrid addressing Enable
- `CTRL.IP_CIRCEN` – Input Circular buffer Enable (CBuff height is independent)
- `IBUF_PIX_START` – Input buffer Start Co-ordinates

In 422 and 420 modes, Chroma is sub-sampled compared to Luma. In RGB data, all three color components are present at full resolution (i.e. no sub-sampling). To process RGB 2 new data modes are introduced. RGB data can be processed `Y1_Y2` data mode as 2 pass solution; with 2 of 3 RGB color components processed in `Y1_Y2` mode and other one in `420_Y` mode. In `Y1_Y2` data mode, Y1 and Y2 stored in separate buffers. RGB can be processed in single pass in `Y1_Y2Y3` mode with Y1 in one buffer and interleaved Y2Y3 separate buffer.

6.7.4.2.15 LDC SL2 Interface (LSE)

LDC Output write interface is handled by LSE sub-module. LSE (Load Store Engine) module is a common component integrated in VPAC to perform data load and store tasks on the SL2 memory for the HWA algorithm core.

VBUSP interface is be used to transfer the data from LDC Core to LSE.

For more LSE details, see *Load Store Engine (LSE)*.

6.7.4.2.15.1 LDC PSA (Parallel Signature Analysis)

LSE integrates a CRC signature capture mechanism on each output channel data to verify the integrity of the HWA's internal paths. When enabled, every valid pixel data from the CORE is sampled by a CRC module to update the signature for the channel before the data is packed and sent to the SL2 buffer. Note that data used for PSA is raw data from the CORE rather than data written into SL2 with container alignment. For LDC, PSA signature is calculated in the same order as CORE data transfer to LSE which is 3D block order as against frame order. At the end of frame condition, the final signature is saved in a separate read-only signature register (`VPAC_LDC_LSE_PSA_SIGNATURE_y y=0.#_of_Output Channel-1`) till the next end of frame condition for software to read and compare it against the golden reference signature. The read-only register keeps the last saved value until a reset (set to 0) or is replaced by another frame data signature.

6.7.4.2.16 LDC LUT Mapped Dual Output

LDC produces parallel 8-bit and 12-bit outputs to support surround view and ADAS applications concurrently. LDC produces parallel 8-bit output from 12-bit input using LUT based implementation. This 8-bit output is written into SL2 using LSE output channels (channel[2] for Luma and channel[3] for Chroma). Though use case requires 8-bit output, hardware is designed to be generic which supports any 8-12bit to 8-12bit conversion.

12 or 8 bit generated by data interpolation block is mapped to 8 to 12 bits using a LUT based mapping. The LUT is similar to the LUTs used in VISS and is a linear LUT with 513 entries.

The LUTs are sized to provide 513 locations of data, to enable linear interpolation for all locations. The internal weights are sized as 3 bits since the maximum delta between 2 steps is only $4095/512 = 8$. The logic is designed to scale for bit width and can support anything from 8 to 12 bits of input to support different use cases. However, since the step size is different depending on the input bit width, the bit selection and weight calculation logic is designed to account for that. LSE Shift operation can be instead of LUT to reduce bit width from 12 down to 8.

The input bit width (IN_BITDEPTH explained above) is specified using a dedicated register. Output is clipped to programmable clip value ($2^{\text{BitClip}-1}$). Combination of IN_BITDEPTH, LUT values and Clip value programming allows any 8-12bit to 8-12bit conversion.

6.7.4.2.17 LDC Band Width Controller

A Bandwidth Limiter is required to limit the mean BW that LDC can request over the VBUSM Read interface. The software sets the maximum allowed bytes per cycle in the register, VPAC_LDC_VBUSMR_CFG[27-16] BW_CTRL.

To determine the maximum allowed bytes per cycle, the software needs to know the configuration of LDC, which determines the maximum input block size. Given a specific configuration, the `ldc_findMaxInputBuffer` utility provided with the functional C model, can be used to give the maximum input block size. The performance requirements determine the maximum number of cycles allowed per block.

6.7.4.2.18 LDC Input Block Fetch Limit

In order to limit the band width hogging by LDC in case of wrong mesh table data, maximum amount of input block pixel data being fetched will be capped at maximum internal memory available for respective data.

In YUV420* modes, limit is imposed by Luma data. Pixel data fetch is stopped on detecting the overflow condition and interrupt event is generated. Maximum of 2 requests can be issued upon overflow detection. In case of mesh data, only interrupt event is generated on detecting overflow condition and there is no stalling of fetch. These events are generated for the first overflow case per frame.

6.7.4.2.19 LDC HTS Interface

The HTS interface is used to synchronize between blocks in VPAC Subsystem. In the case of LDC, it controls the start of LDC operation by issuing `hts_init`. LDC will be waiting for `hts_init` once it is enabled, so LDC is expected to be enabled before issuing `hts_init`.

HTS also controls the LDC output write which will indirectly control all LDC operations (that is, fetch and processing). LDC will start writing output pixel data when only it receives `hts_tstart` for that particular block. Once all output data is written, LDC will generate `hts_tdone` (also `hts_eop` if it is last block of the frame).

6.7.4.2.20 LDC VBUSM Read Interface

VBUSM Read interface has following features

- Data Width – 128 Bit
- Address width – 48 Bit
- Maximum of number of Tags – 32
 - Design can be constrained to use lesser number of Tags
- Maximum Command Size: Programmable
 - 32/64/128/256 Bytes
 - Command will split at maximum command size address boundary
- Chanid Encode: `chanid[1:0]` identify the source/type of the data interface is requesting. `Chanid[11:2]` is tied low.

- Chanid[1:0] decoding
 - 00 – Mesh Data.
 - 01 – Luma data
 - 10 – Chroma data

6.7.4.2.21 Partial Input Frame Storage

LDC can be used to generate images in variety of views. Depending on the use case, some parts of the input image are not used. In order to reduce on-chip memory size requirement in circular buffer mode, only required part of the image is stored. Starting co-ordinate of the stored frame can be configured in *IBUF_PIX_START* register. Default values on of (*StartX*, *StartY*) are zero making backward compatible with previous version (J7ES PG1).

Using programmable *StartY*, Circular buffer start can be aligned with image stored in the local memory. Due to 16-byte alignment requirement on Base address, following restrictions apply on *StartX*.

- 420/422SP/Y1_Y2/Y1_Y2Y3 mode
 - 8-bit format – Multiple of 16
 - 12-bit unpack format – Multiple of 8
 - 12-bit packed format – Multiple of 32
- 422_UYVY mode – Multiple of 8
 - 8-bit format – Multiple of 8
 - 12-bit unpack format – Multiple of 4
 - 12-bit packed format – Multiple of 16

Figure 6-120. Partial Image Buffer View of LDC

6.7.4.2.22 Hybrid Addressing

Circular buffer feature enables other VPAC HWAs feeding data directly to LDC. In this case, input data to LDC is stored on-chip to save BW primarily and latency from DDR. However, in some use cases, on-chip memory allocation won't be sufficient to store required circular buffer. By storing extreme distortion regions in DDR, on-chip circular buffer size requirement can be reduced. This requires hybrid addressing support where some part of image is stored in linear addressing buffer and rest is stored in circular buffer. Hybrid addressing can be enabled by setting *CTRL.HYBD_ADDREN*. Programmable initial and end range of the image can be stored in

linear addressing buffers. Start line of circular buffer is configured by *HYBD_CBUFF_PARAM.STARTLINE* and End line by *HYBD_CBUFF_PARAM.ENDLINE*. Image outside of this range is stored in 2 separate linear buffers.

Figure 6-121. Partial Image Buffer View of LDC

Linear buffers can be stored in independent addresses and each buffer has separate base address. Circular buffer enable should be set when hybrid addressing is enabled.

6.7.4.3 LDC Programmers Guide

6.7.4.3.1 LDC Programming Geometric Distortion Mode

Geometric distortions, barrel and pincushion distortion, can be corrected on UYVY and NV12 data formats. The Mesh based back mapping is used in this mode. An additional affine transform can be configured at the same time.

1. Check and wait for VPAC_LDC_CTRL[2] BUSY to become IDLE (0).

2. Set VPAC_LDC_CTRL[4-3] IP_DATAMODE for UYVY (0) or NV12 data (2). Program VPAC_LDC_CTRL[6-5] IP_DFMT to required data storage format.
3. Set VPAC_LDC_CTRL[1] LDMAEN = 1 to enable lens distortion back mapping.
4. Set the input frame base address in VPAC_LDC_RD_BASE_H / VPAC_LDC_RD_BASE_L registers. Note that the frame base address must be aligned on a 16-byte boundary. In case of YUV420, YUV422SP, Y1_Y2 and Y1_Y2Y3 modes, configure VPAC_LDC_RD_420C_BASE_H / VPAC_LDC_RD_420C_BASE_L registers for Chroma Data.
5. Set the input frame line offset in VPAC_LDC_RD_OFST[15-0] OFST.
6. If reading the input image from a circular buffer:
 - a. Set VPAC_LDC_CTRL[9] IP_CIRCEN = 1.
 - b. LDC computes the row number and applies modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in VPAC_LDC_RD_OFST[29-16] MOD register field. In YUV420 modes, the number of rows in the buffer is MOD/2. In others modes, the number of rows in the buffer is MOD for both Y buffer and Cb/Cr buffer.
7. Set the tile size in VPAC_LDC_REGION_OUT_BLKSZ_j[15-8] OBH and VPAC_LDC_REGION_OUT_BLKSZ_j[7:0] OBW. Note the constraints on OBW in [Table 6-116](#).
8. Set the pixel pad in VPAC_LDC_REGION_OUT_BLKSZ_j[19-16] PIXPAD.
9. Set the input frame size in VPAC_LDC_INPUT_FRSZ[29-16] H and VPAC_LDC_INPUT_FRSZ[13-0] W.
10. Set the output frame size in VPAC_LDC_MESH_FRSZ[29-16] H and VPAC_LDC_MESH_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
11. Set the output compute frame size in VPAC_LDC_COMPUTE_FRSZ[29-16] H and VPAC_LDC_COMPUTE_FRSZ[13-0] W.
12. Set the starting output point in VPAC_LDC_INITXY[12-0] INITX and VPAC_LDC_INITXY[28-16] INITY.
13. Configure SL2 Interface programming registers. Details of LSE configuration is captured in [Section 6.7.4.3.4](#).
14. Set the mesh offset table pointer to the correct address (VPAC_LDC_MESH_BASE_H / VPAC_LDC_MESH_BASE_I[31-0] ADDR and VPAC_LDC_MESH_OFST[15-0] OFST). Set the table down sampling factor for MxM down sampling in VPAC_LDC_MESHTABLE_CFG[2-0] M.
15. Set the Y plane interpolation type to bilinear or bi-cubic in VPAC_LDC_CFG[6] YINT_TYP.
16. If also using affine transform, set the six affine transform parameters in VPAC_LDC_AFF_AB.A, VPAC_LDC_AFF_AB.B, VPAC_LDC_AFF_CD.C, VPAC_LDC_AFF_CD.D, VPAC_LDC_AFF_EF.E, and VPAC_LDC_AFF_EF.F. If affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, and F = 0.
17. If also using perspective transform, enable VPAC_LDC_CTRL[7] PWARPEN and set VPAC_LDC_PWARP_GH[15-0] G and VPAC_LDC_PWARP_GH[31-16] H. If perspective transform is not used, disable VPAC_LDC_CTRL[7] PWARPEN and set VPAC_LDC_PWARP_GH[15-0] G = 0 and VPAC_LDC_PWARP_GH[31-16] H = 0.
18. Set VPAC_LDC_CTRL[0] LDC_EN = 1 to start the LDC operation.
19. Start the HTS init sequencing. LDC fetch/processing is gated with hts_init.
20. Wait for VPAC_LDC_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

6.7.4.3.2 LDC Programming Rotational Video Stabilization (Affine Transformation)

In the rotational video stabilization use case, consecutive frames capturing the same scene are aligned to minimize camera shake. Camera motions cause the frames to have translation or rotation differences. Thus, the frames need to be aligned to maintain a stable output video. The affine transform offers control to account for scaling, rotation, and translation transforms. For example, the rotation use case can be parameterized with the following affine transform parameters:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} a & b \\ d & e \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} c \\ f \end{bmatrix}$$

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} h_o - h_o \cos(\theta) - v_o \sin(\theta) \\ v_o - v_o \cos(\theta) - h_o \sin(\theta) \end{bmatrix}$$

ldc-035

where theta is the angle of rotation. In the scaling case, the affine transform uses:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} \alpha & 0 \\ 0 & \alpha \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} h_o(1-\alpha) \\ v_o(1-\alpha) \end{bmatrix}$$

ldc-036

where alpha is the scale factor. Translation uses an identity matrix along with the translation vector as the affine transform parameters, as in:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} T_h \\ T_v \end{bmatrix}$$

ldc-037

where T_h and T_v are the translation parameters. More complex transforms can be derived and the affine transformation is general so that optimization routines may be used to provide the best parameters to align two frames. In all affine transforms, the perspective warp parameters, g and h , should be set to 0.

The following steps need to be performed by the application to initialize and run LDC to perform affine transform.

1. Check and wait for VPAC_LDC_CTRL[2] BUSY to become IDLE (0).
2. Set VPAC_LDC_CTRL[4-3] IP_DATAMODE and VPAC_LDC_CTRL[6-5] IP_DFMT to required data mode and format.
3. If lens distortion correction is performed at the same time as the affine transform, set VPAC_LDC_CTRL[1] LDMAPEN = 1. Otherwise, set VPAC_LDC_CTRL[1] LDMAPEN = 0.
4. Set the input frame base address in VPAC_LDC_RD_BASE_H / VPAC_LDC_RD_BASE_I. Note that the frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in VPAC_LDC_RD_OFST[15-0] OFST.
6. If reading the input image from a circular buffer:
 - a. Set VPAC_LDC_CTRL[9] IP_CIRCEN = 1.
 - b. If using row address, LDC computes the row number and applies a modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in VPAC_LDC_RD_OFST[29-16] MOD. In YUV420 modes, the number of rows in the Y buffer is MOD and the number of rows in the Cb/Cr buffers is MOD/2. In others modes, the number of rows in the buffer is MOD for both Y buffer and Cb/Cr buffer.
7. Set the tile size in VPAC_LDC_OUT_BLKSZ[15-8] OBH and VPAC_LDC_OUT_BLKSZ[7-0] OBW. Note the constraints on OBW in [Table 6-116](#).
8. Set the pixel pad in VPAC_LDC_OUT_BLKSZ[19-16] PIXPAD.
9. Set the input frame size in VPAC_LDC_INPUT_FRSZ[29-16] H and VPAC_LDC_INPUT_FRSZ[13-0] W.
10. Set the output frame size in VPAC_LDC_MESH_FRSZ[29-16] H and VPAC_LDC_MESH_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
11. Set the output compute frame size in VPAC_LDC_COMPUTE_FRSZ[29-16] H and VPAC_LDC_COMPUTE_FRSZ[13-0] W.
12. Set the starting output point in VPAC_LDC_INITXY[12-0] INITX and VPAC_LDC_INITXY[28-16] INITY.
13. Configure SL2 Interface programming registers. Details of LSE configuration is captured in [Section 6.7.4.3.4](#).
14. If the data format is NV12, set the 420 UV input plane base address in VPAC_LDC_RD_420C_BASE_H / VPAC_LDC_RD_420C_BASE_I. This address must be 16-byte aligned.
15. Set the mesh offset table pointer to the correct address (VPAC_LDC_MESH_BASE_H / VPAC_LDC_MESH_BASE_I and VPAC_LDC_MESH_OFST. Set the table down sampling factor for MxM down sampling in MESHTABLE_CFG.M.
16. Set the Y plane interpolation type to bilinear or bicubic in VPAC_LDC_CFG[6] YINT_TYP.
17. Set the six affine transform parameters in VPAC_LDC_AFF_AB.A, VPAC_LDC_AFF_AB.B, VPAC_LDC_AFF_CD.C, VPAC_LDC_AFF_CD.D, VPAC_LDC_AFF_EF.E, and VPAC_LDC_AFF_EF.F. If

affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, and F = 0.

18. Disable perspective warp transform with VPAC_LDC_CTRL[7] PWARPEN = 0. Set the two perspective transform parameters VPAC_LDC_PWARP_GH[15-0] G = 0 and VPAC_LDC_PWARP_GH[31-16] H = 0.
19. Set VPAC_LDC_CTRL[0] LDC_EN = 1 to start the LDC operation.
20. Start the HTS init sequencing. LDC fetch/processing is gated with hts_init.
21. Wait for VPAC_LDC_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

6.7.4.3.3 LDC Programming Perspective Transformation

Perspective transforms are used to align the image data of two different cameras viewing the same scene from different positions. It can also be used in the case of stereo image rectification to align the epipolar lines of the left/right image pair with their scan lines.

The following steps need to be performed by the application to initialize and run LDC to perform perspective transform.

1. Check and wait for VPAC_LDC_CTRL[2] BUSY to become IDLE (0).
2. Set VPAC_LDC_CTRL[4-3] IP_DATAMODE and VPAC_LDC_CTRL[6-5] IP_DFMT to required data mode and format.
3. If lens distortion correction is performed at the same time as the perspective transform, set VPAC_LDC_CTRL[1] LDMAPEN = 1. Otherwise, set LDMAPEN = 0.
4. Set the input frame base address in VPAC_LDC_RD_BASE_H / VPAC_LDC_RD_BASE_I. Note that the frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in VPAC_LDC_RD_OFST[15-0] OFST.
6. Set the tile size in VPAC_LDC_OUT_BLKSZ[15-8] OBH and VPAC_LDC_OUT_BLKSZ[7-0] OBW. Note the constraints on OBW in [Table 6-116](#).
7. Set the pixel pad in VPAC_LDC_OUT_BLKSZ[19-16] PIXPAD.
8. Set the input frame size in VPAC_LDC_INPUT_FRSZ[29-16] H and VPAC_LDC_INPUT_FRSZ[13-0] W.
9. Set the output frame size in VPAC_LDC_MESH_FRSZ[29-16] H and VPAC_LDC_MESH_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
10. Set the output compute frame size in VPAC_LDC_COMPUTE_FRSZ[29-16] H and VPAC_LDC_COMPUTE_FRSZ[13-0] W.
11. Set the starting output point in VPAC_LDC_INITXY[12-0] INITX and VPAC_LDC_INITXY[28-16] INITY.
12. Configure SL2 Interface programming registers. Details of LSE configuration is captured in [Section 6.7.4.3.4](#).
13. If the data format is NV12, set the 420 UV input plane base address in VPAC_LDC_RD_420C_BASE_H / VPAC_LDC_RD_420C_BASE_I. This address must be 16-byte aligned.
14. Set the mesh offset table pointer to the correct address (VPAC_LDC_MESH_BASE_H / VPAC_LDC_MESH_BASE_I and VPAC_LDC_MESH_OFST. Set the table down sampling factor for MxM down sampling in MESHTABLE_CFG.M.
15. Set the Y plane interpolation type to bilinear or bicubic in VPAC_LDC_CFG[6] YINT_TYP.
16. Set the eight perspective transform parameters in VPAC_LDC_AFF_AB.A, VPAC_LDC_AFF_AB.B, VPAC_LDC_AFF_CD.C, VPAC_LDC_AFF_CD.D, VPAC_LDC_AFF_EF.E, and VPAC_LDC_AFF_EF.F. If affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, F = 0, G = 0 and H = 0. Enable VPAC_LDC_CTRL[7] PWARPEN = 1.
17. Set VPAC_LDC_CTRL[0] LDC_EN = 1 to start the LDC operation.
18. Start the HTS init sequencing. LDC fetch/processing is gated with hts_init.
19. Wait for VPAC_LDC_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

6.7.4.3.4 LDC Programming LSE

Following provides the LSE general programming guideline.

It also captures an additional secondary specific use case configuration values for some registers.

- Frame Size = 1920x1080
- Output Block size = 64x32
- Luma data being consumed by MSC and Chroma is written out by UDMA
 - Block to line conversion done for Luma data via SL2.
 - Chroma data is written out at block level.

- Circular buffer size just to do ping-pong between LDC – MSC(Y) and LDC – UDMA(C)
 - 12-bit pixel data
1. Pixel Data Format
 - a. VPAC_LDC_LSE_BUF_CFG_j (PIX_FMT_PW, PIX_FMT_CNTRSZ, and PIX_FMT_ALIGN) parameters define the pixel output data format for this output channel.
 - b. Common data formats:
 - i. Fully packed 12-bit : PIX_FMT_PW=1, PIX_FMT_CNTRSZ=1, PIX_FMT_ALIGN=0
 - ii. 12-bit unpacked (MSB aligned) : PIX_FMT_PW = 1, PIX_FMT_CNTRSZ=2, PIX_FMT_ALIGN=1
 2. Output SL2 Circular Buffer Configuration
 - a. VPAC_LDC_LSE_BUF_ATTR0_j (buf_stride) – define the line stride size (must be 64 byte multiple)
 - i. VPAC_LDC_LSE_BUF_ATTR0_j[15-6] BUF_STRIDE = 2880 (1920 * 1.5)
 - ii. VPAC_LDC_LSE_BUF_ATTR0_j[15-6] BUF_STRIDE = 96 (64 * 1.5)
 - b. VPAC_LDC_LSE_BUF_ATTR0_j (cbuf_size) – define the size of the circular buffer in the SL2 (number of lines)
 - i. VPAC_LDC_LSE_BUF_ATTR0_j[24-16] CBUF_SIZE = 68 (2*OBH+4)
 - ii. VPAC_LDC_LSE_BUF_ATTR0_j[24-16] CBUF_SIZE = 64 (2*OBH)
 3. Output SL2 Circular Buffer 2D mode Configuration (applicable for LDC only - TBD)
 - a. VPAC_LDC_LSE_BUF_ATTR1_j (buf_blk_width) – defines the number of bytes equivalent to OBW (output block width) pixels.
 - i. VPAC_LDC_LSE_BUF_ATTR1_j.buf_blk_width = 96 (64*1.5)
 - b. VPAC_LDC_LSE_BUF_ATTR1_j (cbuf_bpr) – defines the number of 2D blocks per row in the SL2 circular buffer.
 - i. VPAC_LDC_LSE_BUF_ATTR1_j[25-16] CBUF_BPR_CHAN = 30
 - ii. VPAC_LDC_LSE_BUF_ATTR1_j[25-16] CBUF_BPR_CHAN = 1
 4. Base Address and Channel Enable:
 - a. VPAC_LDC_LSE_BUF_BA_j[23-6] ADDR – defines the SL2 base address of the Circular buffer for this output channel.
 - b. VPAC_LDC_LSE_BUF_BA_j[31] ENABLE – enables this output channel.

6.7.4.3.5 LDC Programming Restrictions and Special Cases

The following list of LDC programming restrictions should be considered:

1. VPAC_LDC_LSE_BUF_ATTR1_j[25-16] CBUF_BPR_CHAN supports 1023 number of block per row. Hence, with output block width of 8, maximum line size supported in SL2 memory is 8184 pixels.
2. In 422 mode, always program as data format as 8-bit (design does not select data format automatically based on mode)
3. Due to hardware limitations, make sure that input block size (height and width) does not cross 1023 (pixels/lines).
 - The hardware generates either PIX_IBLK_MEMOVF or MESH_IBLK_MEMOVF events in this case.
4. VPAC_LDC_CTRL[0] LDC_EN should be high before issuing hts_init.

6.7.5 VPAC Multi-Scaler (MSC)

6.7.5.1 MSC Overview

VPAC_MSC (VPAC Multi-Scaler, hereinafter simply referred to also as MSC) is a Hardware Acceleration (HWA) module in Vision Pre-processing Accelerator (VPAC). MSC supports two sets of multi-output scaling filters to accelerate generation of pyramid (Octave) and intra-octave scales required by Optical Flow processing and DSP vision algorithms.

6.7.5.1.1 MSC Features

- 10 scaled outputs independently mapped to 1 or 2 processing threads (any number up to 10 scaler outputs can be mapped to one thread, while the remaining scaler outputs can be mapped to the other thread)
- Programmable scaling engine:
 - Pyramid or intra-octave scale generation
 - $1x \sim x/4$ image downscaling
 - $1x$ generic separable convolution filtering
 - On-the-fly (OTF) or memory-to-memory (M2M) operation with line buffers in SL2 (thus, frame width not constrained by internal line buffer width).
- Polyphase filters:
 - 5-tap separable filter kernel structure
 - Programmable kernel sizes for vertical/horizontal filter (3, 4, or 5)
 - Polyphase implementation with support of 64 or 32 phases
 - Independent programming of vertical/horizontal filters with initial phase programming option
- Filter Coefficients (shared by all scalers):
 - Coefficients in signed 10-bit number (typically 1-bit integer with 8 fractional bits)
 - Programmable Coefficient shift size to set precision of coefficient number (shift size represents the fractional bit width)
 - 2 dedicated sets of 5-tap single phase filter coefficients (for example, Gaussian) for Pyramid (Octave) generation or custom convolution filtering.
 - 4 sets of 5-tap x 32 phase coefficients
 - Two can be combined to support 5-tap x 64-phase filters
 - First can be configured to hold additional 5-tap single-phase convolution filters for non-resizing application.
- Input/output format support:
 - Each thread can support the following input source formats:
 - One plane (uniform or interleaved format - Y, CbCr interleaved, R)
 - Each Input channel supports 8/12-bit pixel data in 8/12/16-bit pixel container with programmable LSB/MSB alignment
 - Each Output channel supports 8/12-bit pixel data in 8/12/16-bit pixel container with programmable LSB/MSB alignment
- Performance:
 - 1 cycle/pixel per plane
 - Input line skip for thread performing only pyramid-generation (50% less processing time)
- Other features:
 - Programmable Input and Output Region of Interest (ROI) (or clipping) for each scaler
 - Support for Vertical and Horizontal edge Padding (replication) for both luma/chroma data plane inputs
- Functional Safety Support: CRC frame data signature capture on all output channels for fault detection in the data path.

6.7.5.2 MSC Functional Description

6.7.5.2.1 MSC Functional Overview

VPAC_MSC consists of 10 programmable resizers performing multi-thread/multi-scaling operations (1-input to N-outputs and 1-input to M-outputs where $N+M$ is 10 or less). Each processing thread of MSC HWA reads its input plane data from a Shared Memory buffers (SL2) circular line buffers, performs multi-scaling operations (ratios between X and $0.25X$) on the selected thread channel input, and writes out results to SL2 circular line buffers. In case of OTF operation, the source data is generated from another HWA. In case of M2M operation,

the source data is read from the DDR memory. Data transfers from/to SL2 to/from external memory (or another HWA) are handled by VPAC level DMA controller with transfer request events coming from VPAC top level HWA Thread Scheduler (HTS), see *HWA Threads Scheduler (HTS)*.

A typical configuration of the MSC module uses one input plane data to generate 7 intra-octave scales and the next octave image. Multi-pass processing is then utilized to generate up to next 6 or 7 sets of scales/octaves. Since the resolution after each octave is essentially reduced by 4x, the performance requirement for generating an infinite number of scales is bounded by 1.33x of the base input image pixel rate. The second input can be used to enable a pyramid generation processing for another input data or a set of scales/pyramid generation for chroma data as long as the total number of scales needed by both threads is 10 or less. Each resizer in a processing thread can access any coefficient set.

Figure 6-122. Block Diagram of Multi-Scaler Filter Core

For details on MSC integration in VPAC, see [Section 6.7.2, VPAC Subsystem Level](#).

6.7.5.2.2 Resizer Algorithm Details

This section describes the algorithm details of the Horizontal and Vertical Down-Scaling engines.

6.7.5.2.2.1 Multiple Scales Generations

For a high number of scales needed by vision image processing algorithm (for example, 32 or more), there are many options in generating the multiple scales as shown in [Figure 6-123](#). Among the options, the “linear rescale from octave resolution” gives the best tradeoff in video quality and design simplicity. The MSC implements 1-to-N multi-rescaling (that is, from one base image to multi-intra-scales and the next octave image generation) as shown as option B in [Figure 6-123](#).

Figure 6-123. Multiple Scale Generation

6.7.5.2.2.2 Polyphase Filter

Both vertical and horizontal resizers in MSC hardware are implemented using a programmable Polyphase filter structure supporting 5-tap kernel with either 64 or 32 phases.

6.7.5.2.2.2.1 Interpolation/Resampling

Figure 6-124 illustrates the interpolation principle. The assumptions are that the input pixels are evenly spaced. The distance between each input pixel is assumed to be 1. The magnification ratio is given by $64/N$ and $p/64$ is the initial phase of the output data. The output pixels are evenly spaced as well. The distance between each output pixel is given by $N/64$ (in the example below, $N > 64$). The position of the n -th output pixel is given by $(n \times N + p) / 64$.

Figure 6-124. Interpolation Principle

Figure 6-125 illustrates the interpolation principle at the n -th output pixel (o_n) at position x_n . Interpolation method with m and d parameters, are described as:

$$m = \text{floor}((n \times N + p) / 64)$$

$$d = ((n \times N + p) / 64) - m$$

Figure 6-125 illustrates the concept when the filters are configured in 4-tap mode for non-integer rescaling (the first coefficient corresponding to O_{m-2} is set to zero).

Figure 6-125. Interpolation Process

Figure 6-126 illustrates another explanation of the concept of a Polyphase filter using a simple 2-tap linear filter in a design which supports 5 phases.

Figure 6-126. Polyphase Filtering

For each one of the 5 phases, the weights (or filter coefficients) are different and after the 5 phases the weights start repeating, see Figure 6-126.

Figure 6-127 depicts the architecture for the independent polyphase filter unit.

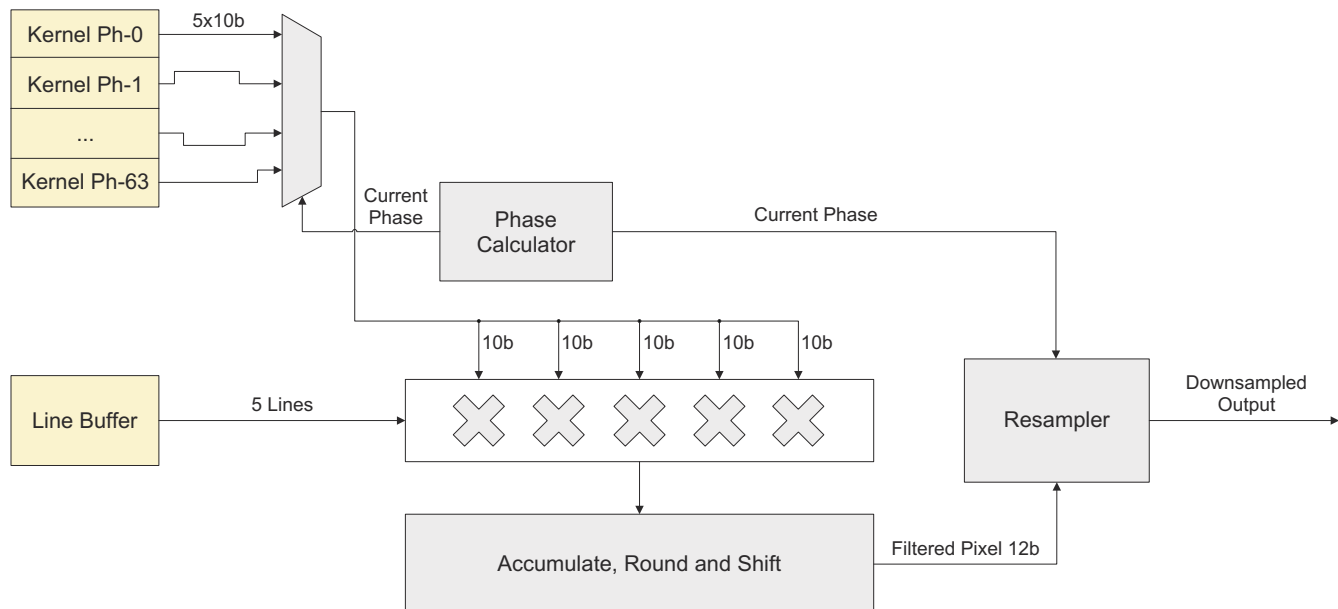

Figure 6-127. Polyphase Filter Unit

Both the horizontal and vertical filter described earlier are an instance of the Polyphase filter unit, though only the vertical filter requires line memories (implemented in SL2 memory space). In all, there will be 20 instances of the Polyphase filter unit, 2 filters per channel and 10 total channels in the VPAC_MSC module.

6.7.5.2.2.2 Phase Calculation and Re-sampler

The phase calculation block calculates the current phase which in turn is used for selecting the right coefficient set and for the output qualifier in the Re-sampler block. The Re-sampler engine then decides whether or not the output created by the interpolation unit is a valid output or not.

6.7.5.2.2.3 Shared Coefficient Buffers

The MSC module supports up to 4 sets of multi-phase coefficients for generic non-integer resizing and up to 10 sets of single-phase coefficients (5x1 entries) for Octave generation and integer resizing applications. The multi-phase coefficients can also be configured in one of two following options:

- 4 sets of 5-tap x 32 phase coefficients
- 1 set of 5-tap x 64 phase coefficients and 2 sets of 5-tap x 32 phase coefficients
- 2 sets of 5-tap x 64 phase coefficients

The 32 phase configuration option allows using independent coefficients for vertical and horizontal resizer to achieve aspect ratio change during the scaling.

6.7.5.2.2.4 Border Pixel Padding

The MSC module replicates missing lines and pixels at top/bottom and left/right sides of the input frame for non-interleaved (luma) and interleaved (chroma) data.

The missing lines at the top/bottom are replicated in the LSE sub-module prior to the vertical scaler and the missing pixels at the left/right sides of each line are replicated in the core prior to the horizontal scaler. For more information about LSE module, see *Load Store Engine (LSE)*.

Replication scheme simply repeats the edge line or pixel to create missing lines/pixels. [Figure 6-128](#) shows horizontal pixel replication.

Figure 6-128. Horizontal Pixel Replication

If a scaling is performed on a sub-frame (ROI) within the input frame, no replicated lines/pixels will be used since the lines/pixels outside the sub-frame are already present in the input frame.

For interleaved data format, the horizontal replication is done separately for U and V data. For U-data, edge U-pixel will be replicated. For V-data, edge V-pixel will be replicated. There is no distinction in the vertical edge padding.

6.7.5.2.2.3 ROI Handling

- ROI supported during scaling generation
 - Only one ROI at Input Frame and one ROI at Output frame per scale
 - ROI definitions (for input as well as all output scales) can be changed at every input frame under software control.
 - ROI for each scale (for output) can be different among scales (as well as with respect to the input). It is set under software Control.
 - The key purpose of ROI is DDR bandwidth reduction. There is additional help by reduction on processing power on DSP and hardware.
- The input ROI is a superset area considering following two scenarios.
 - Multiple ROIs in given Input Frame, if there are multiple ROI for input frame
 - Input Frame area from Overlapped ROI across scales

[Figure 6-129](#) shows an example of multiple ROIs in the source superset ROI area.

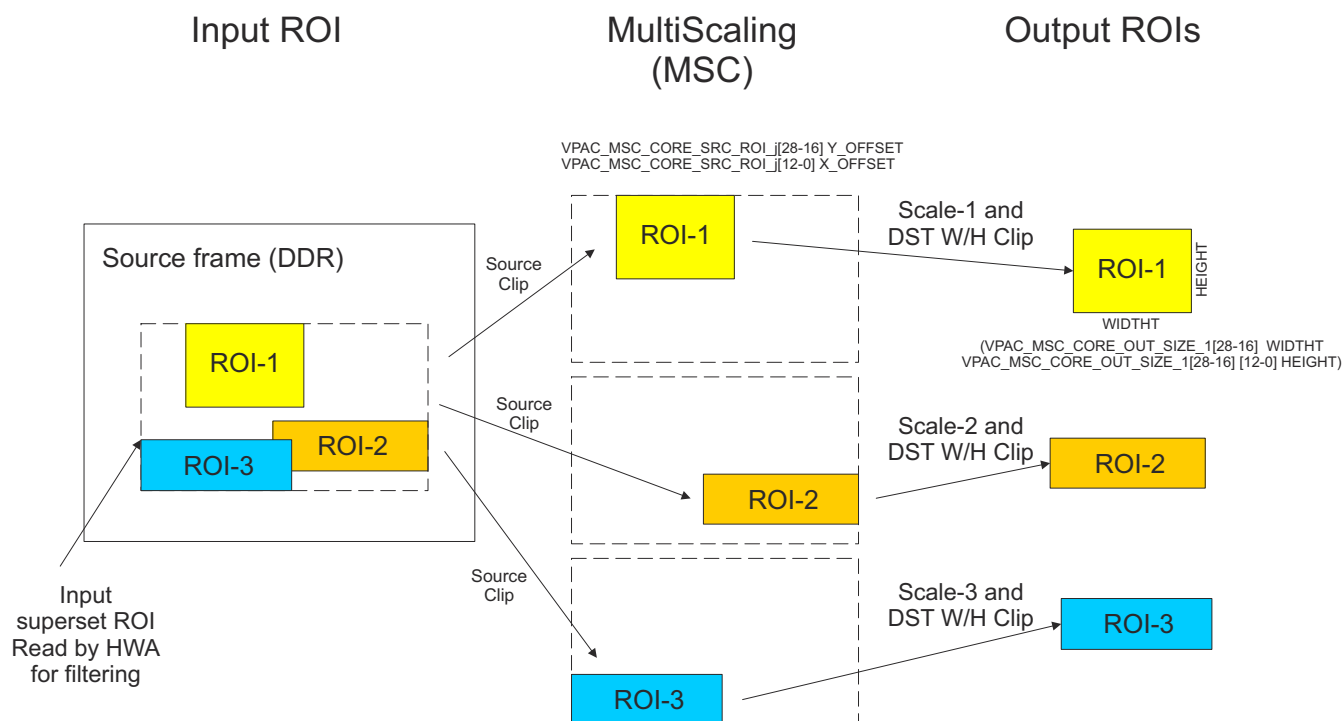

Figure 6-129. Multiple-ROI Support Illustration

Figure 6-130 illustrates another application of generating output ROIs with different scales from a common source region.

Figure 6-130. Multiple-ROI From a Common Source ROI

By defining output ROIs, only the data within ROI in the “superset ROI” scaled output image is saved thus reducing the DDR traffic significantly.

6.7.5.2.3 MSC Data Formats Supported

summarizes data format supported by MSC.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 6-127. Interrupts (continued)

Interrupt	Type	Description
VPAC_MSC_LSE_FR_DONE_EVT_1	Pulse	Frame Processing complete for all filters in the processing thread 1.
VPAC_MSC_LSE_SL2_RD_ERR	Pulse	Set whenever there is an error response on VBUSM read command request for any input channel
VPAC_MSC_LSE_SL2_WR_ERR	Pulse	Set whenever there is an error response on VBUSM write command request for any output channel

All interrupts are single pulse event signals that are mapped to the VPAC level interrupt aggregation logic. The MSC has no mask/set/clear registers for these events. For more information see [Section 6.7.2, VPAC Subsystem](#).

6.7.5.3.2 Interrupt Event Description

6.7.5.3.2.1 VPAC_MSC_LSE_FR_DONE_EVT_0/1 Events

These events are generated when all filters associated with the thread 0 or 1 complete the frame processing. This is set when input EOF (end of frame) event and output EOF (end of frame) events are detected.

6.7.5.3.2.2 VPAC_MSC_LSE_SL2_RD_ERR Interrupt Event

This event is generated whenever the VBUSM read status is something other than 0 (success).

The VPAC status register VPAC_MSC_STATUS_ERROR[4-0] VM_RD_ERR stores the last non-zero RSTATUS value and the input channel number for user to see what type of error has occurred on which channel.

Table 6-128. Encoding for RSTATUS

RSTATUS	Meaning
0	Success
1	Addressing error
2	Protection error
3	Timeout error
4	Data error
5	Unsupported Addressing Mode error
6	RESERVED
7	Exclusive read fail

6.7.5.3.2.3 VPAC_MSC_LSE_SL2_WR_ERR Interrupt Event

This event is generated whenever the VBUSM write status is something other than 0 (success).

The VPAC status register VPAC_MSC_STATUS_ERROR[14-8] VM_WR_ERR stores the last non-zero WSTATUS value and the output channel number for user to see what type of error has occurred on which channel.

Table 6-129. Encoding for WSTATUS

WSTATUS	Meaning
0	Success
1	Addressing error
2	Protection error
3	Timeout error
4	Data error
5	Unsupported Addressing Mode error
6	RESERVED
7	Exclusive write fail

6.7.5.4 MSC Submodule Details

The MSC_LSE (Load Store Engine) handles all interfacing to the SL2 memory space and performs following functions:

- Provides interface to SL2 circular buffers via a common VBUSM master interface
- Manages input and output channel updates in sync with HTS
- Provides data unpacking for core and packing for SL2 interface
- Manages LSE specific configuration registers

The MSC_CORE performs all filtering operations for various 2-in/10-out multi-scaling/multi-thread configurations. It has no direct connection to external interface and it works on a frame data coming in and out in raster scan order.

The internal data transfers between the MSC_LSE and MSC_CORE are done over VBUSP write-only streaming interfaces.

6.7.5.4.1 MSC Configuration Interface (MSC_CFG)

The CFG interface supports a standard 32-bit VBUSP slave interface for register configuration. The MSC configuration registers consist of LSE configuration registers and CORE filter configuration registers. A simple VBUSP switch (CBA SCR) is used to route VBUSP commands to these two configuration sub-modules.

6.7.5.4.2 MSC Load Store Engine (MSC_LSE)

6.7.5.4.2.1 MSC_LSE Overview

[Figure 6-131](#) shows the MSC_LSC block diagram.

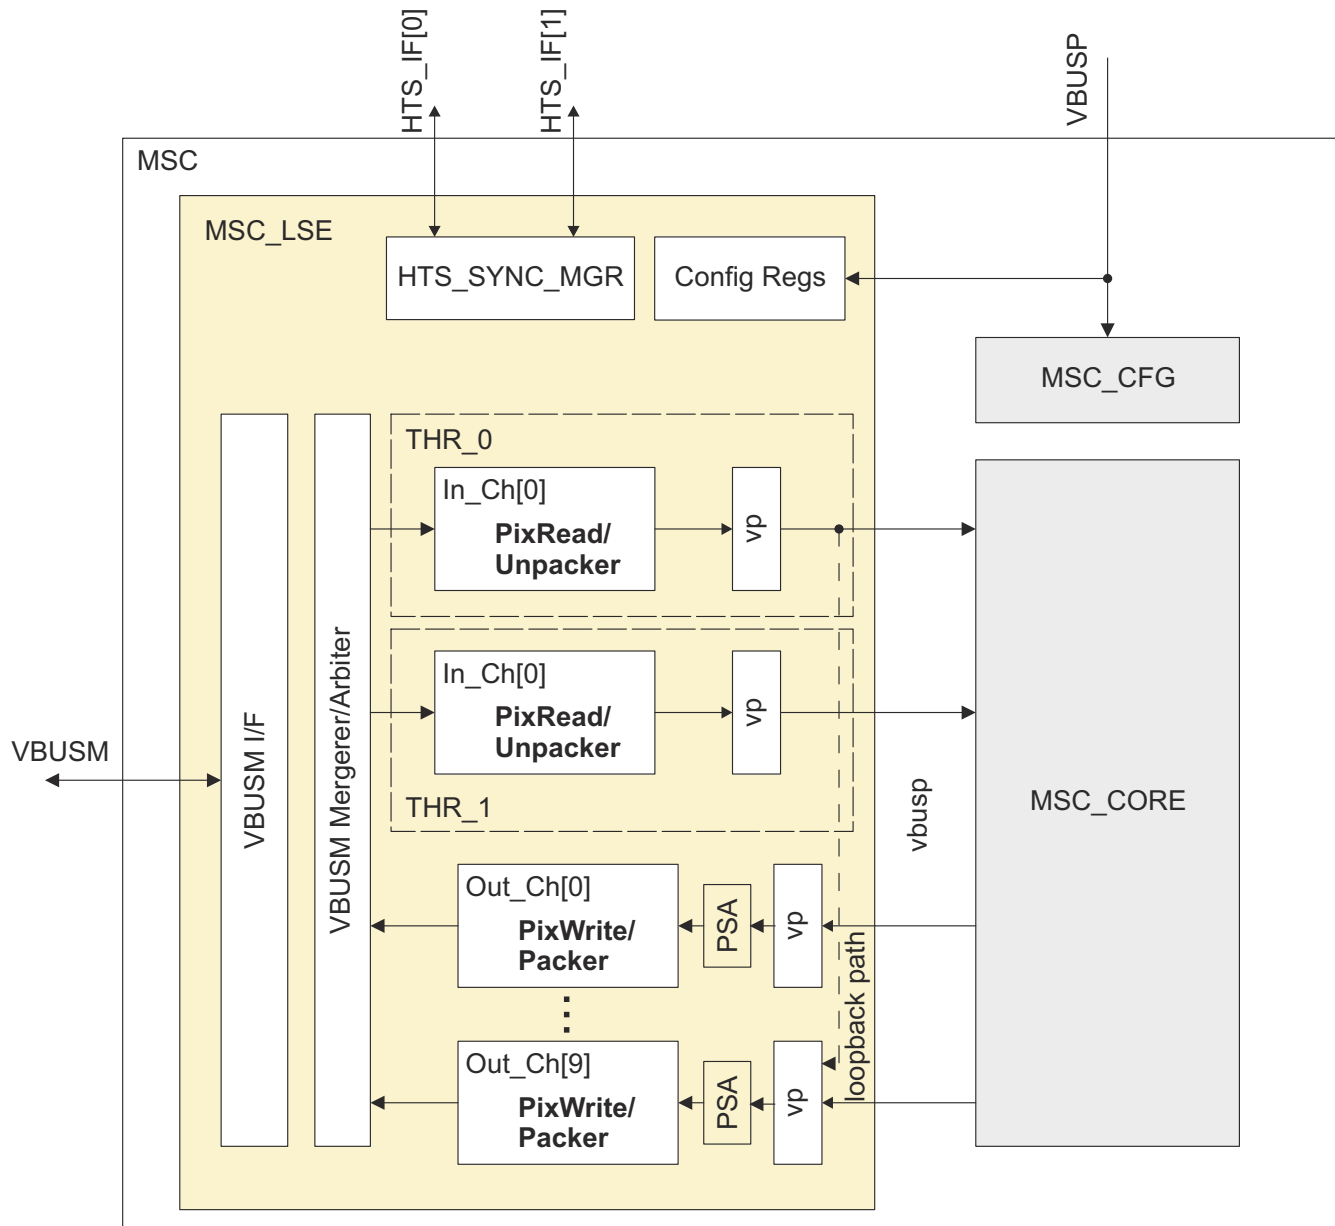

Figure 6-131. MSC_LSC Block Diagram

6.7.5.4.2.1.1 MSC_LSE Features

The MSC_LSE supports following VPAC_LSE features:

- Up to 2 processing threads supported (a thread is a processing chain with its own HTS start/done).
- Input channel features:
 - SL2 input channel per thread with following features for the input channel:
 - Single data plane support
 - 8/12 packed and 12-bit unpacked source format support
 - Up to 5 lines - input kernel height support
 - 1D addressing mode only with CBUF address handling
 - Input Line Skip Support
 - Vertical boundary Edge Padding (Replication only) support
 - Channel enable
- Output Channel Features:
 - Up to 10 SL2 output channels (pixel data output only)

- Single data plane support for each output channel
- Programmable thread mapping for each output channel
- 8/12 packed and 12-bit unpacked output pixel data format support
- 1D addressing mode support with CBUF address handling
- Channel enable
- Video frame data with frame sync signals (along with optional in-band control signals) over a separate vbusp streaming write-slave interface
- HTS synchronization support
- LSE internal data bypass mode support
 - Input channel 0 can be configured to bypass/loopback mode the data to the core and/or directly to the output channel 9 (bypassing the core).

6.7.5.4.2.2 MSC_LSE Internal Data Loopback Channel

The MSC_LSE provides a data loopback channel.

When enabled (VPAC_MSC_LSE_CFG_LSE[0] LOOPBACK_EN), the LSE sends the “loopback-enabled” input channel unpacked data directly to the designated output channel packing logic without going through the HWA_CORE. The looped back data can be packed in a different format in the output channel to perform a data format conversion or can be packed in the same format as the input.

When the loopback mode is enabled, the “loopback” designated output channel is no longer available for HWA_CORE output data transfer. But, the input channel can still operate normally to read in the data for the HWA_CORE (provided that the other output channel is used for transferring out the HWA_CORE output data) by setting VPAC_MSC_LSE_CFG_LSE[1] LOOPBACK_CORE_EN. In this mode, the input channel flow is throttled by both the core and the loopback data path.

The data flow of the loopback mode is also controlled by the HTS synchronization signals.

6.7.5.4.2.3 MSC_LSE PSA Support

As a safety function, LSE integrates a CRC signature capture mechanism on each output channel data to verify the integrity of the HWA internal paths. When enabled (VPAC_MSC_LSE_CFG_LSE[8] PSA_EN), every valid transfer frame data from the MSC is passed through a CRC module to update the signature for the channel before the data is packed and sent to the SL2 buffer. At the end of frame condition, the final signature is saved in a separate read-only signature register (VPAC_MSC_LSE_PSA_SIGNATURE_y[31:0] VAUE = 0,...,Number_of_Output_Channel-1) till the next end of frame condition for software to read and compare it against the golden reference signature.

The PSA signature register is based on the following IEEE 802.3 standard 32-bit CRC polynomial:

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The PSA module is inserted in the LSE data path as shown in [Figure 6-131](#).

6.7.5.4.2.4 MSC_LSE Feature Detailed Description

For detailed LSE feature description, see *Load Store Engine (LSE)*.

6.7.5.4.3 MSC_CORE (HWA Core)

The MSC_CORE (HWA_CORE) is configured as two multi-scaling engines each of which can perform 1-to many (multi) scaling operations on an independent input source. The number of outputs (scaler filters) assigned to each multi-scaling engine is user-configurable.

6.7.5.4.3.1 MSC_CORE Overview

[Figure 6-132](#) shows the architectural overview of the MSC_CORE. Each reconfigurable multi-scaling engine in the MSC_CORE receives its input frame data from its own dedicated VP (vbusp write only slave) interface. VP_IN_0 port is used for the thread #0 (multi-scaling engine-0) and VP_IN_1 port is used for the thread #1 (multi-scaling engine-1). The THREAD_MAP parameter of the MSC_LSE output channel configuration register (VPAC_MSC_LSE_DST_BUF_CFG_j[7] THREAD_MAP) controls which input port is connected to which scaling filter (filter_0 ~ filter_9).

Figure 6-132. MSC_CORE Block Diagram

The scaling filter implements the vertical-before-horizontal architecture in order to avoid intermediate result line buffers that would be needed in the horizontal-before-vertical configuration. This architecture also allows the source frame width to be not restricted by internal line buffer sizes.

Each scaling filter in the MSC_CORE consists of 5-tap (32/64-phase) Polyphase filter based vertical and horizontal resizers. At the input of each resizer, a ROI checker determines the input start position (that is, marks the input data as valid). Output of each resizer is then trimmed to the configured output size of the scaling filter in each respective direction.

For MSC, the vertical input edge padding is performed in the MSC_LSE while the horizontal input boundary padding is done within the MSC_CORE before the horizontal resizer.

6.7.5.4.3.2 Polyphase Filter of Vertical/Horizontal Resizers

6.7.5.4.3.2.1 Filter Data Path Logic

Figure 6-133 shows the micro-architecture of the polyphase filter data path. The 5-tap filter structure can be programmed to perform a 5-tap Gaussian filter (for Octave generation) or a 4-tap bi-cubic downscaling filter (for scale generation). Or, it can be configured to perform a custom convolution filter without resizing. Filter coefficients for any unused taps should be set to 0. For example, in case of a 4-tap filtering, C2(Fi) filter coefficient should be set to 0. For 3-tap filtering, C-2(Fi) and C2(Fi) filter coefficients should be set to 0.

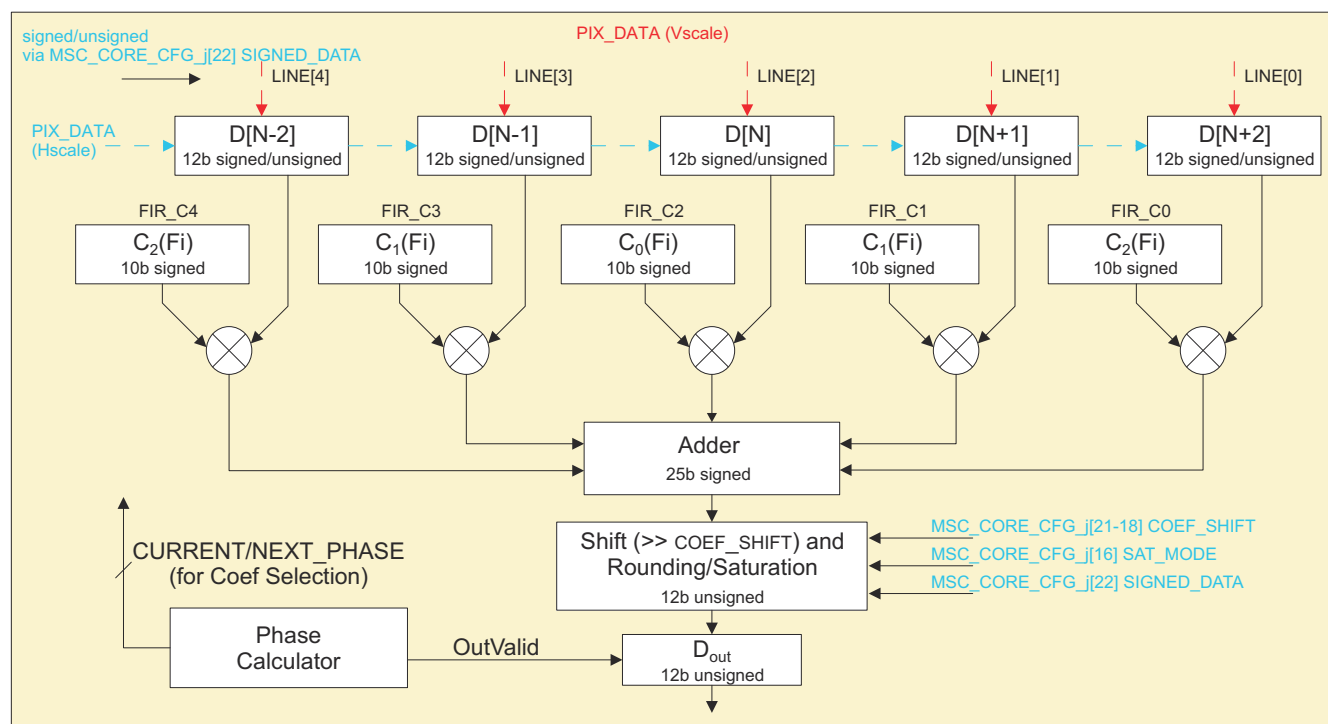

Figure 6-133. Polyphase Filter Micro-Architecture

Kernel Size Configuration

There is no separate configuration required to set the filter kernel size (number of taps) within the polyphase filter. The filter always works as a 5-tap filter but requires unused taps to be masked using the zero coefficients.

Coefficient Precision Selection

The precision of the coefficients is user-configurable using VPAC_MSC_CORE_CFG_j[21-18] COEF_SHIFT which determines the number of fractional bits of the coefficient.

Unsigned/Signed Data Type support

Typically for image resizing, the input and output data are in unsigned (positive) integer numbers in the range of [0..4095]. But, in some non-image convolution filtering (for example, Sobel filter), the input and

output data may be in signed integer data format. The MSC supports a user-selectable data type mode bit (VPAC_MSC_CORE_CFG_j[22] SIGNED_DATA) per resizer to specify whether the input/output data is in signed or unsigned data format. The selection determines the input range and output clipping limits as shown below:

VPAC_MSC_CORE_CFG_0[22] SIGNED_DATA = 0 -> [0..4095]

VPAC_MSC_CORE_CFG_0[22] SIGNED_DATA = 1 -> [-2048..2047]

Note that all filters in the same processing thread should have the SIGNED_DATA bit set to a same value.

Rounding Logic

The rounding is done by “adding 0.5 and dropping fractional bits”. This achieves the following:

For data ≥ 0 : “round to nearest, ties away from zero”

For data < 0 : “round to nearest, ties toward zero”

Output Saturation Logic

For some non-image unsigned data filtering, the result of the final adder could be negative numbers.

To avoid clipping all negative numbers to 0, the MSC filter data processing supports a mode (VPAC_MSC_CORE_CFG_j[22] SAT_MODE = 1) to offset the result by 2048 and then clip the final result to [0..4095] in the output saturation logic to preserve the full data range.

Edge Pixel Replication

Pixel replication in vertical direction (edge line replication) is done in the MSC_LSE.

Pixel replication in horizontal direction (edge pixel replication) is performed in the horizontal filter. For chroma data plane, Cb/Cr pixel replication is done independently with edge Cb/Cr data respectively.

6.7.5.4.3.2.2 Filter Phase Calculation

Figure 6-134 shows the polyphase filter phase calculation logic.

Each polyphase filter includes an accumulator (16b unsigned with 12b fractional bits) to support both the integer and fractional rate decimation filtering. ACC_INIT parameter, defined in VPAC_MSC_CORE_ACC_INIT_j registers for both for vertical and horizontal filtering, is used to initialize the initial phase of the filter. FIRINC parameter, defined in VPAC_MSC_CORE_FIRINC_j registers for both for vertical and horizontal filtering, is used to increment the accumulator after each valid output. The ACCUM, see Figure 6-134, is also decremented by 4096 (equivalent to 1 input sample period) after each valid input line/pixel.

The output of the filter is valid when the integer part of the ACCUM (bits[16-12]) is equal to 0 (meaning the center filter tap has the correct input data). Otherwise, the output of the filter is invalid and no data is written to the SL2 memory.

The fractional part is used to determine which coefficient phase to use. For 64-bit phase mode, COEF_PHASE_SELECT = ACCUM[11-6]. For 32-bit phase mode, COEF_PHASE_SELECT = ACCUM[11-7]. Additional fractional bits are included to minimize the input phase error.

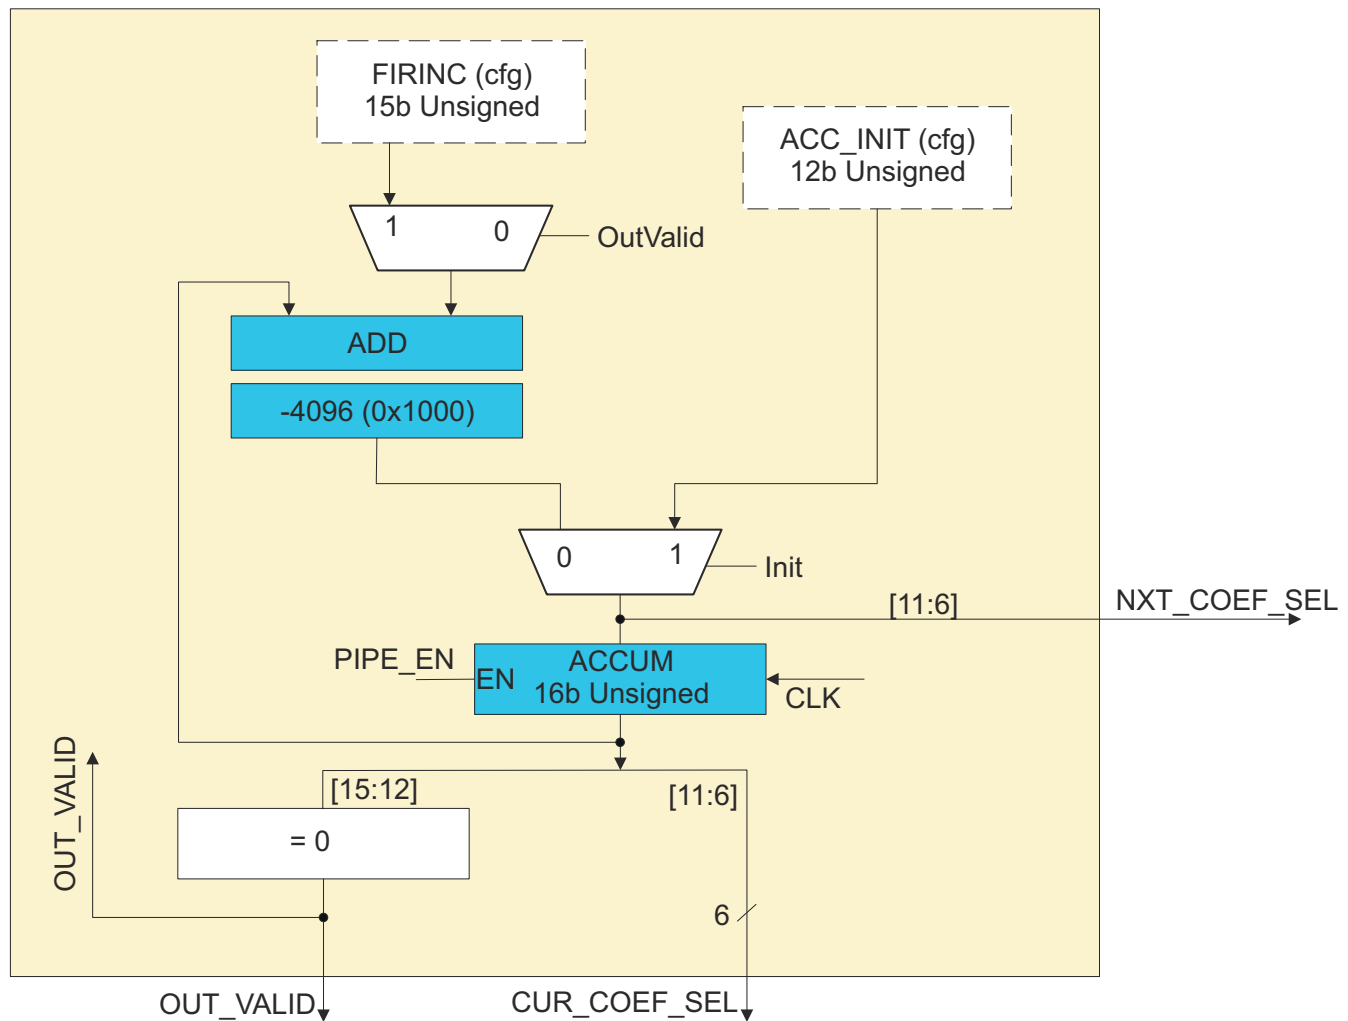

Figure 6-134. Polyphase Filter Phase Calculation Logic

NXT_COEF_SEL is used to pre-fetch the next coefficient from the table in order minimize the critical path delay (particularly for horizontal scaler in which coefficients change on every cycle).

6.7.5.4.3.2.3 Filter Parameters

Table 6-130 lists the parameters used to define the configuration of the resizing (downsampling) vertical/horizontal filters.

Table 6-130. Parameters of the Resizing (Downsampling) Vertical/Horizontal Filters

Parameter	Bit Precision	Description
FIRINC_V VPAC_MSC_CORE_FIRINC_j[30-16] VS	U15Q12 (Unsigned 15b number with 12-bit fraction)	Vertical Resizing Ratio value (vertical filter increment) Valid Range: 4096 (1x scaling) < FIRINC_V < 16384 (1/4x scaling) +1 in the above equation is optional. +1 forces non-repeating coefficients in integer ratio scaling cases.
FIRINC_H VPAC_MSC_CORE_FIRINC_j[14-0] HS	U15Q12 (Unsigned 15b number with 12-bit fraction)	Horizontal Resizing Ratio value (Horizontal filter increment) Valid Range: 4096 (1x scaling) < FIRINC_V < 16384 (1/4x scaling)
ACC_INIT_V VPAC_MSC_CORE_ACC_INIT_j[27-16] VS	U12Q12 (Unsigned 12b number with 12b fraction)	Initial Vertical Resizer Phase Valid Range: 0 < ACC_INIT_V < 4095

Table 6-130. Parameters of the Resizing (Downsampling) Vertical/Horizontal Filters (continued)

Parameter	Bit Precision	Description
ACC_INIT_H VPAC_MSC_CORE_ACC_INIT_j[11-0] HS	U12Q12 (Unsigned 12b number with 12b fraction)	Initial Horizontal Resizer Phase Valid Range: 0 < ACC_INIT_V < 4095

Additionally, [Table 6-131](#) lists the mode parameters defined the filter operation and coefficient selection.

Table 6-131. Filter Mode and Coefficient Selection via VPAC_MSC_CORE_CFG_j Registers

Parameter	Bit Width	Description
SIGNED_DATA VPAC_MSC_CORE_CFG_j[22] SIGNED_DATA	1-bit	Integer type of input and output frame data: 0 : Unsigned 12-bit (default) 1 : Signed 12-bit
UV_MODE VPAC_MSC_CORE_CFG_j[17] UV_MODE	1-bit	Source data interleave format: 0 - non-interleaved (Y data) 1 - interleaved (UV data)
SP_VS_COEF_SEL VPAC_MSC_CORE_CFG_j[15-12] SP_VS_COEF_SEL	4-bits	Single Phase – Vertical Filter Coef Selection N : 5-tap/32-phase Filter Coef Set #0 (Entry N) where N=0-9 10 : Gaussian Filter #0 11 : Gaussian Filter #1 12-15 : Invalid When FilterMode=0 and N <10, then the multi-phase coef set #0 is dedicated for one or more single phase filters.
SP_HS_COEF_SEL VPAC_MSC_CORE_CFG_j[10-7] SP_HS_COEF_SEL	4-bits	Single Phase – Horizontal Filter Coef Selection N : 5-tap/32-phase Filter Coef Set #0 (Entry N+10) where N=0-9 10 : Gaussian Filter #0 11 : Gaussian Filter #1 12-15 : Invalid When FilterMode=0 and N <10, then the multi-phase coef set #0 is dedicated for one or more single phase filters.
VS_COEF_SEL VPAC_MSC_CORE_CFG_j[5-4] VS_COEF_SEL	2-bits	Multi-phase Vertical Coef Selection 00 : 5-tap/32-phase Filter coef set #0 01 : 5-tap/32-phase Filter coef set #1 10 : 5-tap/32-phase Filter coef set #2 11 : 5-tap/32-phase Filter coef set #3
HS_COEF_SEL VPAC_MSC_CORE_CFG_j[3-2] HS_COEF_SEL	2-bits	Multi-phase Horizontal Coef Selection 00 : 5-tap/32-phase Filter coef set #0 01 : 5-tap/32-phase Filter coef set #1 10 : 5-tap/32-phase Filter coef set #2 11 : 5-tap/32-phase Filter coef set #3
PHASE_MODE VPAC_MSC_CORE_CFG_j[1] PHASE_MODE	1-bit	Filter Phase mode selection 0 - 64 phases 1 - 32 phases
FILTER_MODE VPAC_MSC_CORE_CFG_j[0] FILTER_MODE	1-bit	Filter Mode 0 – Single Phase Filter (for example, Gaussian Filter for Pyramid) 1 – Multi-phase Scaling Filter
FILT_SAT_MODE VPAC_MSC_CORE_CFG_j[16] SAT_MODE	1-bit	Filter Output Saturation Mode 0 - [0..4095] clipping 1 - [-2048.. 2047] clip followed by +2048 This parameter is used only when signed_data =0 (unsigned data type).

Table 6-131. Filter Mode and Coefficient Selection via VPAC_MSC_CORE_CFG_j Registers (continued)

Parameter	Bit Width	Description
COEF_SHIFT VPAC_MSC_CORE_CFG_j[21:18] COEF_SHIFT	4-bits	Coef Shift Size: configures the precision of the 10-bit signed filter coefficients (valid Shift range: 5~9) : 5: Shift by 5 (5-bit fraction) 6: Shift by 6 (6-bit fraction) 7: Shift by 7 (7-bit fraction) 8: Shift by 8 (8-bit fraction) 9: Shift by 9 (9-bit fraction) Integer size = 9 - #_of_fraction_bits

6.7.5.4.3.2.4 Single-Phase Filter Parameters

For a single-phase filter configuration (VPAC_MSC_CORE_CFG_j[0] FILTER_MODE = 0), software must ensure that FIRINC parameters (VPAC_MSC_CORE_FIRINC_j[30:16] VS and VPAC_MSC_CORE_FIRINC_j[14:0] HS) are programmed with one of the following values only:

- 0x4000 (1/4 X resizing)
- 0x2000 (1/2 X resizing)
- 0x1000 (1X – no scaling)

VPAC_MSC_CORE_ACC_INIT_j[27:16] VS and VPAC_MSC_CORE_ACC_INIT_j[11:0] HS configuration values are ignored by the MSC hardware (internally set to 0x0) when VPAC_MSC_CORE_CFG_j[0] FILTER_MODE = 0. If any phase offsets are needed, the starting pixel/line locations of the frame and the filter coefficient values should be adjusted to implement the desired phase shift.

6.7.5.4.3.2.5 Interleaved Mode Handling

When the input is in the interleaved data format (for example, YUV420 Chroma data), the horizontal filter supports two sets of 5-input buffers (Cb and Cr buffers) and alternates filtering operation between two. Phase calculation and coefficient updates are done every other sample. Edge replications at the start of the line and at the end of the line are handled separately for Cb and Cr data.

There is no change in how the vertical filter handles an interleaved data format source.

6.7.5.4.3.2.6 Input Skip Line Support

When a processing thread is only performing an octave generation (1/2x single phase resizing), the next input lines can be offset by 2 lines since the output is only generated every other input line times. By skipping lines (VPAC_MSC_LSE_SRC_CFG_j[7] SRC_LN_INC_2), the SL2 access is reduced in half for this mode and the cycle time to complete an Octave generation is equal to 1/2 of the input frame size.

Line N: Read Line N-2, N-1, N, N+1, N+2

Line N+1: Skip

Line N+2: Read Line N, N+1, N+2, N+3, N+4

Line N+3: Skip

Even though “N+1” line processing is skipped, all source lines are still required for proper filtering. Therefore, the DMA transfer from DDR to SL2 should include all lines. VPAC_MSC_CORE_FIRINC_j[30:16] VS should be set to 4096 (1x resizing) to compensate for source line skip (if it is doing a 1/2 resizing).

Horizontal Skip is done normally as 1/2 x resizing by the core HScale Filter.

6.7.5.4.3.3 Scaler Filter Thread Mapping

The scaling filter_# (# = 0..9) is enabled and its input is connected to one of the processing thread source VP ports by configuring the output channel #n buffer configuration:

By mapping each output to a thread explicitly in the output channel configuration register, MSC guarantees that a filter can only be connected to one processing thread.

6.7.5.4.3.4 Filter Coefficients

Since each resizer needs to access the common coefficients independently, the coefficients are stored in registers (instead of memory). Each resizer selects directly from these register using the coefficient selection scheme as shown in Figure 6-135. The same mux is used to select either vertical or horizontal coefficients.

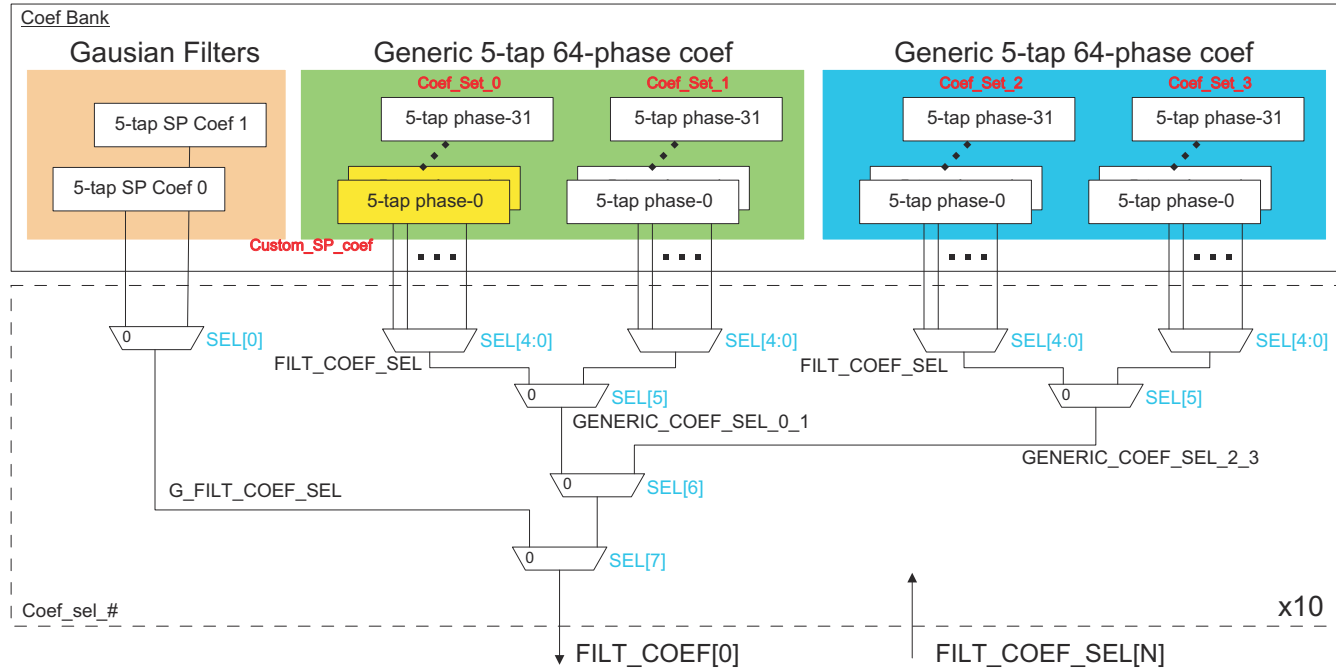

Figure 6-135. Coefficient Selection

6.7.5.4.3.4.1 Filter Coefficient Selection Algorithm

Filter Coefficient Selection is determined using the following algorithm:

```

If
( cfg.filter_mode == 0 ) {
    //
    single phase mode
    If( vertical_filter ) coef_sel = { cfg.sp_vs_coef_src, cfg.sp_vs_coef_sel }
    else coef_sel = { cfg.sp_hs_coef_src, cfg.sp_hs_coef_sel }
    if( coef_sel[4] == 0 ) filt_coef_sel = { 7'b0, coef_sel[0] } // use dedicated
    Gaussian filter set
    else if ( vertical_filter ) filt_coef_sel = { 4'b1001, coef_sel[3:0] } // use one of
    second 16 other custom coefs
    else filt_coef_sel = { 4'b1000, coef_sel[3:0] } // use one of 16 other custom
    coefs
}
else
{
    //
    multiphase mode
    If( vertical_filter ) coef_sel = cfg.vs_coef_sel[1:0]
    else coef_sel = cfg.hs_coef_sel[1:0]
    If ( cfg.phase_mode == 0 ) coef_sel = { 1'b1, coef_sel[1], filter_phase_sel[5:0] } // 64-phase
    mode
    else coef_sel = { 1'b1, coef_sel[1:0], filter_phase_sel[5:1] } // 32-phase
    mode
}

```

where filter_phase_sel comes from the Phase Calculation Logic.

The vertical resizer selects one set of coefficients at the start of each line, saves them locally in the vertical scaler to use the same coefficients for the entire pixels in the line.

The Horizontal resizer selects a new coefficient on each input pixel processing. To reduce timing dependency, the horizontal coefficient selection is made with next phase value from the horizontal scaler's phase calculator one cycle ahead of actual filter calculation.

6.7.5.4.3.4.2 Filter Coefficient Parameter Configuration

Each coefficient table entry consists of 5 coefficients stored in two memory mapped configuration registers - VPAC_MSC_CORE_C210_j and VPAC_MSC_CORE_C43_j. FIR_C4-0 parameters map to C-2, C-1, C0, C1, and C2 coefficients (see [Figure 6-132](#)).

6.7.5.4.3.4.3 3/4/5-Tap Filter Configuration

All filters operate in 5-tap filter mode – requiring 5-tap coefficients regardless of the filter usage. For less-than-5 tap filter configurations, coefficients corresponding to the unused taps should be set to 0.

For example, FIR_C0 and FIR_C4 will need to be set to 0x0 for a 3-tap configuration.

For 4-tap configuration, FIR_C0 will need to be set to 0x0.

6.7.5.4.3.5 Input/Output ROI Trimmers

Each scaler filter implements the ROI scaling as shown below with input and output trimmers. The input trimmer simply marks the beginning of the ROI to indicate where the valid source pixels and lines start in the source image. Doing the source ROI marker allows the exact specification of a sub-image in a common source image (no position or size restriction) while keeping the original boundary pixels (that is, not use the replicated pixels/lines).

The output trimmers then uses destination size parameters (VPAC_MSC_CORE_OUT_SIZE_j[28-16] HEIGHT and VPAC_MSC_CORE_OUT_SIZE_j[12-0] WIDTH) to trim out the exact final output image sizes.

VPAC_MSC does not perform output size correction by stuffing extra pixels in the case the programmed VPAC_MSC_CORE_OUT_SIZE_j[28-16] HEIGHT and VPAC_MSC_CORE_OUT_SIZE_j[12-0] WIDTH exceeds the actual output size of the scaler. In this case, VPAC_MSC simply outputs the actual size.

6.7.5.5 MSC Performance

Since the resizer performs only downscaling operations, the throughput of scaler is mostly dictated by the input processing rate – 1 input pixel per 1 clock cycle. Once the data is made available to the scaler filter after the initial set up and data fetching, the scaler should be fully active except for few cycles at the end of each line to flush the line.

If a processing thread is performing a pyramid generation only, the vertical line skip feature can be enabled to reduce the frame processing time approximately by ½.

6.7.5.6 MSC Clocking

Complete VPAC_MSC module operates on single clock - VPAC0_MSC_CLK.

6.7.5.7 MSC Reset

VPAC_MSC has one synchronous active low reset input. The entire module is reset by this reset.

6.7.5.8 MSC Programmer's Guide

6.7.5.8.1 Programming Model

6.7.5.8.1.1 MSC Programming Guidelines

MSC does not support shadow registers for its configuration registers. All changes must be done prior to the HTS.INIT request for a frame processing.

Input and output channels are individually enabled. It is expected that at least one input and output channels are enabled for each HTS thread enabled.

The MSC does not check for proper programming of all configuration parameters. It is strictly software responsibility to ensure programming of MSC (Core and LSE) registers do not cause conflict with each other.

6.7.5.8.1.2 MSC_Core Programming Details

All filters enabled for a multi-scaling thread are programmed via:

- VPAC_MSC_CORE_CFG_j[0] FILTER_MODE; Coefficient Set Selection - VPAC_MSC_CORE_CFG_j[3-2] HS_COEF_SEL, VPAC_MSC_CORE_CFG_j[5-4] VS_COEF_SEL, VPAC_MSC_CORE_CFG_j[10-7] SP_HS_COEF_SEL, VPAC_MSC_CORE_CFG_j[15-12] SP_VS_COEF_SEL; and filter tap size parameters VPAC_MSC_CORE_CFG_j[11] SP_VS_COEF_SRC and VPAC_MSC_CORE_CFG_j[6] SP_HS_COEF_SRC.
- Coefficients set in VPAC_MSC_CORE_C210_j, VPAC_MSC_CORE_C43_j, VPAC_MSC_CORE_C210_j_k, VPAC_MSC_CORE_C43_j_k registers.
- ROI source offset - VPAC_MSC_CORE_SRC_ROI_j[28-16] Y_OFFSET and VPAC_MSC_CORE_SRC_ROI_j[12-0] X_OFFSET, and size. The size of ROI depends on the X and Y offsets. For full-size set the offsets to 0. Note that the ROI_SIZE may or may not be same as the MSC frame size (set in MSC_FRAME_SIZE_j[28-16] HEIGHT and MSC_FRAME_SIZE_j[12-0] WIDTH) - depending on whether ROI is full or sub-frame sized.
- Output size - VPAC_MSC_CORE_OUT_SIZE_j[28-16] HEIGHT and VPAC_MSC_CORE_OUT_SIZE_j[12-0] WIDTH.
- Filter parameters - VPAC_MSC_CORE_FIRINC_j[14-0] HS, VPAC_MSC_CORE_FIRINC_j[30-16] VS, VPAC_MSC_CORE_ACC_INIT_j[27-16] VS, and VPAC_MSC_CORE_ACC_INIT_j[11-0] HS.

Filter thread mapping is done with output channel configuration parameters (MSC_BUF_CFG_j[7] THREAD_MAP). Specifying the mapping in one register for each channel prevents any resource conflict.

6.7.5.8.1.3 MSC_LSE Programming Details

Two processing threads can be activated independently.

6.7.5.8.1.3.1 Input Thread Configuration:

1. Pixel Data Format
 - a. VPAC_MSC_LSE_SRC_CFG_j[1-0] PIX_FMT_PW, VPAC_MSC_LSE_SRC_CFG_j[3-2] PIX_FMT_CNTRSZ, and VPAC_MSC_LSE_SRC_CFG_j[4] PIX_FMT_ALIGN parameters define the pixel input data format for all input channels of the thread.
 - b. Common data formats:
 - i. Fully packed 12-bit: PIX_FMT_PW = 1, PIX_FMT_CNTRSZ = 1, PIX_FMT_ALIGN = 0
 - ii. Fully packed 8-bit: PIX_FMT_PW = 0, PIX_FMT_CNTRSZ = 0, PIX_FMT_ALIGN = 0
2. Pixel Input Matrix Configuration
 - a. VPAC_MSC_LSE_SRC_CFG_j[15-12] KERN_LN_OFFSET defines the starting line offset number of the input pixel matrix (for 5-tap filter configuration, offset = 0, for 4-tap configuration, offset = 1)
 - b. VPAC_MSC_LSE_SRC_CFG_j[11-8] KERN_SZ_HEIGHT defines the height of the input pixel matrix (for example, MSC = 5, VISS = 1, NF = 5)
 - c. VPAC_MSC_LSE_SRC_CFG_j[21-19] KERN_TPAD_SZ, and VPAC_MSC_LSE_SRC_CFG_j[18-16] KERN_BPAD_SZ defines the number of padding lines required at top and bottom of the frame (for example, for 5-tap filter configuration for MSC, both of these parameters are set to 2. For 4-tap filter configuration for MSC, TPAD_SZ = 1 while BPAD_SZ = 2).
3. Source Frame Size
 - a. VPAC_MSC_LSE_SRC_FRAME_SIZE_j[28-16] HEIGHT and VPAC_MSC_LSE_SRC_FRAME_SIZE_j[12-0] WIDTH – define the width and height (pixels/lines) of the source video frame.
4. Source SL2 Circular Buffer Configuration
 - a. VPAC_MSC_LSE_SRC_BUF_ATTR_j[15-6] BUF_STRIDE – defines the line stride size (must be 64 byte multiple)
 - b. VPAC_MSC_LSE_SRC_BUF_ATTR_j[24-16] CBUF_SIZE – define the size of the circular buffer in the SL2 (number of lines)
 - c. VPAC_MSC_LSE_SRC_BUF_ATTR_j[31-25] START_NIB_OFFSET – defines the line start offset in smaller resolution (start address within the first SL2 512-bit word in 4-bit resolution).

5. Source BA and Enable Configuration
 - a. VPAC_MSC_LSE_SRC_i_BUF_BA_y[23-6] ADDR – defines the SL2 base address of the Circular buffer for the input channel. VPAC_MSC_LSE_SRC_i_BUF_BA_y[31] ENABLE – enables the input channel.

6.7.5.8.1.3.2 Output Channel Configuration

1. Pixel Data Format
 - a. VPAC_MSC_LSE_DST_BUF_CFG_j[1-0] PIX_FMT_PW, VPAC_MSC_LSE_DST_BUF_CFG_j[3-2] PIX_FMT_CNTRSZ, and VPAC_MSC_LSE_DST_BUF_CFG_j[4] PIX_FMT_ALIGN parameters define the pixel output data format for this output channel.
 - b. Common data formats:
 - i. Fully packed 12-bit: PIX_FMT_PW = 1, PIX_FMT_CNTRSZ = 1, PIX_FMT_ALIGN = 0
 - ii. Fully packed 8-bit: PIX_FMT_PW = 0, PIX_FMT_CNTRSZ = 0, PIX_FMT_ALIGN = 0
2. Output Thread Map
 - a. VPAC_MSC_LSE_DST_BUF_CFG_j[7] THREAD_MAP defines the output channel thread mapping.
3. Output SL2 Circular Buffer Configuration
 - a. VPAC_MSC_LSE_DST_BUF_ATTR0_j[15-6] BUF_STRIDE – define the line stride size (must be 64 byte multiple)
 - b. VPAC_MSC_LSE_DST_BUF_ATTR0_j[24-16] CBUF_SIZE – define the size of the circular buffer in the SL2 (number of lines)
4. Base Address and Channel Enable:
 - a. VPAC_MSC_LSE_DST_BUF_BA_j[23-6] ADDR – defines the SL2 base address of the Circular buffer for this output channel.
 - b. VPAC_MSC_LSE_DST_BUF_BA_j[31] ENABLE – enables this output channel.

6.7.5.8.1.4 MSC HTS Programming Details

There is no configuration required for HTS interface in the MSC_HWA. All programming is done in the separate HTS module. It is expected that at least one input and output channel is enabled for each HTS thread. For more details on programming HTS, see *Hardware Accelerator (HWA) Thread Scheduler (HTS)*.

6.7.5.8.1.5 MSC Data Transfer Programming Details

Refer to *VPAC Subsystem Programmer's Guide*.

6.7.5.8.1.6 LSE Interrupt Programming

MSC does not have any interrupt MASK/SET/CLEAR registers. Interrupts are pulse output events that go to the VPAC top level interrupt aggregation logic. For more information about the aggregation logic, see [Section 6.7.2, VPAC Subsystem](#).

MSC does, however, provide a set of statuses for VBUSM interface errors. These status are mapped to VPAC_MSC_STATUS_ERROR and they are cleared by writing all 1's to the status bit field.

6.7.5.8.2 Initialization Sequence

For details, see [Section 6.7.2, VPAC Subsystem Level](#).

6.7.5.8.3 Real-Time Operating Requirements

For details, see [Section 6.7.2, VPAC Subsystem Level](#).

6.7.5.8.4 Power Up/Down Sequence

For details, see [Section 6.7.2, VPAC Subsystem Level](#).

6.7.6 VPAC Noise Filter (NF)

6.7.6.1 NF Overview

The noise filter in VPAC is used for filtering out spatial noise without impacting edges in image.

6.7.6.1.1 NF Supported Features

- Bilateral filtering:
 - Supports filter size up to 5×5
 - Supports true 2D Bilateral filtering
- Generic filtering:
 - Supports filter size up to 5×5 of programmable static weights
- LUT based Bilateral weights generation:
 - 8-bit for weight
- Supported formats:
 - YUV420, 12-bit
 - One plan (interleaved plane and non-interleaved)
- Performance: 1 cycle/pixel
- Line based Input and Output
- Memory-to-memory operation
- Support for ROI:
 - Both Input and Output can be handled via DMA

6.7.6.1.2 NF Not Supported Features

- Filter size higher than 5×5

6.7.6.2 NF Functional Description

6.7.6.2.1 Functional Operation

The noise filter hardware (NF HW) block reads data from memory (DDR or on-chip) to shared memory (SL2 with the help of DMA) and does Bilateral filtering to remove noise. The output of NF HW block can be sent to external memory (DDR) from shared memory (SL2) or can be further re-sized using Scalar hardware.

6.7.6.2.1.1 Overview

Figure 6-136 shows a block diagram of Bilateral noise filter with support for filtering size up to 5×5.

Figure 6-136. Bilateral Noise Filter Block Diagram

6.7.6.2.1.2 NF Integration In VPAC

Figure 6-137 presents VPAC block diagram.

It consists of four hardware module blocks and three infrastructure module blocks.

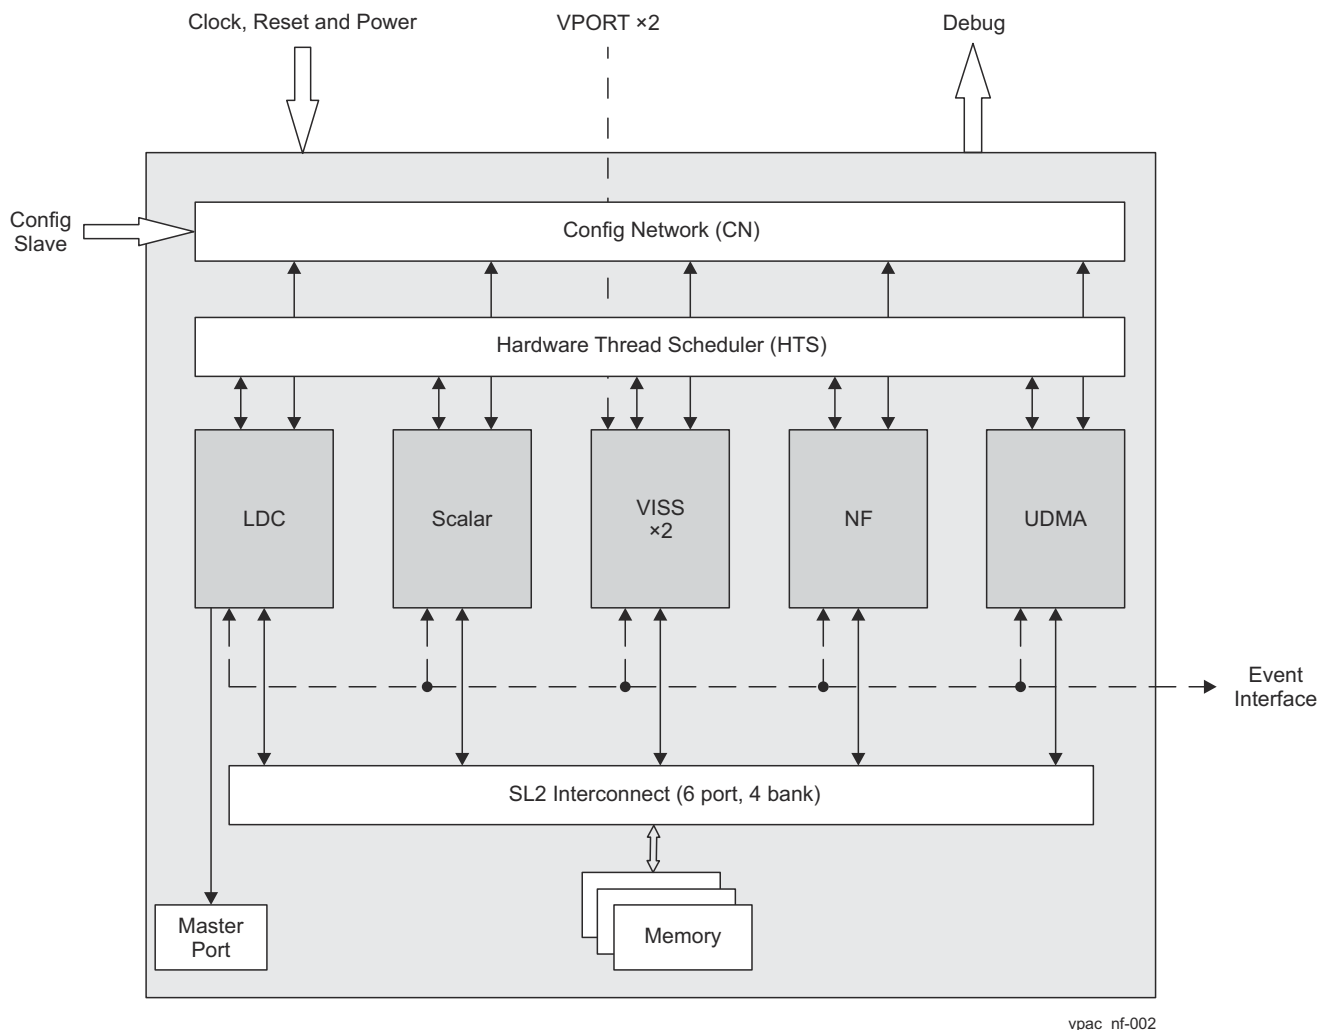

Figure 6-137. VPAC Block Diagram

VPAC hardware blocks:

1. **LDC (Lens Distortion Correction):** LDC hardware block reads data from memory (DDR or on-chip) and applies perspective transform as well as correction of lens distortion (including fisheye lens). The output of LDC block can be sent to external memory (DDR) or sent to other hardware module (Scalar, Noise filter) for further pre-processing via local shared memory (SL2).
2. **Scalar (or Downsampler or Resizer):** Scalar hardware block reads data from memory (DDR or on-chip) to shared memory (SL2) and generates up to 10 scaled output from two inputs with various scaling ratios (between \times and $\times 0.25$). The output of Scalar block can be sent to external memory (DDR) from shared memory (SL2) or can be further noise filtered using Noise filter hardware.
3. **Noise Filter (NF):** NF hardware block reads data from memory (DDR or on-chip) to shared memory (SL2) and does Bilateral filtering to remove noise. The output of NF block can be sent to external memory (DDR) from shared memory (SL2) or can be further re-sized using Scalar hardware.
4. **VISS (Vision ISS):** There are two instances of on-the-fly processing for sensor related processing in VISS hardware.

VPAC infrastructure blocks:

1. **Shared Level 2 (SL2) memory:** It is used to exchanging data across hardware module block (for example: LDC, Scalar and NF) as well as to DMA engine (for example: UDMA).
2. **Hardware Thread Scheduler (HTS):** It is used for IPC communication among various hardware module block for example: LDC, Scalar and NF) as well as to DMA engine (for example: UDMA).
3. **DMA engine (UDMA consisting of CC + DRU)** is inside VPAC boundary. It consists of one CC and two TC.

6.7.6.2.1.3 Algorithm Details

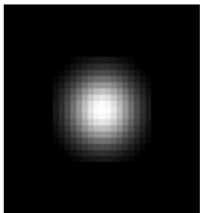

The basic equation for Bilateral filtering is shown in Figure 6-138.

$$BF[I]_p = \frac{1}{W_p} \sum_{q \in S} G_{\sigma_s}(\|p - q\|) G_{\sigma_r}(\|I_p - I_q\|) I_q$$

vpac_nf-003

Figure 6-138. Bilateral Filtering Equation

The range and space parameters are shown in Figure 6-139.

$$BF[I]_p = \frac{1}{W_p} \sum_{q \in S} G_{\sigma_s}(\|p - q\|) G_{\sigma_r}(\|I_p - I_q\|) I_q$$

vpac_nf-004

Figure 6-139. Range and Space Parameters

Range and space parameters:

- space ss: spatial extent of the kernel, size of the considered neighborhood.
- range sr: "minimum" amplitude of an edge.

6.7.6.2.1.4 Data Format Support In VPAC

Table 6-132 summarizes data format support in VPAC that needs to be supported by NF hardware block.

Table 6-132. Data Format Across VPAC

No	Type	Bit-Depth	Chroma Format	Packing	Reasoning
1.	LDC Input	8-bit	YUV422	N/A	External sensor ISP
		12-bit	YUV420	Fully packed	
		12-bit	YUV420	Un-packed	Other source in chip
2.	LDC Output	12-bit	YUV420	Fully packed	
3.	NF Input	12-bit	YUV420	Fully packed	
4.	NF Output	12-bit	YUV420	Fully packed	
5.	Scalar Input	12-bit	YUV420	Fully packed	One plane at a time
6.	Scalar Output	12-bit	YUV420	Fully packed	One plane at a time

Figure 6-140 presents YUV420 2-plane 12-bit fully packed format.

Figure 6-140. YUV420 (2-Plane 12-bit Fully Packed Format)

6.7.6.3 NF Interrupts

6.7.6.3.1 CPU Interrupts

The following interrupts are generated by the NF module (see [Table 6-133](#)):

Table 6-133. Interrupts

Interrupt	Description
NF_FRAME_DONE	Frame processing complete.
NF_SL2_READ_ERROR	Set whenever there is an error response on VBUSM read command request for any input channel.
NF_SL2_WRITE_ERROR	Set whenever there is an error response on VBUSM write command request for any output channel.

All interrupts are single pulse event signals that are mapped to the VPAC level interrupt aggregation logic.

6.7.6.3.2 Interrupt Event Description

6.7.6.3.2.1 NF_FRAME_DONE Event

These events are generated when noise filtering is complete for entire frame. This is set when input end of frame (EOF) event and output EOF events are detected.

6.7.6.3.2.2 NF_SL2_READ_ERROR Event

This event is generated whenever the VBUSM read status is something other than '0' (success).

The VPAC status register (VPAC_NF_LSE_STATUS_ERROR) stores the last non-zero rstatus value for user to see which type of error has occurred.

6.7.6.3.2.3 NF_SL2_WRITE_ERROR Event

This event is generated whenever the VBUSM write status is something other than '0' (success).

The VPAC status register (VPAC_NF_LSE_STATUS_ERROR) stores the last non-zero sstatus value for user to see which type of error has occurred.

6.7.6.4 NF Submodule Details

Following the common hardware partition strategy of VPAC HWA, the Noise Filter is partitioned as shown in [Figure 6-141](#).

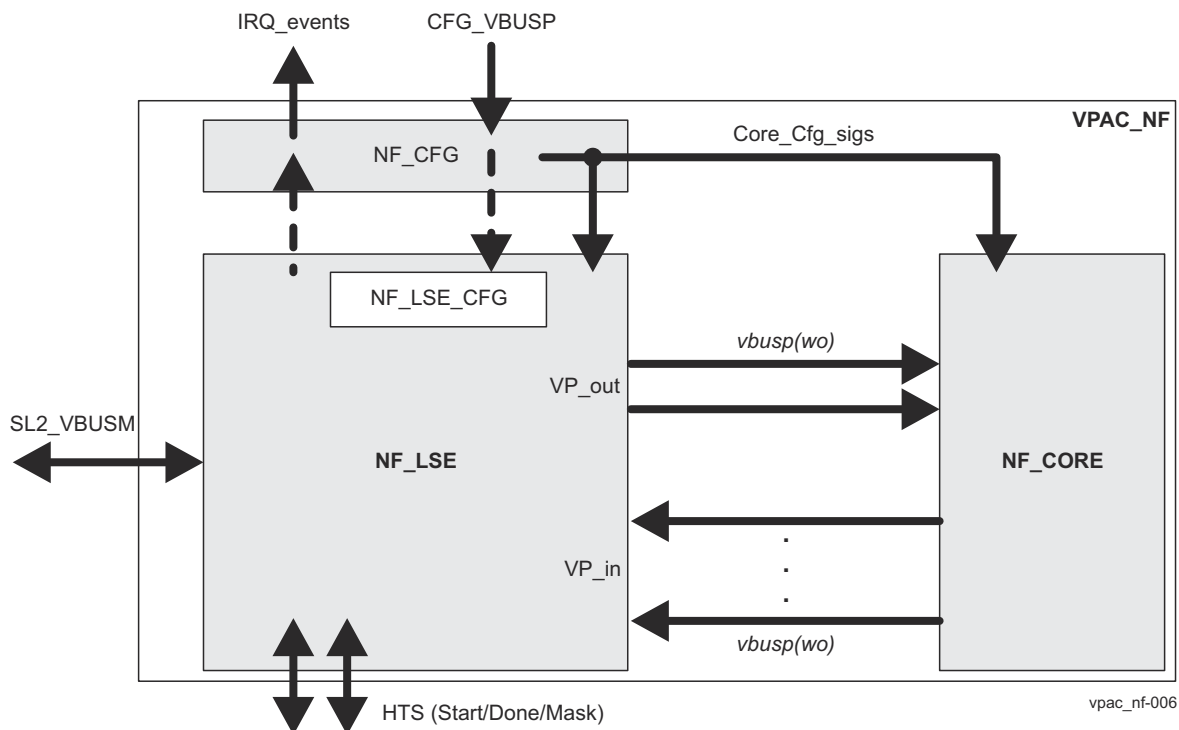

Figure 6-141. NF Hardware Partition

The NF_CFG manages all configuration registers for the NF (top and core) via a common VBUSP slave interface.

The NF_LSE (Load Store Engine) handles all interfacing to the SL2 memory space and performs the following functions:

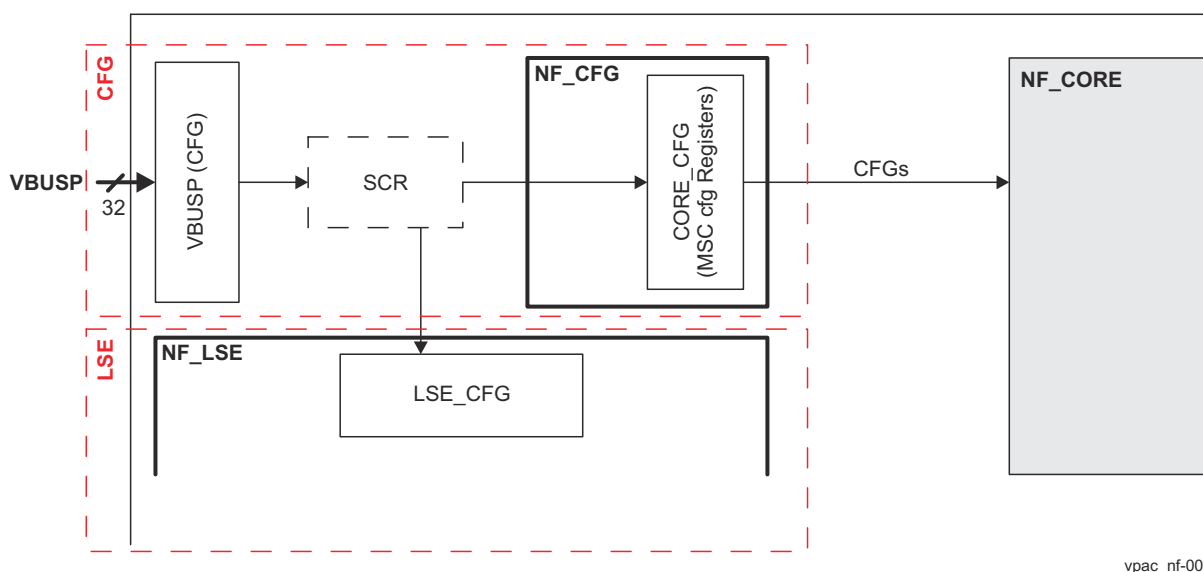

- Provides interface to SL2 circular buffers via a common VBUSM master interface.
- Manages input and output channel updates in sync with Hardware Thread Scheduler (HTS).
- Provides data unpacking for core and packing for SL2 interface.
- Manages LSE specific configuration registers.

The NF_CORE performs noise filtering operations on given input and produces output. It has no direct connection to external interface and it works on a frame data coming in and out in raster scan order.

6.7.6.4.1 NF_CFG

The NF configuration registers consist of LSE configuration registers (see *VPAC_NF_LSE Registers*) and CORE configuration registers (see *VPAC_NF_CORE Registers*).

Figure 6-142 shows NF_CFG block diagram.

vpac_nf-007

Figure 6-142. NF_CFG Block Diagram

6.7.6.4.1.1 VBUSP Configuration Interface

The 32-bit VBUSP slave interface for MMR configuration supports only the linear incrementing mode (in little endian). It does not provide any write/read error status.

6.7.6.4.1.2 Configuration Register Address Map

For details of MMR registers, see *NF Registers*.

6.7.6.4.2 NF_LSE

The NF integrates a VPAC_LSE (Load Store Engine) .

6.7.6.4.2.1 NF_LSE Overview

The NF_LSE supports the following VPAC_LSE features:

- Input channel features:
 - One SL2 input channel with following features for the input channel:
 - Up to 5 lines - input kernel height support
 - Any source pixel start position support with Line Start Offset (in nibble-address resolution)
 - Input Line Skip support
 - Vertical boundary Edge Padding (Replication only) support
- Output Channel Features:
 - Only one SL2 output channels (pixel data output only)
 - Single data plane support for each output channel with no special chroma data interleaving support on the output
- Hardware Thread Scheduler (HTS) synchronization support
 - Start/Done task synchronization signal handling
 - Programmable Done-mask generation schemes
 - End of processing (EOP) generation

6.7.6.4.2.2 NF_LSE Feature Detailed Description

For detailed LSE feature description, refer to *Load Store Engine (LSE) Overview*.

6.7.6.4.3 HTS Interface And Integration

Figure 6-143 shows interfacing with Hardware Thread Scheduler (HTS).

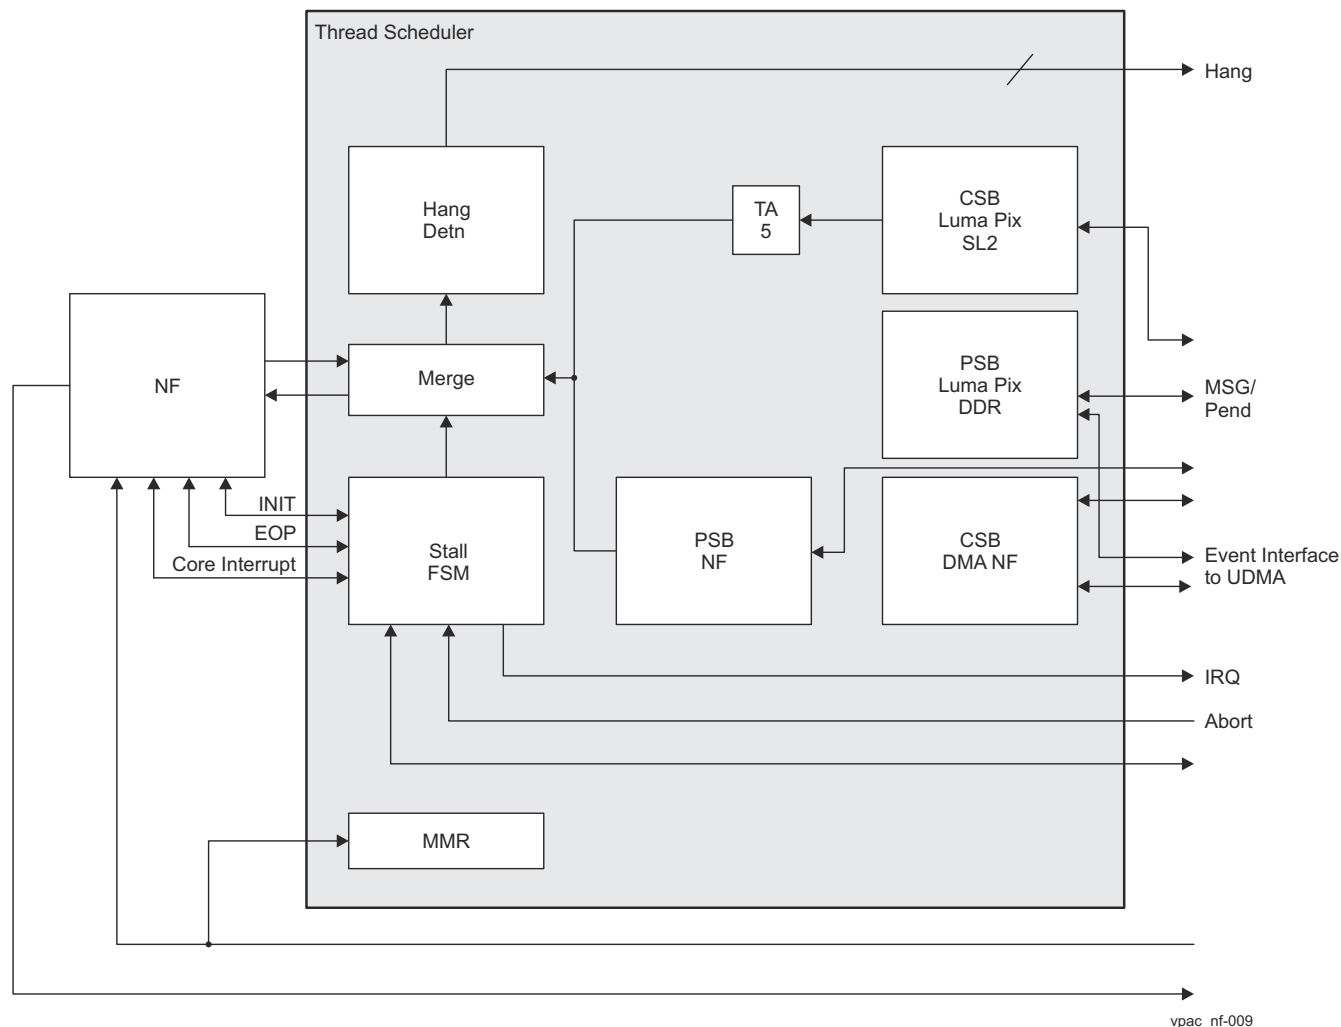

Figure 6-143. Hardware Thread Scheduler (HTS)

6.7.6.4.3.1 Hardware Thread Scheduler (HTS)

The HTS (Hardware Thread Scheduler) supports a 64-bit VBUSM master interface to communicate with a top-level message manager. It performs following functions to flow control data/control for HWA.

- NF HWA Initialization and EOP-Flush
- Handling of IRQ hardware events (that affect flow control)
- Debug/Emulation support (for stalling HTS/DMA transfer)
- Abort/Suspend support

6.7.6.4.3.2 Synchronization With HTS

Scheduling of data transfer in the SL2 interface is controlled by the HTS controller integrated at the VPAC top level. A dedicated HTS is integrated per processing thread to manage start and done flow control signals and to issue DMA service events to trigger DDR from/to SL2 transfers and SL2 from/to HWA.

The following flow control scheme is used:

/* initialization */

1. @ Frame Start up: (HTS) INIT → Frame Initialization

/* First two line processing */

Note

'N' is input kernel height.

1. @ N-2 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
2. @ Input Line Consumed and all output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task
3. @ N-1 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
4. @ Input Line Consumed and output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task

/* Middle Lines processing */

1. @ N-1 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
2. @ Input Line Consumed and output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task
3. Repeat (6) and (7) until Frame_H-3 lines

/* Last two line processing */

1. @ N-1 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
2. @ Input Line Consumed and output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task
3. @ N-2 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
4. @ Input Line Consumed and all output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task
5. @EOP: (PixCntlFSM) EOP

6.7.6.4.4 Noise Filter Core Block Diagram

Figure 6-144 shows the core of the Noise filter. The line buffers are stored in SL2.

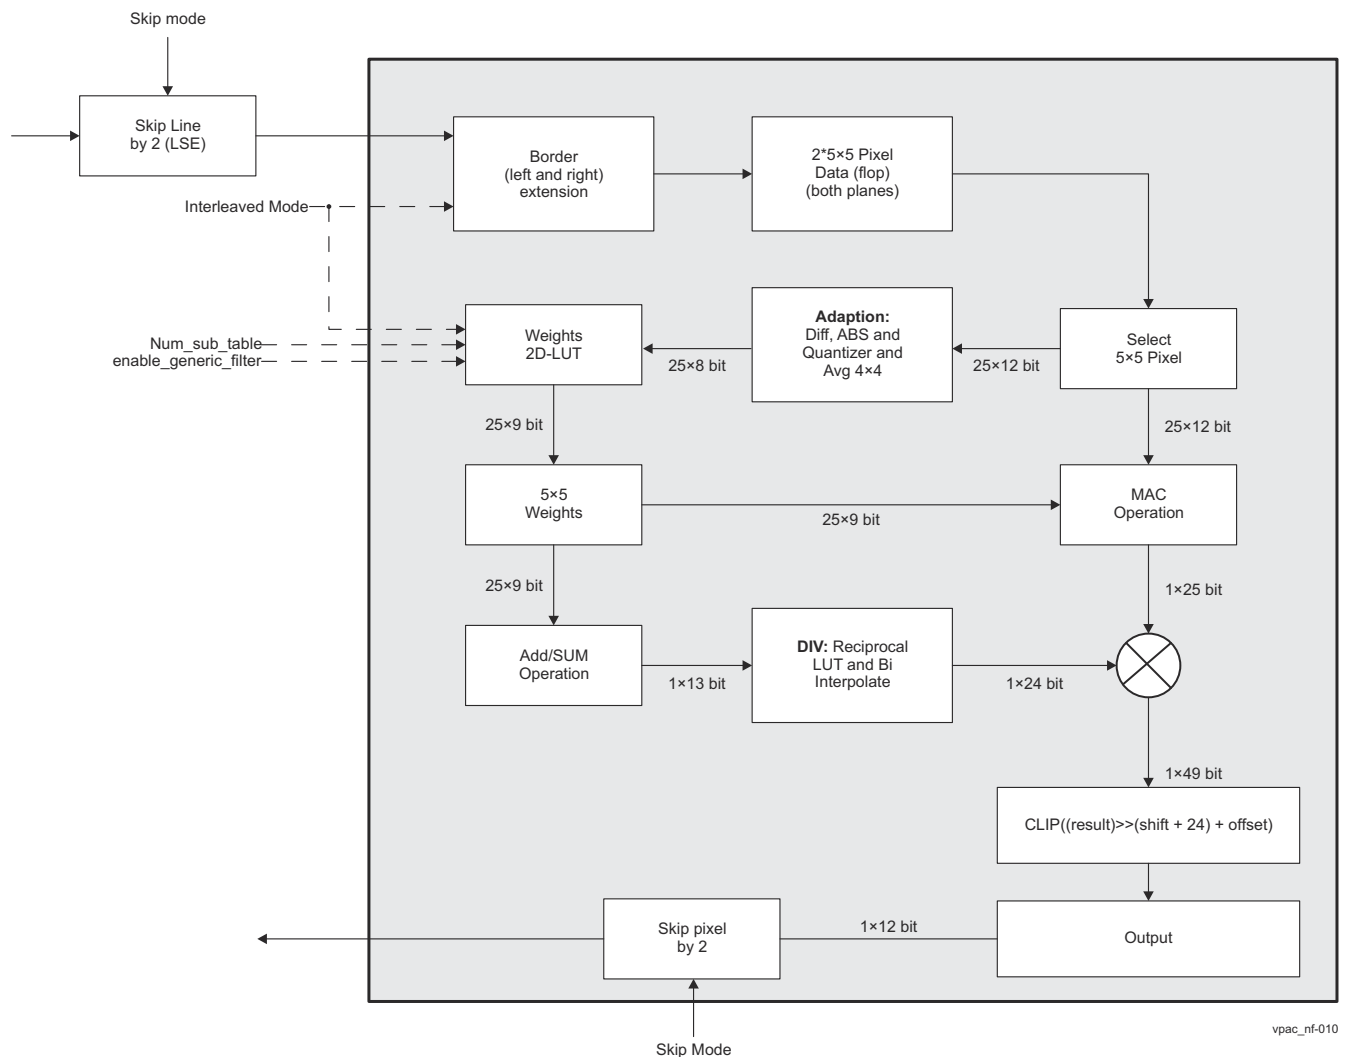

Figure 6-144. NF-CORE Block Diagram

There are two modes of filtering:

1. Bilateral filtering mode: The overall weights are computed based on center pixels. These are 8-bit unsigned weights. The center weight is read from MMR as 8-bit unsigned. The 9th bit for all weight is hardwired to '0'. The MAC operation is signed multiply with addition. As MSB for weight is set '0', it will be act as unsigned multiplier of 12-bit pixel to 8-bit unsigned weight.
2. Generic filtering mode: In this mode, all weights are 9-bit signed value read LUT from initial 24 values read as 9-bit signed value from every 2 bytes (16 bits) locations.

6.7.6.4.4.1 VP Port (NF_LSE To/From NF_CORE Over VBUSP Interface)

The data transfers from/to the MSC_LSE are done through the VP ports with VBUSP write-only streaming protocols.

6.7.6.4.4.2 Space Weight Details

Figure 6-145 shows spatial distance from central pixel to decide spatial weight.

4	3	2	3	4
3	1	0	1	3
2	0		0	2
3	1	0	1	3
4	3	2	3	4

vpac_nf-011

Figure 6-145. Space Distance For 5×5 Pixels

- Total number pixels = 25
 - Number of pixel at distance 0 = 4
 - Number of pixel at distance 1 = 4
 - Number of pixel at distance 2 = 4
 - Number of pixel at distance 3 = 8
 - Number of pixel at distance 4 = 4
- Space range (five, 0-4)
- Please note that Center pixel has 9-bit programmable MMR register for fixed weight

6.7.6.4.4.3 Weight Calculation Logic

6.7.6.4.4.3.1 Combined LUT For Space And Range Weights

In this approach, Bilateral weight is computed for each center pixel based on the input (guide) image:

- i : center pixel index, j : neighbor pixel index
- I_i : center pixel input image intensity, I_j : neighbor pixel input image intensity

$$W_{i,j}^{bf} = \frac{1}{K_i} \exp\left(-\frac{|i-j|^2}{\sigma_s^2}\right) \exp\left(-\frac{|I_i - I_j|^2}{\sigma_c^2}\right),$$

Division LUT
Combined LUT

vpac_nf-012

Figure 6-146. LUT For Combined Weight For Space And Range

The following are details of this approach:

- $(i-j)$ is 3-bit for 5×5: use 3 bits
- $(I_i - I_j)$ is 13-bits: quantize to 8 bits
- Pre-compute $W_{i,j}$ as 8-bit values including normalization and put in a 2D lookup table
- $LUT[i][j]$: i is 3-bit pix index, j is 8-bit image intensity diff
- Lookup value is 8-bit
- Total storage: $5 \times 256 \times 8b = 1280$ Bytes
- Can be reduced further based on symmetric nature of range
- For $1/K_i$ (refer to [Section 6.7.6.4.4.4](#))

The LUT organization is shown in [Figure 6-147](#).

Figure 6-147. LUT Organization For Combined Weights

Figure 6-148 shows details of weight LUT logic for this approach.

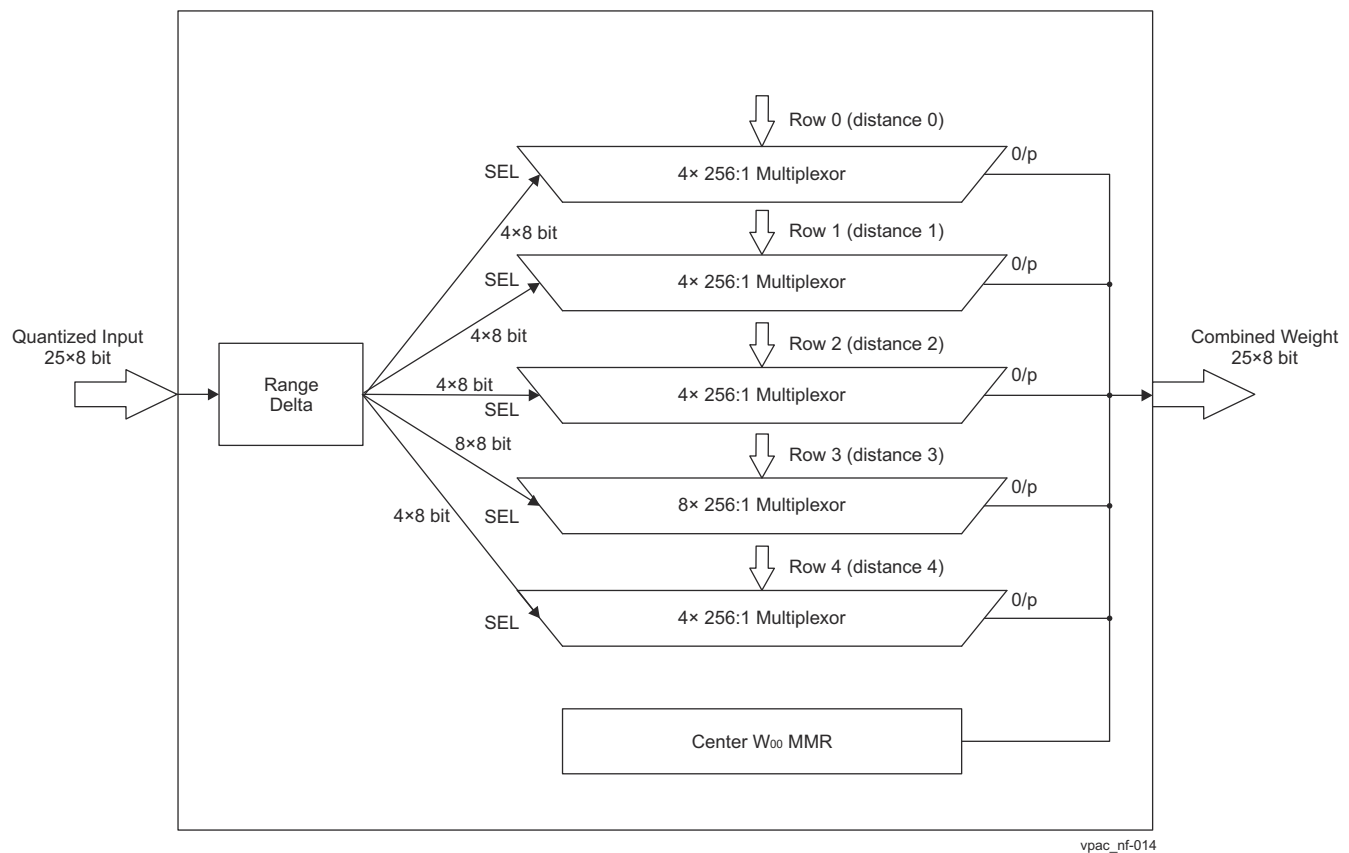

Figure 6-148. Weight LUT Logic

6.7.6.4.4.4 Reciprocal Calculation Logic

1/Ki calculation is done using Reciprocal table.

The following are details of Reciprocal table:

- Table is located in ROM (all values are hardwired)
- 24 bits per entry

- The first 512 entries are not quantized
- The remaining entries are quantized by 16 with Bilinear interpolation during lookup two neighbouring values
- Total of 993 entries

6.7.6.4.4.5 Border Handling

6.7.6.4.4.5.1 Border Handling (Simple)

The noise filter will support boarder extension. It will process two pixel copy in each directions for padding. The output frame size will be equal to input frame size as shown in [Figure 6-149](#). The output there will be border pixels (two in each direction) will be unfiltered, while rest of middle frame is noise filtered. Please note that the output frame size (or resolution) will be identical to input frame (resolution).

Figure 6-149. Border Handling

6.7.6.4.5 Usage As Generic 2D Filter Engine

The given noise filter can be used as generic 2D 5×5 filter core. This mode is enabled by selecting `ENABLE_GENERIC_FILTER` in `CNTR` MMR. In this case, software needs to set necessary MMR to provide co-efficients for 2D convolution. The overall decision for 5×5 co-efficient is shown in [Figure 6-150](#).

Note the order of the weight is Column first then Row second `C0_R0`, `C1_R0`, ... , `C4_R5`, `C5_R5`.

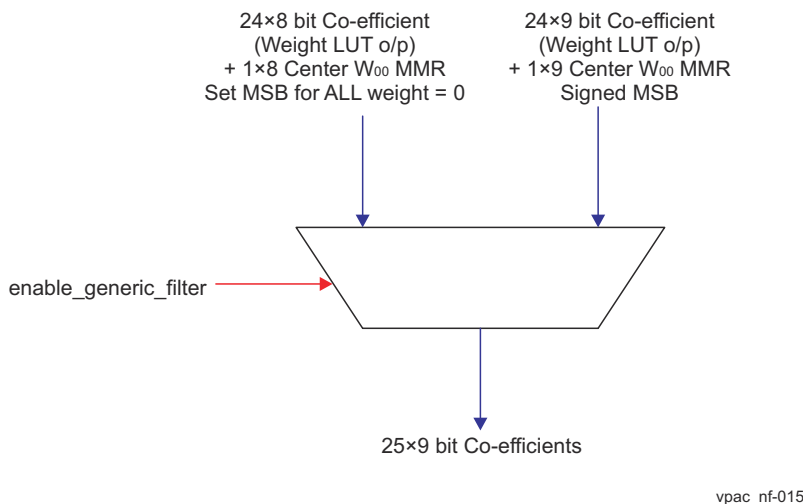

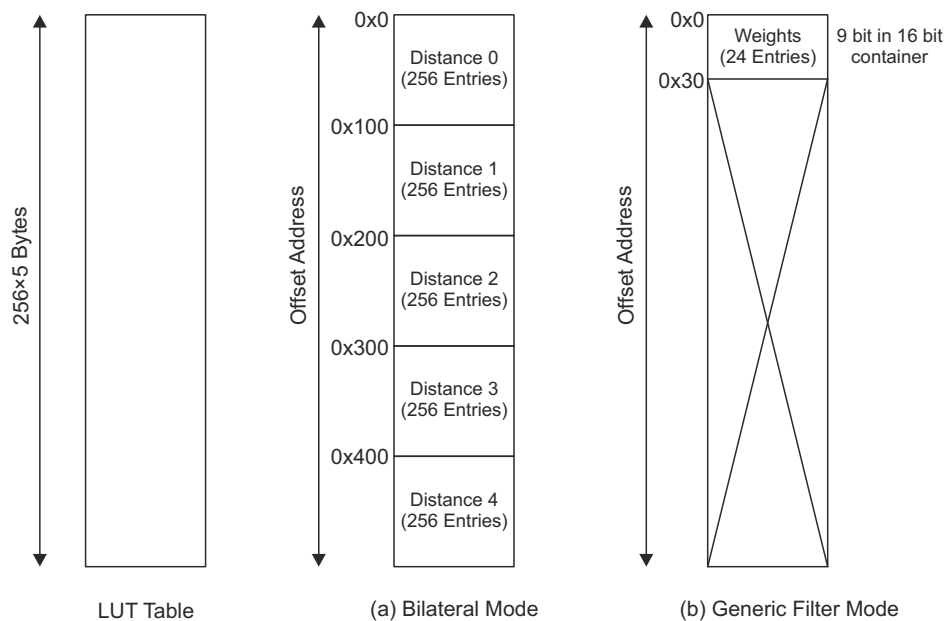

Figure 6-150. 5×5 Weight (Generic 2D Filtering)

[Figure 6-151](#) shows the usage of Weight or Range LUT for Generic Filtering Mode.

vpac_nf-017

Figure 6-151. Weight LUT Usage In Generic Mode**6.7.6.4.6 Adaptive Bilateral Weight Support**

The hardware supports adaptive Bilateral filtering using `num_sub_tables > 0`. The `num_sub_table = 1` means 2 tables within LUT per distance, `num_sub_table = 2` means 4 sub_table within LUT per distance and `num_sub_table = 3` means 8 sub_tables per distance. The tables are stored as interleaved within each distance. For example in case `num_sub_table = 1`, there are two LUT within each distance with even entries coming from LUT1 and odd entries coming from table 2 as shown in Figure 6-152.

vpac_nf-018

Figure 6-152. Interleaved Entries In Table

The adaptation logic consist using 4x4 average of 5x5 window (top left corner) and `num_sub_tables` from MMR as shown below using combo logic below:

- Mask "num_sub_tables" LSB bits out of 8 bits.
- $\text{LSB Bits} = \text{Average_4x4} \gg (12 - \text{num_sub_tables})$
- 8 bits for LUT look up = $(8 - \text{num_sub_table}) \ll \text{num_sub_table} + \text{LSB Bits}$
- Please note that this is constant LSB bits for all 25 pixels that will be replaced for all 25x8 pixels.

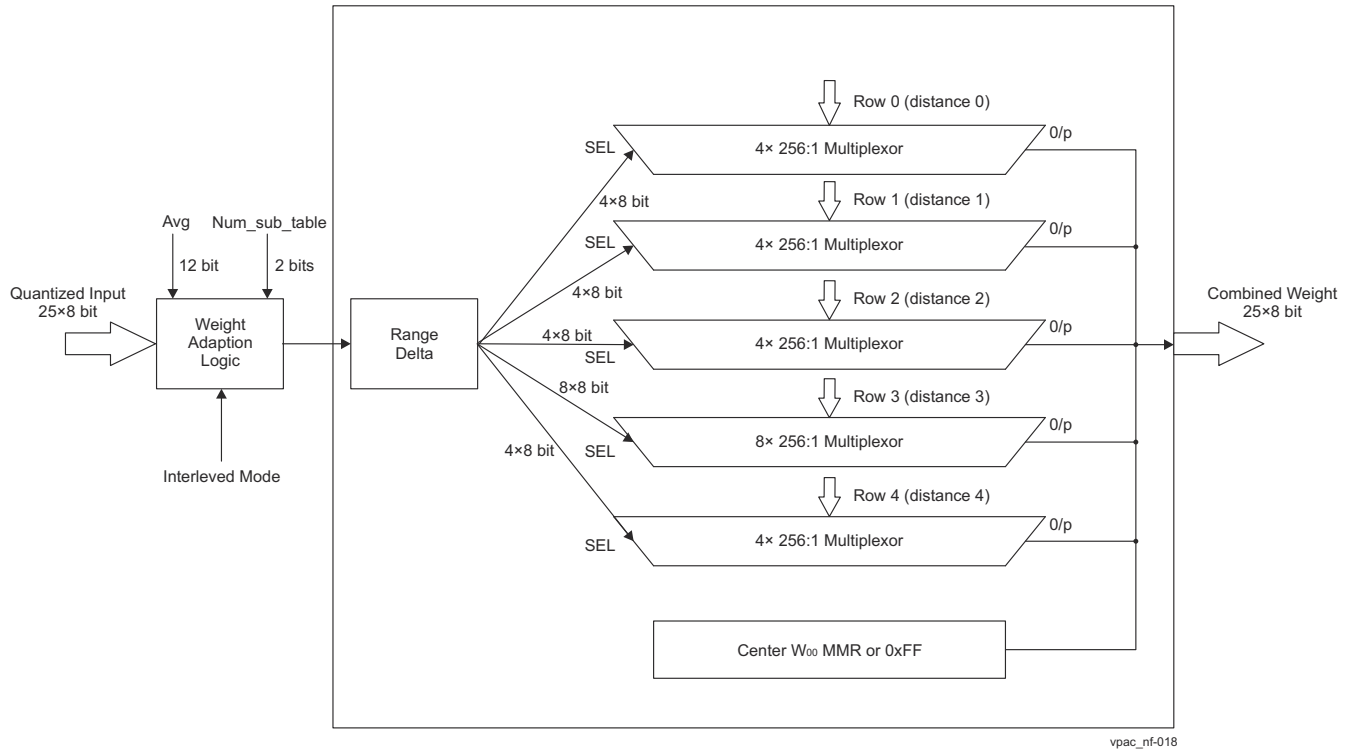

Figure 6-153. Adaptive Bilateral Filtering

6.7.6.4.7 Chroma Handling (Interleaved Mode)

Please note that the given hardware module can support either Luma (Non-Interleaved mode) OR Chroma mode (Interleaved mode) at a time. It can't support two data plane (Luma + Chroma) simultaneously.

When the input is in the interleaved data format (for example: YUV420 Chroma data), the filter core keeps two sets of 5-input samples (Cb and Cr buffers) and alternates filtering operation between two. In this case, core does deinterleaving and maintains two set of data of 6x5 for both planes as shown in block diagram of core. The parameters for Chroma needs to be programmed at every frame differently compared to Luma.

Note software can always do a "force" select which sub table to use by clearing adaptive_mode then sub_table_select defines which table to use, otherwise below defines which sub table is selected.

- Mask "num_sub_tables" LSB bits out of 8 bits.
- $\text{LSB Bits} = \text{Average_4x4} \gg (12 - \text{num_sub_tables})$
- If $(\text{num_sub_tables} \neq 1)$:
 - 8 bits for LUT look up = $(8 - \text{num_sub_table}) \ll \text{num_sub_table} + \text{LSB Bits}$
- Else:
 - 8 bits for LUT look up = $(8 - \text{inputPlaneInterleaving}) \ll \text{inputPlaneInterleaving} + \text{LSB Bits}$
- Please note that this is constant LSB bits for all 25 pixels that will be replaced for all 25x8 pixels.

6.7.6.5 NF Integration Details

6.7.6.5.1 Performance Requirements

The core performance throughput 1 cycle/pixel. The NF module is designed to support 300 MHz.

6.7.6.5.2 Slave VBUSP Interface Clock

Table 6-134. Slave VBUSP Interface Clock

Signal Name	Dir	Default Val	Description
NF_CLK	In	1'd0	Single ended clock

6.7.6.5.3 Clocking

The NF module has one input clock which should run at 300 MHz.

It only has 1 clock IPGeneric

kp_ti_ipg_clk_s1c1fps I_kp_ti_ipg_clk_s1c1fps

6.7.6.6 NF Programmer's Guide

6.7.6.6.1 Programming Model

The full programming of the module, consist of the following four steps (see [Figure 6-154](#)):

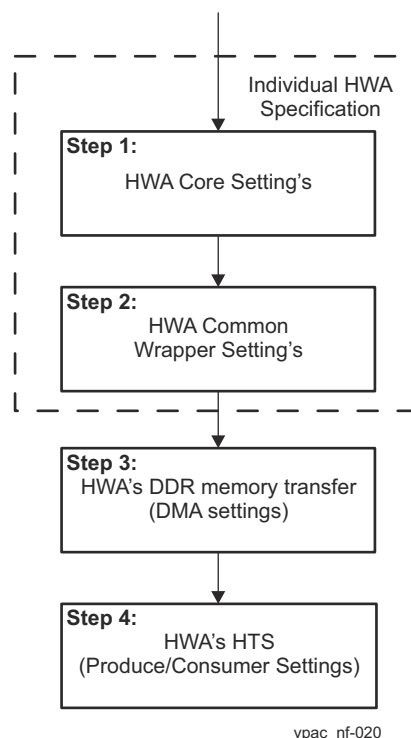

Figure 6-154. Programming Steps

6.7.6.6.1.1 HWA Core Programming Details

There are two use-cases:

- Bilateral Noise Filter Mode: The following core MMR needs to be programmed to enable Bilateral noise filter mode:
 - Set Weight LUT (8-bit unsigned) tables (5×256 values corresponding to various distance from distance in MMR (0x100 onwards))
 - Set Control register fields (Center weight to maximum - 0×255, offset, shift, ...)
 - Set generic_filter_mode to '0'
- Generic 2D Convolution (filtering) Mode: The following core MMR needs to be programmed to enable Bilateral noise filter mode:
 - Set Weight LUT (9 bit unsigned) tables (24 values (each 9-bit signed) in 16 bit container from start of LUT
 - Set Control register fields (Center weight, offset, shift, ...)

- Set generic_filter_mode to '1'

6.7.6.6.1.2 NF SL2 Wrapper Interface Programming Details

The following MMR needs to be programmed as per overall Data flow as well as algorithm needs:

- Set Input (SRC) side SL2 configuration, buffer base address, attributes and sizes
- Set Output (DST) side SL2 configuration, buffer base address, attributes and sizes

6.7.6.6.1.3 HWA HTS Programming Details

For more details of programming, refer to HTS and Section VPAC Subsystem.

Although following are Hardcoded configuration for given HWA (Noise filter (NF)) for HTS:

- Consumer score board: Transaction aggregation
- Number of lines of delay = 5
- ...

6.7.6.6.1.4 HWA Data Transfer Programming Details

For more details, refer to the VPAC Top/UTC specification.

6.7.6.6.2 Initialization Sequence

Refer to Section VPAC Subsystem.

6.7.6.6.3 Real-Time Operating Requirements

Refer to Section VPAC Subsystem.

6.7.6.6.4 Power Up/Down Sequence

Refer to Section VPAC Subsystem.

6.7.6.6.5 Clock Stop

Note NF requires the software to shutdown all traffic and insure the NF is idle before it can assert nf_clkstop_req signal.

Also, no new work/traffic can occur until nf_clockstop_req de-asserts align with nf_clkstop_ack de-assertion. Since the NF will be idle before the assertion of nf_clkstop_req, the assertion of nf_clkstop_ack should occur less than 10 clock cycles in response to the request.

6.8 Depth and Motion Perception Accelerator (DMPAC)

This chapter describes the Depth and Motion Perception Accelerator (DMPAC) in the device.

6.8.1 DMPAC Overview

The Depth and Motion Perception Accelerator (DMPAC) is a power efficient hardware accelerator that computes dense stereo depth maps (*depth*) and dense optical flow vectors (*motion*) from camera inputs.

The image/video sensor-based environmental perception (also known as scene understanding) is at the core of many emerging applications in automotive, industrial and consumer electronics. Typically, this involves detection of all objects in the scene along with their 3D position and motion with regards to the observer or the car by analyzing one or many related input video streams. Various computer vision algorithms are used to achieve these tasks.

A very robust method of obtaining the 3D depth from images is to use two cameras in a stereo setup - two cameras with known relative positions and camera parameters. The two images of the same scene, captured from two different camera poses/perspectives, are analyzed to find disparities among every pixel positions in the images. This is known as the Stereo Disparity map. The disparity values of every pixel can be used to obtain the 3D positions of the object/space they belong to via triangulation.

On the other hand, by analyzing two images from a single camera, captured at two different time instances (that is, two temporal frames in a video), one can determine where each pixel in a past frame moved to in the future frame. This is known as the Optical Flow vector. The flow vectors for each pixel position can be used to obtain 3D structure of the scene, identify moving objects and determine their relative speed and direction of motion.

The DMPAC is dedicated to the aforesaid image processing tasks. The stereo and optical flow processing is partitioned into two top level sub-blocks: the Dense Optical Flow (DOF) engine and the Stereo Disparity Engine (SDE). The DOF and SDE blocks share a common shared local memory, DMA, external messaging and control infrastructure.

6.8.1.1 DMPAC Features

The DMPAC supports the following main features:

- Input image resolution up to 2 MPix with maximum horizontal resolution of up to 2048 pixels and maximum vertical resolution of up to 1024 pixels
- Input pixel format of 12-bit fully packed luminance data, and other formats using the integrated Format Conversion (FOCO) module
- Pixel level output packed in 16bpp and 32bpp formats for stereo disparity estimates and optical flow estimates, respectively
- Simultaneous operation of SDE and DOF, each processing inputs of up to 1 MPix image resolution (1 MPix = 1280 × 720 pixels)
- Resolution vs. frame rate scalability (higher frame rate at lower resolution)
- A Dense Optical Flow (DOF) engine: The DOF engine implements Texas Instruments' proprietary algorithm for estimation/calculation of the optical flow between the input image pair. The algorithm uses hierarchical coarse-to-fine block search strategy leveraging image pyramids in which proprietary binary pixel descriptors are used for pixel correspondence determination. In the scheme accuracy and smoothness of the flow map is enforced using optical flow estimates of the causal neighbors of a pixel in the given and higher (lower resolution) pyramid level (pixels are processed in raster scan order in a pyramid level to refine existing optical flow estimates). The DOF engine supports:
 - Optical flow vector lengths up to +/- 191 pixels in horizontal direction and +/- 62 pixels in vertical direction for each input pixel
 - Dense flow vector map for each input pixel
 - Optical flow vector precision of 1/16th of inter pixel distance
 - Post filtering of the optical flow estimates using 2D median filtering
 - 16 level confidence score for every output flow vector
- A Stereo Disparity Engine (SDE): The SDE implements Texas Instruments' proprietary algorithm in order to find the disparity map between the input image pair. The SDE supports:
 - Disparity search range (SR) of 64/128/192. It can support either "0 to SR-1" or "-3 to SR-4"
 - 1/16th pixel accurate sub-pixel level disparity estimate

- Disparity estimate post processing using 2D median filtering
- 8 level confidence score for each disparity output
- Common top level infrastructure:
 - Shared Level 2 (SL2) memory sub-system, which serves both DOF and SDE blocks, along with the FOCO modules when required as an intermediate storage exchange data across sub-modules (FOCO to DOF/SDE) and from DDR/System Memory
 - A Unified Transfer Controller (UTC), which serves as a DMA engine
 - Messaging and control mechanism via a Hardware Thread Scheduler (HTS) block
 - A Counter, Timer and System Event Trace (CTSET) module, which provides event tracing capability for the SDE and DOF hardware threads

The DMPAC does not support (but relies on other HWAs/processors on the SoC to perform these tasks):

- Epipolar rectification of the stereo input images
- Image pyramid generation for the optical flow input images

7 Interprocessor Communication

This chapter describes the interprocessor communication modules in the device.

7.1 Mailbox.....	714
7.2 Spinlock.....	722

7.1 Mailbox

This chapter describes the mailbox module in the device.

7.1.1 Mailbox Overview

Mailbox module serves to facilitate the communication between the various on-chip processors of the device by providing a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors (users) through a set of registers and associated interrupt signals.

7.1.1.1 Mailbox Features

Each mailbox module supports the following features:

- Parameters configured at design time (see [Table 7-1](#)):
 - Number of mailbox clusters
 - Each mailbox cluster has the same configuration
 - Clusters are accessed via separate VBUS regions. Clusters can be treated as mailbox module instances.
 - Number of users
 - Number of mailbox message queues
 - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Partial writes do not advance the FIFO pointers
- Message reception and queue-not-full notification using interrupts
- Non-intrusive emulation

7.1.1.2 Mailbox Parameters

[Table 7-1](#) shows the configuration of the mailbox module in the device.

Table 7-1. Mailbox Configuration Parameters

Module Instance	Parameters			
	Users (Processors)	Clusters ⁽¹⁾	Message Queues ⁽²⁾	Number of Messages ⁽³⁾
MAILBOX0	4	12	16	4
MAILBOX1	4	12	16	4

(1) Number of mailbox clusters

(2) Number of mailbox message queues (mailboxes per cluster)

(3) Number of messages (FIFO depth) for each message queue

7.1.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

7.1.2.1 System Mailbox Integration

Figure 7-1. Mailbox Integration

Table 7-2 through summarize the MAILBOX integration in the device.

Table 7-2. Mailbox Integration Attributes

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect

Table 7-3. Mailbox Clocks and Resets

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
MAILBOX0	MAILBOX0_RST	MODSS_RST	LPSC	MAILBOX0 hardware reset

Note

For more information on the interconnects, see *System Interconnect*.

For more information on the power, reset, and clock management, see the corresponding sections within *Device Configuration*.

Note

For information about interrupt source description, see *Mailbox Interrupt Requests*.

7.1.3 Mailbox Functional Description

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQ_ENABLE_SET_j (or MAILBOX_IRQ_ENABLE_CLR_j) register.

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each MAILBOX_IRQ_STATUS_RAW_j/MAILBOX_IRQ_STATUS_CLR_j interrupt status register corresponds to a particular user.

7.1.3.1 Mailbox Block Diagram

Figure 7-2 shows the mailbox internal block diagram.

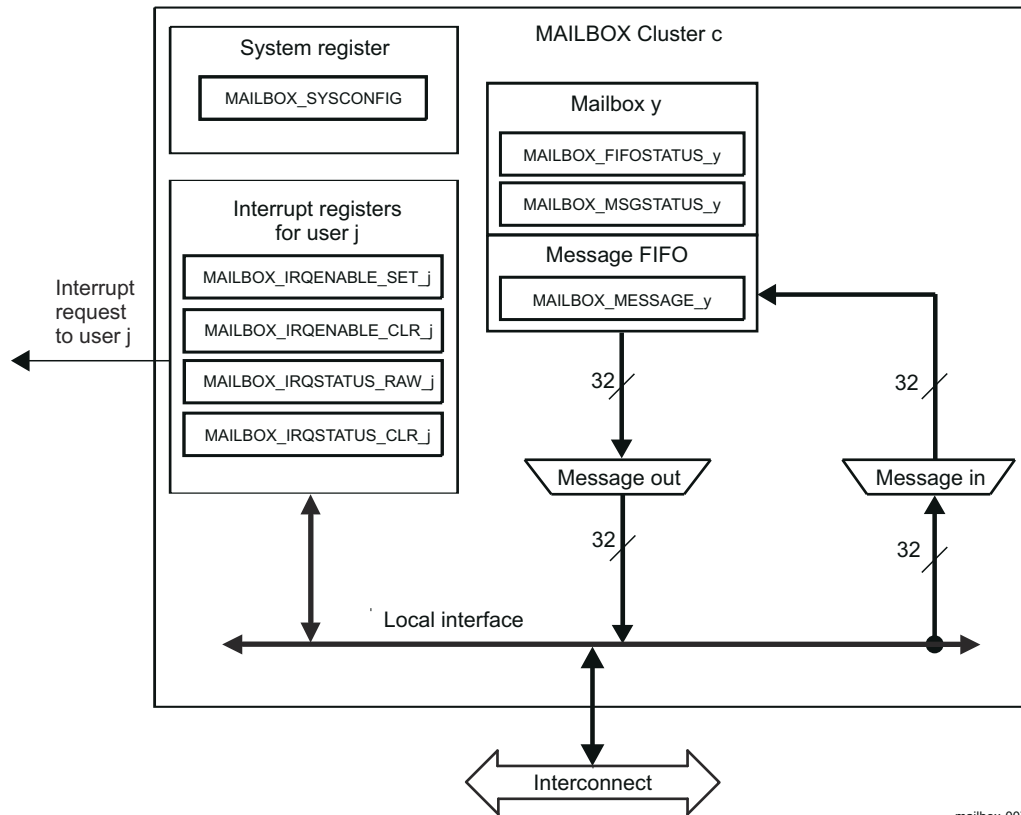

Figure 7-2. Mailbox Block Diagram

j = 0 to 3

y = 0 to 15

7.1.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

7.1.3.3 Mailbox Power Management

The clkstop_idle will be asserted if all of the following are true:

- The VBUSP interface is inactive
- All mailboxes are empty
- There are no enabled events or outstanding interrupts

An enabled event means there is pending action required from one of the users, and it means one or more mailboxes still expect data.

7.1.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

Table 7-4 lists the event flags, and their mask, that can cause module interrupts.

Table 7-4. Interrupt Events

Non-Maskable Event Flag ⁽¹⁾	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQ_STATUS_RAW_j[0+y*2] NEWMSGSTATUSMBY	MAILBOX_IRQ_STATUS_CLR_j[0+y*2] NEWMSG_STATUSMBY	MAILBOX_IRQ_ENABLE_CLR_j[0+y*2] NEWMSG_STATUSMBY	MAILBOX_IRQ_ENABLE_SET_j[0+y*2] NEWMSG_STATUSMBY	Mailbox y receives a new message.
MAILBOX_IRQ_STATUS_RAW_j[1+y*2] NOTFULLSTATUSMBY	MAILBOX_IRQ_STATUS_CLR_j[1+y*2] NOTFULLSTATUSMBY	MAILBOX_IRQ_ENABLE_CLR_j[1+y*2] NOTFULLSTATUSMBY	MAILBOX_IRQ_ENABLE_SET_j[1+y*2] NOTFULLSTATUSMBY	Mailbox y message queue is not full.

(1) MAILBOX_IRQ_STATUS_RAW_j register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQ_STATUS_CLR_j register.

Writing a logical 1 in a bit of the MAILBOX_IRQ_STATUS_CLR_j register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQ_STATUS_RAW_j register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQ_ENABLE_SET_j register. Events are reported in the appropriate MAILBOX_IRQ_STATUS_CLR_j and MAILBOX_IRQ_STATUS_RAW_j registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQ_ENABLE_CLR_j register. Events are only reported in the appropriate MAILBOX_IRQ_STATUS_RAW_j register.

In case of the MAILBOX_IRQ_STATUS_RAW_j register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

7.1.3.5 Mailbox Assignment

7.1.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQ_ENABLE_SET_j register. The receiver reads the MAILBOX_MESSAGE_y register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFO_STATUS_y and/or MAILBOX_MSG_STATUS_y registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQ_ENABLE_SET_j register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFO_STATUS_y or MAILBOX_MSG_STATUS_y registers
- Write the message to the corresponding MAILBOX_MESSAGE_y register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQ_ENABLE_SET_j register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQ_STATUS_CLR_j register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQ_STATUS_CLR_j register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

7.1.3.6 Sending and Receiving Messages

7.1.3.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_y register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

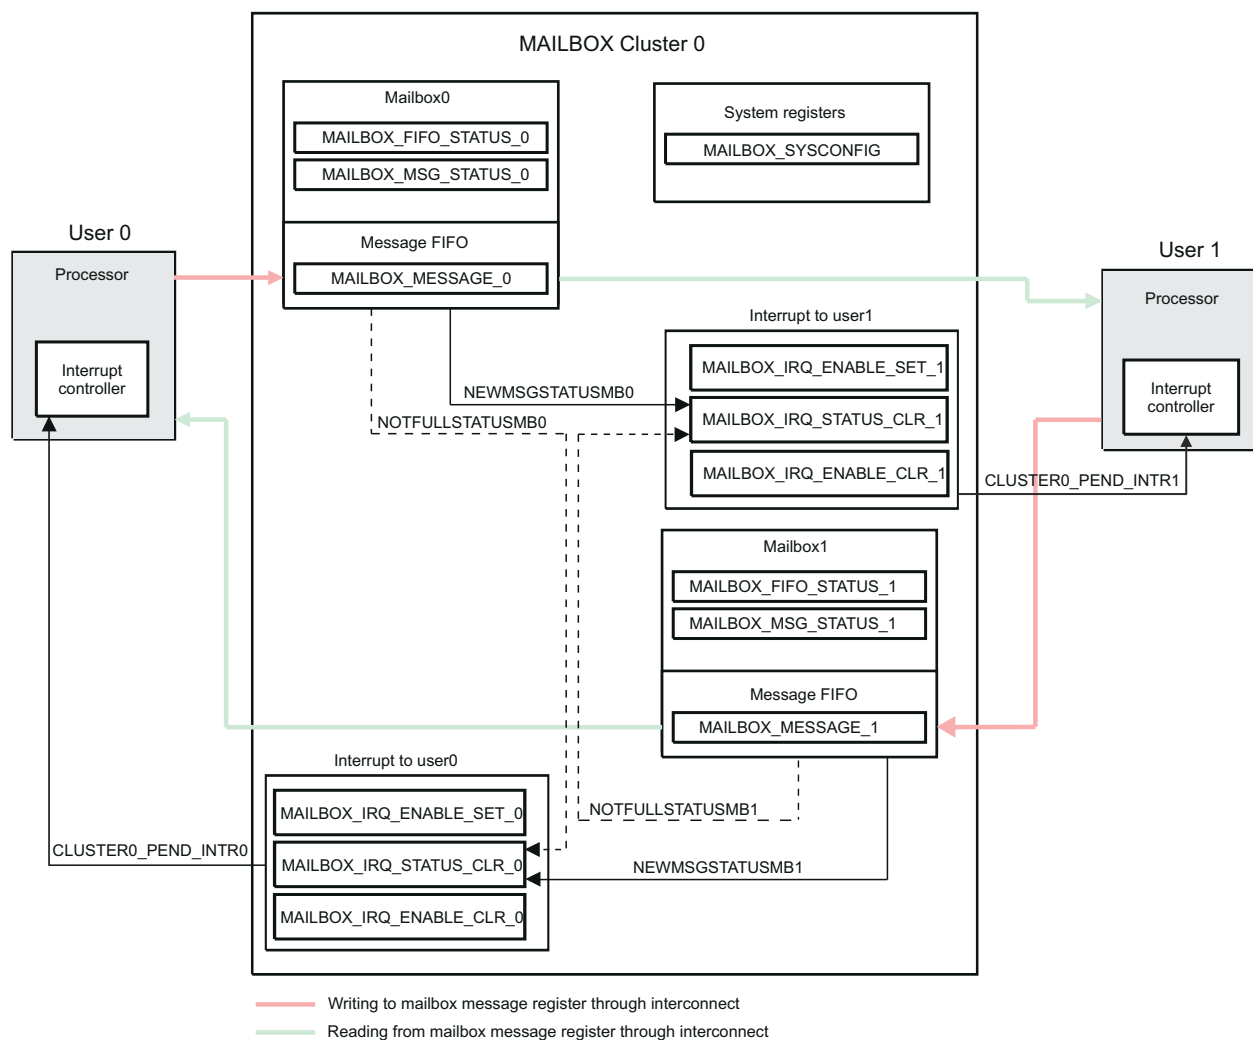

Queue overflow can be avoided by first reading the MAILBOX_FIFO_STATUS_y register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX_MESSAGE_y register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_y register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSG_STATUS_y register.

7.1.3.7 Example of Communication

Figure 7-3 shows an example of communication between two processors.

mailbox-008

Figure 7-3. Example of Communication

7.1.4 Mailbox Programming Guide

7.1.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

7.1.4.1.1 Global Initialization

7.1.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See [Section 7.1.2, Mailbox Integration](#), for further information.

Table 7-5. Global Initialization of Surrounding Modules for MAILBOX

Surrounding Modules	Comments
LPSC	The MAILBOX functional and interface clock must be enabled.
Interrupt Controllers	Processor's (user's) interrupt controller must be configured to enable the interrupt request generation.

7.1.4.1.1.2 Mailbox Global Initialization

7.1.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 7-6. Mailbox Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0] SOFT_RESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG[0] SOFT_RESET	=0x0

7.1.4.1.2 Mailbox Operational Modes Configuration

7.1.4.1.2.1 Mailbox Processing modes

7.1.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

Table 7-7. Sending a Message (Polling Method)

Step	Register/Bit Field/Programming Model	Value
IF: Is FIFO full?	MAILBOX_FIFO_STATUS_y[0] FULL	=0x1
Wait until at least one message slot is available	MAILBOX_FIFO_STATUS_y[0] FULL	=0x0
ELSE		
Write message	MAILBOX_MESSAGE_y[31:0] VALUE	0x-
ENDIF		

7.1.4.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

Table 7-8. Sending a Message (Interrupt Method)

Step	Register/Bit Field/Programming Model	Value
IF: Is FIFO full?	MAILBOX_FIFO_STATUS_y[0] FULL	=0x1
Enable interrupt event	MAILBOX_IRQ_ENABLE_SET_j[1+ y*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 7.1.4.1.3.1 for interrupt handling in sending mode		
ELSE		
Write message	MAILBOX_MESSAGE_y[31:0] VALUE	0x-
ENDIF		

7.1.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

Table 7-9. Receiving a Message (Polling Method)

Step	Register/Bit Field/Programming Model	Value
IF: Number of messages is not equal to 0	MAILBOX_MSG_STATUS_y[2:0] NUM_MESSAGES	≠0x0
Read message	MAILBOX_MESSAGE_y[31:0] VALUE	0x-
ENDIF		

7.1.4.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

Step	Register/Bit Field/Programming Model	Value
Enable interrupt event	MAILBOX_IRQ_ENABLE_SET_j[0 + y*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 7.1.4.1.3.2 for interrupt handling in receiving mode		

7.1.4.1.3 Mailbox Events Servicing

7.1.4.1.3.1 Events Servicing in Sending Mode

[Table 7-11](#) describes the events servicing in sending mode.

Table 7-11. Events Servicing in Sending Mode

Step	Register/Bit Field/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQ_STATUS_CLR_j[1 + y*2]	0x1
Write message	MAILBOX_MESSAGE_y[31:0] VALUE	0x--
Write 1 to acknowledge interrupt	MAILBOX_IRQ_STATUS_CLR_j[1 + y*2]	0x1

7.1.4.1.3.2 Events Servicing in Receiving Mode

[Table 7-12](#) describes the events servicing in receiving mode.

Table 7-12. Events Servicing in Receiving Mode

Step	Register/Bit Field/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQ_STATUS_CLR_j[0 + y*2]	0x1
IF: Number of messages is not equal to 0?	MAILBOX_MSG_STATUS_y[2:0] NUM_MESSAGES	≠0x0
Read message	MAILBOX_MESSAGE_y[31:0] VALUE	0x--
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQ_STATUS_CLR_j[0 + y*2]	0x1
ENDIF		

7.2 Spinlock

This chapter describes the Spinlock module of the device.

7.2.1 Spinlock Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device.

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

7.2.2 Spinlock Functional Description

7.2.2.1 Spinlock Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset.

7.2.2.2 Spinlock Power Management

The Spinlock module supports the Power Idle interface. Software must arrange to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

1. Software must check that all controllers that may be using the Spinlock module are either:
 - a. Already powered off (all in-use flags are 0)
 - b. Notified that Spinlock is not available and the notification is acknowledged
2. If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the SPINLOCK_SYSTATUS register. If any locks are held, they are orphaned because they are not held by any controller that is still active. Alternatively, you may decide to wait a timeout period to allow any active controller to clean up its locks before powering down.

The Spinlock module may now be powered off.

7.2.2.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

7.2.2.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the

SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_y[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_y[0] TAKEN = 0), where y = 0h to FFh.

When the status of lock y (where y = 0 to 255) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_y register returns 0 and sets the lock to Taken (locked). When the status of lock y is Taken, a read returns 1 and does not change the state of the lock.

A write to the SPINLOCK_LOCK_REG_y register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

Figure 7-4 shows the SPINLOCK_LOCK_REG_y register state diagram.

Figure 7-4. Lock Register State Diagram

Note

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

7.2.3 Spinlock Programming Guide

7.2.3.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

7.2.3.1.1 Basic Spinlock Operations

The main Spinlock operations are:

- Clear all the Taken spinlocks by writing 0 to SPINLOCK_LOCK_REG_y (only after a system bug recovery)
- Take a spinlock by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit
- Release spinlock by writing 0 to SPINLOCK_LOCK_REG_i[0] TAKEN bit

7.2.3.1.1.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_y registers at system startup to insure that all locks are initialized to Not Taken.

Table 7-13. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = 1?	SPINLOCK_SYSTATUS[0] IU0	=1
Free the 256 locks	SPINLOCK_LOCK_REG_y[0] TAKEN (y = 0 to 255)	0x0
END		

7.2.3.1.1.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software must disable interrupts. Then it must read the SPINLOCK_LOCK_REG_y[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it must proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition must be reattempted. To prevent unknown interrupt disabled time, interrupts must be re-enabled and then disabled before reattempting to acquire the lock. [Figure 7-5](#) shows the described above procedure.

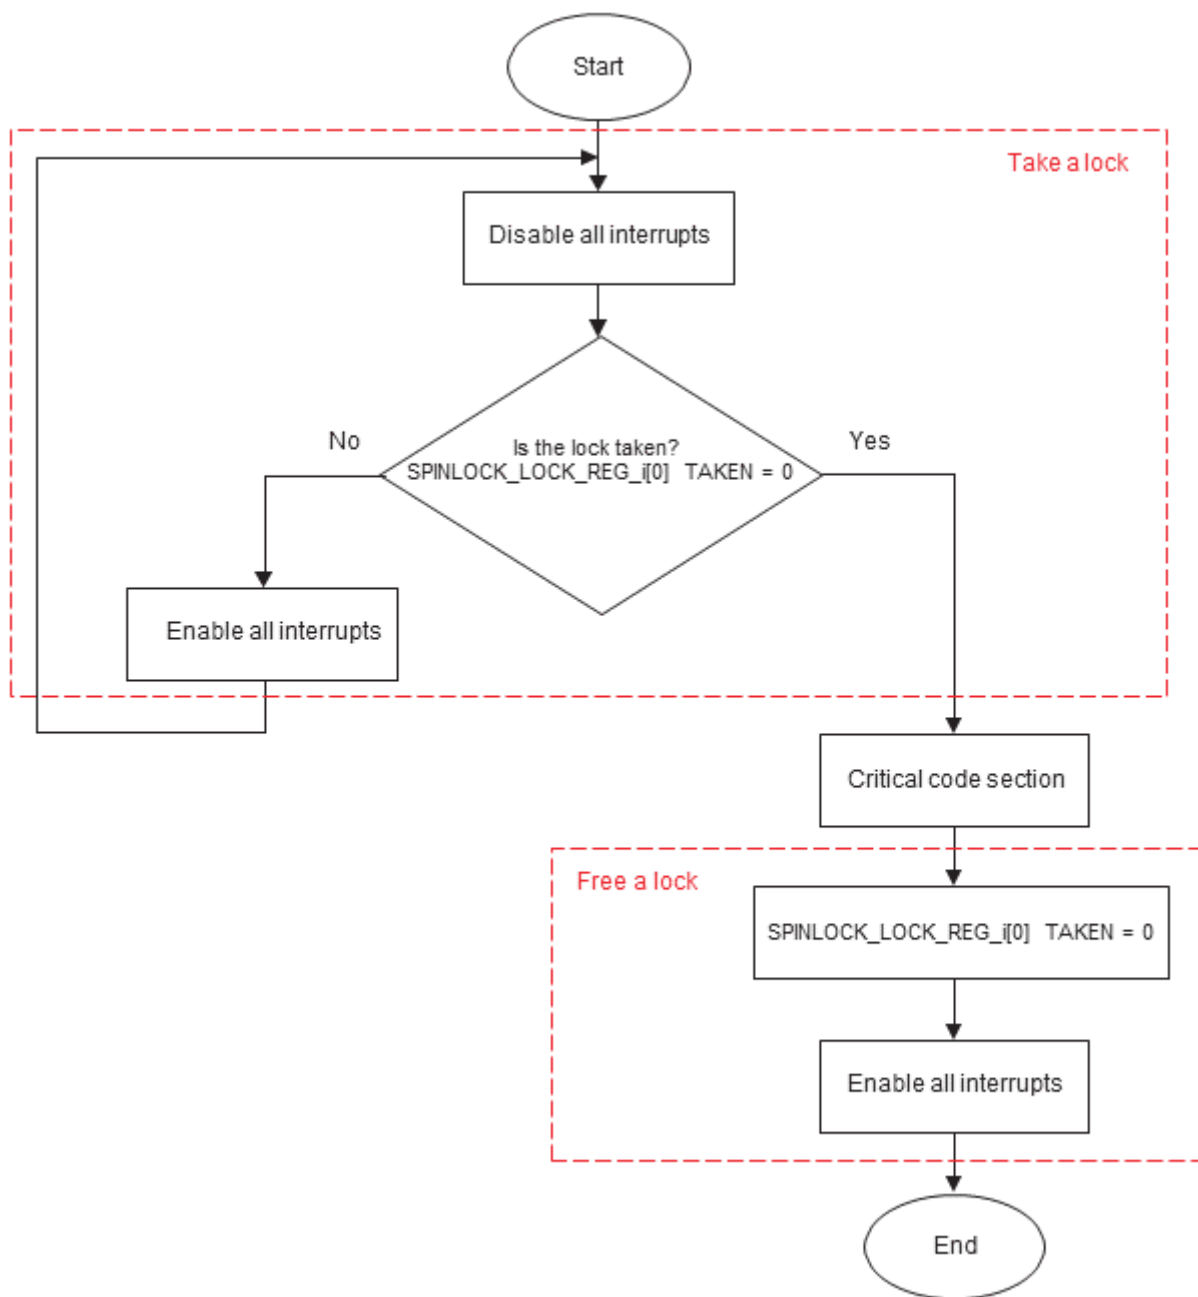

Figure 7-5. Take and Release Spinlock

Table 7-14. Register Call Summary

Register Name
SPINLOCK_LOCK_REG_y[0] TAKEN

Table 7-15. Subprocess Call Summary

Subprocess Name	Description
Disable (Mask) All Interrupts	For information about disabling/enabling all interrupts in an Arm® processor, refer to Arm <i>Technical Reference Manual</i> , available at infocenter.arm.com/help/index.jsp .
Enable (Unmask) All Interrupts	For information about disabling/enabling all interrupts in other processors, refer to the corresponding processor chapter.

8 Memory Controllers

This chapter describes the memory controllers in the device.

8.1 Multicore Shared Memory Controller (MSMC)	727
8.2 DDR Subsystem (DDRSS)	751
8.3 Peripheral Virtualization Unit (PVU)	795
8.4 Region-based Address Translation (RAT) Module	800

8.1 Multicore Shared Memory Controller (MSMC)

This section describes the Multicore Shared Memory Controller (MSMC) for the device.

8.1.1 MSMC Overview

The Multicore Shared Memory Controller (MSMC) forms the heart of the compute cluster (COMPUTE_CLUSTER0) providing high-bandwidth resource access both to and from all of the connected processing elements and the rest of the system. MSMC serves as the data-movement backbone of the compute cluster.

Figure 8-1 shows an overview of the MSMC and its surrounding modules.

Figure 8-1. MSMC Overview

MSMC supports the following features:

- 8MB (5 banks x 1.6MB) SRAM with ECC:
 - Shared coherent level 2/level 3 memory-mapped SRAM
 - Shared coherent level 3 cache
- 512-bit processor port bus and 40-bit physical address bus
- Coherent unified bi-directional interfaces to connect to processors or device masters
- One infrastructure master interface
- Single external memory master interface
- Supports distributed virtual system
- Supports internal DMA engine – DRU (Data Routing Unit)
 - DMA in/out L2 SRAM, MSMC, DDR and system
 - L2, L3 cache pre-warming and post flushing
- Bandwidth management with starvation bound
- Two-level QoS support for real-time/nonreal-time split

- Security firewall flush support for SRAM/cache and external memory
- Functional reliability:
 - SEC/DED protection on all data and tag memories with hardware scrubbing
 - SEC/DED protection on all data pipelines
 - Data memory address hamming protection
 - Coherent interconnect transaction metadata parity protection
- One interconnect messaging interface that supports DMA/prefetch requests to DRU
- Trace and debugging support
- Supports dynamic clock gating on all logic units
- MSMC is always on when VD_CORE is on

8.1.1.1 MSMC Not Supported Features

MSMC does not support the following:

- RAM address decode protection
- Direct cache resize changes from one non-zero cache size configuration to another non-zero cache size configuration. In this case software is required to manually transition down to zero cache size configuration first, followed by a second transition from zero cache size configuration to the new non-zero cache size configuration.
- MSMC SRAM or SDRAM traffic during an MSMC cache resize transition. The traffic during this transition has undefined behavior.

8.1.2 MSMC Functional Description

8.1.2.1 MSMC Block Diagram

Figure 8-2 shows a high-level view of the MSMC module that includes the main interfaces, memory, and subunits.

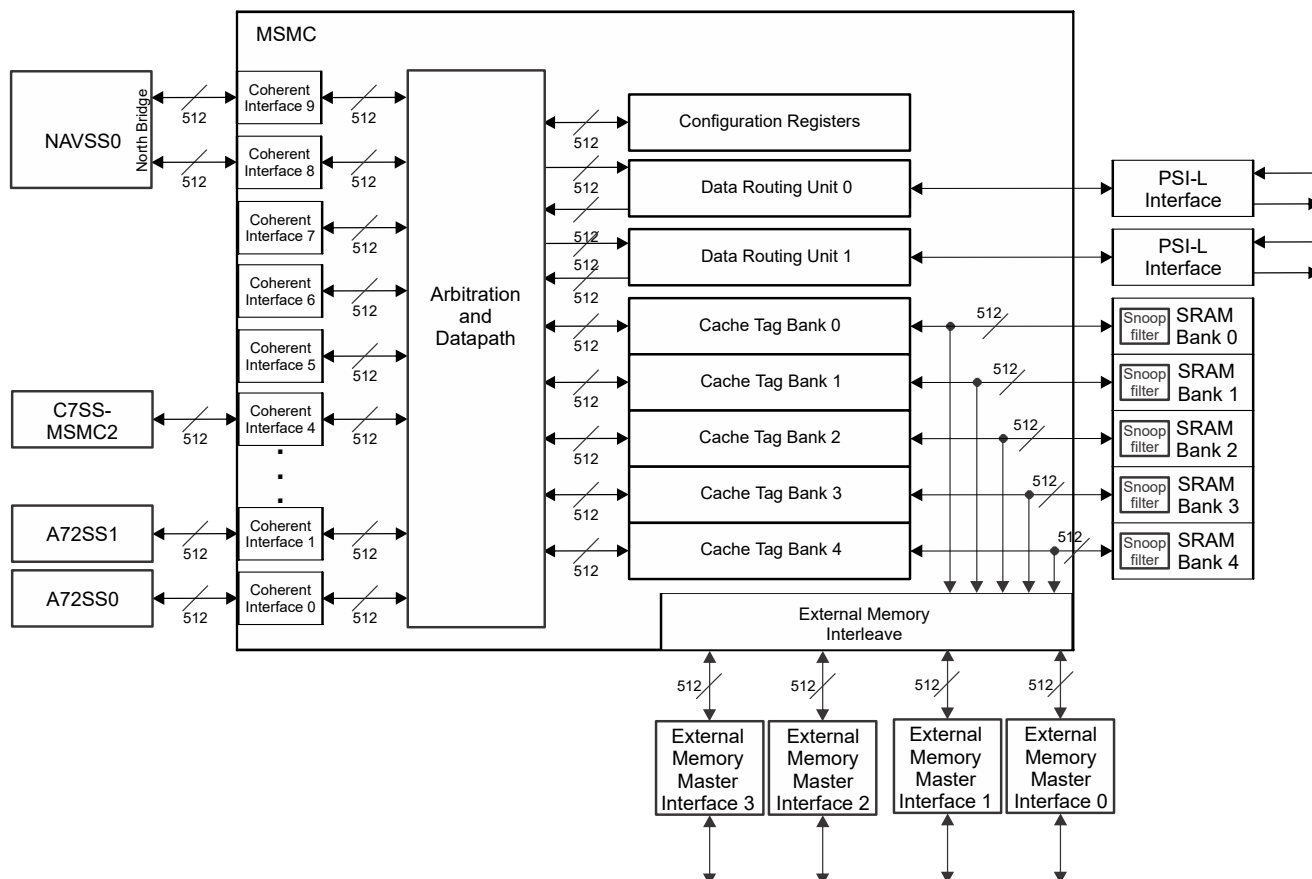

Figure 8-2. MSMC Functional Block Diagram

MSMC directly incorporates on-chip SRAM controllers to provide the compute cluster with low-latency memory. In addition, the individual memory banks can maintain coherence with the connected caching masters as well as the system slave ports.

8.1.2.2 MSMC On-Chip Memory Banking

MSMC on-chip SRAM supports physical and virtual banking to maximize the available bandwidth to all masters. The total SRAM space is divided into five physical banks, and each physical bank contains two virtual sub-banks. These virtual banks provide access to that physical memory bank every MSMC_CLK cycle.

Figure 8-3 shows the MSMC memory organization. Each SRAM bank provides 64 bytes per MSMC_CLK cycle.

Figure 8-3. MSMC Memory Organization

8.1.2.3 MSMC Snoop Filter and Data Cache

Each MSMC SRAM bank implements the memory-mapped SRAM snoop filter in its own memory structure similar to a cache tag memory. The snoop filter tracks atomic coherent blocks at the same granularity as the level 3 cache for external memory: 128 bytes.

MSMC also implements a combined snoop filter and level 3 cache for the connected external memory space. As with the memory-mapped SRAM, the snoop filter exists to optimize performance of coherent external memory data cached in the attached level 1 and level 2 coherent caches. The external memory snoop filter is a 32-way set-associative cache structure which tracks coherent data at the same granularity as the SRAM snoop filter: 128 bytes.

SoC and DRU transactions use snoop filter allocation policy which directs allocations strictly into the data-backed portion (ways) of the L3 cache. Random way selection only occurs when the targeted data-backed or non-data-backed portion (ways) of the L3 cache set are fully occupied. This applies also to CPU transactions, if the `MSMC_CACHE_CTRL[10] ALLOCATION_POLICY` bit is set to 0x0. When the `MSMC_CACHE_CTRL[10] ALLOCATION_POLICY` bit is set to 0x1, all CPU transactions use a randomized allocation policy which can select between both data-backed and non-data-backed ways.

The level 3 snoop filter/cache randomly chooses a way to replace when allocating a new cache line. The foundation of this random replacement is a 24-bit maximal period Linear Feedback Shift Register (LFSR) tuned to minimize any bias. The state of the LFSR supplies two to five bit allocation pointers depending on the configured cache size/number of ways. Each bank houses its own separately initialized LFSR which updates upon each allocation. For debugging purposes, MSMC supplies a linear mode replacement policy which initializes to the configured number of ways, eventually decrement to zero with allocations, and wrap back around to the total number of ways. Software can enable the linear replacement policy by writing 0x1 to the `MSMC_CACHE_CTRL[8] REPLACEMENT_POLICY` bit.

8.1.2.3.1 Way Partitioning

The random replacement implementation attempts to minimize any allocation bias throughout the ways for a large number of allocations. However, it can be useful to introduce purposeful bias to help keep the state of certain tasks resident in the cache. To serve this end, MSMC supports programmable way-partitioning based on real-time versus nonreal-time traffic.

To accomplish this without introducing other unpredictable bias MSMC provides groups of AND-OR masks which can be attached to a group of IDs. The AND-OR masks consist of two fields: a two-bit AND field and a two-bit OR field. MSMC applies these two fields to the lower two bits of the randomly chosen allocation way. [Figure 8-4](#) shows how MSMC calculates the final allocation pointer using the initial random state and the user-defined AND-OR mask.

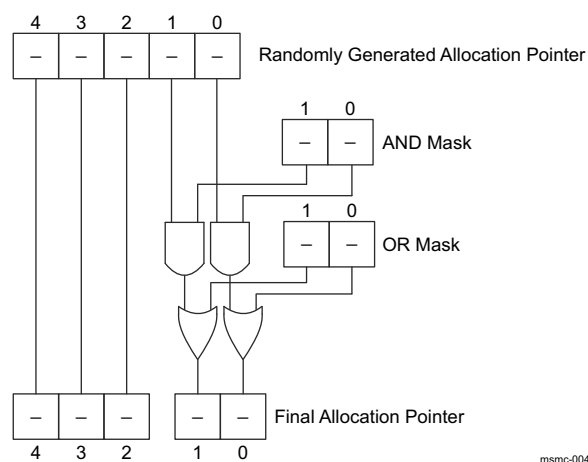

Figure 8-4. Way Partition Allocation Pointer Generation

The two-bit masks allow rough partitioning for quadrants of the cache. Depending on the configured cache size, the cache consists of 0-7 groups of 4 ways each, for a maximum of 32 ways. The upper 3 bits in the allocation

pointer determine which group of 4 ways. The final two bits determine selection between the 4 ways within that group. [Table 8-1](#) describes the possible values for the AND-OR mask and the resulting available ways.

Table 8-1. AND-OR Mask Way Selection

Way 3	Way 2	Way 1	Way 0	AND Mask	OR Mask
X	X	X	X	11	00
X	X			-1	10
		X	X	01	00
X		X		1-	01
	X		X	10	00
X				--	11
	X			-0	10
		X		0-	01
			X	00	00

The AND-OR masks are programmed via the following bit fields:

- MSMC_RT_WAY_SELECT[6-5] OR_MASK
- MSMC_RT_WAY_SELECT[1-0] AND_MASK
- MSMC_NRT_WAY_SELECT[6-5] OR_MASK
- MSMC_NRT_WAY_SELECT[1-0] AND_MASK

MSMC also provides software control over the number of cache way groups real time and non-real time transactions are each allowed to allocate into. The MSMC_RT_WAY_SELECT2[19-16] DATABACKED_GROUPS and MSMC_NRT_WAY_SELECT2[19-16] DATABACKED_GROUPS fields control the number of data backed way groups to be allocatable by real-time and non-real-time transactions, respectively. Similarly, the MSMC_RT_WAY_SELECT2[27-24] NON_DATABACKED_GROUPS and MSMC_NRT_WAY_SELECT2[27-24] NON_DATABACKED_GROUPS fields control the number of way groups without data backing that can be allocated by real-time and non-real-time transactions, respectively.

For any setting of these values MSMC minimizes the number of way groups that are simultaneously allocatable by both real-time and non-real-time transactions. For example, if there are 3 way groups with data backing and both real-time and non-real-time transactions are configured to be allocatable in 2 data backed way groups, then one way group will be allocatable by only real-time transactions, one only by non-real-time transactions, and one that is allocatable by both real-time non-real-time transactions.

If DATABACKED_GROUPS is set to 0h or is a value greater than the value of the MSMC_CACHE_CTRL[3-0] CACHE_SIZE filed, then MSMC will defer to the CACHE_SIZE setting to determining what way groups are available for any data-allocating transactions. Similarly, if NON_DATABACKED_GROUPS is set to 0h or is a value greater than the value of (8-CACHE_SIZE), then MSMC will defer to (8-CACHE_SIZE) when determining what way groups are available for any non-data allocating transactions.

8.1.2.3.2 Cache Size Configuration and Associativity

MSMC has registers to provide software control to determine which portion of the on-chip SRAM will be used as cache data store. To maximize this flexibility, the associativity of the level 3 data cache scales with the desired cache size. The 32 ways in each snoop filter set are separated into 8 groups of 4 ways each as shown in [Table 8-2](#).

Table 8-2. Cache Way Grouping

	Group 0	Group 1	Group 2	Group 3
Way 0	0	4	8	12
Way 1	1	5	9	13
Way 2	2	6	10	14
Way 3	3	7	11	15
	Group 4	Group 5	Group 6	Group 7
Way 0	16	20	24	28

Table 8-2. Cache Way Grouping (continued)

	Group 0	Group 1	Group 2	Group 3
Way 1	17	21	25	29
Way 2	18	22	26	30
Way 3	19	23	27	31

The MSMC_CACHE_CTRL[3-0] CACHE_SIZE bit field controls the cache size by selecting how many way groups are backed with data. [Table 8-3](#) describes the encodings of the CACHE_SIZE field.

Table 8-3. Cache Size Field Encodings

CACHE_SIZE	Number of Active Way Groups	Total Active Data Ways
0x0	0	0 ways
0x1	1	4 ways
0x2	2	8 ways
0x3	3	12 ways
0x4	4	16 ways
0x5	5	20 ways
0x6	6	24 ways
0x7	7	28 ways
0x8	8	32 ways

Writing a new value to the CACHE_SIZE field begins the cache size transition process. The MSMC hardware sets the MSMC_CACHE_CTRL[4] SZ_TRANSITION bit to 0x1 during this transition process. When the transition process completes hardware sets SZ_TRANSITION to 0x0. During this transition time window:

- Further writes to the CACHE_SIZE field are ignored
- Reads to the CACHE_SIZE field reflect the previous field value.

After setting a new CACHE_SIZE value, software can poll the SZ_TRANSITION bit to know when the transition is complete. At that point the new CACHE_SIZE value can be read in the MSMC_CACHE_CTRL[3-0] CACHE_SIZE bit field.

As the cache scales up in size, the memory-mapped space shrinks by the same amount, appearing as though the cache grows from the top of the memory mapped region down. This provides a single contiguous memory-mapped window starting from the SRAM base address. The memory space occupied by the cache is no longer accessible as memory-mapped SRAM and any accesses to this space return an addressing error.

8.1.2.3.3 Write Back Invalidate

Through the MSMC_WBINV_CTRL register MSMC provides control for software to trigger a coherent invalidation of MSMC external or internal SRAM snoop filters. If the MSMC_WBINV_CTRL[0] EMIF_SF_WBINV bit is set to 1h, then MSMC will invalidate the external snoop filter, writing back any dirty data to EMIF. If the MSMC_WBINV_CTRL[4] SRAM_SF_WBINV bit is set to 1h, then MSMC will invalidate the internal SRAM snoop filter and write back any dirty data into its own SRAM. If both fields are written to simultaneously, then MSMC will invalidate the external snoop filter before invalidating the internal SRAM snoop filter immediately afterwards. As part of the write back invalidation procedure, MSMC will request all coherent masters to invalidate any lines that MSMC is tracking.

When the write back invalidation of the external or internal SRAM SF is triggered the MSMC_WBINV_CTRL[8] WBINV_ACTIVE bit is set to 1h until all invalidations are complete at which time the bit is reset to 0h.

Due to shared hardware between snoop filter invalidation and cache resizing for looping through all of the snoop filter entries, any write to EMIF_SF_WBINV, SRAM_SF_WBINV, or the MSMC_CACHE_CTRL[3-0] CACHE_SIZE field will be ignored if the WBINV_ACTIVE bit is 1h. Similarly, writes to EMIF_SF_WBINV and SRAM_SF_WBINV are ignored if a cache resize is in progress.

MSMC will maintain coherency for any transactions that arrive during a write back invalidation procedure, although the snoop filter state for any addresses they access is not guaranteed to be invalid until the operation is complete. The snoop filter state for any address accessed during the invalidation of the associated snoop filter

depends on whether or not the access occurs before or after MSMC has performed its write back invalidation on that particular snoop filter entry.

8.1.2.4 MSMC Access Protection Checks

To support potential software polling/reconfiguration for functional reliability, MSMC does not trigger error status for configuration accesses to unimplemented addresses. All reads of unimplemented addresses return data as zero and writes are ignored. This model should support a simple DMA "read, compare, and write-back" model for checking the MSMC configuration state.

8.1.2.5 MSMC Null Slave

MSMC implements a null slave endpoint to handle accesses which cannot be sent to their intended destination. This can happen for several reasons listed in [Table 8-4](#). Commands routed to null slave return to the originating master with the appropriate response status listed in [Table 8-4](#). MSMC prioritizes protection error status over addressing error status when both can be applied to a single command.

Table 8-4. Null Slave Response Status

Description	Response Status
Firewall Flush	Protection Error
Invalid Memory Range	Addressing Error
Coherent Command to DMA	Success
Disabled Endpoint	Addressing Error
Real-time to DMA	Addressing Error

MSMC captures command information and triggers an event when routing unexpected command to null slave. Any of the conditions in [Table 8-4](#) which respond with a faulted response status (except firewall failures) triggers null slave error interrupt and logs appropriate command information to the MSMC_NULL_SLV_STAT0 and MSMC_NULL_SLV_STAT1 registers. The following bit fields capture that command information:

- ADDR
- BYTECNT
- ROUTEID
- PRIVID
- OPCODE
- MEMTYPE
- EMU
- SEC
- PRIV

For more information about the MSMC interrupts, see [Section 8.1.2.8](#).

MSMC captures a single null slave error event into the MSMC_NULL_SLV_STAT0 and MSMC_NULL_SLV_STAT1 registers.

8.1.2.6 MSMC Resource Arbitration

When access requests arrive at the MSMC slave ports, the requests may target the same endpoint and hence need arbitration. These endpoint arbiters implement a multi-layer fairness arbitration scheme with starvation bounds to allow the user control to partition system bandwidth.

In each arbitration cycle, each arbiter prioritizes all active requests using the following prioritized layers until it selects a unique winner:

1. Transaction-tagged priority - Each active requestor pushes out a priority based on all of the currently active transactions in its pipeline. The highest priority requestors are chosen.
2. Fair-Share State - The arbiter selects the requestor(s) with the highest internal Fairshare state.
3. Static Priority - Finally, the arbiter uses a static priority to break any remaining ties after levels 1 and 2.

In addition to the three levels the arbiter tracks a starvation count for each requestor to each arbiter. Every time a request wins arbitration, all loser requests have their starvation count decremented. Every time a requestor wins arbitration for an active request, the starvation count resets to the initial state. If the starvation count reaches

zero, that requestor priority level elevates to the highest priority level. Once the starved active request wins arbitration the priority level reverts back to the normal value. These starvation bounds can be programmed via the MSMC_SBNDCOH0 through MSMC_SBNDCOH12 registers.

Note

Not all MSMC_SBNDCOHx registers are used on this device.

The three-layer arbitration scheme is not sufficient to ensure a bound on the minimum bandwidth experienced by lower priority requests relative to higher priority requests. Consequently, a starvation bound can be defined to limit that minimum bandwidth experienced by the lower priority requests relative to higher priority requests.

Since MSMC introduces multiple virtual channels feeding the same physical arbiter, the starvation mechanism is expanded to specify bounds for these channels.

Table 8-5. Starvation Bound Definitions

Port	Channel	Resource Target	Register Name and Field
Cache coherent 0	Real-time	External memory	MSMC_SBNDCOH0[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH0[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH0[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH0[7-0] SBNDM_NRT
Cache coherent 1	Real-time	External memory	MSMC_SBNDCOH1[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH1[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH1[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH1[7-0] SBNDM_NRT
Cache coherent 4	Real-time	External memory	MSMC_SBNDCOH4[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH4[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH4[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH4[7-0] SBNDM_NRT
Cache coherent 5	Real-time	External memory	MSMC_SBNDCOH5[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH5[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH5[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH5[7-0] SBNDM_NRT
Cache coherent 6	Real-time	External memory	MSMC_SBNDCOH6[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH6[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH6[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH6[7-0] SBNDM_NRT
Cache coherent 7	Real-time	External memory	MSMC_SBNDCOH7[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH7[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH7[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH7[7-0] SBNDM_NRT
Cache coherent 8	Real-time	External memory	MSMC_SBNDCOH11[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH11[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH11[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH11[7-0] SBNDM_NRT
Cache coherent 9	Real-time	External memory	MSMC_SBNDCOH12[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH12[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH12[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH12[7-0] SBNDM_NRT

Table 8-5. Starvation Bound Definitions (continued)

Port	Channel	Resource Target	Register Name and Field
DRU	Real-time	External memory	MSMC_SBNDDR[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDDR[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDDR[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDDR[7-0] SBNDM_NRT
Responses Snoops	Real-time	External memory	MSMC_SBNDR[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDR[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDR[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDR[7-0] SBNDM_NRT

The starvation bounds specified through the registers in [Table 8-5](#) apply to each trip an access requires through an arbitration point. The number of potential arbitrations should be considered when programming the starvation bounds. The following are few common examples of round-trip command arbitration for reads:

- Non-coherent SRAM read: Command central arbitration > Data SRAM arbitration > Response central arbitration
- Coherent SRAM read: Command central arbitration > Snoop central arbitration > Snoop response central arbitration > Read response central arbitration

Depending on whether caching and coherence are enabled and the state of the system, the number of potential arbitrations for a given access may vary and starvation should be considered accordingly.

8.1.2.7 MSMC Error Detection and Correction

MSMC protects both on-chip memory resources and data busses throughout the MSMC pipelines. A mixture of SEC/DED (single-error correct/double-error detect) hamming code and simple parity protect the on-chip memory resources.

Note

MSMC aligns to the device architecture for system reliability using ECC aggregators to report detected parity and EDC faults both from scrubbing and functional access. The MSMC associated ECC aggregators are part of COMPUTE_CLUSTER0. For more information, see *Compute Cluster ECC Aggregators* in *Compute Cluster*.

For information about the ECC aggregator functionality, see *ECC Aggregator*.

8.1.2.7.1 On-chip SRAM and Pipeline Data Protection

The on-chip data memory and data bus pipelines share the same Hamming EDC strategy to maximize protection across MSMC. Two EDC data/hamming pairs combine to form each 64 bytes of data. When functional accesses read data from the memory the EDC code travels through the MSMC pipeline with the data protecting all of those data pipelines in addition to the memory. Consumers of the protected data pairs should perform the EDC check and correction as needed before utilizing the data.

MSMC does not protect stored memory data all of the time. This requires memory initialization after reset to avoid spurious errors. In addition, read-modify-write combine cycle is also needed in case of any write access to the memory that does not commit to a full EDC quanta.

MSMC stores each 532-bit data + hamming code separately in the on-chip SRAM in the following way:

- SRAM[255:0] -> 256-bit Data Word 0
- SRAM[265:256] -> 10-bit Hamming Word 0
- SRAM[266:521] -> 256-bit Data Word 1
- SRAM[531:522] -> 10-bit Hamming Word 1

8.1.2.7.2 On-chip SRAM L3 Cache Tag and Snooper Filter Protection

The level 3 cache/snooper filter tags stored in on-chip SRAM are also SEC/DED protected similarly to the data storage. Due to timing closure including all of the tag bits for a given set into one hamming data + code word is

not possible. Instead, the 32 ways are broken into 8 groups of 4 ways each comprising hamming data (100 bits) + code (9 bits). The MSMC core logic outputs 8 logical SRAM interfaces for the tag memories based on the EDC protection quanta sizes. The hamming protection bits are stored at the most significant bit positions of the total data + hamming word inside the logical memory instance.

8.1.2.7.3 On-chip SRAM Memory Mapped SRAM Snoop Filter Protection

MSMC stores the memory mapped SRAM snoop filter state in a separate memory from the tags and protects this information with simple parity. Each snoop filter entry requires five data bits and eight coherent blocks are stored together as a parity data word, resulting in one parity bit to every 40 data bits. The parity bit resides at the most significant bit position in the total parity + data word.

8.1.2.7.4 Background Parity Refresh (Scrubbing)

The MSMC has scrubbing engine that periodically cycles through each location of each memory bank in the MSMC, reading and correcting the data, recalculating the parity bits for the data and storing the data and parity information.

The frequency with which each scrubbing cycle is initiated and the delay between each burst by the scrubbing engine is programmed using the MSMC_SMEDCC register. The MSMC_SMEDCC[7-0] REFDEL bitfield controls the number of MSMC_CLK cycles between each scrub. To prevent the bursts from the scrubbing engine from posing a significant performance impact, the value in the REFDEL field is pre-scaled by 1024 in functional mode. A value of 0 is interpreted to be the same as a value of 1. At reset, REFDEL = 0 and a new scrub burst is issued 1024 cycles after the previous one ends. The operation of the scrubbing engine is enabled by default at reset but may be disabled by setting the MSMC_SMEDCC[31] SEN bit to 0x0.

8.1.2.8 MSMC Interrupts

The MSMC has the following registers for interrupt control:

- MSMC_SMIRSTAT - Raw interrupt status
- MSMC_SMIRWS - Raw interrupt software set
- MSMC_SMIRC - Raw interrupt software clear
- MSMC_SMIESTAT - Enable interrupt status
- MSMC_SMIEWS - Enable interrupt software set
- MSMC_SMIEC - Enable interrupt software clear
- MSMC_SMESTAT - Raw and Enabled Interrupt Status

Each bit in these registers represents a single event or interrupt supported by MSMC, which generates only one interrupt. This is the null slave error interrupt (MSMC_NULL_SLAVE_ERROR). MSMC sets this event when routing a command through the MSMC null slave port which results in an unsuccessful response status. Commands failing firewall checks do not trigger the null slave error interrupt event in MSMC.

8.1.2.8.1 Raw Interrupt Registers

MSMC sets the associated bit in the MSMC_SMIRSTAT register when a software or hardware event occurs. Software can trigger the event by setting the corresponding bit in the MSMC_SMIRWS register. MSMC keeps the MSMC_SMIRSTAT bit asserted until software clears it by setting the corresponding bit in MSMC_SMIRC. Both MSMC_SMIRWS and MSMC_SMIRC are write-only registers and do not implement any actual state.

8.1.2.8.2 Interrupt Enable Registers

Software can enable an event by setting the associated bit in the MSMC_SMIEWS register, and MSMC will assert the same bit in the MSMC_SMIESTAT register in response. The bit of MSMC_SMIESTAT remains asserted until software disables the event by setting the corresponding bit in the MSMC_SMIEC register. Both MSMC_SMIEWS and MSMC_SMIEC are write-only registers and do not implement any actual state.

8.1.2.8.3 Triggered and Enabled Interrupts

The MSMC_SMESTAT register is a read-only reflection of events that are both triggered and enabled. It is a combination of MSMC_SMIRSTAT and MSMC_SMIESTAT.

8.1.2.9 MSMC Memory Regions

Device masters access MSMC controlled resources through two memory map windows - internal and external.

Table 8-6 shows all MSMC associated memory regions including detailed breakdown of the MSMC internal memory mapped window.

Table 8-6. MSMC Memory Regions

Region	Start Address	End Address	Region Size
Internal memory mapped window			
MSMC Coherent Interface for A72SS0	0x00 6000 0000	0x00 60FF FFFF	16 MB
MSMC Coherent Interface for A72SS1	0x00 6100 0000	0x00 61FF FFFF	16 MB
MSMC Coherent Interface for C71SS0	0x00 6400 0000	0x00 64FF FFFF	16 MB
MSMC Coherent Interface for C71SS1	0x00 6500 0000	0x00 65FF FFFF	16 MB
MSMC Coherent Interface for C71SS2	0x00 6600 0000	0x00 66FF FFFF	16 MB
MSMC Coherent Interface for C71SS3	0x00 6700 0000	0x00 67FF FFFF	16 MB
MSMC Coherent Interface for the NB0 Port of North Bridge in NAVSS0	0x00 6B00 0000	0x00 6BFF FFFF	16 MB
MSMC Coherent Interface for the NB1 Port of North Bridge in NAVSS0	0x00 6C00 0000	0x00 6CFF FFFF	16 MB
DRU0 Configuration Registers	0x00 6D00 0000	0x00 6D0F FFFF	1 MB
DRU1 Configuration Registers	0x00 6D10 0000	0x00 6D1F FFFF	1 MB
MSMC Configuration Registers	0x00 6E00 0000	0x00 6EFF FFFF	16 MB
MSMC SRAM	0x00 7000 0000	0x00 707F FFFF	8 MB
External memory mapped window			
2 GB External SDRAM Space	0x00 8000 0000	0x00 FFFF FFFF	2 GB
32 GB External SDRAM Space ⁽¹⁾	0x08 0000 0000	0x0F FFFF FFFF	32 GB
Other MSMC associated memory regions			
Compute Cluster ECC Aggregator 0 Configuration Registers	0x4D 2000 0000	0x4D 2000 03FF	1 KB
Compute Cluster ECC Aggregator 1 Configuration Registers	0x4D 2000 0400	0x4D 2000 07FF	1 KB
Compute Cluster ECC Aggregator 2 Configuration Registers	0x4D 2000 0800	0x4D 2000 0BFF	1 KB

(1) The first 2 GB of this region are inaccessible.

As shown in Table 8-6 software accesses the memory-mapped on-chip SRAM as part of the MSMC memory mapped space.

8.1.2.10 MSMC Hardware Coherence

MSMC supports hardware cache coherence between CPU cache-coherent masters and peripherals accessing MSMC through the system slave ports for shared SRAM and DDR data range spaces. Hardware coherence support abstracts away the cache memory systems of supported components from software, simplifying software implementation.

MSMC does not support memory coherence for the following spaces:

- DDRSS configuration space
- MSMC configuration space
- System-on-chip master port peripherals/memory
- CPU local resources such as memory-mapped level 2 SRAM
- Any other memory not directly connected to MSMC

To stay coherent with each other, caches inside coherent masters typically track more states than the traditional valid/dirty combinations. MSMC uses the ACE coherence protocol which supports these five MOESI states:

- Modified - Cache line is unique (no other caches currently have it) and dirty
- Owned - Cache line is shared (other caches may have it) and dirty
- Exclusive - Cache line is unique (no other caches have it) and clean
- Shared - Cache line is shared (other caches may have it) and clean

- Invalid - No allocated line

In order to maintain coherence between cached masters, MSMC can initiate requests to coherent masters for shared regions of memory. These requests are referred to as "snoop requests".

The following example demonstrates how coherence is maintained between DMA and CPU, when DMA writes to shareable memory space.

1. DMA (noncaching master) issues a write to shareable space.
2. MSMC coherence controller issues Invalidate and Writeback snoop to all CPUs.
3. All CPUs invalidate the line from their cache and respond with dirty data if necessary
4. MSMC merges the DMA write data with the victim and commits to memory.

The following example demonstrates how coherence is maintained between DMA and CPU, when DMA reads from shareable memory space.

1. DMA issues a read to shareable space.
2. MSMC coherence controller issues a ReadOnce snoop to the CPU.
3. CPU responds with cached data.
4. MSMC returns the read data to DMA.

8.1.2.10.1 Snoop Filter Broadcast Mode

As described in [Section 8.1.2.3](#) MSMC implements inclusive snoop filters for both memory-mapped SRAM and external memory shared space to limit the amount of required snoop traffic. Both the SRAM and external snoop filters encode the following states for each coherent memory block in their respective filtering structures:

- INVALID - This memory block must be in Invalid state in all coherent CPUs. Since the external snoop filter is inclusive of all cached coherent data, a miss in the snoop filter is functionally equivalent to this state.
- CPU_SHARED - This memory block may be cached in Shared or Owned state in the associated coherent CPU.
- CPU_UNIQUE - This memory block may be cached in Shared, Owned, Exclusive, or Modified state in the associated coherent CPU.
- BROADCAST_SHARED - This memory block may be cached in Shared or Owned states in multiple coherent CPUs.
- BROADCAST_UNIQUE - This memory block may be cached in Shared, Owned, Exclusive, or Modified states in multiple coherent CPUs. Typically lines only reach this state when MSMC encounters a snoop filter parity error or broadcast mode is enabled.

As a safeguard MSMC provides a "Broadcast Mode" configuration that forces MSMC to treat all snoop filter entries as BROADCAST_UNIQUE. This results in snoops generated to all applicable coherent masters for snoop filter hits and misses. All allocations are killed when broadcast mode is set.

Because there are no cache allocations in this mode, inclusivity is lost. Coherency is maintained as long as broadcast mode is set but dynamic change of broadcast mode (that is, enable to disable) is not supported. System must invalidate L2 caches of all snoopable coherent masters connected to MSMC before they can disable broadcast mode again after enabling it to maintain coherence. To enable the broadcast mode feature the MSMC_COHCTRL[0] BCM bit should be set to 0x1.

Note

Broadcast mode is expected to be used as a debug feature only as performance will be significantly impacted once this mode is enabled.

8.1.2.11 MSMC Quality-of-Service

As an orthogonal axis to arbitration priority MSMC provides two classes of traffic, real-time (RT) and nonreal-time (NRT), to maintain quality-of-service (QoS) guarantees and alleviate head-of-line blocking issues. The currently implemented dataflows supported by the QoS hardware are:

- SoC coherent slave - MSMC SRAM
- SoC coherent slave - External memory

- DRU coherent slave - MSMC SRAM
- DRU coherent slave - External memory

At a high-level priority and QoS represent orthogonal axes controlling the latency (priority) and bandwidth protection (QoS) for multiple data flows routed through the MSMC. To accomplish this MSMC provides a dedicated buffering at each arbitration point that can only be consumed by RT traffic. This way NRT traffic cannot completely starve out RT requests.

The SoC coherent, DRU coherent, and external memory interfaces need dedicated credits to support QoS. Each of these interfaces implements additional threading to exchange these dedicated credits.

Table 8-7. QoS Threading

Thread Index	[0]	[2]
SoC Coherent Slave	CPU	RT_CPU
DRU Coherent Slave	CPU	RT_CPU
External Memory Master	CPU	RT_CPU

The RT_CPU thread provides a completely separate pool of credits, where necessary, to implement the dedicated buffers for RT traffic.

Note

There is no software control over the MSMC QoS hardware.

Note

Interfaces which do not support QoS features denote all traffic as nonreal-time.

8.1.2.12 MSMC Memory Regions Protection

There is no built-in firewall to protect the on-chip and external memory regions. MSMC relies on the system distributed firewall structure to protect these memory windows. MSMC receives a "pass/fail" attribute on each of its entry points including the DRU interfaces which it uses to route the transaction to either the addressed endpoint (pass) or to the internal null slave (fail). Transactions carrying the "fail" return Protection Error on read or write status. Since these failed transactions route through the null slave endpoint no snoops, allocations, or other hardware side-effects occur as a result of these transactions.

8.1.2.13 MSMC Cache Tag View

MSMC implements debug hardware to allow software to query the state of the SRAM snoop filter and L3 cache tag/snoop filter. Software can query the tag structures using the MSMC_DBGTAGCTL and MSMC_DBGTAGVIEW registers in the following sequence:

1. Write the desired tag or snoop filter information to the MSMC_DBGTAGCTL register and wait for status return
2. Read the MSMC_DBGTAGVIEW register to collect the values populated from step 1

The write in step 1 triggers population of the MSMC_DBGTAGVIEW register with the appropriate values from the tag or snoop filter memory. The following are important notes about this feature:

- Writing invalid values into the MSMC_DBGTAGCTL register results in undefined values in the MSMC_DBGTAGVIEW register.
- All writes to MSMC_DBGTAGCTL triggers re-population of MSMC_DBGTAGVIEW, regardless of whether MSMC_DBGTAGVIEW has been read since the last write to MSMC_DBGTAGCTL
- This feature is intended for debug use when the system is halted or quiet. If software writes MSMC_DBGTAGCTL during active operation MSMC will find an empty cycle on the tag/snoop filter memory to read the contents and return to MSMC_DBGTAGVIEW. However, if there are accesses in flight which operate on the desired tag or snoop filter block the contents of MSMC_DBGTAGVIEW will reflect whatever was in the memory at the time of read.

- Security considerations for cache tag view must be comprehended in the firewalls present before all MSMC request interfaces. MSMC does not perform additional security checks.

8.1.2.14 MSMC R50+ Features

8.1.2.14.1 Way Group Partitioning

Real-time and non-real-time transactions are an example of transactions that should, ideally, have orthogonal processing, so it is important that they are allocated in separate way groups to take advantage of per-way-group hazarding.

In addition to having a configurable number of cache way groups be backed with data, MSMC also provides software control over the number of cache way groups real time and non-real time transactions are each allowed to allocate into. The DATABACKED_GROUPS fields within the RT_WAY_SELECT and NRT_WAY_SELECT memory-mapped registers control the number of data backed way groups to be allocatable by real-time and non-real-time transactions, respectively. Similarly, the NON_DATABACKED_GROUPS fields within the RT_WAY_SELECT and NRT_WAY_SELECT memory-mapped registers control the number of way groups without data backing that can be allocated by real-time and non-real-time transactions, respectively.

For any setting of these values MSMC will minimize the number of way groups that are simultaneously allocatable by both real-time and non-real-time transactions. For example, if there are 3 way groups with data backing and both real-time and non-real-time transactions are configured to be allocatable in 2 data backed way groups, then one way group will be allocatable by only real-time transactions, one only by non-realtime transactions, and one that is allocatable by both real-time non-real-time transactions. This is shown in [Figure 8-5](#).

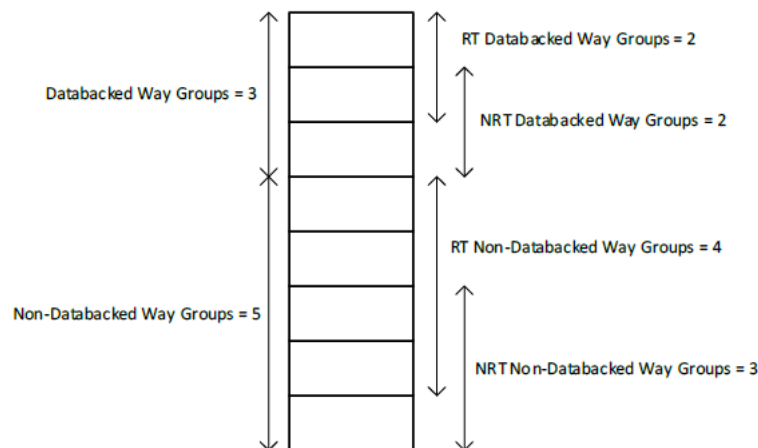

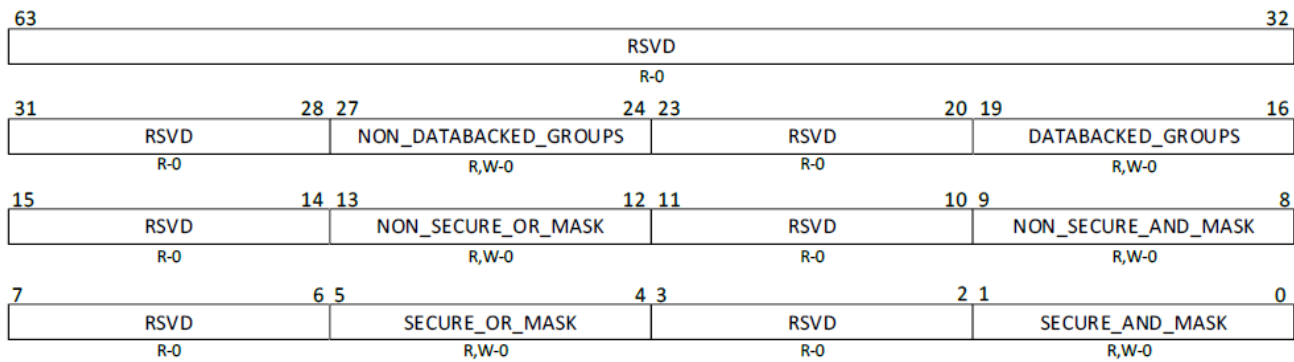

Figure 8-5. Way Group Partitioning

If DATABACKED_GROUPS is set to '0' or is a value greater than the value in the CACHE_SIZE field within the CACHE_CTRL memory mapped register, then MSMC defers to the CACHE_SIZE setting to determine what way groups are available for any data-allocating transactions. Similarly, if NON_DATABACKED_GROUPS is set to '0' or is a value greater than the value of (8-CACHE_SIZE), then MSMC defers to (8- CACHE_SIZE) when determining what way groups are available for any non-data-allocating transactions.

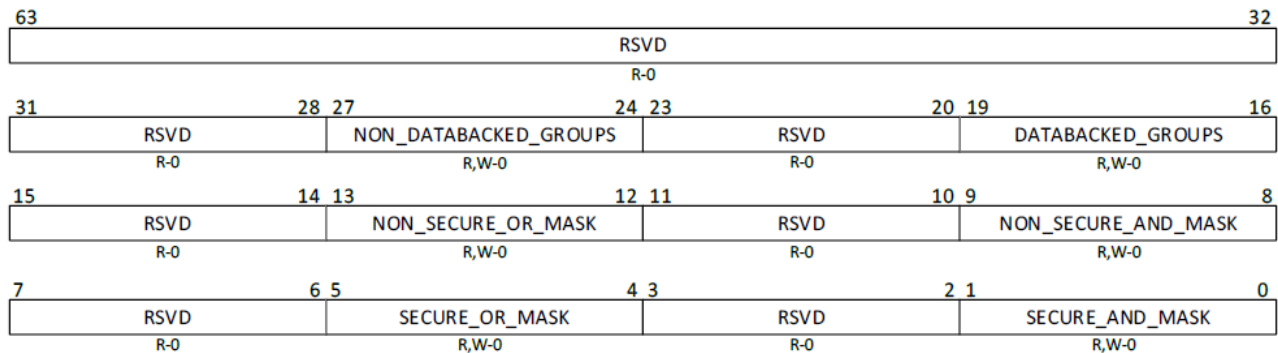

8.1.2.14.1.1 MMRs Related to Way Group Partitioning Feature

8.1.2.14.1.1.1 RT_WAY_SELECT [Address = 0x8000]

Bits	Name	Description
63:28	Reserved	Reserved
27:24	NON_DATABACKED_GROUPS	Number of non-data backed way groups available to RT allocations
23:20	Reserved	Reserved
19:16	DATABACKED_GROUPS	Number of data backed way groups available to RT allocations

11:10	Reserved	Reserved
9:8	NON_SECURE_AND_MASK	ANDmask for way-select

Bits	Name	Description
7:6	Reserved	Reserved
5:4	SECURE_OR_MASK	ORmask for way-select
3:2	Reserved	Reserved
1:0	SECURE_AND_MASK	ANDmask for way-select

8.1.2.14.2 Write Back Invalidate

Through the WBINV_CTRL memory-mapped-register MSMC provides control for software to trigger a coherent invalidation of MSMC's external and/or internal SRAM snoop filter(s). If a '1' is written to the EMIF_SF_WBINV field in the register, then MSMC will invalidate the external snoop filter, writing back any dirty data to EMIF. If a '1' is written to the SRAM_SF_INV field in the register, then MSMC will invalidate the internal SRAM snoop filter and write back any dirty data into its own SRAM. If both fields are written to simultaneously, then MSMC will invalidate the external snoop filter before invalidating the internal SRAM snoop filter immediately afterwards. As part of the write back invalidation procedure, MSMC will request all coherent masters to invalidate any lines that MSMC is tracking. The behavior tree is shown in the figure below.

When the write back invalidation of the external and/or internal SRAM SF is triggered the WBINV_ACTIVE field of the WBINV_CTRL memory mapped register will be set to '1' until all invalidations are complete at which time it will be reset to '0'. Due to shared hardware between snoop filter invalidation and cache resizing for looping through all of the snoop filter entries, any write to EMIF_SF_WBINV, SRAM_SF_WBINV, or the CACHE_SIZE field within the CACHE_CTRL memory mapped register will be ignored if the WBINV_ACTIVE bit is '1'. Similarly, writes to EMIF_SF_WBINV and SRAM_SF_WBINV are ignored if a cache resize is in progress.

MSMC will maintain coherency for any transactions that arrive during a write back invalidation procedure, although the snoop filter state for any addresses they access is not ensured to be invalid until the operation is complete. The snoop filter state for any address accessed during the invalidation of the associated snoop filter is dependent on whether or not the access occurs before or after MSMC has performed its write back invalidation on that particular snoop filter entry.

4	SRAM_SF_WBINV	Trigger internal SRAM write back invalidation
3:1	Reserved	Reserved
0	EMIF_SF_WBINV	Trigger external memory write back invalidation

8.1.2.14.3 FFI Support

In the scenarios where ASIL-B endpoint is hung, MSMC supports unwinding of this situation by auto responding/dropping pending commands. Below is the description of how MSMC handles different command types in FFI scenario. Note: For details on FFI sequence please refer Compute Cluster Spec.

1. CPU read/write: The CPU read/write requests to SRAM/EMIF and responses will be killed at the interface when FFI is active for the corresponding CPU.
2. SDMA and cache warm transactions from DRU: DRU (ASIL-B) can be reset if any of the ASIL-B CPUs are in FFI, since SDMA/cwarm transactions are not tracked in MSMC. The SDMA/cwarm requests and responses will be killed at the interface when FFI is active.
3. SDMA transactions from SoC ports: Traffic mastered by ASIL-D SoC ports and targeted to any ASIL-B CPU is not tracked in MSMC. If the slave CPU is in FFI, then the master SoC will not receive responses. In that case ASIL-D timeout gaskets will initiate recovery of ASIL-D SoC master.
4. Snoops: Snoop responses are faked in RMW queue so that the state machine is not stuck waiting for snoop responses.
5. DVM Sync-complete: DVM completes are faked in RMW queue so that the state machine is not stuck waiting for DVM completes.
6. CPU, SDMA, Snoop transactions: When in FFI, make sure local arb is free from partial transactions by reverting the local arb state machines back to reset/idle states when FFI is active.
7. Timeout gaskets: Timeout gaskets in MSMC track master timeout as well as slave far-side credit return timeout and generate timeout interrupts when either of them times out.

Timeout gaskets are located at CPU and DRU interfaces.

"111"	"1111111111111111111111"

8.1.2.14.3.1 FFI Event Sequence

The following is the sequence of events that FFI go through from failure to recovery:

1. CPU crash: One or more of the masters in ASIL-B domain (C7x/ARM/DRU) crashes. The crash is manifested as the master not being able to respond to commands. For example, CPU1 crashes and stops responding to commands.
2. Crash detection: The timeout gasket connected to the malfunctioning CPU1 generates timeout interrupt `gskt_cpu1_if_timed_out_intr`. For proper interrupt generation make sure `gskt_cpu1_if_enable_timeout_detect` is driven high and a valid timeout value on `gskt_cpu1_if_timeout_val` is driven as well. These MSMC-level tieoffs are driven by SoC level control registers. `gskt_cpu1_if_timed_out_intr` is sticky and needs to be cleared during recovery.
3. FFI req generation: When the SoC interrupt controller receives the timeout interrupt, `gskt_cpu1_if_timed_out_intr`, it will trigger the corresponding FFI req, `ffi_cpu1_if_ffi_req`.
4. MSMC FFI mode: MSMC receives `ffi_cpu1_if_ffi_req` and enters FFI mode where it will kill the commands from and responses to CPU1 at the interface. It will internally unwind snoop responses and credit returns that CPU1 is otherwise responsible for. During this time ASIL-D to ASIL-D traffic will be uninterrupted. For example, SoC to DDR or MSMC SRAM will proceed. Any access to CPU1 (SDMA) from other masters will not receive responses during this time. Since software is aware that CPU1 is FFI, it will stop sending new commands to CPU1. There is a scenario where ASIL-B master could have sent a command to CPU1 just before it entered FFI, that's the reason all ASIL-B masters are forced to FFI in a typical use case. If ASIL-D master sends the command to CPU1 just before it enters FFI, then the ASIL-D master's timeout gaskets will trigger unwinding of that ASIL-D master.
5. Power-down and Reset: FFI req is followed by the usual power-down and reset sequence. So, `ffi_cpu1_if_ffi_req` is followed by issuing `cpu1_pwr_scr_disable_req` and waiting for `cpu1_pwr_scr_disable_ack`. Once the ack is received CPU1 can be safely reset.
6. Recovery: When CPU1 is in reset, `ffi_cpu1_if_ffi_req` will be de-asserted, followed by reset de-assertion and `cpu1_pwr_scr_disable_req` de-assertion. Now, CPU1 can resume normal functional operation.

8.1.2.14.4 Broadcast Mode

This is not a new feature but a behavior update in existing feature. Previously, when broadcast mode is set (i.e. snoop filter is disabled) MSMC only sends broadcast snoop for cache hits. This new update keeps cache hit behavior as is; however, broadcast snoop is sent for cache misses as well. Note that all allocations are killed when broadcast mode is set in this new update.

Because there are no cache allocations in this mode, inclusivity is lost. Coherency is maintained as long as broadcast mode is set but dynamic change of broadcast mode from high to low (i.e. Broadcast mode enable to disable) is not supported.

System must invalidate L2 caches of all snoopable coherent masters connected to MSMC before they can disable Broadcast mode again after enabling it to maintain coherence.

This mode is expected to be used as a debug feature only, as performance is significantly impacted once this mode is enabled.

8.1.2.14.5 DRU and SDMA Access Constraints (Access ARC Removal)

The following SDMA access restrictions exist:

- ARM to DRU CFG accesses are restricted – This means:
 - ARMs cannot program DRU TRs or use DRU
 - ARMs cannot access CLEC
 - Cache warm operation for ARM I2 caches is not supported
- For all CPU coherent ports, CPU to CPU SDMA accesses are restricted
- SOC (non-LDP) port to DRU and CPU L2 SDMA accesses are restricted

This is a build time configuration, so restriction may be different for a different MSMC configuration.

8.1.2.14.6 EMIF Interleaving

There are two separate paths an EMIF access can take from the master to EMIF slave. 1. Through RMW queue, 2. Direct path (Bypass RMW queue). Coherent master accesses go through RMW queue path and non-coherent/SoC master accesses take a direct path to EMIF, bypassing RMW queue.

0111	0000 0111	10100	rs%gs = 0 && rs != 0	Interleaved DDR0,1,2. DDR2 in hybrid region DDR0,1,2 have all ECC ON or OFF
1111	0000	00000	rs%gs = 0 && rs = 0xC (32G)	Full interleaving of DDR0,1,2,3 DDR0,1,2,3 have all ECC OFF
1111	1111	11000	rs%gs = 0 && rs != 0	Full interleaving of DDR0,1,2,3 DDR0,1,2,3 have all ECC ON
1111	0000 0111 1000 1111	01000	rs%gs = 0 && rs != 0	Interleaved DDR0,1,2. DDR3 in hybrid region DDR0,1,2 have all ECC ON or OFF. DDR3 has independent ECC
1111	0000 1111	11000	rs%gs = 0 && rs != 0	Interleaved DDR0,1,2,3. DDR3 in hybrid region DDR0,1,2,3 have all ECC ON or OFF

When ECC is enabled, the corresponding DDR size will be effectively reduced. $\text{Max_memory} = (\text{ddr_ram_size} / 576) * 512$. The div-by-576 is an integer division. If the address falls out of max_memory range, the access will land in the next EMIF.

Programming Model for 2xEMIF case:

Case-1:DDR0 = DDR1:2x {512M, 1G, 1.5G, 2G, 3G, 4G, 6G, 8G}

Separated DDRs:

region_size= DDR0+DDR1 sizes granule_size = DDR0 size emifs_active = both DDRs active

hybrid_select = Choose hybrid_select such that anything that is outside the region goes to the EMIF specified in hybrid_select. If its default(0), MSMC will route it out via its EMIF0 port.

`ecc_enable`= enabled/disabled on any DDR For example, if we have 2x1G DDRs then,

`region_size`= 2G, `granule_size` = 1G, `emifs_active` = 3, `hybrid_select` = x, `ecc_enable` = {0, 1, 2, 3}

Interleaved DDRs:

`region_size`= DDR0+DDR1 sizes `granule_size` < DDR0 size `emifs_active` = both DDRs active

`hybrid_select` = Choose `hybrid_select` such that anything that is outside the region goes to the EMIF specified in `hybrid_select`. If its default(0), MSMC will route it out via its EMIF0 port.

`ecc_enable`= enabled on both DDRs or disabled on both DDRs For example, if we have DDR0 = 1G and DDR1 = 1G then,

`region_size`= 2G, `granule_size` < 1G, `emifs_active` = 3, `hybrid_select` = x, `ecc_enable` = {0, 3}

Case-2:DDR0 < DDR1:(512M,1G) ; (512M, 2G) ; (1G, 2G) ; (1G, 3G) ; (2G, 3G)

There are two ways to accomplish separated DDRs: case-A and case-B.Separated DDRs-A:

`region_size` = 2xDDR0 size `granule_size` = DDR0 size `emifs_active`. = both DDRs active `hybrid_select`. = DDR1

`ecc_enable` = enabled/disabled on any DDR

For example, if we have DDR0 =1G and DDR1 = 2G then,

`region_size`= 2G, `granule_size` = 1G, `emifs_active` = 3, `hybrid_select` = 2, `ecc_enable` = {0, 1, 2, 3}

Separated DDRs-B:

`region_size` = DDR0 size `granule_size` = DDR0 size `emifs_active`. = both DDRs active `hybrid_select`. = DDR1

`ecc_enable` = enabled/disabled on any DDR

For example, if we have DDR0 =1G and DDR1 = 2G then,

`region_size`= 1G, `granule_size` = 1G, `emifs_active` = 3, `hybrid_select` = 2, `ecc_enable` = {0, 1, 2, 3}

Interleaved DDRs:

`region_size` = 2xDDR0 size `granule_size` < DDR0 size `emifs_active`. = both DDRs active `hybrid_select`. = DDR1

`ecc_enable` = enabled on both DDRs or disabled on both DDRs. For example, if we have DDR0 =1G and DDR1 = 2G then,

`region_size`= 2G, `granule_size` < 1G, `emifs_active` = 3, `hybrid_select` = 2, `ecc_enable` = {0, 3}

Case-3:DDR0 > DDR1: (1G,512M) ; (2G, 512M) ; (2G, 1G) ; (3G, 1G) ; (3G, 2G). *This case is not officially supported to have consistent system-level constraints for 2, 3, 4 EMIFs interleaving cases.

MSMC RTL supports it with the following programming model.Separated DDRs:

`region_size` = DDR0 size `granule_size` = DDR0 size `emifs_active`. = both DDRs active `hybrid_select`. = DDR1

`ecc_enable` = enabled/disabled on any DDR

For example, if we have DDR0 =2G and DDR1 = 1G then,

`region_size`= 2G, `granule_size` = 2G, `emifs_active` = 3, `hybrid_select` = 2, `ecc_enable` = {0, 1, 2, 3}

Interleaved DDRs:

`region_size` = 2xDDR1 size `granule_size` < DDR1 size `emifs_active`. = both DDRs active `hybrid_select`. = DDR0

`ecc_enable` = enabled on both DDRs or disabled on both DDRs. For example, if we have DDR0 =2G and DDR1 = 1G then,

`region_size`= 2G, `granule_size` < 1G, `emifs_active` = 3, `hybrid_select` = 1, `ecc_enable` = {0, 3}

8.1.2.14.7 QoS Fix/RT Hazarding

MSMC can send information to EMIF, about real time transactions that are currently stalled in MSMC so EMIF can drain the original transaction that is being hazarded upon. Once the transaction makes progress from EMIF, eventually the hazard is removed in MSMC.

Every command that is sent from MSMC to EMIF will have a queue ID encoded in its cmsband. If a command is stuck in EMIF, and there is another transaction in MSMC that is hazarded on the command that is stuck in EMIF, then MSMC sends the encoded queue ID of MSMC hazard to EMIF as and when the hazard is detected. EMIF compares the cmsband encoding of the originally stalled command in EMIF and the queue ID of hazard map encoding which it receives from MSMC when a hazard is detected. If EMIF finds a match between these two encoded queue IDs then it will trigger a drain such that the command originally stuck in EMIF makes progress and thus ultimately recovering MSMC from hazard.

For MSMC→EMIF commands that bypass the RMW queue, queue ID is meaningless so encode it in such a way that EMIF does not match any of the hazard queue ID encodings.

For EMIF compare MSBAND bits [8:5] for Queue ID/Transaction ID. Compare MSBAND bits [12:9] for Bank ID, if 12:9 = 0xF means it's via EMIF bypass path and not coming from a bank.

8.2 DDR Subsystem (DDRSS)

This section describes the DDR Subsystem (DDRSS) for the device.

8.2.1 DDRSS Overview

The DDR subsystem in this device comprises DDR controller, DDR PHY and wrapper logic to integrate these blocks in the device. The DDR subsystem is referred to as DDRSS and is used to provide an interface to external SDRAM devices which can be utilized for storing program or data. DDRSS is accessed via MSMC, and not directly through the system interconnect.

The DDRSS supports:

- Memory Types:
 - LPDDR4
- Memory Bus Features:
 - 32-bit width with in-line ECC
 - Up to 2 ranks (in one package)
 - SDRAM address range up to 8 GB
- System Bus Interface:
 - 512-bit data width
 - Little endian only
 - Address aliasing prevention to block accesses to unpopulated SDRAM region
 - Clock asynchronous to DDR clock
- Configuration Bus Interface:
 - 32-bit data width
 - Linear incrementing addressing mode
 - 32-bit aligned accesses only
 - Little endian only
 - Clock asynchronous to DDR clock
- Key Features:
 - Full coherency across all commands
 - Bank interleaving
 - Priority based scheduling
 - Scheduling based on bank openness
 - Class of Service (CoS) - Three latency classes supported
 - Read/write scheduling to avoid turn-around time
 - Prioritized refresh scheduling
 - Dynamic change of refresh rate via software for extended temperatures
 - Statistical counters for performance management
- SDRAM ECC Features:
 - In-line ECC
 - Read-modify-write ECC for sub-word writes
 - ECC address error logging
 - Statistical counters for counting ECC errors
 - Injecting ECC errors during normal operation for validation
- Low Power Features:
 - Self-refresh entry and exit via software or hardware clock stop request
 - System bus clock stop via hardware clock stop request when controller is idle
 - Automatic idle power saving mode when no or low activity is detected
 - DDR and system bus clock frequency change using self-refresh via software or hardware clock stop request
 - Turning off SoC power after DDR is put into self-refresh (DDR reset and CKE I/O retention)
 - Tri-stating of all DDR I/O cells via software while driving CKE and RSTN pins during self-refresh
 - LPDDR4 Frequency Set Point (FSP)
 - I/O retention managed by an external device through dedicated pin
- Functional Reliability Features:

- ECC on data pipe
- Parity on address and command pipes
- Data EDC on the master port interface
- Command parity on the master port interface
- Data EDC on the configuration port interface
- Command parity on the configuration port interface
- MSMC2DDR bridge AXI bus timeout
- DDR PHY Features:
 - Automatic and software controllable initialization and calibration (ZQ) for the DDR PHY and I/O cells
 - Automatic and software controllable delay line calibrations with Voltage and Temperature (VT) compensation
 - Automatic and software controllable write levelling with VT compensation
 - Automatic read DQS gate training per rank with VT compensation
 - Automatic and software controllable DQ/DQS eye training per rank
 - Automatic and software controllable read and write data bit deskew
 - Automatic and software controllable Command/Address (CA) levelling with VT compensation for LPDDR4
 - Automatic and software controllable CA bit deskew for LPDDR4
 - Refreshes to SDRAM during leveling and training
 - No seeding requirement based on board topology for any of the leveling and training algorithms
 - Dynamic/automatic I/O Receiver disable when read transfer is not on going
 - Capability of disabling data macros and I/O cells when not in use

8.2.2 DDRSS Environment

This section describes the DDRSS0 external connections (environment).

Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

8.2.3 DDRSS Functional Description

8.2.3.1 DDRSS MSMC2DDR Bridge

The MSMC2DDR bridge is part of the DDRSS and connects the DDR controller and MSMC data paths.

8.2.3.1.1 VBUSM.C Threads

Note

VBUS (VBUSM and VBUSP) is the device interconnect communication protocol. The letter "C" in "VBUSM.C" stands for Coherence Extension and denotes the interface is dedicated to COMPUTE_CLUSTER0. The VBUS protocol is beyond the scope of the device documentation as it is purely hardware oriented. For details about the device interconnect and the associated software controls, see *System Interconnect*.

The MSMC2DDR bridge supports two threads on the VBUSM.C interface. They are as follows:

- High Priority Thread (HPT) - traffic received on VBUSM.C thread 2 belongs to HPT.
- Low Priority Thread (LPT) - traffic received on VBUSM.C thread 2 belongs to LPT.

HPT has priority over LPT. Therefore, the execution of commands from the command FIFO can be out-of-order. As a result, the read data can also be returned out-of-order. This ensures that the HPT will be guaranteed execution even when LPT is fully blocked.

The MSMC2DDR bridge maintains data coherency across threads. Therefore, any HPT transactions that depend on the LPT transactions due to address conflicts are blocked until execution of the corresponding LPT transactions. This might result in a scenario where HPT can be blocked because of blockage on LPT. Once the LPT blockage has cleared, the blockage on the dependent HPT commands is also cleared.

HPT transactions can use global credits as well as thread 2 credits. LPT transactions can only use global credits.

On the command interface, the MSMC2DDR bridge gives back global credits on the VBUSM.C interface only if the available credits on the command queue in the DDR controller are greater than the DDRSS_V2A_CTL_REG[16-12] CRIT_THRESH field.

On the read data return interface, HPT traffic is prioritized over LPT traffic. The MSMC2DDR bridge sends HPT read data if there is at least 1 global or 1 thread 2 credit available.

The MSMC2DDR bridge sends LPT read data if there is no HPT data to send, and:

- There are at least 2 global credits available, or
- There is at least 1 global credit available and it is the last data phase

8.2.3.1.2 Class of Service (CoS)

Commands arriving on LPT and HPT to the DDRSS0 carry the VBUSM.C priority whereas the DDR controller uses another priority. The MSMC2DDR bridge has the following registers for flexible mapping of the VBUSM.C priority to DDR controllers's priority:

- Range match registers:
 - DDRSS_V2A_R1_MAT_REG
 - DDRSS_V2A_R2_MAT_REG
 - DDRSS_V2A_R3_MAT_REG
- Priority map registers:
 - DDRSS_V2A_LPT_DEF_PRI_MAP_REG
 - DDRSS_V2A_LPT_R1_PRI_MAP_REG
 - DDRSS_V2A_LPT_R2_PRI_MAP_REG
 - DDRSS_V2A_LPT_R3_PRI_MAP_REG
 - DDRSS_V2A_HPT_DEF_PRI_MAP_REG
 - DDRSS_V2A_HPT_R1_PRI_MAP_REG
 - DDRSS_V2A_HPT_R2_PRI_MAP_REG
 - DDRSS_V2A_HPT_R3_PRI_MAP_REG

This allows the system to essentially create different classes of service based on the initiator (Route ID) and the priority of the commands.

Each thread has a set of corresponding priority map registers to map the incoming priority on that thread to appropriate priority for the DDR controller as shown in Figure 8-7. The default values of these registers are such that inherently the HPT traffic has higher priority than the LPT traffic inside the DDR controller, but these settings can be changed via software per system needs.

Note

For information about Route ID, see *Route ID* in *System Interconnect*.

Figure 8-7. DDRSS CoS Mapping Diagram

8.2.3.1.3 AXI Write Data All-Strobes

The DDR controller data path is connected to the MSMC2DDR bridge through AXI interface. To enable higher performance and lower latency, the bridge drives the AXI AWALLSTRB signal to a "1" when the AXI write data do not have any byte enable holes. This allows the DDR controller to accept and start processing the write command as soon as possible without waiting for all data. The DDRSS_CTL_377[16] AXI0_ALL_STROBES_USED_ENABLE bit must be set to a 0x1 to utilize this feature. The controller ignores the AWALLSTRB signal if AXI0_ALL_STROBES_USED_ENABLE is set to 0x0.

8.2.3.1.4 Inline ECC for SDRAM Data

For SDRAM data integrity, the MSMC2DDR bridge supports inline ECC on the data written to or read from the SDRAM. ECC is enabled by programming the bits in the DDRSS_ECC_CTRL_REG register. ECC is stored together with the data so that a dedicated SDRAM device for ECC is not required. When using this inline ECC feature the inline ECC inside the DDR controller must be disabled by setting to 0x0 the DDRSS_CTL_206[17-16] ECC_ENABLE field.

8-bit single error correction double error detection (SECDED) ECC is calculated over 64-bit data quanta. For every 512-byte data block 64 bytes of ECC is stored inline. Thus 1/9th of the total SDRAM space is used for ECC storage and the rest 8/9th is available for system use. From system point of view that 8/9th of the SDRAM data space are seen as consecutive byte addresses. Even if there are non-ECC protected regions the previously described 1/9th-8/9th rule still applies and consecutive byte addresses are seen from system point of view.

The ECC is calculated for all accesses that are within the address ranges protected by ECC. The address ranges are specified through the following registers:

- DDRSS_ECC_R0_STR_ADDR_REG
- DDRSS_ECC_R0_END_ADDR_REG
- DDRSS_ECC_R1_STR_ADDR_REG
- DDRSS_ECC_R1_END_ADDR_REG
- DDRSS_ECC_R2_STR_ADDR_REG
- DDRSS_ECC_R2_END_ADDR_REG

The ECC is read and verified during reads if both the DDRSS_ECC_CTRL_REG[0] ECC_EN and DDRSS_ECC_CTRL_REG[2] ECC_CHK bits are set to 0x1. For 1-bit ECC error, the MSMC2DDR bridge corrects the data and returns it to the requestor. Although the error is corrected on the returned data, the SDRAM is not corrected. It is responsibility of the system software to correct the ECC error at that location.

It is also responsibility of the system software to pre-load the ECC protected region with known data before functional reads and writes are performed. This can be done by writing to the SDRAM with ECC enabled (DDRSS_ECC_CTRL_REG[0] ECC_EN = 0x1 and DDRSS_ECC_CTRL_REG[1] RMW_EN = 0x1) and ECC check disabled (DDRSS_ECC_CTRL_REG[2] ECC_CHK = 0x0). Once the data is loaded in the SDRAM, ECC check must be enabled (DDRSS_ECC_CTRL_REG[2] ECC_CHK = 0x1) before using the DDR interface.

8.2.3.1.4.1 ECC Cache

The MSMC2DDR bridge implements a 128-line deep ECC cache for improving inline ECC performance. Each cache line can be allocated to an initiator in the system based on its Route ID. The Route ID allocation to cache line can be done by writing to the DDRSS_ECC_RID_INDX_REG and DDRSS_ECC_RID_VAL_REG registers. Since the bridge uses unallocated cache lines for all read accesses without Route ID allocation, one or more locations in the cache should be kept unallocated for better performance. To ensure that at least one cache line remains unallocated, in the case all cache lines are allocated by software, the bridge automatically unallocates the 127th cache line. Write accesses without Route ID allocation result in ECC and data writes to the SDRAM, when the DDRSS_ECC_CTRL_REG[4] WR_ALLOC bit is set to 0x0. When DDRSS_ECC_CTRL_REG[4] WR_ALLOC is set to 0x1, an unassigned cache-line is allocated to write accesses without Route ID allocation.

8.2.3.1.4.2 ECC Statistics

For 1-bit ECC error, the MSMC2DDR bridge logs the address location for the error in an internal 2-level deep FIFO. It stores the first two 1-bit ECC errors. The DDRSS_ECC_1B_ERR_ADR_LOG_REG register shows the address on top of the internal FIFO. Software should write 0x1 to the DDRSS_ECC_1B_ERR_ADR_LOG_REG[28:0] ECC_1B_ERR_ADR field to pop the FIFO and display the next address stored. The FIFO is loaded with the address for the next 1-bit ECC error if it is not full. If a single address is associated with more than one ECC error, that address is logged twice.

The number of 1-bit ECC errors can be counted using the DDRSS_ECC_1B_ERR_CNT_REG register. The MSMC2DDR bridge also supports programming a threshold in the DDRSS_ECC_1B_ERR_THRSH_REG register. When the 1-bit error count is equal to or greater than the programmed threshold, the bridge sets the DDRSS_V2A_INT_RAW_REG[3] ECC1BERR bit and also triggers the DDR0_DDRSS_DRAM_ECC_CORR_ERR_LVL_0 interrupt. When servicing the interrupt, software needs to clear the error count otherwise further interrupts will not be triggered. For 2-bit ECC errors, the bridge sets the DDRSS_V2A_INT_RAW_REG[4] ECC2BERR bit and also triggers the DDR0_DDRSS_DRAM_ECC_UNCORR_ERR_LVL_0 interrupt. The bridge does not correct the data for these uncorrectable errors. Along with generating the interrupt, the bridge also reports an error to the requesting initiator and sends all zeros for the data. The bridge also logs the address location for the error in the DDRSS_ECC_2B_ERR_ADR_LOG_REG register.

The MSMC2DDR bridge sets the DDRSS_V2A_INT_RAW_REG[5] ECCM1BERR bit and triggers the DDR0_DDRSS_DRAM_ECC_UNCORR_ERR_LVL_0 interrupt whenever it receives multiple 1-bit errors in different data words of the same SDRAM burst. This is done because the probability of receiving multiple 1-bit errors in different data words of the same SDRAM burst is very low. If this occurs, the chances are that there were multi-bit errors in each data word. Therefore, for reliability, pessimistic approach is taken to report these as a fatal error. The threshold for the number of 1-bit errors that result in an uncorrected error, reporting can

be set by writing to the DDRSS_ECC_CTRL_REG[12-8] COR_ECC_THRESH field. For reliability, the threshold is always kept at 0/1 meaning 1-bit error in 2 or more data words is reported as a 2-bit error. For debug, the threshold can be changed to a higher value. Note that since these are multiple 1-bit errors, the statistic logging is done in the DDRSS_ECC_1B_ERR_CNT_REG and DDRSS_ECC_1B_ERR_ADR_LOG_REG registers.

8.2.3.1.5 Opcode Checking

The MSMC2DDR bridge checks the VBUSM.C opcode received for unsupported opcodes and flags error for debug purposes. Only opcode values for read and write operations are supported.

If an unsupported VBUSM.C opcode is received for an access, the bridge sets the DDRSS_V2A_INT_RAW_REG[0] OERR bit to 0x1 and triggers the DDR0_DDRSS_V2A_OTHER_ERR_LVL_0 interrupt. The opcode and the Route ID for the command caused error are logged in the DDRSS_V2A_OERR_LOG_REG[17-12] OERR_OP_CODE and DDRSS_V2A_OERR_LOG_REG[11-0] OERR_ROUTE_ID fields.

Since the bridge does not know how to process the command with an unsupported opcode, it discards the command and does not respond with any status on the write status or the read status buses.

8.2.3.1.6 Address Alias Prevention

The MSMC2DDR bridge checks the VBUSM.C address received against the valid SDRAM address space programmed in the DDRSS_V2A_CTL_REG register. If the VBUSM.C address for an access falls outside the programmed range the bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[1] AERR bit and also triggers the DDR0_DDRSS_V2A_OTHER_ERR_LVL_0 interrupt. The address and the Route ID for the command caused error are logged in the DDRSS_V2A_AERR_LOG1_REG and DDRSS_V2A_AERR_LOG2_REG registers.

The valid address range can be programmed using the DDRSS_V2A_CTL_REG[9-5] SDRAM_IDX and DDRSS_V2A_CTL_REG[4-0] REGION_IDX fields. [Table 8-14](#) summarizes the scenarios for determining valid address range and interrupt generation.

Table 8-14. REGION_IDX and SDRAM_IDX Scenarios

Condition	Description
REGION_IDX = SDRAM_IDX	DDR region size is equal to the connected SDRAM size. It is SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX < SDRAM_IDX	DDR region size is less than the connected SDRAM size. It is SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX > SDRAM_IDX	DDR region size is greater than the connected SDRAM size. Address error is generated if the address received falls outside the connected SDRAM size.

A write access outside the programmed range is discarded. A write error associated status is sent back to the VBUSM.C interface.

A read access outside the programmed range is executed on the SDRAM interface as a normal read, but data will contain all zeroes before forwarding it to the VBUSM.C interface. A read error associated status is sent back to the VBUSM.C interface along with the read data containing all zeroes.

When inline ECC is enabled, the available SDRAM size is reduced by 1/9th of the size programmed in the SDRAM_IDX field. Therefore, the bridge reports an error if an access falls outside the reduced SDRAM size when inline ECC is enabled. The reduced SDRAM size limit applies to all accesses, both to the protected and non-protected ECC regions.

8.2.3.1.7 Data Error Detection and Correction

The MSMC2DDR bridge performs data error detection and correction (EDC) on write data received. The EDC is performed over 256-bit data quanta and uses a Hamming code algorithm supporting single error correction and double error detection.

If the write data has a single bit error the bridge indicates a single bit error through the ECC aggregator interrupts. The write data will be corrected and written to the SDRAM. The address, the error position,

and the Route ID for the command caused error are logged in the DDRSS_V2A_1B_ERR_LOG1_REG and DDRSS_V2A_1B_ERR_LOG2_REG registers. The number of 1-bit EDC errors is kept in the DDRSS_V2A_1B_ERR_CNT_REG register.

If the write data has a double bit error the bridge indicates a double bit error through the ECC aggregator interrupts. The write will be executed on the SDRAM interface as a normal write and the data inside the SDRAM will be corrupted. The address and the route ID for the command caused the error are logged in the DDRSS_V2A_2B_ERR_LOG1_REG and DDRSS_V2A_2B_ERR_LOG2_REG registers. The bridge does not respond with a write error associated status for 2-bit EDC errors.

The bridge implements four EDC checkers that check EDC on each 256-bit quanta of a 1024-bit data word, in a single clock cycle. Therefore, when ECC errors occur on multiple 256-bit quanta in the same 1024-bit word, the error reported and logged is for the least significant 256-bits. If different quanta in the same 1024-bit word have single and double bit errors simultaneously, both errors are reported via interrupts but the address and Route ID associated with only the double bit error are logged.

The bridge generates an EDC code for the read data and sends it along with its read response for checking by the receiving system master.

8.2.3.1.8 AXI Bus Timeout

The MSMC2DDR bridge has a timeout counter that expires when no AXI transaction can be sent to the DDR controller or no AXI response is received from the controller for a programmed time interval. The counter only counts when there are pending commands in the bridge and the AXI bus is idle. Therefore, the bridge will not time out during low-power modes. The time interval can be programmed by writing to the DDRSS_V2A_BUS_TO[23-0] BUS_TIMER field.

Upon the expiry of the counter, the bridge terminates all pending commands in its internal FIFOs, returns error responses, sets the DDRSS_V2A_INT_RAW_REG[2] TOERR bit and triggers the DDR0_DDRSS_V2A_OTHER_ERR_LVL_0 interrupt.

After a timeout occurs, the bridge terminates any new commands received and returns error response. Writing a value of 0x0 to the DDRSS_V2A_BUS_TO[23-0] BUS_TIMER field exits the timeout mode. The other method to exit the timeout mode is to reset the DDRSS0, thus resetting the MSMC2DDR bridge, the DDR controller, and the DDR PHY.

8.2.3.2 DDRSS Interrupts

The DDRSS0 generates the following interrupts:

- DDR0_DDRSS_PLL_FREQ_CHANGE_REQ_0
- DDR controller interrupts:
 - DDR0_DDRSS_CONTROLLER_GLOBAL_ERROR_NONFATAL_0
 - DDR0_DDRSS_CONTROLLER_GLOBAL_ERROR_FATAL_0
 - DDR0_DDRSS_CONTROLLER_0
- DDR PHY interrupts:
 - DDR0_DDRSS_HS_PHY_GLOBAL_ERROR_0
- ECC aggregators interrupts:
 - DDR0_DDRSS_CTL_ECC_AGGR_CORR_ERR_LVL_0
 - DDR0_DDRSS_CTL_ECC_AGGR_UNCORR_ERR_LVL_0
 - DDR0_DDRSS_VBUS_ECC_AGGR_CORR_ERR_LVL_0
 - DDR0_DDRSS_VBUS_ECC_AGGR_UNCORR_ERR_LVL_0
 - DDR0_DDRSS_CFG_ECC_AGGR_CORR_ERR_LVL_0
 - DDR0_DDRSS_CFG_ECC_AGGR_UNCORR_ERR_LVL_0
- MSMC2DDR bridge interrupts:
 - DDR0_DDRSS_DRAM_ECC_CORR_ERR_LVL_0
 - DDR0_DDRSS_DRAM_ECC_UNCORR_ERR_LVL_0
 - DDR0_DDRSS_V2A_OTHER_ERR_LVL_0

The MSMC2DDR bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[0] OERR bit, if the VBUSM.C access has an unsupported opcode.

The MSMC2DDR bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[1] AERR bit, if the VBUSM.C address for an access that falls outside the DDR space programmed in the DDRSS_V2A_CTL_REG register.

The MSMC2DDR bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[2] TOERR bit, if it detects a hang on its interface to the DDR controller.

The MSMC2DDR bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[3] ECC1BERR bit, if the threshold for 1-bit ECC errors is met.

The MSMC2DDR bridge sets to 0x1 the DDRSS_V2A_INT_RAW_REG[4] ECC2BERR bit, in case of 2-bit errors for a read access performed within the SDRAM address range protected by ECC.

The DDRSS0 asserts particular interrupt line only if the interrupts are enabled by writing 0x1 to the corresponding bit in the DDRSS_V2A_INT_SET_REG register. The interrupts can be disabled by writing 0x1 to the corresponding bit in the DDRSS_V2A_INT_CLR_REG register.

When interrupts are enabled, the corresponding bits in the DDRSS_V2A_INT_STAT_REG register are also set if an interrupt condition occurs. The interrupts can be cleared once serviced by writing 0x1 to the corresponding bit in the DDRSS_V2A_INT_STAT_REG register as well as writing to the DDRSS_V2A_EOI_REG register.

Table 8-15 shows the events that are generated by the MSMC2DDR bridge.

Table 8-15. MSMC2DDR Bridge Events

Event Flag	Event Mask	Description
DDRSS_V2A_INT_RAW_REG[4] ECC2BERR DDRSS_V2A_INT_STAT_REG[4] ECC2BERR	DDRSS_V2A_INT_SET_REG[4] ECC2BERR_EN DDRSS_V2A_INT_CLR_REG[4] ECC2BERR_EN	Generated in case of 2-bit errors for a read access within the ECC protected SDRAM address range. For more information, see Section 8.2.3.1.4.2 .
DDRSS_V2A_INT_RAW_REG[3] ECC1BERR DDRSS_V2A_INT_STAT_REG[3] ECC1BERR	DDRSS_V2A_INT_SET_REG[3] ECC1BERR_EN DDRSS_V2A_INT_CLR_REG[3] ECC1BERR_EN	Generated in case of meeting the threshold for 1-bit ECC errors. For more information, see Section 8.2.3.1.4.2 .
DDRSS_V2A_INT_RAW_REG[2] TOERR DDRSS_V2A_INT_STAT_REG[2] TOERR	DDRSS_V2A_INT_SET_REG[2] TOERR_EN DDRSS_V2A_INT_CLR_REG[2] TOERR_EN	Generated in case of a hang of the interface between the MSMC2DDR bridge and the DDR controller. For more information, see Section 8.2.3.1.8 .
DDRSS_V2A_INT_RAW_REG[1] AERR DDRSS_V2A_INT_STAT_REG[1] AERR	DDRSS_V2A_INT_SET_REG[1] AERR_EN DDRSS_V2A_INT_CLR_REG[1] AERR_EN	Generated if the VBUSM.C address for an access falls outside the programmed range. For more information, see Section 8.2.3.1.6 .
DDRSS_V2A_INT_RAW_REG[0] OERR DDRSS_V2A_INT_STAT_REG[0] OERR	DDRSS_V2A_INT_SET_REG[0] OERR_EN DDRSS_V2A_INT_CLR_REG[0] OERR_EN	Generated if an unsupported VBUSM.C opcode is received for an access. For more information, see Section 8.2.3.1.5 .

8.2.3.3 DDRSS Memory Regions

Table 8-16 shows all memory regions associated with the DDRSS0.

Table 8-16. DDRSS0 Memory Regions

Region	Start Address	End Address	Region Size
DDRSS0 wrapper logic registers	0x00 0298 0000	0x00 0298 01FF	512 B
DDR controller registers	0x00 0299 0000	0x00 0299 1FFF	8 KB
DDR PHY independent module registers	0x00 0299 2000	0x00 0299 3FFF	8 KB
DDR PHY registers	0x00 0299 4000	0x00 0299 7FFF	16 KB
DDRSS0_ECC_AGGR_CTL registers	0x4D 200B 0000	0x4D 200B 03FF	1 KB
DDRSS0_ECC_AGGR_VBUS registers	0x4D 200B 0400	0x4D 200B 07FF	1 KB

Table 8-16. DDRSS0 Memory Regions (continued)

Region	Start Address	End Address	Region Size
DDRSS0_ECC_AGGR_CFG registers	0x4D 200B 0800	0x4D 200B 0BFF	1 KB
External SDRAM data space - region 0 (32-bit low memory space)	0x00 8000 0000	0x00 FFFF FFFF	2 GB
External SDRAM data space - region 1 (high memory space) ⁽¹⁾	0x08 0000 0000	0x09 FFFF FFFF	8 GB

(1) The first 2 GB of this region are inaccessible.

8.2.3.4 DDRSS ECC Support

The DDRSS0 aligns to the device architecture for system reliability and uses the following ECC aggregators for detection and reporting of ECC errors:

- DDRSS0_ECC_AGGR_CTL
- DDRSS0_ECC_AGGR_VBUS
- DDRSS0_ECC_AGGR_CFG

For information about the ECC aggregator functionality, see *ECC Aggregator*.

8.2.3.5 DDRSS Dynamic Frequency Change Interface

This interface is used for handshaking between DDRSS0 and CTRL_MMR0 to dynamically change DDR clock frequency to support LPDDR4 Frequency Set Point (FSP). The frequency change can be initiated either by a SoC processor or by the DDRSS0.

The associated CTRL_MMR0 registers for processor initiated frequency change are:

- CTRLMMR_CHNG_DDR4_FSP_REQ
- CTRLMMR_CHNG_DDR4_FSP_ACK

The associated CTRL_MMR0 registers for DDRSS0 initiated frequency change are:

- CTRLMMR_DDR4_FSP_CLKCHNG_REQ
- CTRLMMR_DDR4_FSP_CLKCHNG_ACK

The sequence for an SoC processor initiated frequency change is as follows:

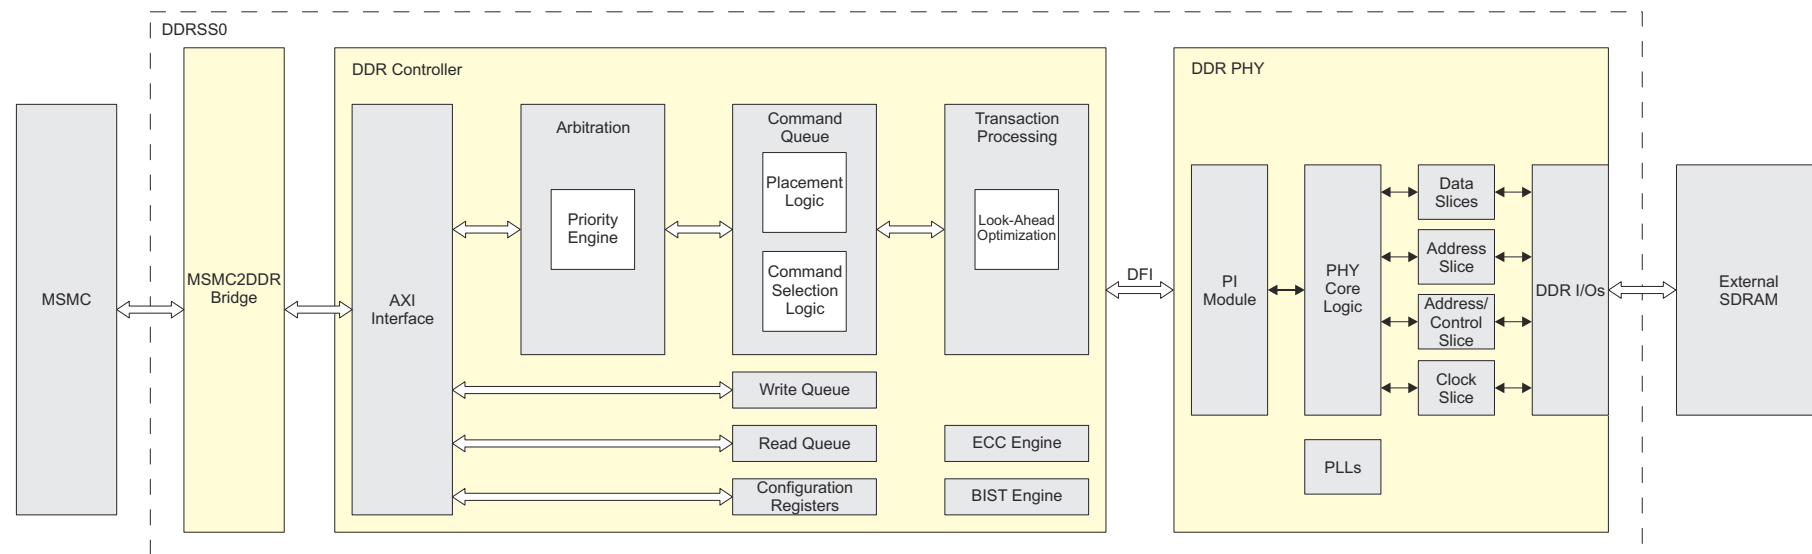

1. The processor writes the desired frequency to the CTRLMMR_CHNG_DDR4_FSP_REQ[1-0] REQ_TYPE field.
2. The processor sets to 0x1 the CTRLMMR_CHNG_DDR4_FSP_REQ[8] REQ bit to initiate frequency change.
3. The processor programs PLL12 according to the CTRLMMR_CHNG_DDR4_FSP_REQ[1-0] REQ_TYPE value.
4. The processor polls the CTRLMMR_CHNG_DDR4_FSP_ACK[7] ACK and CTRLMMR_CHNG_DDR4_FSP_ACK[0] ERROR bits to check if the frequency change has been completed successfully.

The sequence for DDRSS0 initiated frequency change is as follows:

1. DDRSS0 requests frequency change by asserting the CTRLMMR_DDR4_FSP_CLKCHNG_REQ[7] REQ bit and the CTRLMMR_DDR4_FSP_CLKCHNG_REQ[1-0] REQ_TYPE field. The REQ bit is also connected to the DDR0_DDRSS_PLL_FREQ_CHANGE_REQ_0 interrupt.
2. Software reads the CTRLMMR_DDR4_FSP_CLKCHNG_REQ[1-0] REQ_TYPE value and programs PLL12 accordingly.
3. After the DDRSS0_FCLK has been changed software should set to 0x1 the CTRLMMR_DDR4_FSP_CLKCHNG_ACK[0] ACK bit.

8.2.3.6 DDR Controller Functional Description

Figure 8-8 shows the DDR controller blocks along with the DDR PHY and MSMC2DDR bridge.

The ECC Engine block of the DDR controller is not supported.

BIST Engine is not supported.

Figure 8-8. DDR Controller Functional Blocks

8.2.3.6.1 DDR PHY Interface (DFI)

The DDR controller and DDR PHY are connected via DDR PHY Interface (DFI) which is used for transferring control information and data between the PHY and the controller. There are DFI programmable parameters which software can interact with through some of the DDR controller (see *DDR Controller Registers*), PI (see *PI Registers*) and DDR PHY (see *DDR PHY Registers*) registers. For more information about DFI, see <http://www.ddr-phy.org/>.

8.2.3.6.2 Command Queue

The DDR controller contains a command queue which uses a placement algorithm to determine the order of commands to be placed into the command queue. The placement logic follows many rules to determine where new commands should be inserted into the queue, relative to the contents of the command queue at a time. Placement is determined by considering address collisions, source collisions, data collisions, command types and priorities. The placement logic also attempts to maximize efficiency of the DDR controller through command grouping and bank splitting.

8.2.3.6.2.1 Placement Logic

The placement logic is a 2-stage queue which determines the order of commands that run in the DDR controller. The placement logic follows rules for determining placement of new commands into the queue, relative to the contents of the command queue at that time. Placement is determined by considering coherency, address collisions, source collisions, data collisions, user assigned priority, latency, age, and command type to offer low latency for critical masters while optimizing bandwidth for all masters. A second reordering stage allows ready-to-run commands to start even if the head-of-queue command is not yet ready to run. Some of the rules used in the placement logic can be individually enabled or disabled via the DDRSS_CTL_274 through DDRSS_CTL_277 registers. In addition, the queue can be disabled completely, resulting in an in-line queue that services requests in the order that they arrive.

The DDR controller also has a full look-ahead facility that reduces the effect of page misses by pre-conditioning rows for upcoming requests by using “spare” cycles in preceding transactions.

8.2.3.6.2.2 Command Selection Logic

After a command is in the command queue, command selection logic determines the method of pulling commands from the queue for running. On each clock cycle, the selection logic scans the entries of the command queue for determining the command to run. Commands for running are based on bank readiness, availability of at least 1 burst of data (writes), availability of storage for at least 1 burst of data (reads), bus turnaround timing, and conflicts. Similar to the placement rules, a command does not run before a command that was placed ahead of it in the command queue if it conflicts with address, source ID, or bank commands. Lower priority commands can run ahead of higher priority commands if the higher priority commands are not ready to run, as long as they do not conflict with commands that are ahead in the command queue.

8.2.3.6.3 Low Power Control

The DDR controller contains an arbitration block that has software programmable interface for low power control. Placement of and removal from the various memory low power modes is controlled through programming of registers in the DDR controller. The user can also monitor the status of the memory devices through a programmable register. This interface supports a lock option allowing software to execute additional commands through this interface without worrying about state changes through other interfaces.

8.2.3.6.4 Transaction Processing

The transaction command processing logic is used to process the commands in the command queue. The logic organizes the commands to the memories in such a way that data throughput is maximized. Bank opening and closing cycles are used for data transfers. The logic reviews the entire command queue for look-ahead of which banks have to be accessed in the future and ensures that the programmed memory timing conditions are met. This flexibility allows the controller to be tuned to extract the maximum performance out of memories. During processing, the controller examines the commands and issues the appropriate set of signals to the memory.

8.2.3.6.5 BIST Engine

Note

BIST Engine is not supported.

The DDR controller has a BIST engine that supports MOV13N and limited MOV1 algorithms, a self-refresh retention test, an idle retention test and a memory initialization test for detecting the following faults:

- All address decoder faults
- All memory cell stuck-at faults
- All transition faults
- Most unlinked inversion coupling faults
- Most unlinked idem potent coupling faults
- Most idem potent coupling that are linked with inversion coupling faults

The DDR controller also supports BIST on ECC lanes for out-of-band ECC configuration. The following are the BIST related registers:

- DDRSS_CTL_194 through DDRSS_CTL_205
- DDRSS_CTL_302 through DDRSS_CTL_311

8.2.3.6.6 ECC Engine

Note

The ECC Engine block of the DDR controller is not supported.

The ECC engine can confirm the data accuracy and remove or identify bit errors if they occur. It checks for errors in both the data and the check code on all read transactions. The DDR controller can detect single-bit and double-bit data errors and can correct single-bit errors. The ECC engine supports interrupts, register storage of ECC error signatures, signaling of ECC errors, ECC scrubbing and write-back, automatic ECC corruption and ECC error forcing. The DDR controller supports inline ECC, which means a portion of the memory device connected to the controller is reserved for storing the ECC check codes and is not available for user data storage. ECC can be enabled or disabled through the DDRSS_CTL_206[17-16] ECC_ENABLE field. When enabled, all read data is checked for ECC (and optionally corrected) and ECC is computed and stored on all write data. Single-bit errors can be corrected and double-bit errors can be flagged. ECC information is not returned and ECC scrubbing is supported to maintain memory contents. The DDRSS_CTL_206 through DDRSS_CTL_227 registers contain the ECC related software controls.

8.2.3.6.7 Address Mapping

The DDR controller automatically maps SoC addresses to the SDRAM memory in a contiguous block. Addressing starts at address 0x0 and ends at the highest available address according to the size and number of SDRAM memories present. This mapping depends on the programmed values in the DDR controller registers and is based on the actual size of the available SDRAM memories. The size is configured via the DDRSS_CTL_286[2-0] MEMDATA_RATIO_0 and DDRSS_CTL_287[10-8] MEMDATA_RATIO_1 fields and that must be initialized at power-up.

8.2.3.6.8 Paging Policy

The DDR controller offers a flexible paging policy that allows open page operation, closed page operation, or an auto-precharge-per-command option that allows both modes simultaneously. Auto-precharge-per-command allows marking a particular master or transaction (for example, a CPU cache) as a closed-page transaction. This type of transaction reduces power and improves latency for the next transaction to a different row in the same SDRAM bank. Other transactions can be marked as open page transactions. This type of transaction reduces power and improves latency and bandwidth to the next transaction to the same row in the same SDRAM bank.

8.2.3.6.9 DDR Controller Initialization

Once the power to the SDRAM and SoC is stable, the DDR controller must be initialized. It then automatically initializes the external memory. The general steps to initialize the DDR controller are as follows:

1. Reset the DDRSS0 through the DDRSS0_RST signal. This resets all DDR controller registers.

2. Issue write register commands to configure the SDRAM protocols and the settings for the DDR controller. Keep the DDRSS_CTL_0[0] START bit to 0x0 during this initialization step.
3. Set to 0x1 the DDRSS_CTL_0[0] START bit. This triggers the controller to execute initialization sequence using the settings written to its registers. If the DDRSS_CTL_88[0] PWRUP_SREFRESH_EXIT bit is set to 0x0, the DDR controller issues MRWs and requests a ZQCL.

The DDR controller waits for the DDR PHY to assert the dfi_init_complete signal, which indicates that the PHY and SDRAM are ready to accept commands. When this signal asserts, the controller begins its initialization routine. The DDR controller sets to 0x1 bit [9] in the DDRSS_CTL_293[31-0] INT_STATUS_0 field when initialization is complete and it is ready to accept commands.

For information about the DDR PHY initialization, see [Section 8.2.3.7.5](#).

8.2.3.6.10 Programming LPDDR4 Memories

LPDDR4 memories are specified to run at high frequency and include additional features such as CA training, write leveling, and ODT. At these high speeds, the DDR PHY also supports read data-eye training and gate training. Leveling and training operations are all performed through the PI module.

8.2.3.6.10.1 Frequency Set Point (FSP)

LPDDR4 memories use frequency set points to allow the memory to easily switch between two different frequencies without ever being in an un-trained state. There are two frequency set points - frequency set point 0 and frequency set point 1.

FSP is controlled through the following bits:

- DDRSS_CTL_192[0] DFS_ALWAYS_WRITE_FSP
- DDRSS_CTL_163[16] DISABLE_UPDATE_TVRCG
- DDRSS_CTL_192[16] FSP_OP_CURRENT
- DDRSS_CTL_191[24] FSP_PHY_UPDATE_MRW
- DDRSS_CTL_192[8] FSP_STATUS
- DDRSS_CTL_192[24] FSP_WR_CURRENT
- DDRSS_CTL_193[17-16] FSP0_FRC
- DDRSS_CTL_193[25-24] FSP1_FRC
- DDRSS_CTL_190[8] MR_FSP_DATA_VALID_F0
- DDRSS_CTL_190[16] MR_FSP_DATA_VALID_F1
- DDRSS_CTL_190[24] MR_FSP_DATA_VALID_F2
- DDRSS_CTL_166[4-0] TCKFSPE_F0
- DDRSS_CTL_168[4-0] TCKFSPE_F1
- DDRSS_CTL_171[4-0] TCKFSPE_F2
- DDRSS_CTL_166[12-8] TCKFSPX_F0
- DDRSS_CTL_168[28-24] TCKFSPX_F1
- DDRSS_CTL_171[12-8] TCKFSPX_F2
- DDRSS_CTL_166[31-16] TVREF_LONG_F0
- DDRSS_CTL_169[15-0] TVREF_LONG_F1
- DDRSS_CTL_171[31-16] TVREF_LONG_FN

8.2.3.6.10.1.1 FSP Mode Register Programming During Initialization

Before initialization, the user should program the FSP-related mode registers (MR1, MR2, MR3, MR11, MR12, MR13, MR14 and MR22) with the relevant values, and the DDRSS_CTL_21[28-24] DFIBUS_FREQ_F2, DDRSS_CTL_21[20-16] DFIBUS_FREQ_F1 and DDRSS_CTL_21[12-8] DFIBUS_FREQ_F0 fields with the frequency set to use. These mode registers are programmed through the following fields:

- DDRSS_CTL_175[7-0] MR1_DATA_F0_0
- DDRSS_CTL_175[23-16] MR1_DATA_F1_0
- DDRSS_CTL_176[7-0] MR1_DATA_F2_0
- DDRSS_CTL_182[23-16] MR1_DATA_F0_1
- DDRSS_CTL_183[7-0] MR1_DATA_F1_1
- DDRSS_CTL_183[23-16] MR1_DATA_F2_1

- DDRSS_CTL_175[15-8] MR2_DATA_F0_0
- DDRSS_CTL_175[31-24] MR2_DATA_F1_0
- DDRSS_CTL_176[15-8] MR2_DATA_F2_0
- DDRSS_CTL_182[31-24] MR2_DATA_F0_1
- DDRSS_CTL_183[15-8] MR2_DATA_F1_1
- DDRSS_CTL_183[31-24] MR2_DATA_F2_1
- DDRSS_CTL_176[31-24] MR3_DATA_F0_0
- DDRSS_CTL_177[7-0] MR3_DATA_F1_0
- DDRSS_CTL_177[15-8] MR3_DATA_F2_0
- DDRSS_CTL_184[15-8] MR3_DATA_F0_1
- DDRSS_CTL_184[23-16] MR3_DATA_F1_1
- DDRSS_CTL_184[31-24] MR3_DATA_F2_1
- DDRSS_CTL_178[23-16] MR11_DATA_F0_0
- DDRSS_CTL_178[31-24] MR11_DATA_F1_0
- DDRSS_CTL_179[7-0] MR11_DATA_F2_0
- DDRSS_CTL_186[7-0] MR11_DATA_F0_1
- DDRSS_CTL_186[15-8] MR11_DATA_F1_1
- DDRSS_CTL_186[23-16] MR11_DATA_F2_1
- DDRSS_CTL_179[15-8] MR12_DATA_F0_0
- DDRSS_CTL_179[23-16] MR12_DATA_F1_0
- DDRSS_CTL_179[31-24] MR12_DATA_F2_0
- DDRSS_CTL_186[31-24] MR12_DATA_F0_1
- DDRSS_CTL_187[7-0] MR12_DATA_F1_1
- DDRSS_CTL_187[15-8] MR12_DATA_F2_1
- DDRSS_CTL_180[7-0] MR13_DATA_0
- DDRSS_CTL_180[15-8] MR14_DATA_F0_0
- DDRSS_CTL_180[23-16] MR14_DATA_F1_0
- DDRSS_CTL_180[31-24] MR14_DATA_F2_0
- DDRSS_CTL_187[31-24] MR14_DATA_F0_1
- DDRSS_CTL_188[7-0] MR14_DATA_F1_1
- DDRSS_CTL_188[15-8] MR14_DATA_F2_1
- DDRSS_CTL_181[31-24] MR22_DATA_F0_0
- DDRSS_CTL_182[7-0] MR22_DATA_F1_0
- DDRSS_CTL_182[15-8] MR22_DATA_F2_0
- DDRSS_CTL_189[15-8] MR22_DATA_F0_1
- DDRSS_CTL_189[23-16] MR22_DATA_F1_1
- DDRSS_CTL_189[31-24] MR22_DATA_F2_1

In addition, the following fields must also be programmed before asserting the DDRSS_CTL_0[0] START bit:

- DDRSS_CTL_165[25-16] TFC_F0
- DDRSS_CTL_166[4-0] TCKFSPE_F0
- DDRSS_CTL_166[12-8] TCKFSPX_F0
- DDRSS_CTL_164[25-16] TVRCG_ENABLE_F0
- DDRSS_CTL_165[9-0] TVRCG_DISABLE_F0
- DDRSS_CTL_168[9-0] TFC_F1
- DDRSS_CTL_168[20-16] TCKFSPE_F1
- DDRSS_CTL_160[28-24] TCKFSPX_F1
- DDRSS_CTL_167[9-0] TVRCG_ENABLE_F1
- DDRSS_CTL_167[25-16] TVRCG_DISABLE_F1
- DDRSS_CTL_170[25-16] TFC_F2
- DDRSS_CTL_171[4-0] TCKFSPE_F2
- DDRSS_CTL_171[12-8] TCKFSPX_F2
- DDRSS_CTL_169[25-16] TVRCG_ENABLE_F2
- DDRSS_CTL_170[9-0] TVRCG_DISABLE_F2
- DDRSS_CTL_21[1-0] DFIBUS_BOOT_FREQ

- DDRSS_CTL_20[25-24] DFIBUS_FREQ_INIT
- DDRSS_CTL_149[24] DFS_ENABLE
- DDRSS_CTL_191[24] FSP_PHY_UPDATE_MRW

The following bits may or may not be modified, depending on what operations are needed after a frequency change occurs:

- DDRSS_CTL_192[0] DFS_ALWAYS_WRITE_FSP
- DDRSS_CTL_89[16] DFS_ZQ_EN

Once the DDRSS_CTL_0[0] START bit is asserted, the DDR controller programs the mode registers in the memory devices with these values using the FSP-OP and FSP-WR values from the DDRSS_CTL_180[7-0] MR13_DATA_0 field. Once initialization is complete, either the PHY, PI, or controller will have updated the frequency set points with the needed values.

8.2.3.6.10.1.2 FSP Mode Register Programming During Normal Operation

During normal operation, the DDR controller may modify the FSP mode register values in memory. To do this, the user should program the DDRSS_CTL_164[1-0] MRW_DFS_UPDATE_FRC field with the frequency set that the DDR controller is using and program the appropriate new values in the FSP-related mode registers previously listed. Since there are two copies of each of these mode registers in the memory device (other than MR13), the user should also identify the appropriate frequency set points for operation and writing in the DDRSS_CTL_192[16] FSP_OP_CURRENT and DDRSS_CTL_192[24] FSP_WR_CURRENT bits.

Generally, the user should not modify the mode registers for the frequency set being used, and therefore should program the DDRSS_CTL_192[24] FSP_WR_CURRENT with the opposite value of the DDRSS_CTL_192[16] FSP_OP_CURRENT bit.

Once established the values to write, the frequency set in the DDR controller to use, and the frequency set points, the user should program the DDRSS_CTL_159[26-0] WRITE_MODEREG field for the operation:

- Set bit [24] to 1h for all chips to be written with new values, or identify the target chip select in bits [15-8].
- Set bit [26] to 1h for a FSP-write operation. A write to this bit targets the mode registers MR1, MR2, MR3, MR11 and MR22 for writing. MR12 and MR14 are also written if the DDRSS_CTL_191[24] FSP_PHY_UPDATE_MRW bit is set to 0h.
- Set bit [25] to 1h to trigger the operation.

All of these bits may be programmed simultaneously.

Note

When the DDRSS_CTL_159[26-0] WRITE_MODEREG field is written with bit [26] set to 1h, the corresponding MR13 mode register is updated automatically with the value in the DDRSS_CTL_180[7-0] MR13_DATA_0 or DDRSS_CTL_187[23-16] MR13_DATA_1 fields, except that the value in the DDRSS_CTL_192[24] FSP_WR_CURRENT bit will define the value written in MR13 [6] and the value in the DDRSS_CTL_192[16] FSP_OP_CURRENT bit will define the value written in MR13 [7]. This write occurs before the other mode register writes, which means that the user may inadvertently write the wrong frequency set point mode or switch to the new frequency set point.

8.2.3.6.10.1.3 FSP Mode Register Programming During Dynamic Frequency Scaling

During a hardware DFS operation, the FSP mode registers are used to switch from one frequency set to the other. Before a hardware frequency change can be requested, the following must be programmed:

- DDRSS_CTL_193[17-16] FSP0_FRC
- DDRSS_CTL_193[25-24] FSP1_FRC
- DDRSS_CTL_192[24] FSP_WR_CURRENT
- DDRSS_CTL_192[16] FSP_OP_CURRENT
- DDRSS_CTL_190[24] MR_FSP_DATA_VALID_F2
- DDRSS_CTL_190[16] MR_FSP_DATA_VALID_F1
- DDRSS_CTL_190[8] MR_FSP_DATA_VALID_F0

FSP mode register writes are required as part of the DFS operation. To accomplish this, three mode register writes are issued to MR13, and additional mode register write to each of the FSP mode registers. These commands are issued at three times:

1. After frequency change entry and before the memory is placed into self refresh the first mode register write to MR13 is issued. This writes the value from the DDRSS_CTL_180[7-0] MR13_DATA_0 and DDRSS_CTL_187[23-16] MR13_DATA_1 fields for all bits other than the FSP-WR bit which will be defined as opposite of the FSP-OP bit. Then mode register writes to all the other FSP mode registers are issued.
2. After the memory is in self-refresh, the MR13 is written again. This write causes the FSP-OP bit to toggle, and to set the VRCG bit. At this point, the frequency change should take place.
3. After the frequency change, one final mode register write to MR13 is performed to clear the VRCG bit. The DFS operation will update the FSP mode registers and the DDRSS_CTL_192[8] FSP_STATUS bit once it is complete.

8.2.3.6.10.2 Data Bus Inversion (DBI)

LPDDR4 memories support data bus inversion (DBI) for signal integrity and power savings. The DDR controller can support DBI on the read or write path, or on both. DBI functions by ensuring that in each data byte, there are no more than four '1' bits. This can be used to confirm data transmission, and also for power savings.

DBI is controlled through the following:

- The DDRSS_CTL_291[16] RD_DBI_EN bit
- The DDRSS_CTL_291[8] WR_DBI_EN bit

Before enabling controller-level data bus inversion, the DBI mode must be enabled in the memories through a write to bits [7-6] of MR3. The system behavior depends on the value of the memory mode register bits, the DDRSS_CTL_291[16] RD_DBI_EN or DDRSS_CTL_291[8] WR_DBI_EN bit, and the value of each byte of data.

If the DDRSS_CTL_291[8] WR_DBI_EN bit is set to 1h, the user should ensure that the memory mode register WR DBI bit is also set to 1h. When both of these bits are set, the DDR controller examines each byte of the incoming write data and identifies the number of '1' bits within each byte. If a byte of data has 5 or more '1' bits, the DDR controller automatically flips the data bits in that byte and drives the dfi_wrddata_mask/dfi_wrddata_mask_p1 signal that corresponds to that byte to '1'. If the number of '1' bits within a byte is 4 or less or the DDRSS_CTL_291[8] WR_DBI_EN bit is set to 0h, then the data is sent to the DRAMs unchanged. On the DRAM, if the dfi_wrddata_mask/dfi_wrddata_mask_p1 signal is driven to '1', the DRAM re-inverts that byte before storing the data and if the dfi_wrddata_mask/dfi_wrddata_mask_p1 signal is set to '0', the DRAM stores the data as received.

For the read path, if the memory mode register RD DBI bit is set to 1h, the DDRSS_CTL_291[16] RD_DBI_EN bit should also be set to 1h. When both of these bits are set, the DDR controller examines the input signal dfi_rddata_dbi_n/dfi_rddata_dbi_n_w1. If the signal is driven to '1' for a byte, the DDR controller inverts the associated byte before sending it to the requestor. If the dfi_rddata_dbi_n/dfi_rddata_dbi_n_w1 signal is held to '0' for a byte, the data is sent out to the requestor unchanged.

8.2.3.6.10.3 On-Die Termination

LPDDR4 memories provide two different types of on-die termination (ODT) - ODT for the DQ and ODT for the CA buses.

8.2.3.6.10.3.1 LPDDR4 DQ ODT

LPDDR4 supports termination for the DQ and DQS input signals, but this termination does not utilize an ODT input pin. Instead, the ODT is controlled by the command. The functionality is enabled through bits [2-0] of mode register MR11, where a value of 0h disables the ODT functionality. The DQ ODT settings can be programmed through the following fields:

- DDRSS_CTL_178[23-16] MR11_DATA_F0_0
- DDRSS_CTL_186[7-0] MR11_DATA_F0_1
- DDRSS_CTL_178[31-24] MR11_DATA_F1_0
- DDRSS_CTL_186[15-8] MR11_DATA_F1_1
- DDRSS_CTL_179[7-0] MR11_DATA_F2_0
- DDRSS_CTL_186[23-16] MR11_DATA_F2_1

These field values are written to the associated mode registers when the DDR controller issues a MRW to the memory.

When DQ ODT is enabled, RTT is asserted with a write or masked write command.

8.2.3.6.10.3.2 LPDDR4 CA ODT

LPDDR4 can terminate the CA bus, including the CS and CLK signals. The value on the ODT input pin, ODT_CA, on the DRAM and the settings in the mode registers determine if CA ODT is enabled in the memories and the RTT termination resistance. The functionality is enabled through bits [6-4] of mode register MR11, where the value of 0h disables ODT functionality. Bits [5-3] of MR22 control individual aspects of the CA ODT when ODT is not disabled. The CA ODT settings can be programmed through the following fields:

- DDRSS_CTL_178[23-16] MR11_DATA_F0_0
- DDRSS_CTL_178[31-24] MR11_DATA_F1_0
- DDRSS_CTL_179[7-0] MR11_DATA_F2_0
- DDRSS_CTL_186[7-0] MR11_DATA_F0_1
- DDRSS_CTL_186[15-8] MR11_DATA_F1_1
- DDRSS_CTL_186[23-16] MR11_DATA_F2_1
- DDRSS_CTL_181[31-24] MR22_DATA_F0_0
- DDRSS_CTL_182[7-0] MR22_DATA_F1_0
- DDRSS_CTL_182[15-8] MR22_DATA_F2_0
- DDRSS_CTL_189[15-8] MR22_DATA_F0_1
- DDRSS_CTL_189[23-16] MR22_DATA_F1_1
- DDRSS_CTL_189[31-24] MR22_DATA_F2_1

These field values are written to the associated mode registers when the DDR controller issues a MRW to the memory.

8.2.3.6.10.4 Byte Lane Swapping

The DDR controller supports byte lane swapping on the board or a DIMM for better timing or routing. In most cases, this swapping is invisible to the user as data byte lanes are swapped when data is being written, and then unswapped as data is read. However, mode register reads does not un-swap the data. Therefore, the user must be aware of the location of the 0th byte of the data in order to process the information from the mode registers correctly.

Whether byte lane swapping is used or not, the user must program the following fields:

- DDRSS_CTL_286[11-8] DEVICE0_BYTE0_CS0
- DDRSS_CTL_286[19-16] DEVICE1_BYTE0_CS0
- DDRSS_CTL_286[27-24] DEVICE2_BYTE0_CS0
- DDRSS_CTL_287[3-0] DEVICE3_BYTE0_CS0
- DDRSS_CTL_287[19-16] DEVICE0_BYTE0_CS1
- DDRSS_CTL_287[27-24] DEVICE1_BYTE0_CS1
- DDRSS_CTL_288[3-0] DEVICE2_BYTE0_CS1
- DDRSS_CTL_288[11-8] DEVICE3_BYTE0_CS1

Unique parameters are provided for each chip select to allow for different byte swapping on each chip select. Each field contains one bit for each byte of the memory data bus. If a device is not being used, the DEVICE_x_BYTE0_CS_y field should be programmed to 0h, but if the device is being used, then only one bit of the DEVICE_x_BYTE0_CS_y field should be set to 1h.

8.2.3.6.10.5 DQS Interval Oscillator

The DDR controller includes a feature to control the internal DQS clock tree oscillator in the LPDDR4 memories. This oscillator is used to track the delay variance of the DQS clock tree that will occur over time due to temperature and voltage. This feature allows the oscillator to be initiated and results read. If the result is outside of the programmed allowable variance, the DDR controller informs the PHY. The DDR controller does not perform any training functions as a part of or a result of this oscillator measurement - the PHY is expected to handle all training requirements.

The DQS oscillator is controlled through the following fields:

- DDRSS_CTL_26[16] DQS_OSC_ENABLE
- DDRSS_CTL_28[31-24] DQS_OSC_HIGH_THRESHOLD
- DDRSS_CTL_28[23-16] DQS_OSC_NORM_THRESHOLD
- DDRSS_CTL_27[14-0] DQS_OSC_PERIOD
- DDRSS_CTL_29[15-8] DQS_OSC_PROMOTE_THRESHOLD
- DDRSS_CTL_30[0] DQS_OSC_REQUEST
- DDRSS_CTL_29[7-0] DQS_OSC_TIMEOUT
- DDRSS_CTL_27[19-16] FUNC_VALID_CYCLES
- DDRSS_CTL_30[23-8] OSC_BASE_VALUE_0_CS0
- DDRSS_CTL_31[15-0] OSC_BASE_VALUE_1_CS0
- DDRSS_CTL_31[31-16] OSC_BASE_VALUE_2_CS0
- DDRSS_CTL_32[15-0] OSC_BASE_VALUE_3_CS0
- DDRSS_CTL_32[31-16] OSC_BASE_VALUE_0_CS1
- DDRSS_CTL_33[15-0] OSC_BASE_VALUE_1_CS1
- DDRSS_CTL_33[31-16] OSC_BASE_VALUE_2_CS1
- DDRSS_CTL_34[15-0] OSC_BASE_VALUE_3_CS1
- DDRSS_CTL_29[31-16] OSC_VARIANCE_LIMIT
- DDRSS_CTL_27[31-24] TOSCO_F0
- DDRSS_CTL_28[7-0] TOSCO_F1
- DDRSS_CTL_28[15-8] TOSCO_F2

Once the DDR controller has been initialized, before the controller reaches its terminal power-on state, a request is generated to the oscillator module to set the initial base values. These values are read from the memories and stored in the OSC_BASE_VALUE_x_CSy fields.

Following a frequency change, the base values to be used for comparison must be updated. As part of the operation, the frequency change task generates a subtask request to the DQS oscillator. This request, like the initialization request, will run the oscillator and then load the resulting values into the OSC_BASE_VALUE_x_CSy fields.

Once the base values have been updated, the DDR controller sets to 1h bit [31] in the DDRSS_CTL_293[31-0] INT_STATUS_0 field indicating DQS oscillator base value update interrupt.

8.2.3.6.10.5.1 Oscillator State Machine

A state machine inside the DDR controller tracks oscillator-related commands and wait times. The basic flow is as follows:

1. If the oscillator function is enabled by setting the DDRSS_CTL_26[16] DQS_OSC_ENABLE bit to 1h, the process begins when a request is received to run the oscillator function. This request can be issued automatically during the initialization process, during a frequency change process, as a software request by setting the DDRSS_CTL_30[0] DQS_OSC_REQUEST bit to 1h, or through a programmable periodic timer (the DDRSS_CTL_28[23-16] DQS_OSC_NORM_THRESHOLD, DDRSS_CTL_28[31-24] DQS_OSC_HIGH_THRESHOLD, or DDRSS_CTL_29[7-0] DQS_OSC_TIMEOUT fields). Once this process has started, the memory is not allowed to enter any low power modes until complete.
2. If the request is through initialization, MR23 is written with the value of the DDRSS_CTL_190[7-0] MR23_DATA field defining the number of cycles to run the oscillator.
3. An MPC is issued to start the oscillator. If there are multiple DRAM devices on a rank, the MPC is issued to all devices on the rank at the same time, and then the state machine proceeds to the next rank and issues MPCs to that rank, and so on.
4. The state machine waits the cycles defined by the DDRSS_CTL_27[14-0] DQS_OSC_PERIOD field and the cycles specified in the DDRSS_CTL_27[31-24] TOSCO_F0, DDRSS_CTL_28[7-0] TOSCO_F1, and DDRSS_CTL_28[15-8] TOSCO_F2 fields to allow the operation to complete and the results to be stored.
5. The state machine issues a read to MR18.
6. The state machine waits the number of cycles specified in the DDRSS_CTL_51[27-24] TMRR field, and then stores the result in a temporary location. If there are multiple DRAM devices on a rank, the MRR captures the mode register content for all devices on that rank.
7. The state machine issues a read to MR19.

8. The state machine waits the number of cycles specified in the DDRSS_CTL_51[27-24] TMRR field, and then stores the result in a temporary location. If there are multiple DRAM devices on a rank, the MRR captures the mode register content for all devices on that rank.
9. The values read in MR18 and MR19 represent the LSB and MSB of the DQS oscillator count. The DDR controller combines them and compares the result. If multiple devices exist on a rank, the comparison is made between each device and the base value.
 - a. If this is the initial read or a read related to a DFS operation, the values are stored in the OSC_BASE_VALUE_x_CSy fields. The DDR controller drives a 1h value on the dfi_function signal and asserts the dfi_function_valid signal for the number of cycles defined by the DDRSS_CTL_27[19-16] FUNC_VALID_CYCLES field.
 - b. If the value is FFFFh, an overflow condition occurred during the measurement process. The DDR controller sets to 1h bit [0] in the DDRSS_CTL_294[12-0] INT_STATUS_1 field indicating DQS oscillator measurement overflow interrupt and ignores the value.
 - c. If the difference between the measured value and the base value is lower than or equal to the value programmed in the DDRSS_CTL_29[31-16] OSC_VARIANCE_LIMIT field, the DDR controller returns to idle state. If the request was issued through software, the DDR controller sets to 1h bit [30] in the DDRSS_CTL_293[31-0] INT_STATUS_0 field indicating DQS oscillator request complete interrupt.
 - d. If the difference between the measured value and the base value is greater than the value programmed in the DDRSS_CTL_29[31-16] OSC_VARIANCE_LIMIT field, the DDR controller sets to 1h bit [1] in the DDRSS_CTL_294[12-0] INT_STATUS_1 field indicating DQS oscillator out of variance interrupt. The DDR controller also drives a 2h value on the dfi_function signal and asserts the dfi_function_valid signal for the number of cycles defined by the DDRSS_CTL_27[19-16] FUNC_VALID_CYCLES field. The measured value will replace the base value for any device for which the measured value is outside the variance. This base value update does not set to 1h bit [31] in the DDRSS_CTL_293[31-0] INT_STATUS_0 field.

8.2.3.6.10.6 Per-Bank Refresh (PBR)

Refresh commands are important memory operations to preserve memory contents, but they are also disruptive to system transaction flow. To minimize the impact, the DDR controller implements refresh on a per-bank basis. This does increase the quantity of refresh commands, but allows banks that are not targeted by the refresh to be accessed for read and write commands.

PBR is controlled through the following fields:

- DDRSS_CTL_228[12-8] AREF_MAX_CREDIT
- DDRSS_CTL_228[4-0] AREF_MAX_DEFICIT
- DDRSS_CTL_227[20-16] AREF_NORM_THRESHOLD
- DDRSS_CTL_71[28-24] AREF_PBR_CONT_DIS_THRESHOLD
- DDRSS_CTL_71[20-16] AREF_PBR_CONT_EN_THRESHOLD
- DDRSS_CTL_71[3-0] PBR_BANK_SELECT_DELAY
- DDRSS_CTL_71[8] PBR_CONT_REQ_EN
- DDRSS_CTL_67[0] PBR_EN
- DDRSS_CTL_70[31-16] PBR_MAX_BANK_WAIT
- DDRSS_CTL_67[8] PBR_NUMERIC_ORDER
- DDRSS_CTL_59[16] TREF_ENABLE
- DDRSS_CTL_68[15-0] TREFI_PB_F0
- DDRSS_CTL_69[15-0] TREFI_PB_F1
- DDRSS_CTL_70[15-0] TREFI_PB_F2

8.2.3.6.10.6.1 Normal Operation

Per-bank refresh commands may be issued to all banks or to a single bank, and may be issued to each bank in any order if programmed for this behavior. However, all banks must be refreshed before the same bank can be issued a new per-bank refresh command. The DDR controller can issue the commands in any order, and subsequent per-bank refresh sequences can be a completely different order than the last command. The order of banks is specified via the DDRSS_CTL_67[8] PBR_NUMERIC_ORDER bit. It is potentially advantageous to execute out-of-numerical order to prevent an active bank from stalling refresh operations to any other banks.

The PBR logic is part of the auto-refresh logic. The auto-refresh logic is responsible for maintaining the debit / credit counts for refresh that ensure that refresh commands are occurring as needed. The DRAM allows the user to postpone a maximum of 8 refresh commands which means that the user can wait as much as 9 x TREFI_PB_Fx cycles before issuing a refresh command. The DDR controller keeps track of how many refreshes it has skipped (DDRSS_CTL_228[4-0] AREF_MAX_DEFICIT) or advanced (DDRSS_CTL_228[12-8] AREF_MAX_CREDIT) and ensures that the DRAM requirements are satisfied. The PBR logic issues refresh commands to single banks if enabled via the DDRSS_CTL_67[0] PBR_EN bit and in accordance with the programmed values. The DDRSS_CTL_59[16] TREF_ENABLE bit must also be set to 1h for the PBR logic to work. The auto-refresh logic issues refresh commands to all banks and high priority refresh commands if the refresh count falls below a certain threshold.

When a refresh is required, the PBR logic issues a per-bank refresh command to a specific bank. If that bank is currently being accessed by the DDR controller core, the command will be held off. If the command is held off beyond the number of cycles specified in the DDRSS_CTL_70[31-16] PBR_MAX_BANK_WAIT field, the PBR logic inhibits the active process in the DDR controller core, closes the bank, executes the PBR command and then un-inhibits the core to allow the interrupted process to continue. Once the bank is free, the PBR command is issued. The bank will be blocked from accesses within the number of clocks programmed into the DDRSS_CTL_71[3-0] PBR_BANK_SELECT_DELAY field and the refresh will occur and then release the bank.

8.2.3.6.10.6.2 Continuous Refresh Request Mode

The PBR logic can be temporarily modified to continuously assert refresh requests. This option may be desirable when the auto-refresh logic is running at a deficit and the user wishes to run per-bank refreshes instead of auto-refreshes to restore the refresh count.

Setting the DDRSS_CTL_71[8] PBR_CONT_REQ_EN bit to 1h enables this mode. Automatic mode falls between the normal priority and high priority commands in terms of priority. When enabled, if the number of all-bank refresh commands pending exceeds the value programmed into the DDRSS_CTL_71[20-16] AREF_PBR_CONT_EN_THRESHOLD field, then the DDR controller automatically begins issuing per-bank refresh commands. As refreshes occur, the pending command count drops. Once that value meets the value programmed in the DDRSS_CTL_71[28-24] AREF_PBR_CONT_DIS_THRESHOLD field, the DDR controller stops automatically issuing per-bank refresh commands.

If however the refresh command pending count exceeds the value programmed into the DDRSS_CTL_227[20-16] AREF_NORM_THRESHOLD field, the DDR controller temporarily suspends the PBR logic, and the auto-refresh logic issues all-bank refresh commands until the refresh logic catches up. Once caught up, the PBR logic is resumed.

8.2.3.7 DDR PHY Functional Description

The DDR PHY provides functionality to interface the DDR controller to SDRAM devices. The PHY has a slice based and DQS-delay architecture. It contains data, address, address/control and clock slices and uses programmable clock delay lines to align write data, read data capture, and DQS gating from the I/O pads across the DFI interface to the DDR controller.

8.2.3.7.1 Data Slice

The data slice transfers data between the DDR controller and the SDRAM devices. The data slice is a module that interfaces to the DQ, DM, and DQS signals of the SDRAM and is duplicated as many times as necessary to create the current SoC SDRAM data width.

The write data path logic (from DFI to pads) and the read data path logic (from pads to DFI) are contained within the data slice. Termination and directional controls for the data path related I/Os are also contained in this slice.

8.2.3.7.2 Address Slice

The address slice transfers address information between the DDR controller and the SDRAM devices and contains 6 address bits.

The address write data path logic (from DFI to pads) and the read data path logic (loopback only) are contained within the address slice. Termination and directional controls for the address path related I/Os also exist in this slice.

8.2.3.7.2.1 Address Swapping

The address slice has the ability to programmably change which DFI address bits that are connected to the I/O pads. Address signals can be swapped within an address slice without restrictions. The swapping is done via the DDRSS_PHY_1053[23-0] PHY_ADR_ADDR_SEL_0 field.

8.2.3.7.3 Address/Control Slice

The address/control slice is a module that interfaces to the control, command, and address connections of the SDRAM and is duplicated as many times as necessary to create the appropriate width for the SoC. The address/control signals within a slice have per bit delay line control.

8.2.3.7.4 Clock Slice

The clock slice creates the clock signal used by the SDRAM. The slice also disables the clock when instructed by the DDR controller through the DFI bus. When the clock is disabled, the CK pin drives low and the CKN drives high. Duty cycle correction is also applied in the memory clock slice.

8.2.3.7.5 DDR PHY Initialization

Once the power to the SDRAM and SoC is stable, the DDR PHY must be reset and initialized before normal traffic can commence. Once the initialization has completed, the DDR PHY asserts the dfi_init_complete signal to notify the DDR controller that the PHY and SDRAM are ready to accept commands.

The procedure to initialize the DDR PHY is as follows:

1. Reset the DDRSS0 through the DDRSS0_RST signal. This resets all DDR PHY registers.
2. Program all needed PHY registers.
3. The dfi_init_start is then asserted by the DDR controller. The PHY slice master delay lines locks and then the PHY asserts the dfi_init_complete signal. This indicates that the PHY and SDRAM are ready to accept commands. The PHY is now ready for normal traffic.

For information about the DDR controller initialization, see [Section 8.2.3.6.9](#).

8.2.3.7.6 DDR PHY Dynamic Frequency Scaling (DFS)

The DDR PHY supports Dynamic Frequency Scaling (DFS) as defined by the DFI specification. This feature allows the PHY to be configured for multiple frequency sets, and have the DFI bus dynamically specify which frequency set to use at a given time. Before using a frequency set in normal operation, leveling operation should be performed on that set. Failure to do so may result in invalid operation. Once leveling has been performed with each frequency set, the user can freely switch between frequencies without need to repeat the leveling, unless the leveling environment requires periodic updates for voltage and temperature compensation.

This DDR PHY contains registers for each frequency set. This feature creates a lookup table that may be accessed through the DDRSS_PHY_1281[17-16] PHY_FREQ_SEL_INDEX and DDRSS_PHY_1281[8] PHY_FREQ_SEL_MULTICAST_EN fields, which gives a flexibility in controlling these frequency set registers with a simple register interface. This fact should be taken into account when reading and writing these registers.

The DDRSS_PHY_1280[1-0] PHY_FREQ_SEL and DDRSS_PHY_1281[17-16] PHY_FREQ_SEL_INDEX fields operate independently, but if the PHY_FREQ_SEL_INDEX field specifies a frequency set different than the one currently being used, accidental write to or read from invalid registers may happen.

Reads from frequency based registers return only the value that correlates to the frequency set identified in the DDRSS_PHY_1281[17-16] PHY_FREQ_SEL_INDEX field. For writes to the frequency based registers, the resulting write depends on the value of the DDRSS_PHY_1281[8] PHY_FREQ_SEL_MULTICAST_EN bit. If it is set to 0x1, all frequency sets are concurrently written. If the PHY_FREQ_SEL_MULTICAST_EN bit is set to 0x0, only the frequency set identified in the PHY_FREQ_SEL_INDEX field is written.

For example, consider a write to DDRSS_PHY_130[9-0] PHY_RDDQS_DM_FALL_SLAVE_DELAY_0 with the following settings:

- DDRSS_PHY_1281[17-16] PHY_FREQ_SEL_INDEX = 0x0001 (frequency set 1)
- DDRSS_PHY_1281[8] PHY_FREQ_SEL_MULTICAST_EN = 0x0.

In this case, only the frequency set 1 version of the DDRSS_PHY_130[9-0] PHY_RDDQS_DM_FALL_SLAVE_DELAY_0 field is written. If the same settings are used,

but with PHY_FREQ_SEL_MULTICAST_EN = 0x1, then all frequency-indexed versions of PHY_RDDQS_DM_FALL_SLAVE_DELAY_0 are written.

8.2.3.7.7 Chip Select and Frequency Based Register Settings

Some register settings within the PHY are chip select based. The DDRSS_PHY_6[0] PHY_PER_CS_TRAINING_INDEX_0 bit allows access to a particular chip select copy. The PHY_PER_CS_TRAINING_INDEX_0 bit is associated with data slice 0. The following bits are associated with the other data slices:

- DDRSS_PHY_262[0] PHY_PER_CS_TRAINING_INDEX_1
- DDRSS_PHY_518[0] PHY_PER_CS_TRAINING_INDEX_2
- DDRSS_PHY_774[0] PHY_PER_CS_TRAINING_INDEX_3

When writing to chip select based registers, if the DDRSS_PHY_5[24] PHY_PER_CS_TRAINING_MULTICAST_EN_0 bit is set to 0x1, then all chip select copies receive the same data. The PHY_PER_CS_TRAINING_MULTICAST_EN_0 bit is associated with data slice 0. The following bits are associated with the other data slices:

- DDRSS_PHY_261[24] PHY_PER_CS_TRAINING_MULTICAST_EN_1
- DDRSS_PHY_517[24] PHY_PER_CS_TRAINING_MULTICAST_EN_2
- DDRSS_PHY_773[24] PHY_PER_CS_TRAINING_MULTICAST_EN_3

Some register settings in the PHY are frequency based. As already described, the DDRSS_PHY_1281[17-16] PHY_FREQ_SEL_INDEX field allows access to a particular frequency copy. When writing to frequency based registers, if the DDRSS_PHY_1281[8] PHY_FREQ_SEL_MULTICAST_EN bit is set to 0x1, then all frequency copies receive the same data. [Table 8-17](#) shows the frequency based register settings.

DDRSS_PHY_1412[31-0] PHY_PAD_CLK_DRIVE	
DDRSS_PHY_1413[17-0] PHY_PAD_CLK_DRIVE2	

Some register settings in the PHY are both chip select based and frequency based. For them, the PHY_PER_CS_TRAINING_INDEX_0/1/2/3 bits and the DDRSS_PHY_1281[17-16] PHY_FREQ_SEL_INDEX field apply to the register access. The DDRSS_PHY_1281[8] PHY_FREQ_SEL_MULTICAST_EN bit applies as well. [Table 8-18](#) shows the chip select based and frequency based register settings.

8.2.3.7.8 Low-Power Modes

The DDR PHY provides a means to reduce the operational power when it is not actively transferring read or write data for an extended period of time. This is done using the DFI low power interface. Using this interface, the DDR controller communicates to the PHY that it may enter its own low-power state and informs the PHY how quickly it requires the PHY to recover if a low-power state is entered. This DDR PHY has the following power modes:

- **Idle:** This is a period in which no read or write activity is being performed by the DDR controller. The PHY is not in any low power state, and is ready to accept commands at any time.
- **Read/Write:** This describes the time period when the PHY is actively performing a read or write operation triggered by the DDR controller.
- **Light Sleep:** This is a low-power state in which the master delay lines and their logic receive a clock, but all other slice logic is gated off. The PHY PLLs remain in an active state. Register reads and writes to data and address slices are not permitted. The PHY returns quickly to functional operation after an exit from light sleep. After exiting the PHY initializes the slave delay settings automatically. The master delay line macro maintains lock. This mode is entered if the dfi_lp_wakeup signal is driven with a value less than or equal to the programmed value in bits [3:0] of the the DDRSS_PHY_1318[15-8] PHY_LP_WAKEUP field. If low power idle state is enabled, the value must also be greater than the value of bits [7:4] in the DDRSS_PHY_1318[15-8] PHY_LP_WAKEUP field.
- **Deep Sleep:** This is an ultra low-power state in which clocking to the data, address, and address/control slices is disabled. The PLLs are in a power down state. Pad calibration functions are frozen. When in this mode, no DFI accesses or register reads and writes can be performed. This mode is entered if the dfi_lp_wakeup signal is driven with a value greater than the programmed value in bits [3:0] of the the DDRSS_PHY_1318[15-8] PHY_LP_WAKEUP field.
- **Low Power Idle:** This is a low power version of idle where the data slices are placed in a light sleep mode while still allowing accesses to the data slice register address space. The DDRSS_PHY_1318[16] PHY_LS_IDLE_EN bit enables this low power idle state. The mode is entered if the dfi_lp_wakeup signal is driven with a value less than or equal to the programmed value of bits [7:4] in the DDRSS_PHY_1318[15-8] PHY_LP_WAKEUP field.

In general, if the SDRAM is placed into a power-down mode, the DDR PHY should enter light sleep. If the SDRAM is placed in a self-refresh mode, the DDR PHY could enter deep sleep.

The DDRSS_PHY_1319[9-0] PHY_LP_CTRLUPD_CNTR_CFG field controls the number of clock controller cycles between de-assertion of the dfi_lp_req signal and de-assertion of the dfi_lp_ack signal during exit of light sleep and low power idle modes.

Within each data slice, the DQ, DM and DQS I/O's are disabled when not being written to or read from. The gate feedback pads are constantly enabled to control the read DQS gate open logic. The following fields control disabling the gate feedback pad for the corresponding slice during deep sleep mode:

- DDRSS_PHY_79[26-24] PHY_FDBK_PWR_CTRL_0
- DDRSS_PHY_335[26-24] PHY_FDBK_PWR_CTRL_1
- DDRSS_PHY_591[26-24] PHY_FDBK_PWR_CTRL_2
- DDRSS_PHY_847[26-24] PHY_FDBK_PWR_CTRL_3

8.2.3.7.9 Training Support

Training of the DDR PHY and SDRAM is necessary to support high-speed operation. The general training flow as follows:

1. I/O calibration
2. CA/CS training (VREF CA)
3. Write leveling
4. Read DQS gate training
5. Read data eye training
6. Write data eye training (VREF DQ)

8.2.3.7.9.1 Write Leveling

When the write leveling algorithm has completed, the final write DQS delay settings can be found in the following fields:

- DDRSS_PHY_120[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_0
- DDRSS_PHY_376[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_1
- DDRSS_PHY_632[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_2
- DDRSS_PHY_888[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_3
- DDRSS_PHY_121[1-0] PHY_WRLVL_THRESHOLD_ADJUST_0
- DDRSS_PHY_377[1-0] PHY_WRLVL_THRESHOLD_ADJUST_1
- DDRSS_PHY_633[1-0] PHY_WRLVL_THRESHOLD_ADJUST_2
- DDRSS_PHY_889[1-0] PHY_WRLVL_THRESHOLD_ADJUST_3

After write leveling is complete, the following fields can be checked to obtain the leveling status:

- DDRSS_PHY_50[16-0] PHY_WRLVL_STATUS_OBS_0
- DDRSS_PHY_306[16-0] PHY_WRLVL_STATUS_OBS_1
- DDRSS_PHY_562[16-0] PHY_WRLVL_STATUS_OBS_2
- DDRSS_PHY_818[16-0] PHY_WRLVL_STATUS_OBS_3

After write leveling is complete, software can always override the results by writing directly to the following fields:

- DDRSS_PHY_120[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_0
- DDRSS_PHY_376[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_1
- DDRSS_PHY_632[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_2
- DDRSS_PHY_888[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_3

If the clock path to the SDRAM is longer than the DQS path to the SDRAM, the leveling result from the first SDRAM along the memory clock path always returns a small value greater than zero because the DQS signal needs to be moved slightly to the right to line up with the memory clock. If the clock path to the SDRAM is shorter than the DQS path to the SDRAM, the DQS signal may need to be moved close to a cycle before it lines up with the memory clock. The leveling result indicates to the slice that the DQS needs to be delayed almost a cycle. This would then result in the write data being a cycle later than expected by the SDRAM based on when the write command is received. In reality, the DQS needs to be negatively delayed to align to the memory clock in the proper cycle. To create this “negative” delay, the command bus needs to be delayed one cycle so that when the DQS is delayed almost one cycle, the DQS appears “early” with respect to the write command. For example, if the memory clock path for slice 0 is expected to be about 1/16th cycle shorter than the DQS path, a write leveling result of 0x1E0 would be expected. The DDRSS_PHY_131[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_0 field enables the data slice 0 to understand if this is an expected delay or if this is a “negative” delay condition. When the result contained in DDRSS_PHY_120[25-16] PHY_CLK_WRDQS_SLAVE_DELAY_0 field is greater than the DDRSS_PHY_131[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_0 field, the command bus is delayed by one cycle. [Table 8-19](#) shows examples of programming this field for various expected delays. The following fields are associated with the other data slices:

- DDRSS_PHY_387[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_1
- DDRSS_PHY_643[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_2
- DDRSS_PHY_889[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_3

Table 8-19. PHY Write Level Delay Values

Expected Delay	PHY_WRLVL_DELAY_EARLY_THRESHOLD_x x = 0, 1, 2, 3	Command Bus Impact
0.25 cycle	0x200 (off)	None
1.00 cycle	0x200 (off)	None

Table 8-19. PHY Write Level Delay Values (continued)

Expected Delay	PHY_WRLVL_DELAY_EARLY_THRESHOLD_ x x = 0, 1, 2, 3	Command Bus Impact
0.00 cycles	0x1E0	1 cycle delay if result is > 0x1E0

The DDRSS_PHY_132[16] PHY_WRLVL_EARLY_FORCE_ZERO_0 bit works with the DDRSS_PHY_131[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_0 field for slice 0. The following fields are associated with the other slices:

- DDRSS_PHY_388[16] PHY_WRLVL_EARLY_FORCE_ZERO_1 and DDRSS_PHY_387[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_1
- DDRSS_PHY_644[16] PHY_WRLVL_EARLY_FORCE_ZERO_2 and DDRSS_PHY_643[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_2
- DDRSS_PHY_900[16] PHY_WRLVL_EARLY_FORCE_ZERO_3 and DDRSS_PHY_899[25-16] PHY_WRLVL_DELAY_EARLY_THRESHOLD_3

When the write leveling result satisfies the early threshold condition, the DQS is ideally aligned to clock but there is a cycle of latency added to the command path. Setting the PHY_WRLVL_EARLY_FORCE_ZERO_**x** bit to 0x1 forces the PHY_CLK_WRDQS_SLAVE_DELAY_**x** value to 0x0 so there is no command latency impact.

The PHY_WRLVL_THRESHOLD_ADJUST_**x** fields contain the results of the PHY_WRLVL_DELAY_PERIOD_THRESHOLD_**x** and PHY_WRLVL_DELAY_EARLY_THRESHOLD_**x** calculations from the write leveling process. This allows for direct observation of the leveling results. It also allows to rewrite leveling results if desired. This can be useful in case leveling is performed once and the same results are used in the future. The PHY_WRLVL_DELAY_EARLY_THRESHOLD_**x** and PHY_WRLVL_DELAY_PERIOD_THRESHOLD_**x** results can be applied through the PHY_WRLVL_THRESHOLD_ADJUST_**x** fields without having to go through the leveling process again.

The previously mentioned PHY_WRLVL_DELAY_PERIOD_THRESHOLD_**x** fields are accessed through the following registers:

- DDRSS_PHY_132[9-0] PHY_WRLVL_DELAY_PERIOD_THRESHOLD_0
- DDRSS_PHY_388[9-0] PHY_WRLVL_DELAY_PERIOD_THRESHOLD_1
- DDRSS_PHY_644[9-0] PHY_WRLVL_DELAY_PERIOD_THRESHOLD_2
- DDRSS_PHY_900[9-0] PHY_WRLVL_DELAY_PERIOD_THRESHOLD_3

8.2.3.7.9.2 Read Gate Training

When the read gate training algorithm has completed, the final read DQS slave delay settings can be found in the following fields:

- DDRSS_PHY_130[25-16] PHY_RDDQS_GATE_SLAVE_DELAY_0 (cycle fraction)
- DDRSS_PHY_386[25-16] PHY_RDDQS_GATE_SLAVE_DELAY_1 (cycle fraction)
- DDRSS_PHY_642[25-16] PHY_RDDQS_GATE_SLAVE_DELAY_2 (cycle fraction)
- DDRSS_PHY_898[25-16] PHY_RDDQS_GATE_SLAVE_DELAY_3 (cycle fraction)
- DDRSS_PHY_131[3-0] PHY_RDDQS_LATENCY_ADJUST_0 (cycle offset)
- DDRSS_PHY_387[3-0] PHY_RDDQS_LATENCY_ADJUST_1 (cycle offset)
- DDRSS_PHY_643[3-0] PHY_RDDQS_LATENCY_ADJUST_2 (cycle offset)
- DDRSS_PHY_899[3-0] PHY_RDDQS_LATENCY_ADJUST_3 (cycle offset)

After read gate training is complete, the following fields can be checked to obtain the training status:

- DDRSS_PHY_54[17-0] PHY_GTLVL_STATUS_OBS_0
- DDRSS_PHY_310[17-0] PHY_GTLVL_STATUS_OBS_1
- DDRSS_PHY_566[17-0] PHY_GTLVL_STATUS_OBS_2
- DDRSS_PHY_822[17-0] PHY_GTLVL_STATUS_OBS_3

After read gate training is complete, software can always override the results by writing directly to the PHY_RDDQS_GATE_SLAVE_DELAY_**x** and PHY_RDDQS_LATENCY_ADJUST_**x** fields.

8.2.3.7.9.3 Read Data Eye Training

When the read gate training algorithm has completed, the final read DQS slave delay settings can be found in the following fields:

- DDRSS_PHY_121[17-8] PHY_RDDQS_DQ0_RISE_SLAVE_DELAY_0
- DDRSS_PHY_122[25-16] PHY_RDDQS_DQ1_RISE_SLAVE_DELAY_0
- DDRSS_PHY_123[25-16] PHY_RDDQS_DQ2_RISE_SLAVE_DELAY_0
- DDRSS_PHY_124[25-16] PHY_RDDQS_DQ3_RISE_SLAVE_DELAY_0
- DDRSS_PHY_125[25-16] PHY_RDDQS_DQ4_RISE_SLAVE_DELAY_0
- DDRSS_PHY_126[25-16] PHY_RDDQS_DQ5_RISE_SLAVE_DELAY_0
- DDRSS_PHY_127[25-16] PHY_RDDQS_DQ6_RISE_SLAVE_DELAY_0
- DDRSS_PHY_128[25-16] PHY_RDDQS_DQ7_RISE_SLAVE_DELAY_0
- DDRSS_PHY_377[17-8] PHY_RDDQS_DQ0_RISE_SLAVE_DELAY_1
- DDRSS_PHY_378[25-16] PHY_RDDQS_DQ1_RISE_SLAVE_DELAY_1
- DDRSS_PHY_379[25-16] PHY_RDDQS_DQ2_RISE_SLAVE_DELAY_1
- DDRSS_PHY_380[25-16] PHY_RDDQS_DQ3_RISE_SLAVE_DELAY_1
- DDRSS_PHY_381[25-16] PHY_RDDQS_DQ4_RISE_SLAVE_DELAY_1
- DDRSS_PHY_382[25-16] PHY_RDDQS_DQ5_RISE_SLAVE_DELAY_1
- DDRSS_PHY_383[25-16] PHY_RDDQS_DQ6_RISE_SLAVE_DELAY_1
- DDRSS_PHY_384[25-16] PHY_RDDQS_DQ7_RISE_SLAVE_DELAY_1
- DDRSS_PHY_633[17-8] PHY_RDDQS_DQ0_RISE_SLAVE_DELAY_2
- DDRSS_PHY_634[25-16] PHY_RDDQS_DQ1_RISE_SLAVE_DELAY_2
- DDRSS_PHY_635[25-16] PHY_RDDQS_DQ2_RISE_SLAVE_DELAY_2
- DDRSS_PHY_636[25-16] PHY_RDDQS_DQ3_RISE_SLAVE_DELAY_2
- DDRSS_PHY_637[25-16] PHY_RDDQS_DQ4_RISE_SLAVE_DELAY_2
- DDRSS_PHY_638[25-16] PHY_RDDQS_DQ5_RISE_SLAVE_DELAY_2
- DDRSS_PHY_639[25-16] PHY_RDDQS_DQ6_RISE_SLAVE_DELAY_2
- DDRSS_PHY_640[25-16] PHY_RDDQS_DQ7_RISE_SLAVE_DELAY_2
- DDRSS_PHY_889[17-8] PHY_RDDQS_DQ0_RISE_SLAVE_DELAY_3
- DDRSS_PHY_890[25-16] PHY_RDDQS_DQ1_RISE_SLAVE_DELAY_3
- DDRSS_PHY_891[25-16] PHY_RDDQS_DQ2_RISE_SLAVE_DELAY_3
- DDRSS_PHY_892[25-16] PHY_RDDQS_DQ3_RISE_SLAVE_DELAY_3
- DDRSS_PHY_893[25-16] PHY_RDDQS_DQ4_RISE_SLAVE_DELAY_3
- DDRSS_PHY_894[25-16] PHY_RDDQS_DQ5_RISE_SLAVE_DELAY_3
- DDRSS_PHY_895[25-16] PHY_RDDQS_DQ6_RISE_SLAVE_DELAY_3
- DDRSS_PHY_896[25-16] PHY_RDDQS_DQ7_RISE_SLAVE_DELAY_3
- DDRSS_PHY_122[9-0] PHY_RDDQS_DQ0_FALL_SLAVE_DELAY_0
- DDRSS_PHY_123[9-0] PHY_RDDQS_DQ1_FALL_SLAVE_DELAY_0
- DDRSS_PHY_124[9-0] PHY_RDDQS_DQ2_FALL_SLAVE_DELAY_0
- DDRSS_PHY_125[9-0] PHY_RDDQS_DQ3_FALL_SLAVE_DELAY_0
- DDRSS_PHY_126[9-0] PHY_RDDQS_DQ4_FALL_SLAVE_DELAY_0
- DDRSS_PHY_127[9-0] PHY_RDDQS_DQ5_FALL_SLAVE_DELAY_0
- DDRSS_PHY_128[9-0] PHY_RDDQS_DQ6_FALL_SLAVE_DELAY_0
- DDRSS_PHY_129[9-0] PHY_RDDQS_DQ7_FALL_SLAVE_DELAY_0
- DDRSS_PHY_378[9-0] PHY_RDDQS_DQ0_FALL_SLAVE_DELAY_1
- DDRSS_PHY_379[9-0] PHY_RDDQS_DQ1_FALL_SLAVE_DELAY_1
- DDRSS_PHY_380[9-0] PHY_RDDQS_DQ2_FALL_SLAVE_DELAY_1
- DDRSS_PHY_381[9-0] PHY_RDDQS_DQ3_FALL_SLAVE_DELAY_1
- DDRSS_PHY_382[9-0] PHY_RDDQS_DQ4_FALL_SLAVE_DELAY_1
- DDRSS_PHY_383[9-0] PHY_RDDQS_DQ5_FALL_SLAVE_DELAY_1
- DDRSS_PHY_384[9-0] PHY_RDDQS_DQ6_FALL_SLAVE_DELAY_1
- DDRSS_PHY_385[9-0] PHY_RDDQS_DQ7_FALL_SLAVE_DELAY_1
- DDRSS_PHY_634[9-0] PHY_RDDQS_DQ0_FALL_SLAVE_DELAY_2
- DDRSS_PHY_635[9-0] PHY_RDDQS_DQ1_FALL_SLAVE_DELAY_2
- DDRSS_PHY_636[9-0] PHY_RDDQS_DQ2_FALL_SLAVE_DELAY_2
- DDRSS_PHY_637[9-0] PHY_RDDQS_DQ3_FALL_SLAVE_DELAY_2

- DDRSS_PHY_638[9-0] PHY_RDDQS_DQ4_FALL_SLAVE_DELAY_2
- DDRSS_PHY_639[9-0] PHY_RDDQS_DQ5_FALL_SLAVE_DELAY_2
- DDRSS_PHY_640[9-0] PHY_RDDQS_DQ6_FALL_SLAVE_DELAY_2
- DDRSS_PHY_641[9-0] PHY_RDDQS_DQ7_FALL_SLAVE_DELAY_2
- DDRSS_PHY_890[9-0] PHY_RDDQS_DQ0_FALL_SLAVE_DELAY_3
- DDRSS_PHY_891[9-0] PHY_RDDQS_DQ1_FALL_SLAVE_DELAY_3
- DDRSS_PHY_892[9-0] PHY_RDDQS_DQ2_FALL_SLAVE_DELAY_3
- DDRSS_PHY_893[9-0] PHY_RDDQS_DQ3_FALL_SLAVE_DELAY_3
- DDRSS_PHY_894[9-0] PHY_RDDQS_DQ4_FALL_SLAVE_DELAY_3
- DDRSS_PHY_895[9-0] PHY_RDDQS_DQ5_FALL_SLAVE_DELAY_3
- DDRSS_PHY_896[9-0] PHY_RDDQS_DQ6_FALL_SLAVE_DELAY_3
- DDRSS_PHY_897[9-0] PHY_RDDQS_DQ7_FALL_SLAVE_DELAY_3
- DDRSS_PHY_129[25-16] PHY_RDDQS_DM_RISE_SLAVE_DELAY_0
- DDRSS_PHY_385[25-16] PHY_RDDQS_DM_RISE_SLAVE_DELAY_1
- DDRSS_PHY_641[25-16] PHY_RDDQS_DM_RISE_SLAVE_DELAY_2
- DDRSS_PHY_897[25-16] PHY_RDDQS_DM_RISE_SLAVE_DELAY_3
- DDRSS_PHY_130[9-0] PHY_RDDQS_DM_FALL_SLAVE_DELAY_0
- DDRSS_PHY_386[9-0] PHY_RDDQS_DM_FALL_SLAVE_DELAY_1
- DDRSS_PHY_642[9-0] PHY_RDDQS_DM_FALL_SLAVE_DELAY_2
- DDRSS_PHY_898[9-0] PHY_RDDQS_DM_FALL_SLAVE_DELAY_3

Read data eye training for LPDDR4 devices does return data on the DM pin so the DBI data is trained along with the other DQ pins. In this case, the PHY_RDDQS_DM_RISE_SLAVE_DELAY_x and PHY_RDDQS_DM_FALL_SLAVE_DELAY_x fields receive their own unique values.

After read data eye training is complete, no error condition is noted in the read leveling status fields. The RISE and FALL field results in the previously described registers can be checked to look for values that appear out of place (for example, near 0x000, near 0x100 or greater) or to look for a DQ that is much different than the rest. After read data eye training is complete, software can always override the results by writing directly to the PHY_RDDQS_DQy_RISE_SLAVE_DELAY_x, PHY_RDDQS_DQy_FALL_SLAVE_DELAY_x, PHY_RDDQS_DM_RISE_SLAVE_DELAY_x and PHY_RDDQS_DM_FALL_SLAVE_DELAY_x fields.

8.2.3.7.9.4 Write DQ Training

The data that is written to the SDRAM during training is created within the data slice. The following data pattern options are available:

- Clock pattern - An alternating pattern of "1" and "0" is applied to each DQ/DM. The phase of the 1/0 pattern is identical on the DQ/DM pins.
- LFSR pattern - The same LFSR pattern that is used for data loopback can be applied to the DQ/DM pins. The LFSR is reset at the start of the pattern and each burst of data is different according to the progression of the LFSR.
- User defined pattern - A user defined pattern can also be applied to the DQ/DM pins. Independent data for each bit covering a full burst of 16 can be loaded into register fields to supply the training data. The same data pattern is repeated for every burst. The pattern is defined through the following fields:
 - DDRSS_PHY_36[31-0] PHY_USER_PATT0_0
 - DDRSS_PHY_292[31-0] PHY_USER_PATT0_1
 - DDRSS_PHY_548[31-0] PHY_USER_PATT0_2
 - DDRSS_PHY_804[31-0] PHY_USER_PATT0_3
 - DDRSS_PHY_37[31-0] PHY_USER_PATT1_0
 - DDRSS_PHY_293[31-0] PHY_USER_PATT1_1
 - DDRSS_PHY_549[31-0] PHY_USER_PATT1_2
 - DDRSS_PHY_805[31-0] PHY_USER_PATT1_3
 - DDRSS_PHY_38[31-0] PHY_USER_PATT2_0
 - DDRSS_PHY_294[31-0] PHY_USER_PATT2_1
 - DDRSS_PHY_550[31-0] PHY_USER_PATT2_2
 - DDRSS_PHY_806[31-0] PHY_USER_PATT2_3

- DDRSS_PHY_39[31-0] PHY_USER_PATT3_0
- DDRSS_PHY_295[31-0] PHY_USER_PATT3_1
- DDRSS_PHY_551[31-0] PHY_USER_PATT3_2
- DDRSS_PHY_807[31-0] PHY_USER_PATT3_3
- DDRSS_PHY_40[15-0] PHY_USER_PATT4_0
- DDRSS_PHY_296[15-0] PHY_USER_PATT4_1
- DDRSS_PHY_552[15-0] PHY_USER_PATT4_2
- DDRSS_PHY_808[15-0] PHY_USER_PATT4_3

These patterns can be used in any combination and if multiple patterns are requested, the final results are based on the largest leading edge found and the smallest trailing edge found across the patterns selected.

8.2.3.7.9.5 CA Training

CA bits can be swizzled between any bit positions via the DDRSS_PHY_1053[23-0] PHY_ADR_ADDR_SEL_0 field.

When the memory subsystem consists of more than one LPDDR device on the full bus width (two 16 bit devices on a 32 bit bus), all devices receive the same CA bits at some timing relative to each other depending on board placement and routing. In these cases, the DDR PHY can only supply a single CA training value for all devices to use together. Since each device may not receive ideal timing, the CA timing margin is reduced in the overall memory subsystem. Either a single one (any of them) or any combination of the devices participating in the training can be individually selected via the DDRSS_PHY_1357[20-16] PHY_CALVL_DEVICE_MAP field.

In case of two channels, each one can be assigned to a specific chip select and data slices. The DDRSS_PHY_1293[31-24] PHY_CALVL_CS_MAP field is used to map each CS rank to the appropriate DQ slice for training data return.

Bit 1 of the DDRSS_PHY_1038[25-24] PHY_ADR_CALVL_RANK_CTRL_0 field enables current training results to be taken into account along with new training results, instead of discarding previous results. This can be used to train each rank or channel and construct an aggregate for all of them. Each rank or channel then receives the same CA training timing that is the best case possible for all of them. This may result in the setup/hold margin for the CA bits being narrower than any single rank or channel could achieve by itself.

Note

When multiple frequency sets are supported, then all ranks for a given frequency set must be trained before changing to a new frequency. Failure to do so results in rank aggregation not being performed completely with possible data corruption due to rank training being improper.

In case of multiple channels each rank of a channel must use the same CA swizzle. Each rank of a channel must also use the same DQ swizzle.

If the memory device DQ bits are not received in the same order at the PHY as the LPDDR device sent them, then the DQ data has been swizzled, and must be reordered back to its original form before CA training can interpret the results. The following fields specify the DQ swizzling in the corresponding data slice:

- DDRSS_PHY_114[31-0] PHY_DQ_DM_SWIZZLE0_0
- DDRSS_PHY_370[31-0] PHY_DQ_DM_SWIZZLE0_1
- DDRSS_PHY_626[31-0] PHY_DQ_DM_SWIZZLE0_2
- DDRSS_PHY_882[31-0] PHY_DQ_DM_SWIZZLE0_3
- DDRSS_PHY_115[3-0] PHY_DQ_DM_SWIZZLE1_0
- DDRSS_PHY_371[3-0] PHY_DQ_DM_SWIZZLE1_1
- DDRSS_PHY_627[3-0] PHY_DQ_DM_SWIZZLE1_2
- DDRSS_PHY_883[3-0] PHY_DQ_DM_SWIZZLE1_3

The PHY_DQ_DM_SWIZZLE0_x fields contain the bit position to map the received read DQ bits for proper comparison with the training pattern bits.

After CA training is complete the DDRSS_PHY_1043[31-0] PHY_ADR_CALVL_OBS1_0 field can be read to obtain training status information.

After CA training is complete, software can always override the results by writing to the following fields:

- DDRSS_PHY_1065[18-8] PHY_ADR0_CLK_WR_SLAVE_DELAY_0
- DDRSS_PHY_1066[10-0] PHY_ADR1_CLK_WR_SLAVE_DELAY_0
- DDRSS_PHY_1067[10-0] PHY_ADR2_CLK_WR_SLAVE_DELAY_0
- DDRSS_PHY_1068[10-0] PHY_ADR3_CLK_WR_SLAVE_DELAY_0
- DDRSS_PHY_1069[10-0] PHY_ADR4_CLK_WR_SLAVE_DELAY_0
- DDRSS_PHY_1070[10-0] PHY_ADR5_CLK_WR_SLAVE_DELAY_0

Note

The PHY_ADR_x_CLK_WR_SLAVE_DELAY_0 fields can be programmed between 0x000 and 0x600. While training is permitted to set these fields below 0x0C0, the final result is always greater than 0x0C0. If software overrides training results, values less than 0x0C0 should never be programmed. The same restriction applies also to the PHY_GRP_y_SLAVE_DELAY__x fields.

8.2.3.7.9.6 CS Training

When the CS training algorithm has completed, the final CS slave delay settings can be found in the following fields:

- DDRSS_PHY_1399[10-0] PHY_GRP0_SLAVE_DELAY_0
- DDRSS_PHY_1399[26-16] PHY_GRP1_SLAVE_DELAY_0
- DDRSS_PHY_1400[10-0] PHY_GRP2_SLAVE_DELAY_0
- DDRSS_PHY_1400[26-16] PHY_GRP3_SLAVE_DELAY_0
- DDRSS_PHY_1401[10-0] PHY_GRP0_SLAVE_DELAY_1
- DDRSS_PHY_1402[10-0] PHY_GRP1_SLAVE_DELAY_1
- DDRSS_PHY_1403[10-0] PHY_GRP2_SLAVE_DELAY_1
- DDRSS_PHY_1404[10-0] PHY_GRP3_SLAVE_DELAY_1

After CS training is complete, the DDRSS_PHY_1289[31-0] PHY_CSLVL_OBS1 field can be read to obtain training status information.

After CS training is complete, software can always override the results by writing directly to the PHY_GRP_y_SLAVE_DELAY__x fields.

8.2.3.7.10 Data Bus Inversion (DBI)

Data bus inversion is supported in the DDR PHY. The PHY only passes the DBI information between the DDR controller and SDRAM devices. It does not perform DBI generation and decode. If the DDRSS_PHY_102[8] PHY_DBI_MODE_0 bit is set to 0x1 the SDRAM DBI information for slice 0 is passed to the DDR controller. The following bits are associated with the other slices:

- DDRSS_PHY_358[8] PHY_DBI_MODE_1
- DDRSS_PHY_614[8] PHY_DBI_MODE_2
- DDRSS_PHY_870[8] PHY_DBI_MODE_3

8.2.3.7.11 I/O Pad Calibration

I/O pad calibration runs at initialization time by default but it can also be programmed to operate in a background mode after initialization. Bits [3:1] of the DDRSS_PHY_1330[12-0] PHY_CAL_MODE_0 field enable the periodic calibration mechanism and determine the base clock frequency of the interval counter. The DDRSS_PHY_1331[31-0] PHY_CAL_INTERVAL_COUNT_0 field then sets a timer to indicate how frequently calibration is performed. When the timer expires, the calibration runs in background, independent of other traffic running through the PHY. When the calibration is complete, the updated PVTP/PVTN/PVTR codes are transferred to the PHY I/O cells. Whether or not the update of the memory clock PVTP/PVTN/PVTR codes is applied at the same time as the remaining I/O cells is controlled through the DDRSS_PHY_1298[8] PHY_CONTINUOUS_CLK_CAL_UPDATE bit. If the automatic update of the memory clock codes is disabled through the PHY_CONTINUOUS_CLK_CAL_UPDATE bit, the DDRSS_PHY_1298[0] SC_PHY_UPDATE_CLK_CAL_VALUES bit can be used to trigger a manual update.

8.2.3.7.12 DQS Error

A DQS error results from a mismatch between the expected number of read DQS pulses and the actual number of read DQS pulses. Counters exist at DDR PHY level to track the number of DQS errors in each data slice. Counter information can be obtained by reading the following fields:

- DDRSS_PHY_1363[31-0] PHY_DS0_DQS_ERR_COUNTER
- DDRSS_PHY_1364[31-0] PHY_DS1_DQS_ERR_COUNTER
- DDRSS_PHY_1365[31-0] PHY_DS2_DQS_ERR_COUNTER
- DDRSS_PHY_1366[31-0] PHY_DS3_DQS_ERR_COUNTER

The DQS error signals from each data slice are accumulated at PHY level and can be used to generate a dfi_error signal. Bit 2 of the DDRSS_PHY_1361[26-24] PHY_ERR_MASK_EN field is used to mask the DQS error from generating a dfi_error or being reported on dfi_error_info[2].

8.2.3.8 PI Functional Description

The PHY Independent (PI) module is part of the DDR PHY and can perform PHY independent leveling without involvement of the DDR controller. The PI can also initialize the SDRAM independent of the DDR controller. The PI module provides an interface between the PHY core logic and the DDR controller.

8.2.3.8.1 PI Initialization

The PI module can be used to perform SDRAM initialization before training instead of the DDR controller. The following steps represent the main actions of the initialization process:

1. Set to 0x1 the DDRSS_PI_139[8] PI_DRAM_INIT_EN bit.
2. Enable the PI by setting to 0x1 the DDRSS_PI_0[0] PI_START bit.
3. Enable the DDR controller.
4. The PI, DDR controller and PHY core are involved in a process of specific hardware communication between them that does not require software intervention.
5. The PI starts the power-up sequence which includes the SDRAM initialization timing, the SDRAM mode register programming and training.
6. After completion of the power-up sequence, the PI notifies the DDR controller through the dfi_init_complete signal.
7. The DDR controller can now access the SDRAM.

8.3 Peripheral Virtualization Unit (PVU)

This chapter describes the PVU module, part of the main NAVSS.

8.3.1 PVU Overview

The Peripheral Virtualization Unit (PVU) module provides TLBs (translation look-aside buffers) for a static virtual address translation on a CBA VBUSM bus.

Figure 8-9 shows a top-level overview of the PVU module.

Figure 8-9. PVU Overview

8.3.1.1 PVU Features

Each PVU supports the following features:

- Implements a channelized TLB for virtual address translation
- Supports a pre-configured number of virtIDs (channels). See [Section 8.3.1.2](#).
- Supports mapping of virtIDs to TLBs with a programmable number of DMA channel support
- Supports a pre-configured number of entries per channel of the TLB. See [Section 8.3.1.2](#)
- Supports TLB chaining to extend the search but at a latency penalty
- Supports a 48-bit address size
- Supports page sizes of 4 KB, 16 KB, 64 KB, 2 MB, 32 MB, 512 MB, 1 GB, and 16 GB
- Support TLBs in software mode, where they are maintained by software only
- Produces a fault interrupt when the TLB misses or upon a permission error.

8.3.1.2 PVU Parameters

shows the PVU configuration parameters set during SoC design.

8.3.2 PVU Functional Description

8.3.2.1 Functional Operation Overview

The Peripheral Virtualization Unit, PVU, module provides TLBs, translation look-aside buffers, for a static virtual address translation on a CBA VBUSM bus. This is in contrast to a dynamic translation TLB that works with an MMU, such as the Arm® processor SMMU. The module acts as a VBUSM retiming bridge that also performs the address translation. Each of the TLBs has its own set of private entries. It is a static translation because all the entries must be programmed by software and there is no hardware to fetch new translation entries when a transaction does not match any of the provided entries.

The entire PVU can be enabled or disabled via the PVU_ENABLE register.

8.3.2.2 PVU Channels

The module supports a number of channels (see [Section 8.3.1.2](#)), each having its own independent TLB and translation entries. This allows a single PVU to handle the translations for many masters, as well as keep their translations from interfering with each other.

The mapping of transactions to TLBs is made using mapping registers (PVU_VIRTID_MAP1 and PVU_VIRTID_MAP2). Each channel can be mapped to a virtID, or as a sub range of a DMA virtID. This allows the software to decide how the transactions are mapped to TLBs. It can be purely based on virtID, so that each virtual space has its own TLB. Or, it can be partly based on a highly channelized master, such as a DMA, can have 4 TLBs dedicated for channels where the sub-class on the upper chanid bits determine which of the 4 TLBs to use. This DMA mode allows for different classes of DMA traffic, such as descriptors or buffers, to be in their own TLBs and not interfere with each other. Since the TLB mapping is relatively simple, it is software's responsibility to control the definition of virtIDs in peripherals and DMAs so that they map to TLBs as required.

8.3.2.3 TLB

Each PVU channel contains a single traditional TLB. The TLB contains a number of entries that store the translation recipes, and these entries are used only for this TLB. Any activity for other TLBs or PVU channels will not impact this TLB.

8.3.2.4 TLB Entry

A TLB entry consists of the virtual address base and LPAE (Large Physical Address Extension) fields defined by Arm® architecture, stored in TLB Entry registers. This entry then includes the translated base address, size of the page, and other attributes of the page. When written by software, these fields must be written in the same way for correct operation.

The base addresses must be aligned to the defined page size.

8.3.2.5 TLB Selection

The first step of the module is to map the transaction to a specific TLB by comparing the virtID, chanID upper bits, and those programmed in PVU_VIRTID_MAP1 and PVU_VIRTID_MAP2. This mapping determines which TLB to select from the virtID. That TLB is used for the remainder of the pipeline. If there is no match then the PVU automatically misses.

8.3.2.6 DMA Classes

The first N virtIDs can be reserved for DMA class usage in the PVU_VIRTID_MAP1 register. These virtIDs map to TLBs along with classes that are defined in the chanID bits 10 to 11 on the bus. This creates four classes per virtID, that can select from four TLBs, allowing the transaction to restrict its translations to smaller sets from known distinct memory segments (such as the DMA accessing descriptors or buffers). A set of bitfields define the class mapping, which defines the final class value to use for an input class, and can be used to restrict the number of classes if all four are not used (by mapping 2 to 0 and 3 to 1 for example to limit to two classes). Then the final TLB selection is calculated as:

$$\text{virtID} \times 4 + \text{final class value}$$

The unused classes cause unused TLBs as entry points, but they can be used in chaining.

8.3.2.7 General virtIDs

After the first N virtIDs for DMA class usage, the remaining virtIDs up to the maximum allowed (as set in PVU_VIRTID_MAP2) are for general usage. Each of these map one to one to a TLB, where the calculation is:

$$\text{dma_cnt} \times 4 + (\text{virtID} - \text{dma_cnt})$$

There are no classes used for this range of virtIDs. An input virtID that is beyond the MAX_CNT bitfield value will produce an error.

8.3.2.8 TLB Lookup

The next step of the module is to check the input address, which uses the bits just above the 4-kB size, bits 12 and up, as the virtual address base. This is compared against all the TLB entries for that TLB, given the size in each entry. The size affects which address bits need comparing for an entry. The minimum size of 4 kB, so address bits 12 and up are compared. But if the size is 64 kB, then bits 16 and up are compared, as the lower bits fall into the size of the page. In addition to the address, the psecure bit is used to match against the secure level of the transaction. Only secure transaction are allowed to match an entry with psecure set, while only non-secure transactions are allowed to match an entry with psecure clear. If the entry is valid and the base compare matches and the secure level matches then the entry is used for the translation and checks.

8.3.2.9 TLB Miss

If the TLB lookup results in no matches and there is no chaining to another TLB (described later), then this is called a TLB miss. If the TLB misses, since there is no back-fill (such as from an MMU), the result is that the translation fails and will fault (a fault is when there is no physical address available). The transaction will be marked as in error with the flush signal, and a later slave will perform the flush that will return a bus error and read data as zeros. The PVU will record the fault as an interrupt and log the fault in the exception logging read-only registers.

8.3.2.10 Multiple Matching Entries

The PVU does not support multiple entries in a TLB that match the same virtual address. This is an illegal condition for software to program, as there is no mechanism to select one over the other. The PVU will have unpredictable results if this occurs, with the one requirement that the input transactions will never transition from a non-secure attribute to a secure attribute even in this illegal condition. This means that there is no support for background and foreground translating entries in the same TLB (which would be the result if a real MMU were used also). If software user wants to use a foreground and background method (that is not MMU compliant), he can place the foreground entries in earlier TLBs that are chained together, and the background entries are in the later TLBs, so that no single TLB has overlapping entries. The background entry would only be hit when the address falls within the background range but not any of the foreground ranges.

8.3.2.11 TLB Disable

A special case is when a TLB should go through a lookup but is disabled through the PVU_CHAIN_j[31] EN bit, or the entire PVU is disabled through the PVU_ENABLE[0] EN bit. If a lookup is requested when the TLB or PVU is disabled, then the transaction will pass and no translation will occur (output address is the same as the input address). Also, if the atype=1 then it will change to atype=0 on the output so that the resulting bypass transaction does not get routed right back to the PVU. Any other atype value will be maintained on the output. Any entries set in the disabled TLB are ignored as well as the chaining setting (described in [Section 8.3.2.12](#)) is also ignored, so once a disabled TLB is used then the chain is ended. Software must take care to not include any disabled TLBs in chains that must be fully searched – if a TLB must be disabled then the chain must be updated first to skip over that TLB and any virtIDs that directly map to that TLB initially must not be used.

8.3.2.12 TLB Chaining

If the TLB has a chain enabled by writing a non-zero chain value, then the TLB lookup will continue for the transaction using the chained TLB number. There is a latency penalty to resume the lookup at the chained TLB, but it allows more TLB resources to be used for virtIDs that might need more translations. If a TLB misses and has a chain value of zero then the overall result is a miss. Any TLB logs are always applied to the original TLB of the chain, and not the chained TLB.

TLB chaining can be defined in the PVU_CHAIN_j[11:0] CHAIN register bitfield.

8.3.2.13 TLB Permissions

The TLB entry contains permissions for the page that must be checked before the translation can be used. These include if the page has *supervisor* access for read, write, or execute, and has *user* access for read, write, or execute. The supervisor or user is based on the transaction priv[0] signal (0 = user, 1 = supervisor). The access type is based on the transaction dtype[0] and dir signals (dtype[0] = 0 and dir = 1 is a read, dtype[0] = 0 and dir = 0 is a write, dtype[0] = 1 and dir = 1 is an execute). The transaction signals are checked against these permissions. If they are allowed then the translation continues. If the page does not allow this transaction then the check fails and flush signal set is on the bus, like for a firewall, indicating that the transaction is no longer valid and must return an error. PVU does not perform the error signaling, so a later module must support it. A fault interrupt is produced.

The pperm entry bits define four additional checks. If pperm[0] is clear then user privilege access is not allowed, and a matching transaction with the CBA bus priv signal set to 0 (indicating user access) will result in an error. If pperm[1] is set then write access is not allowed, and a matching transaction that is a write will result in an error. If pperm[2] is set then instruction execute is not allowed, and a matching transaction that has the CBA bus dtype signal set to 1 (instruction fetch) will result in an error. If pperm[3] is set then supervisor instruction execute is not allowed, and a matching transaction that has the CBA bus priv signal non-zero (above user) and the CBA bus dtype signal set 1 (instruction fetch) will result in an error. If all these checks pass then the translation is allowed.

The pprefetch entry bit determines whether the translation allows prefetch transactions. If set, then any transaction with the pfable signal set are allowed. But if pprefetch=0 then those transactions with pfable set will fault as prefetch is defined as not supported.

8.3.2.14 Translation

If all the checks pass, then the translated address is replaced and the transaction can proceed to the output. Only the address bits above the page size are replaced, and all the lower bits are copied from the transaction. The memory attributes are also replaced on the transaction. These attributes include the memory type, shareability, and allocation policies. In addition, the prefetchable request is only copied if the page allows prefetch, and otherwise it is forced clear, but the transaction is still allowed to continue (just the prefetch will not occur).

8.3.2.15 Memory Attributes

Table 8-20 shows the mapping of page attributes to the bus memory attributes.

Table 8-20. Page Attributes to Bus Memory Attributes Mapping

Bus Signal	Page Attribute	Translated Bus Signal
cinner	piallopol	cinner = piallopol
couter	poallopol	couter = poallopol
memtype	pmemtype	memtype = pmemtype
sdomain	posable, pisable	sdomain[1] = posable, sdomain[0] = pisable
pable	pprefetch	pable = pable AND pprefetch

8.3.2.16 Faulted Transactions

A faulted transaction will have the flush bit set on the outgoing transaction so that it will return errors by the interconnect. The atype will be set to 0 since the memory attributes have not been replaced. And the outgoing transaction address will have the upper bits set to the fault_addr parameter value (see Section 8.3.1.2), which defines an interconnect address that will always return errors and not interfere with any valid slave traffic (such as to memory).

8.3.2.17 Non-Virtual Transactions

The module must not receive a transaction that does not have the atype set to an intermediate address, but if it does, there is no translation performed for that transaction. The transaction is simply copied to the output without modification.

8.3.2.18 Allowed virtIDs

Software can control the limit of usable virtIDs in the PVU by PVU_VIRTID_MAP2[11:0] MAX_CNT register. This sets the maximum virtID allowed value. If the PVU receives a transaction with a higher virtID signal, then the transaction will be treated as a fault and error, and no TLB lookup will be performed.

8.3.2.19 Software Control

The software can control all the TLB entries directly. The TLB can be programmed at any time by software, and writes to the TLB take precedence over lookups. This allows the update to be reflected as soon as possible in the translations. But there is no guarantee about the timing of the update against any bus transactions, so the only way to guarantee an endpoint uses the updated table is to stall the endpoint until the update has been completed (using the write status). This allows software to directly populate TLB entries for known translation as well as locking entries down so that they cannot be replaced.

8.3.2.20 Fault Logging

The module will log faults into exception logging registers. It will capture that type of fault, the address that faulted, and the attributes of the transaction that faulted. It will also set an interrupt. The module can only store one fault. When the software clears the interrupt status then the fault is also cleared and another can be captured. If another fault occurs while one is pending then that fault log is lost.

There is a logging Enable/Disable bit per TLB and if disabled then faults from that TLB will not be logged. PVU_EXCEPTION_LOGGING_DISABLE register allows to disable types of faults, and when disabled that type of fault will not be logged. There are additional fault status fields per TLB that capture fault status that would have been logged but could not because another fault was already logged. These status bits stay set until cleared by software.

A TLB fault that occurs after chaining will set the fault status of the original TLB, and not of the last TLB in the chain.

8.3.2.21 Alignment Restrictions

All accesses through the module must not cross 4-kB page boundaries. The module does not perform any checks for this requirement.

8.4 Region-based Address Translation (RAT) Module

This section describes the RAT functionality.

8.4.1 RAT Functional Description

8.4.1.1 RAT Operation

The RAT module performs a region based address translation. It translates a 32-bit input address into a 48-bit output address. Any input transaction that starts inside of a programmed region will have its address translated, if the region is enabled. Any disabled region is ignored from the translation lookup.

RAT has 16 regions, with each region having dedicated registers that define its attributes:

- Base address of the region, via the RAT_BASE_k register.
- Size of the region, via the RAT_CTRL_k register.
- Translated base address (48-bit). It is defined by 32-bit lower address via the RAT_TRANS_L_k register, and 16-bit upper address via the RAT_TRANS_U_k register.

The input addresses are compared against all the enabled regions in parallel. The region size defines how many of the lowest address bits are included in the region space, starting from a 1B space to a 4GB space. Then the upper bits not part of the region are used for the lookup and comparison, matching those bits of the input addresses against the region base address. The region matches when it is enabled and the compare matches. The first region that matches has the output address set with the region translated base address upper bits. The lower bits that are part of the region size are copied from the input address to the output address. If there are no region matches then the input address is copied to the output address entirely.

RAT does not automatically correct transactions that cross region boundaries, that is, start inside of a region and end outside of it, or start outside of a region and end inside of it. If a boundary crossing transaction is detected, then RAT annuls the transaction as illegal, generates an interrupt and logs an error, as explained in *RAT Error Logging*.

Note

The region base address and translated base address must be aligned to the defined region size. For example, if the defined region size is 64KB, then the two addresses must be 64KB aligned. This is software responsibility as RAT does not perform such alignment check. Regions that are not aligned have unpredictable results.

Moreover, multiple region definitions must not overlap in their covered address space. RAT does not check for this, so it is software responsibility to take care of it. Overlapping regions may lead to unpredictable results.

8.4.1.2 RAT Error Logging

The error log consists of a series of registers that capture the details of the transaction, including the input address that caused the error. These registers are the following:

- RAT_EXCEPTION_LOGGING_HEADER0 and RAT_EXCEPTION_LOGGING_HEADER1
- RAT_EXCEPTION_LOGGING_DATA0 through RAT_EXCEPTION_LOGGING_DATA3

The RAT module can capture one error before it is cleared by software. The error logging is enabled by default, but can be disabled via the RAT_EXCEPTION_LOGGING_CONTROL[0] DISABLE_F bit. Upon error logging an interrupt is also generated. To clear the log, software must either read the final error logging register, or manually clear the RAT_EXCEPTION_PEND_CLEAR[0] PEND_CLR bit by setting it to 0x1. This will clear the error status, and not the actual log registers, but it does allow the next error to be captured into the log registers. If the status is not cleared and additional errors are detected, they are not logged.

After an error occurs and is cleared (whether by reading the final error logging register or by clearing the status bit), the RAT_EOI_REG register must be written to guarantee the next interrupt pulse will be produced.

See the RAT section of the Module Integration chapter of this document for the RAT Source ID mapping which is associated with the EXCEPTION_LOGGING_HEADER0[23-8] SRC_ID field for each RAT module.

9 Interrupts

9.1 Interrupt Architecture

The SoC has many peripherals and a large number of event sources (interrupt, time sync or DMA). The use of events is completely dependent on a user's specific application, which drives a need for maximum flexibility in which event sources are used in the system. It is also completely up to software control as to how the events are serviced.

The SoC includes the following interrupt servicing modules (hosts):

- Security Management Subsystem (WKUP_SMS0):
 - 2 Arm Cortex-M4F cores
 - 2 Nested vectored interrupt controller (NVIC)
- Compute cluster:
 - Six processor subsystems:
 - Two Quad-core Arm Cortex-A72 microprocessor unit (A72SS0)
 - 4 Single-core C71x DSP subsystems (C71SS[3:0])
 - Two interrupt controllers, both integrated inside the MSMC wrapper:
 - Arm generic interrupt controller (GIC-500) supports the A72 microprocessor units
 - Cluster level event controller (CLEC) supports the C71x DSPs
- Microcontroller units (R5FSS0, R5FSS1, R5FSS1, MCU_R5FSS0), each implementing:
 - Two Arm Cortex-R5F cores
 - Vectored interrupt manager (VIM)

Most of the system events are routed directly to the various processing elements but in some cases it is impractical to route all events of a certain group (for example, GPIO events) to each processing element. For this purpose, the SoC integrates several interrupt router (INTRTR) instances. Each interrupt router aggregates a number of system events and can route each event to a given processing element by using simple combinational logic (a set of multiplexors). Event selection is controlled through the associated registers within each interrupt router.

The following interrupt router instances are part of the SoC interrupt architecture:

- WKUP domain GPIO interrupt router (WKUP_GPIOMUX_INTRTR0):
 - Provides selection of active module interrupts for the WKUP_GPIOx modules
- MAIN domain GPIO interrupt router (GPIOMUX_INTRTR0):
 - Provides selection of active module interrupts for the MAIN domain GPIOx modules
- MAIN-to-MCU domain level interrupt router (MAIN2MCU_LVL_INTRTR0):
 - Provides selection of active MAIN domain module *level* interrupts for routing to MCU domain processing elements
 - Reduces the number of event voltage domain crossings
- MAIN-to-MCU domain pulse interrupt router (MAIN2MCU_PLS_INTRTR0):
 - Provides selection of active MAIN domain module *pulse* interrupts for routing to MCU domain processing elements
 - Reduces the number of event voltage domain crossings

In addition, the following interrupt router instances are part of the SoC time sync architecture:

- Time sync event router (TIMESYNC_INTRTR0):
 - Provides selection of active common platform time synchronization (CPTS) events for routing to CPTS capable modules
- Compare event router (CMPEVT_INTRTR0):
 - Provides selection of active CPTS counter compare events for routing as processor interrupts or DMA events

For more details on time sync routers, see *Time Sync Routers*.

The SoC also has the following interrupt router instances within the Navigator Subsystems:

- MAIN domain Navigator Subsystem interrupt router (NAVSS0_INTR_ROUTER_0)
 - Provides selection of active module interrupts from various sub-modules within the MAIN NavSS.
- MCU domain Navigator Subsystem interrupt router (MCU_NAVSS0_INTR_ROUTER_0)
 - Provides selection of active module interrupts from various sub-modules within the MCU NavSS.

9.2 Interrupt Controllers

9.2.1 Generic Interrupt Controller (GIC)

This section describes the Generic Interrupt Controller (GIC) module in the device.

9.2.1.1 GIC Overview

The device GIC is a TI module that is based on the Arm GIC-500 interrupt controller. The Arm GIC-500 is a high-performance, area-optimized, built-time configurable interrupt controller which detects, manages, and distributes system interrupts to the Arm® Cortex®-A72 processors in the Compute Cluster.

The Arm GIC-500 is compliant to the Arm GICv3 standard. It only supports cores that implement the Armv8 architecture and the GIC CPU interface with the standard GIC Stream Protocol Interface (such as A72).

The GIC includes additional logic (TI wrapper) to fully integrate the Arm GIC-500 into the SoC.

The GIC module is located inside the MSMC_WRAP logical block in the Compute Cluster, along with the cluster level interrupt controller (CLEC), which serves the C71x DSPs.

9.2.1.1.1 GIC Features

Note

This chapter provides only a brief description of the GIC functionality and features. For more details on this module, refer to the *Arm®CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

The Arm GIC-500 supports the following features in the device:

- Module revision: r1p1
- Supports all A72 cores
- 16 software generated interrupts (SGIs) per core
- 16 private peripheral interrupts (PPIs) per core
- 960 shared peripheral interrupts (SPIs)
- Locality-specific peripheral interrupts (LPIs), used for message-based interrupts
- Interrupt translation service (ITS)
 - Device isolation
 - ID translation for message-based interrupts
 - This allows virtual machines to program devices directly
- Interrupt masking and prioritization
- Programmable, affinity-based interrupt routing
- 32 priorities for each interrupt
- Three different interrupt groups
 - Group 0
 - Non-secure group 1
 - Secure group 1

Additionally, the GIC wrapper logic provides the following features:

- Synchronizes interrupt inputs to GIC clock
- Implements AXI2VBUSM and VBUSM2AXI bridges
 - Used for bus protocol conversion (AXI-to-VBUSM and VBUSM-to-AXI, respectively)
- Implements an integrated ECC aggregator
 - Only used to inject errors (for testing purposes)

9.2.1.1.2 GIC Not Supported Features

The GIC does not support the following features:

- GICv2 backwards compatibility
- AWID-based LPI mapping

9.2.1.2 GIC Functional Description

Note

This chapter provides only a brief description of the GIC functionality and features. For more details on this module, refer to the *Arm® CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

9.2.1.2.1 Arm GIC-500

The Arm GIC-500 is responsible for detecting, managing and communicating system interrupts to all A72 cores in the device. The main difference between the Arm GIC-500 and previous Arm GIC versions is the direct communication with the CPU(s). Previously, an interrupt controller would set a pending bit to a CPU and that CPU would then have to query an interrupt controller MMR to find out what to do. Now, the Arm GIC-500 sends interrupts to a CPU via a dedicated message interface and the CPU communicates back about interrupts through the same interface. The CPU now uses writes and reads to system registers instead of over the memory interface. This leads to reduced latency and the ability to route interrupts to different CPUs based on a set of rules.

The Arm GIC-500 is divided into three main sections:

- **Distributor:** The Distributor receives interrupts from the wire interrupts and the programming interface. It is responsible for prioritizing these interrupts and sending them to the CPU interface via the GIC Stream Protocol Interface.
- **Redistributor:** There is one Redistributor per core. Each Redistributor holds the state that is individual to a particular core (such as the settings for PPIs and SGIs). It also stores the LPIs for that core after they have been generated using the ITS.
- **ITS:** The ITS is responsible for translating message-based interrupts from device peripherals into LPIs. The user can also use the ITS to manage existing LPIs. Note that the ITS is not used for other types of interrupt

9.2.1.2.2 GIC Interrupt Types

The GIC supports four types of interrupts:

- **Software Generated Interrupts (SGIs):** There are 16 SGIs (ID0-ID15). These are inter-processor interrupts. SGIs can be sent using either Arm system registers or by writing to the Software Generated Interrupt Register (GICD_SGIR).
- **Private Peripheral Interrupts (PPIs):** There are 16 PPIs (ID16-ID31). These are wired interrupts dedicated to a specific CPU. Many are reserved to specific functions via convention. These can be either active-low levels (by default), or rising edge triggered (software programmable).
- **Shared Peripheral Interrupts (SPIs):** There are 960 SPIs (ID32-ID991). These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GIC. These are active-high levels (by default), or rising edge triggered (software programmable).
- **Locality-Specific Peripheral Interrupts (LPIs):** There are 57,344 of these. These interrupts are used for message-based interrupts from a peripheral. They are generated through writes to the GIC slave interface. The information associated with these is located in memory. The GIC keeps a small 64-entries cache on-board in order to reduce latency either for specific interrupts or for most-recently-used. LPIs can be routed to different CPUs based on programmed rules.

The mapping of PPIs and SPIs can be found in section TBD .

9.2.1.2.3 GIC Interfaces

The GIC has the following main interfaces:

- A pair of 64-bit VBUSM write-only and read-only master interfaces
 - AXI2VBUSM bridge converts the standard 64-bit AXI4 master interface into this pair of interfaces
 - The AXI4 master interface allows the GIC ITS and redistributors to access main memory
- 32-bit VBUSM slave interface
 - Provides access to Arm GIC-500 internal resources
 - Handles all message-based interrupts. Message-based interrupts can generate SPIs or LPIs, depending on the register that is written

- VBUSM2AXI bridge converts this interface into an 32-bit AXI4 slave interface
- 32-bit VBUSP slave interface
 - Provides access to internal ECC aggregator
- Physical interrupt and power signals
 - Inputs: CPU active signals, SPIs and PPIs (can be programmed as either level-sensitive, or edge-triggered)
 - Outputs: Error signals and wake-up requests
- GIC Stream Protocol Interface
 - Consists of a pair of AXI4-Stream interfaces (one upstream and one downstream 16-bit AXI4-Stream interface) that the GIC uses to send interrupts to the core and receive notifications when the core activates interrupts
 - There is a pair of physical interfaces, one in each direction, for each cluster

9.2.1.2.4 GIC Interrupt Outputs

Table 9-1 lists the interrupts that are generated by the GIC.

Table 9-1. GIC Interrupt Outputs

Interrupt Name	Description
GIC_AXIM_ERR	GIC bus error interrupt. This interrupt is triggered if the GIC receives an error on a bus transaction, such as a decode or protection error. This is a pulse-high interrupt. If this interrupt occurs, the GIC might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
GIC_ECC_FATAL	GIC uncorrectable ECC error interrupt. Indicates an uncorrectable 2-bit error detected in one of the ITS cache memories. This is a pulse-high interrupt. If this interrupt occurs, the GIC might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
GIC_PWRm_WAKE_REQUEST_n	GIC wake requests for A72 cores. Asserted state indicates that an interrupt is pending for a processor that has set the PROCESSORSLEEP bit in the GICR_WAKER register. This bit indicates that the SoC should wake up the indicated CPU so that it can process the interrupt.
GIC_PWRm_WAKE_REQUEST_n	

9.2.1.2.5 GIC ECC Support

The Arm GIC-500 has built-in SECDED ECC on its memories to protect against errors. The syndrome generation and checking is done internally.

Additionally, the TI GIC wrapper integrates an ECC aggregator (GIC_ECC_AGGR) in order to allow errors to be injected for testing purposes. The generic ECC aggregator functionality is described in [Section 12.10.6, ECC Aggregator](#). Note that the GIC_ECC_AGGR supports only a subset of this functionality.

9.2.1.2.6 GIC AXI2VBUSM and VBUSM2AXI Bridges

The GIC uses the AXI4 master interface to allow the ITS and redistributors to access main memory. It is expected that the main memory (attached to a CBASS VBUSM port) holds the following:

- ITS translation tables
- ITS command queue, which is written by software in order to program the ITS
- LPI configuration table, which holds the priorities and enable bits for LPIs
- LPI pending tables, which can hold information on whether each LPI is pending on each core

The AXI2VBUSM bridge converts the standard 64-bit AXI4 master interface into a pair of 64-bit VBUSM write-only and read-only master interfaces. AXI4 has a separate command channel for read and write, and the AXI2VBUSM bridge keeps them separate, so that the system may prioritize or arbitrate the traffic between them as appropriate.

The GIC uses the AXI4 slave interface to provide access to the programming interfaces of all its parts (distributor, redistributors, ITS). The VBUSM2AXI bridge converts the standard 32-bit VBUSM master interface into an 32-bit AXI4 slave interface.

Note

The AXI2VBUSM and VBUSM2AXI bridges do not implement any MMRs.

9.2.2 Cluster Level Event Controller (CLEC)

9.2.2.1 CLEC Overview

The CLEC supports the following features:

- Supports software scalable event routing mechanism
 - RAM-based interrupt event routing table
- Supports aggregation of incoming interrupt events from:
 - SoC peripherals
 - MSMC
 - DRU
 - C71SS
- Supports distribution of each aggregated interrupt event to one or more of the following:
 - SoC (could be routed to the GIC externally)
 - DRU
 - A72SS
 - C71SS
- Supports originating interrupt events through the following mechanisms:
 - MMR writes to trigger new events
 - Reporting errors detected by the CLEC
- 2048 input events
- 128 output events
- Can handle both level and pulse input interrupts
 - SoC out interrupt is always level regardless of input interrupt type (pulse or level)
- Can be used for inter-processor communication (IPC) between A72 and C71
- Shares SPI (shared peripheral interrupt) input events with GIC

9.2.2.2 CLEC Functional Description

9.2.2.2.1 CLEC Interrupt Event Routing

The CLEC routes events according to a RAM-based interrupt event routing table. This table holds one entry for each supported external interrupt/event number, plus some additional entries for CLEC internal events. External in this context means "external to the CLEC", and corresponds to all interrupt events arriving at the CLEC from other sources. Internal refers to events that the CLEC generates internally, or in response to an MMR write that triggers the event.

The routing table memory has 2048 entries in size. Each routing table entry contains the following details:

- Outgoing event number: Each incoming event can be mapped to any outgoing event number
- Secure / Non-secure: Each incoming event can be claimed as a secure event
- Destination port configuration: This configuration allows for both single-cast and broadcast events

For each incoming interrupt event, the CLEC does the following processing:

- Validates the interrupt event number. For out-of-range event numbers, the CLEC triggers an "invalid event number" event
- Non-secure read/write to registers associated with a secure event will generate a privilege error
- Looks up the event in the routing table
- For each port in the destination bitmap that has a bit set, it queues the event to that destination
 - Queuing to multiple destinations happens in parallel, not sequentially, to minimize latency
 - If no bits are set, the event is dropped silently, but an interrupt dropped event is asserted. This event gets routed as determined by the routing table

Note

For events mapped to DRU and ARM, only event mapping number is looked at and they are not qualified by CLEC_MRR_j[21-16] RTMAP. Hence, this bit field is "don't care" for events that have CLEC_MRR_j[15-8] EXT_EVNUM set to 128 or higher.

Since the routing table is a shared resource, the CLEC only routes one new event per cycle. The routing state machine arbitrates among all incoming event sources round-robin, with the exception that internally generated error events have priority over all other event sources.

The CLEC routes events to their destinations and also maintains pending interrupt information in an CLEC_EFR_k register. Firmware needs to clear this pending interrupt bit in an interrupt service routine (ISR).

9.2.2.2.2 CLEC Virtualization, Isolation and Access Control

The CLEC provides direct support for virtual-machine isolation via a hypervisor. Each event's register window is deliberately spaced 64KB apart. This enables allocating individual event numbers to virtual machines via stage-2 translation. The 64KB spacing allows this to work even with the largest translation granule supported by ARM (64KB).

Individual functions associated with an event within each event's window are spaced 4KB apart. This allows a standard operating system to open up, for instance, write access to an CLEC_ESR_j register for a single task, while blocking access to the event routing details in CLEC_MRR_j register.

The CLEC implements event lock registers (CLEC_GELRS / CLEC_GELRNS) that allow hypervisor to lock down the configuration of events, while still permitting write access to the event send register (CLEC_ESR_j) for that event.

In current implementation, the CLEC provides basic support for isolating virtual machines by partitioning incoming events in the address map. However, it does not provide any support for limiting event numbers assigned for outgoing events in CLEC_MRR_j[15-8] EXT_EVNUM. If such isolation is necessary, software can implement it in the hypervisor via para-virtualization calls, via trap-and-emulate for full virtualization.

9.2.2.2.3 CLEC Memory Protection

The CLEC implements minimal memory protection checks. It relies on protection mechanisms outside to control accesses from various masters. Chip-level firewalls control which masters may access the CLEC. MMUs provide finer-grain control for programmable processors that access the CLEC.

Specifically, the CLEC returns the following errors:

- Address error on a read or write to unimplemented space
- Address error on a read to a write-only register
- Address error on a write to a read-only register
- Privilege error on a non-secure read or write to registers associated with a secure event (CLEC_MRR_j[31] S = 1 for that event)
- Privilege error on a write to CLEC_ESR_j on an event whose CLEC_MRR_j[30] ESE = 0
- Privilege error on a write to CLEC_MRR_j on an event when CLEC_GELRS[0] LOCK = 1

Any further access control must be implemented with firewalls and/or MMU configuration outside the CLEC.

9.2.2.2.4 CLEC ECC Support

Standard ECC aggregator strategy is used to implement ECC protection on the SRAM used to implement the CLEC routing table. The CLEC has two ports connected to the ECC_AGGR at the MSMC_WRAP level. For RAM_ID values of CLEC ECC-protected memories, see , *Compute Cluster ECC Aggregators*. For details on the generic ECC_AGGR functionality, see [Section 12.10.6, ECC Aggregator](#).

9.2.2.2.5 CLEC Intra-Core Communication

In order to support intra-core synchronization inside Compute Cluster, associated C71/A72 events are routed through the CLEC.

9.2.2.2.6 CLEC Event Maps

See *Interrupt Sources* for CLEC event mapping.

9.2.2.2.6.1 CLEC ESM Event Routing

9.2.3 Other Interrupt Controllers

All other device interrupt controllers are described in their respective chapters and/or third party documentation.

9.3 Interrupt Routers

9.3.1 INTRTR Overview

The interrupt router (INTRTR) module provides a mechanism to mux M interrupt inputs to N interrupt outputs, where all M inputs are selectable to be driven per N output. There is one register per output (MUXCNTL_N) that controls the selection.

There are several INTRTR modules in the device. Their purpose is described in *Interrupt Architecture*.

[Table 9-3](#) summarizes the configuration details for the various interrupt routers.

Table 9-3. INTRTR Modules Configuration

Module	Number of Inputs	Number of Outputs	Input Interrupt Type
WKUP_GPIOMUX_INTRTR0	118	32	Pulse
GPIOMUX_INTRTR0	180	64	Pulse
MAIN2MCU_LVL_INTRTR0	317	64	Level
MAIN2MCU_PLS_INTRTR0	99	48	Pulse
NAVSS0_INTR_ROUTER_0	490	440	Level
MCU_NAVSS0_INTR_ROUTER_0	261	64	Level

The user should take the following into account when programming the MUXCNTL_N register:

- Avoid programming this register when input interrupts are active. This could lead to spurious asynchronous output toggles which may lead to unpredictable behavior.

The recommended general programming sequence is as follows:

1. Disable interrupt by writing '0' to the INT_ENABLE bit field. Do not change mux control configuration settings (ENABLE bit field) at this time.
2. Change the mux control configuration settings. INT_ENABLE needs to remain '0' at this time.
3. Enable interrupt by writing '1' to INT_ENABLE. Do not change mux control configuration settings at this time.

9.4 Interrupt Sources

Note

See Appendix Spreadsheet for Interrupt Inputs and Outputs details.

10 Data Movement Architecture (DMA)

10.1 DMA Architecture.....	814
10.2 Navigator Subsystem (NAVSS).....	888
10.3 Peripheral DMA (PDMA).....	956
10.4 Data Routing Unit (DRU).....	1019

10.1 DMA Architecture

This section describes the DMA (data movement) architecture in the device.

10.1.1 Overview

The DMA architecture specifies the data structures used by Texas Instruments standard communications modules to facilitate direct memory access (DMA) and to provide a consistent application programming interface (API) to the host software in multi-core devices. The data structures and the API used to manipulate them will be jointly referred to as NAVSS.

Frequent tasks are commonly offloaded from the host processor to peripheral hardware to increase system performance. Significant performance gains may result from careful design of the host software and communication module interface. In networking systems, packet transmission and reception are critical tasks. Texas Instruments has developed the NAVSS standard, which is aimed at maximizing the efficiency of interaction between the host software and communications modules.

The design goals for NAVSS are as follows:

- Minimize host interaction
- Maximize memory use efficiency
- Maximize bus burst efficiency
- Maximize symmetry between transmit/receive operations
- Maximize scalability for number of connections, buffer sizes, queue sizes, and protocols supported
- Minimize protocol specific features
- Minimize complexity

NAVSS architecture is shown on [Figure 10-1](#).

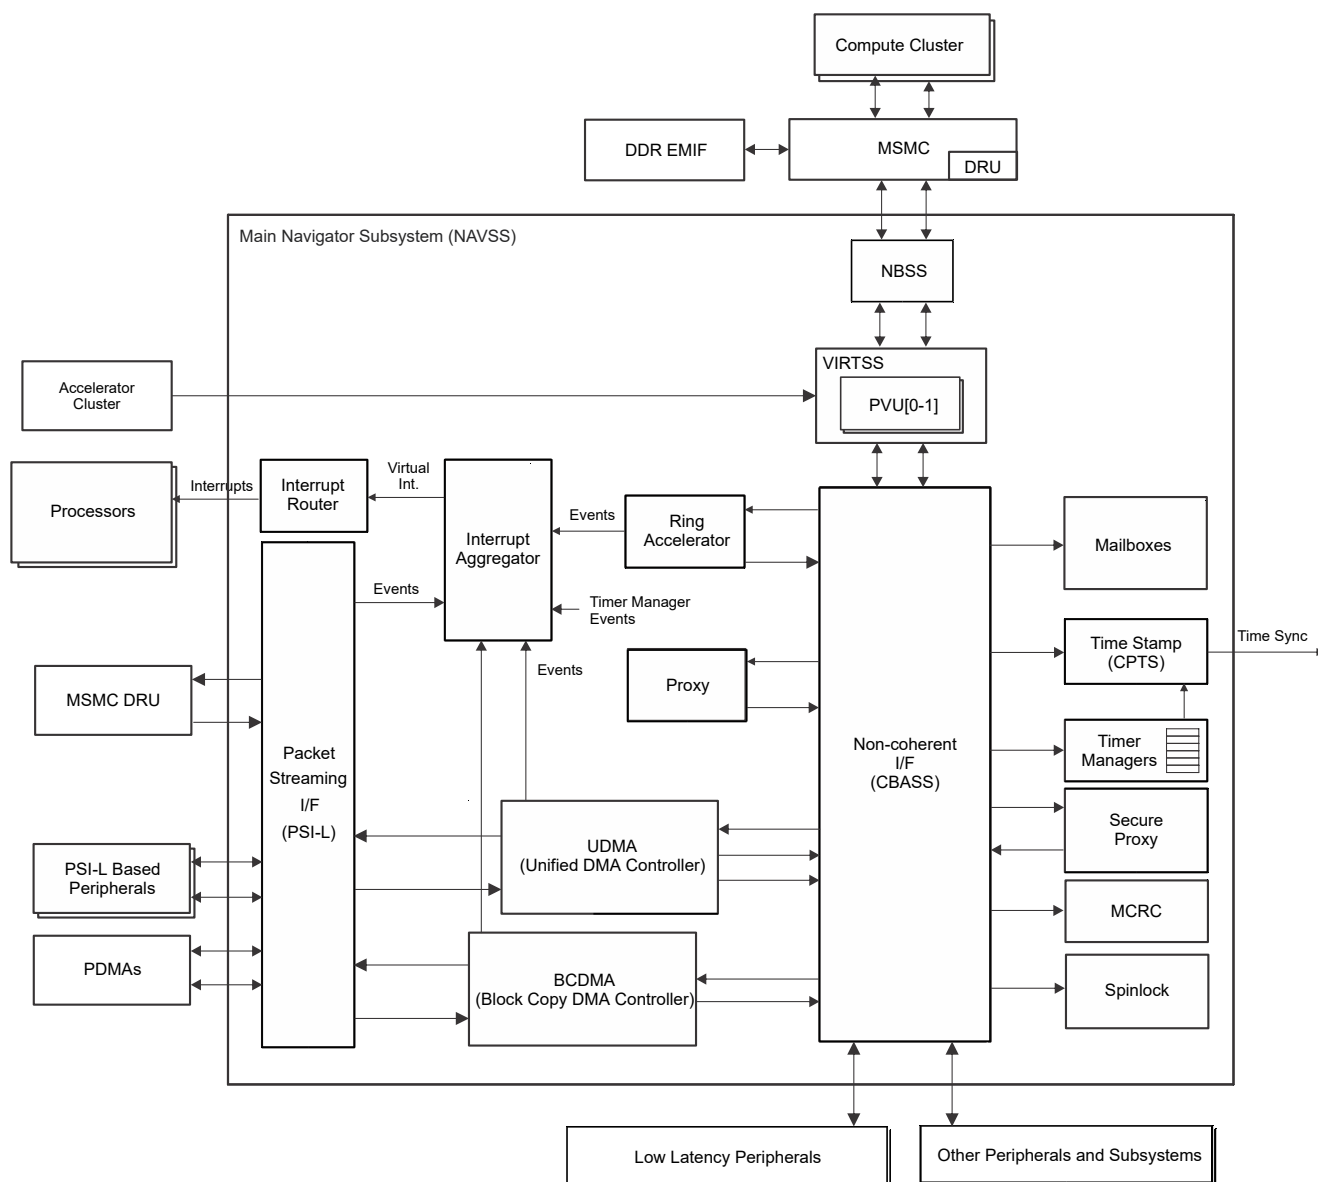

Figure 10-1. NAVSS Overview

10.1.1.1 Navigator Subsystem

The Navigator Subsystem (NAVSS hardware) is a container which groups together as much as possible the components which provide the Hardware to Software boundary for data movement control in the system. All of the components which control work handoff (queuing, interrupts, monitoring and debugging) are included in the NAVSS which in turn is located as close as possible to the various host processors to which services are provided. Other DMA components such as DRUs, UTC, and PDMAs exist outside the NAVSS but all are controlled by the root complexes provided in NAVSS.

The SoC has two NAVSSes: one in main and one in MCU domain.

10.1.1.2 Ring Accelerator (RA)

The ring accelerator (RINGACC or RA) is a hardware module that is responsible for accelerating management of various types of queues in the system. The RA accelerates passing of packets between a producer and consumer in normal system memory (including cached memory). The RA is capable of accelerating the read/write pointer maintenance and occupancy tracking operations.

The ring accelerator operates like a bus infrastructure bridge in that it passes transactions through it between a source and destination interface. As transactions are passed, the RA modifies the address, byte count, and transaction identifiers and internally updates the occupancies/pointers.

Each queue that the RA provides can operate in either exposed-ring-mode or private-queue-mode.

- The exposed ring mode allows software to directly access the underlying ring structure to add or remove items from the tail or head of the ring respectively. Whenever items are added or removed from a ring, the host software is required to write to a corresponding doorbell register to increment or decrement the ring occupancy. When using the exposed ring mode, no proxy is required between the software and the RA but all queue add operations require a memory fence to be performed to ensure that the data has landed in a snoopable cache before the doorbell register is written.
- The private queue mode provides an abstract view of the ring so that the host software does not need to know the actual physical address location or current read or write indexes of the ring. The private queue mode provides a memory window for each ring which when written redirects the write to the address pointed to by the write pointer and when read redirects the read to the address pointed to by the read pointer. The same address range is always used to push or pop elements from a given queue.

Rings are an implementation of a logical queue with the following limitations:

- Each ring has a finite size. When rings are used in exposed ring mode the following conditions apply:
 - A separate operation is required to write/read the contents of a ring and to update the occupancy of the ring
 - It is not straightforward to allow multiple producers to write to a ring or multiple consumers to read from a ring. Additional synchronization and pointer passing is required since rings require software to manage one of the pointers for the queue.
 - An exposed ring cannot be used when software or hardware needs to both read and write the same queue (such as for a DMA RX free queue where errors can have the DMA write the element back onto the same RX free queue). Since software owns one side of the pointers and hardware owns the other, they cannot be kept coherent if either side needs to update either at any time.

The RA allows each ring to be configured to a different primary element size. Element sized chunks of data are placed onto and retrieved from rings when queuing or de-queueing occurs. Element sizes can be as small as 4 bytes or as large as 256 bytes.

10.1.1.3 Proxy

The proxy provides a mechanism for software to access the RA coherently when the processor does not support large bursts. The RA requires a single burst for each operation so that it maintains atomicity and coherence by relying on the atomicity of the bursts on the bus interconnect fabric, since it only delivers a single burst to the RA before the next. Since processors are usually limited in the size of a burst they can deliver natively, such as 32 to 128 bits, they cannot be used directly with the data access region of the RA for larger element sizes. The proxy solves this gap by providing a temporary space for the software to form a larger burst of data before it is sent to the RA. The proxy allows smaller processor accesses to the data and only forwards to the RA when the entire data burst is complete, as directed by the software. Each proxy hardware can support multiple threads of software (whether on the same or different processors) operating on bursts at the same time, and they do not interfere with each other, as long as each thread of software only operates on its thread in the proxy. Each proxy thread also supports access to any RA queue via different offsets similar to how the RA provides access to the queues via different offsets.

For writing data to the RA, the software will write the data in native sized writes to the proxy thread it has been assigned. The proxy simply accepts the writes into a buffer reserved for that thread. Only when the software writes to the completion byte offset (last byte of the burst) then will the proxy take the entire burst of data written (including the final write data) and send it to the RA as a single write burst. After the completion write, the software can begin building a new data burst. For reading data from the RA, the software will read the data in native sized reads to the proxy thread. For the first read, the proxy will read the entire burst from the RA, so that it atomically gets the next element off the queue. This entire data is stored in the proxy thread buffer, and the requested portion is returned to software. Then software can read any location within the burst and the proxy will read it from the buffer. When software is done reading the data, it must read the completion byte offset so that

the proxy 'knows' that the read burst is completed, and that for the next read it must read a burst from the RA queue again. A single proxy thread can only be used for a single data burst at a time, so once starting a write it should complete before starting another write or a read, and similarly once starting a read, it should complete before starting another read or a write. If software needs to read and write at the same time, it should use two proxy threads. Similarly if there are multiple threads of software that need to access RA at the same time, they should use separate proxy threads.

10.1.1.4 Secure Proxy

A special version of a proxy is the secure proxy that provides secured access to RA queues for communication to the security master of the system. The secure proxy provides basically the same function as a normal proxy. The data burst size is fixed for message sizes to the security master, so there is no support for all the element sizes of the RA. The security master locks down the RA queue to access and direction for each proxy thread so that the software cannot access anything they shouldn't, so the software only sees a single queue (unlike the normal proxy), and any attempts to access another queue or access it in violation of how the security master defined and an error will be flagged. This allows for a much more controlled setup for passing messages to the security master.

10.1.1.5 Interrupt Aggregator (INTA)

The interrupt aggregator (INTR_AGGR or INTA) is a hardware module which provides a persistent view of the real time status of various DMA components within the overall SoC DMA system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

The INTA block provides the following functions:

- Conversion of local event signal lines into global events
- Performing an 'Y-split' operation of global events
- Counting global events
- Steering and aggregation of global events into specified bit positions in one of N interrupt cause registers
- SoC interrupt-architecture-compliant set/clear and mask set/clear functionality to cover interrupt cause registers
- Output of virtual interrupt sources to the Interrupt Router module

10.1.1.6 Interrupt Router (IR)

The interrupt router (INTR_ROUTER or IR) is a hardware module which allows for virtual interrupt sources which were output from the INTA block to be crossbar switched onto physical interrupts which are connected to the system level Interrupt Controller (ARM GIC or other interrupt controller).

10.1.1.7 Unified DMA – Third Party Channel Controller (UDMA-C)

Note

In this SoC, UDMA-P (see [Section 10.1.1.10](#)) serves UDMA-C functions. That is, there is no discrete UDMA-C controller in this SoC device.

The Unified DMA 3rd-Party Channel Controller is intended to perform similar (but significantly upgraded) functions to the EDMA Channel Controller engine on previous SoC devices. The UDMA-C module supports the transmission of Transfer Request packets from memory mapped data structures to data channels within UTCs in the system and reception of Transfer Response packets from data channels in UTCs in the system into memory mapped data structures. Up to 512 (configuration specific) third-party DMA control channels are provided within the UDMA-C. Each control channel corresponds to a single third party DMA data channel in a separate UTC. Transfer Request messages provide transfer parameters which are to be used by the UTC channels to move data in the system (previously implemented as PARAM entries). Transfer Response messages are sent back from the UTC in a one to one relationship with Transfer Request packets and provide an indication of both completion of a data transfer and whether or not any exception or error occurred during the data transfer.

The UDMA-C controller maintains state information for each of its channels which allows Transfer Request packet transmission and Transfer Response packet reception operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for the transmission of Transfer Request packets. The ordering and rate of Transfer Response receive operations is directly controlled by the order in which those packets are received on the Rx PSI-L interface. A block diagram of a UDMA-C module is shown Figure 10-2.

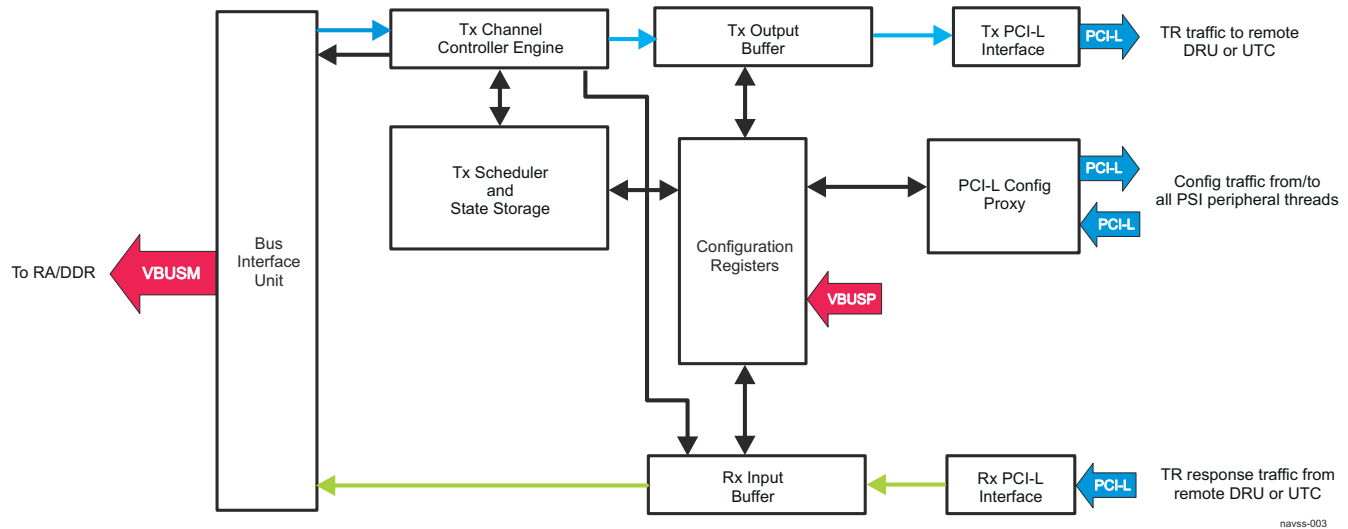

Figure 10-2. UDMA-C Block Diagram

10.1.1.8 Unified Transfer Controller (UTC)

The Unified Transfer Controller is intended to perform similar functions to the EDMA Transfer Controller engine used on previous devices. The UTC engine is generally classified as a third-party DMA. This designation comes from the fact that the engine is not actually the source or sink of the data which is being moved but is instead an intermediary 3rd-party that performs the data move on behalf of the source and sink.

The UTC engine accepts Transfer Response messages from the UDMA-P via a PSI-L interface which provide instructions to copy data between a source read interface and a destination write interface. The sequence of operations that can be instructed includes up to 4-dimensional nested loops. Multiple types of Transfer Request messages are specified and each UTC instance in the system may support all types or any specified subset. The TR formats are specified in detail in a later section. When a Transfer Request has been completed, the UTC returns a Transfer Response message back to the originating UDMA-P. The UTC has the ability to generate events at specified completion points when processing a Transfer Request. These events are sent back to the Interrupt Aggregator block.

An UTC instance may be configured to only support VBUSM to VBUSM block copies or they may also optionally support 'split' operations where a read engine is instructed by a TR to read data from a VBUSM interface and send the data to the Packet Streaming fabric via a PSI-L master interface. A similar split operation is supported for writes where data is received into a PSI-L slave interface and is then routed to a write engine which has been instructed by a TR to move the data into a set of memory locations.

10.1.1.9 Data Routing Unit (DRU)

For purposes of the K3 Data Movement architecture, the DRU is essentially a UTC which supports only the block copy mode subset of the Transfer Request message formats. The DRU typically will provide the highest performance block copy data movement capability of any DMA engine within the SoC. The data routing unit (DRU) is a high bandwidth, flexible routing engine with programmable DMA transfer requests. It enables user to perform high speed data transfers between memory mapped slave endpoints, processor caches and shared caches. DRU behaves like a DMA transfer controller, moving data at CC_ARMSS frequency.

10.1.1.10 Unified DMA – Peripheral Root Complex (UDMA-P)

The UDMA-P is intended to perform similar (but significantly upgraded) functions as the packet-oriented DMA used on previous SoC devices. The UDMA-P module supports the transmission and reception of various packet types. The UDMA-P is architected to facilitate the segmentation and reassembly of SoC DMA data structure compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each connected peripheral. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be ongoing. The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An external DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for Transmit operations. The ordering and rate of Receive operations is indirectly controlled by the order in which blocks are pushed into the DMA on the Rx PSI-L interface.

The UDMA-P also supports acting as both a UTC and UDMA-C for its internal channels. Channels in the UDMA-P can be configured to be either Packet-Based or Third-Party channels on a channel by channel basis.

A block diagram of the UDMA-P Controller is shown in Figure 10-3.

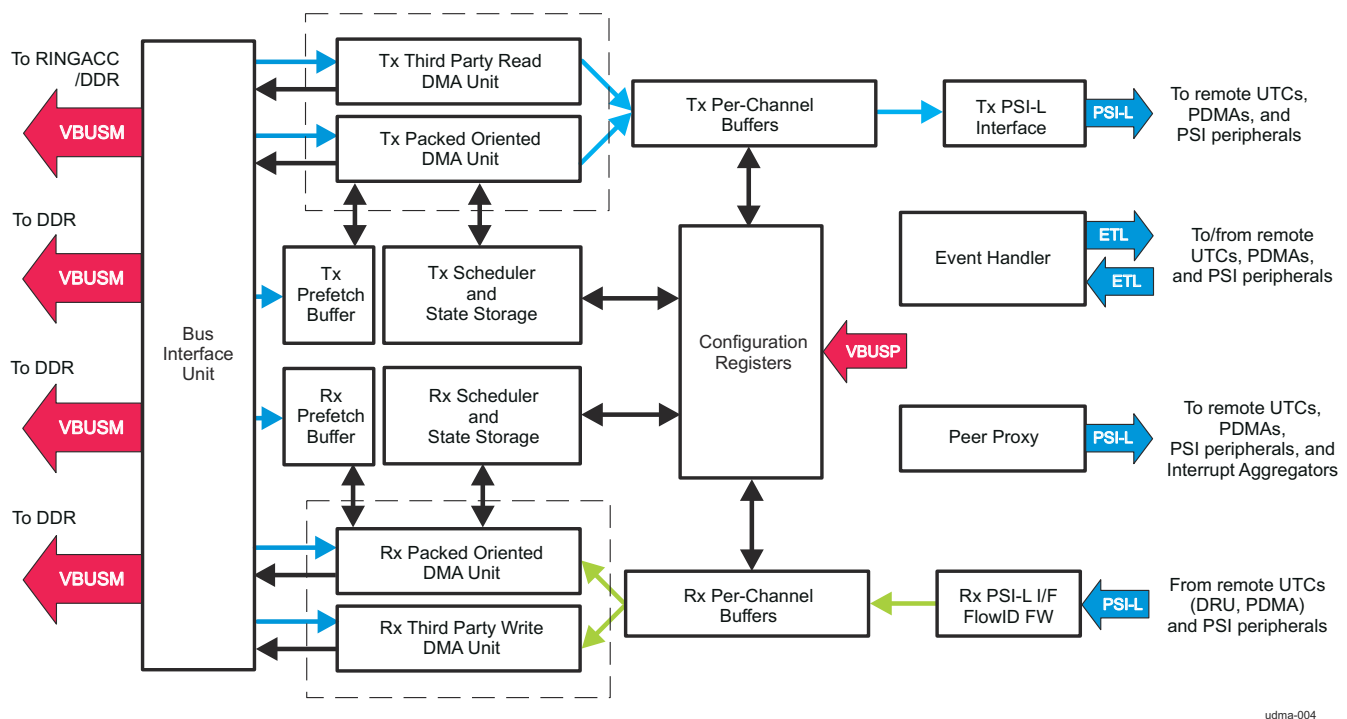

Figure 10-3. UDMA-P Block Diagram

10.1.1.11 Peripheral DMA (PDMA)

The Peripheral DMA is a simple DMA which has been architected to specifically meet the data transfer needs of peripherals which perform data transfers using memory mapped registers accessed via a standard non-coherent bus fabric. The PDMA module is intended to be located close to one or more peripherals which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only statically configured Transfer Request operations. The PDMA is only responsible for performing the data movement transactions which interact with the peripherals themselves. Data which is read from a given peripheral is packed by a PDMA source channel into a PSI-L data stream which is then sent to a remote peer UDMA-P destination channel which then performs the movement of the data into memory. Likewise, a remote UDMA-P source channel fetches data from memory and transfers it to a peer PDMA destination channel over PSI-L which then performs the writes to the peripheral.

The Peripheral DMA architecture is intentionally heterogeneous (UDMA-P + PDMA) to right size the data transfer complexity at each point in the system to match the requirements of whatever is being transferred to

or from. Peripherals are typically FIFO based and do not require multi-dimensional transfers beyond their FIFO dimensioning requirements, so the PDMA transfer engines are kept simple with only a few dimensions (typically for sample size and FIFO depth), hardcoded address maps, and simple triggering capabilities.

Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs round-robin scheduling between channels in order to share the underlying DMA hardware.

10.1.1.12 Embedded DMA

Embedded DMA refers to a DMA-capable master module which either follows an industry standard hardware/software Application Programming Interface (API) or is a module which does not natively comply with the TI DMA architecture requirements. It is assumed that modules which include Embedded DMA will provide their own dedicated software drivers and interoperability with other DMA entities in the system will be accomplished with software bridging code. None of the remainder of this chapter has any effect on the operation or architecture of Embedded DMA functions.

10.1.1.13 Definition of Terms

Host	The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts.
Channel	A channel refers to the sub-division of information (flows) that is transported across a DMA engine. Each channel has associated state information. Channels are used to segregate information flows based on the protocol used, scheduling requirements (for example, CBR, VBR, ABR), or concurrency requirements (that is, blocking avoidance). Information flow within a channel is a stream of strongly ordered information.
Data Buffer	A data buffer is a single data structure that contains payload information for transmission to or reception from a channel.
Buffer Descriptor	A buffer descriptor is a single data structure that contains information about one or more data buffers.
Packet Descriptor	A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. All Monolithic type descriptors are packet descriptors (and are also a Data Buffer).
Queue	A queue is a list of strongly ordered entries which is typically used to pass work between a producer and a consumer. Queue entries in most cases are references to a work payload which is being passed but in some cases (Transfer Request Packets for example) queue entries may actually contain data which is being transferred. Queues are used throughout UDMA whenever communication is required between entities. Queues can have multiple different implementations and UDMA uses two of the most common: linked lists and rings.
Linked list	A linked list is a data structure in which each entry stores not only the entry data but also a chaining pointer to the next entry in the list. The last entry in each list has its chaining pointer set to NULL (typically encoded as 0x0). The list manager maintains a pointer to the head element on the list and to the tail element on the list. Since the chaining pointer is stored with the entry data, linked lists have a length which is dynamically changeable and limited only by the ability to allocate additional entries which are to be queued/de-queued. Linked lists are present in Host Descriptors to chain multiple descriptors to form a packet
Ring	A ring is a data structure in which a contiguous memory block defined by M N-byte entries (total size is $M \times N$ bytes) is statically allocated and sequentially written/read in order to pass data or data references. Rings are also referred to as circular buffers because when the last element in the contiguous memory array is written, the pointers wrap back to the beginning address for the ring and start the process all over again. The Ring Accelerator component uses rings in order to implement logical queues
Free Descriptor/Buffer Queue	A free descriptor/buffer queue is a list of available descriptors with pre-linked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Ring Accelerator.
Free Descriptor Queue	A free descriptor queue is a list of available descriptors that are not yet linked with buffers that are to be used by the receive ports for monolithic type descriptors. Free Descriptor Queues are implemented by the Ring Accelerator.
Packet Queue	A packet queue is a list of valid (that is, populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes. Packet Queues are implemented by the Ring Accelerator.
Memory	Memory is an area of data storage managed by the host. This area is visible to the port as a 64-bit addressable area.
Device Driver	A device driver is application independent software that runs on the host for purposes abstracting the low level hardware so that upper level software can use the hardware without knowing every bit field location or initialization sequence.. General device driver functions include port initialization, transmit packet queuing, and receive packet processing.

SOP Start of Packet. This refers to the descriptor/buffer that is the first buffer in a packet.

MOP Middle of Packet. This refers to the descriptors/buffers that are neither the first or last buffers in a packet.

EOP End of Packet. This refers to the descriptor/buffer that is the last buffer in a packet.

10.1.2 DMA Hardware/Software Interface

The intent of the TI Data Movement (DMA) architecture is to provide a uniform hardware/software interface which includes a rich set of mechanisms that software can make use of to transfer data with low overhead and reasonable complexity. To this goal, the number of components which software is required to interact with on an ongoing real time basis has been kept to a minimum and is as follows (in order of anticipated frequency of access):

- Interrupt Aggregator
- Ring Accelerator
- UDMA-P/C (for managed flow control and error/exception handling only)
- Block-Copy DMA (BCDMA)

When interrupts are used, the interrupt aggregator will provide the vast majority of interrupt sources from all DMA components in the system. All non-exception/non-debug packet and TR completion signaling originates from the Interrupt Aggregator and the INTA provides a uniform set of registers that can be queried to quickly determine the cause of a specific interrupt. Events from PSI-L/ETL components are all routed to the host via the Interrupt Aggregator.

The Ring Accelerator provides the primary means by which work is sent to or received from the UDMA-P DMA engines (and the UTC/DRU, and PDMA engines whose control operations are proxied by the UDMA-P).

The UDMA-P are primarily fronted by the RA and the INTA but for real time operations like software controlled flow control (via pause) some registers in the UDMA-P blocks may be directly manipulated.

Each BCDMA instance includes an inbuilt ring control mechanism which is the primary means by which work is sent to or received from these DMAs. Each DMA instance also includes both static configuration type memory mapped registers and some real-time accessible memory mapped registers for monitoring and control of each individual channel.

Data structures are used to pass anytime information between components in the system. These components may be hardware or software. The following sections describe the data structures which are used within a UDMA/BCDMA based system for passing information. These data structures include data buffers, packet descriptors, buffer descriptors, queues (including transmit queues, transmit completion queues, and receive queues) and the configuration registers that are provided in the various components. The following sections provide a detailed description of these data structures.

10.1.2.1 Data Buffers

A data buffer is a byte aligned contiguous block of memory used to store packet payload data. Each buffer is described in an entry in either a packet descriptor or in a buffer descriptor. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form packets. Data buffers may be allocated anywhere within the 64-bit memory space.

The Buffer Length field of the packet/buffer descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.

10.1.2.2 Descriptors

Descriptors are so named because their primary function is to describe other data structures.

The UDMA architecture provides 4 basic types of descriptors each of which has specific characteristics intended to address different requirements. [Table 10-1](#) shows the different types of descriptors and their characteristics.

Table 10-1. UDMA Descriptor Types and Attributes

Descriptor Type	Includes Valid Packet Info	Provides Number of Slots to Link In External Data Buffers	Provides Local Packet Data Storage	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Host Packet Descriptor	✓	1		✓	✓	Used to describe packet and SOP buffer in applications that require Host OS compatible data structures (i.e. applications where the descriptors and buffers cannot be managed independently but must instead be pre-linked by the Host software). These applications inherently require a separate descriptor for each buffer.
Host Buffer Descriptor		1			✓	Used to describe non-SOP buffers in applications that require Host OS compatible data structures
Monolithic Packet Descriptor	✓	0	✓	✓		Used to provide descriptor and data information in one contiguous data structure.
Transfer Request Packet Descriptor		0				Used to feed transfer request sequences to the UDMA third party channel controller

As [Table 10-1](#) shows, two of the four different descriptor types (the Host Packet Descriptor and Monolithic Packet Descriptor) provide packet level information that is useful to both the ports and the Host in order to properly process the packet. These descriptors are referred to as Packet Descriptors and will always appear as the first descriptor (or only descriptor in the case of Monolithic types) within a packet.

Software must allocate descriptors on 16-byte address boundaries. 16-byte is the minimum granularity that UDMA supports. This is intended for better memory utilization by allowing on-chip descriptors which are not a power of 2 in length to be packed into arrays with little wasted memory space.

Even though descriptors and buffers may be allocated on any 16-byte alignment, careful consideration of the alignment effects should be made based on the storage location and any cache related affects that may exist. If data structures are placed in off-chip SDRAM the burst size and alignment restrictions of the memory devices must be considered in order to avoid performance issues related to continually fetching mis-aligned blocks. In this case, the memory efficiency can be reduced to 50% because two memory bank lines are read for every line sized data fetch. Similarly, placing more than one descriptor or buffer object within a single cache line can cause the adjacent object to become corrupted during cache line writeback operations.

Software/application specific control information may be added to the end of any of the packet descriptor types using as many extra words as necessary but the above alignment rules still apply.

The Block Copy DMA architecture provides a single descriptor type, whose characteristics are shown in [Table 10-2](#).

Table 10-2. Block Copy DMA Descriptor Types and Attributes

Descriptor Type	Includes Valid Packet Info	Provides Number of Slots to Link In External Data Buffers	Provides Local Packet Data Storage	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Transfer Request Packet Descriptor		0				Used to feed transfer request sequences to the UDMA third party channel controller

10.1.2.2.1 Host Packet Descriptor

Host Packet Descriptors are designed to be used when the application requires support for true, unlimited fragment count scatter/gather type operations. The Host Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a Host Packet Descriptor
- Source and Destination Tags
- Packet Type
- Packet Length
- Protocol Specific Region Size
- Protocol Specific Control/Status Bits
- Pointer to the first valid byte in the SOP data buffer
- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the packet
- Software specific information

Note

A Host Packet Descriptor must start on a 64 Byte Boundary

Host Packet Descriptors always contain 48 bytes of required information and may also contain optional software specific information and protocol specific information. How much optional information (and therefore the allocated size of the descriptors) is required is application dependent.

The Host Packet descriptor layout is shown below.

Packet Info (16 bytes)
Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)
Extended Packet Info Block (Optional) Includes Timestamp and Software Data (16 bytes)
Protocol Specific Data (Optional) (0 to M bytes where M is a multiple of 4)
Other Software Data (Optional and User Defined)

Host Packet Descriptors may be linked with zero or more additional Host Buffer Descriptors in a singly linked list fashion to form packets. Each Host Packet consists of a single Host Packet Descriptor followed by a chain of zero or more Host Buffer Descriptors linked together using the Next Descriptor Pointer fields in the descriptors. The last descriptor in a Host packet has a zero Next Descriptor Pointer.

The 'Other Software Data' portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store completely private data. This region is not used in any way by hardware components in a UDMA system and these modules will not modify any bytes within this region.

The contents of the Host Packet Descriptor words are detailed in [Table 10-3](#) through [Table 10-19](#).

Table 10-3. Host Packet Descriptor Packet Information Word 0 (PD Word 0)

Bits	Name	Description	Rx Overwrite
31:30	2'd1	64-bit Host Packet Descriptor Type Identifier	Yes
29	Extended Packet Info Block Present	This field indicates the presence of the Extended Packet Info Block in the descriptor. 0 = EPIB is not present 1 = 16 byte EPIB is present	Yes

Table 10-3. Host Packet Descriptor Packet Information Word 0 (PD Word 0) (continued)

Bits	Name	Description	Rx Overwrite
28	Protocol Specific Region Location	This field indicates the location of the Protocol Specific Words: 0 = PS Words are located in the descriptor 1 = PS Words are located in the SOP Buffer immediately prior to the data.	Yes
27:22	Protocol Specific Valid Word Count	This field indicates the valid number of 32-bit words in the protocol specific region. This is encoded in increments of 4 bytes as follows: 0 = 0 bytes 1 = 4 bytes ... 16 = 64 bytes ... 32 = 128 bytes 33-63 = RESERVED	Yes
21:0	Packet Length	The length of the packet in bytes. If the Packet Length is less than the sum of the buffer lengths, then the packet data will be truncated. A Packet Length greater than the sum of the buffers is an error unless the packet length is set to 0x3FFFFFF. If the packet length is set to all 1s (0x3FFFFFF) the Tx port will disable truncation and will transmit as much data as is specified in the Buffer Length fields. On Rx, if the received data exceeds 4M-1 bytes, the packet length field will saturate to a value of 0x3FFFFFF. The valid range for an exact packet length is 0 to 4M-1 bytes. If the packet length is set to 0, the port will not actually transmit any information. Instead, the port will perform buffer/descriptor reclamation as instructed in the return information in word 2.	Yes

Table 10-4. Host Packet Descriptor Packet Information Word 1 (PD Word 1)

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
27:24	Protocol Specific Flags	This field contains protocol specific flags/information that can be assigned based on the packet type.	Yes
23:14	Packet ID	Unique Packet ID for packet within FlowID	Yes
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

Table 10-5. Host Packet Descriptor Packet Information Word 2 (PD Word 2)

Bits	Name	Description	Rx Overwrite
31:27	Packet Type	This field indicates the type of this packet and is encoded as follows: 0-31 = Application specific	Yes
26:19	RESERVED	Reserved	No
18	Return Policy	This field indicates the return policy for this packet. 0 = Entire packet (still linked together) should be returned to queue specified in bits 15:0. 1 = Each buffer should be returned to queue specified in bits 15:0 of Word 2 in their respective descriptors. The Tx DMA will return each buffer in sequence.	No
17	Early Return	This field indicates that each buffer pointer should be immediately returned to the specified queue when data transfer is started from the packet instead of waiting for the entire buffer to be emptied. This flag is used to enable in-place reception of packets on a Receive Channel while the source packet is in the process of being transferred on a Transmit Channel. 0 = Buffer/Package descriptor pointers should only be returned after all reads have been completed 1 = Buffer/Package descriptor pointers should be returned immediately upon fetching the descriptor and beginning to transfer data.	No

Table 10-5. Host Packet Descriptor Packet Information Word 2 (PD Word 2) (continued)

Bits	Name	Description	Rx Overwrite
16	Return Push Policy	This field indicates how a Transmit or Receive DMA should return the descriptor pointers to the free queues This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. The Rx DMA will only use this field when an error occurs during reception and the DMA must return descriptors back to the free queue from which they came. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator.	No
15:0	Packet Return Queue/ Ring Num	This field indicates the ring number in the RA that the descriptor is to be returned to after transmission is complete. The value 0xFFFF is reserved.	No

Table 10-6. Host Packet Descriptor Packet Information Word 3 (PD Word 3)

Bits	Name	Description	Rx Overwrite
31:24	Source Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_hi_sel field in the flow configuration table entry.	Configurable
23:16	Source Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_lo_sel field in the flow configuration table entry.	Configurable
15:8	Dest Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_hi_sel field in the flow configuration table entry.	Configurable
15:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_lo_sel field in the flow configuration table entry.	Configurable

Table 10-7. Host Packet Descriptor Linking Word 0 (PD Word 4)

Bits	Name	Description	Rx Overwrite
31:0	Next Descriptor Pointer LSB	The 32 LSBs of the 48-bit, 16-byte aligned (min), memory address of the next buffer descriptor in the packet. If the value of this pointer is zero then the current buffer is the last buffer in the packet. The host sets the Next Descriptor Pointer.	Yes

Table 10-8. Host Packet Descriptor Linking Word 1 (PD Word 5)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED	Reserved	Yes
19:16	Next Descriptor Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	Yes
15:0	Next Descriptor Pointer MSB	The 16 MSBs of the 48-bit next descriptor pointer	Yes

Table 10-9. Host Packet Descriptor Buffer 0 Info Word 0 (PD Word 6)

Bits	Name	Description	Rx Overwrite
31:0	Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will be written during reception. If the protocol specific words are placed at the beginning of the SOP buffer, this pointer will point to the PS words. The offset to the data in that case must be calculated by the consumer using the Protocol Specific Valid Word Count from Word 2. These are the 32 LSBs of the 48-bit buffer pointer.	Yes

Table 10-10. Host Packet Descriptor Buffer 0 Info Word 1 (PD Word 7)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED	Reserved	Yes

Table 10-10. Host Packet Descriptor Buffer 0 Info Word 1 (PD Word 7) (continued)

Bits	Name	Description	Rx Overwrite
19:16	Buffer 0 Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	Yes
15:0	Buffer 0 Pointer MSB	The 16 MSBs of the 48-bit buffer pointer	Yes

Table 10-11. Host Packet Descriptor Buffer 0 Info Word 2 (PD Word 8)

Bits	Name	Description	Rx Overwrite
31:22	RESERVED	Written to 0	Yes
21:0	Buffer 0 Length	The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. This value will be overwritten during reception.	Yes

Table 10-12. Host Packet Descriptor Original Buffer Info Word 0 (PD Word 9)

Bits	Name	Description	Rx Overwrite
31:22	RESERVED		No
21:0	Original Buffer 0 Length	The Buffer Length field indicates the original size of the buffer in bytes. Data bytes are in the buffer. This value will not be overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the host at initialization. Since the buffer length in PD Word 8 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.	No

Table 10-13. Host Packet Descriptor Original Buffer Info Word 1 (PD Word 10)

Bits	Name	Description	Rx Overwrite
31:0	Original Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will not be overwritten during reception. This value is read by the RX DMA to determine the actual buffer location as allocated by the host at initialization. Since the buffer pointer in PD Words 6/7 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information. This field contains the 32 LSBs of the 48-bit original buffer pointer	No

Table 10-14. Host Packet Descriptor Original Buffer Info Word 2 (PD Word 11)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED	Reserved	Yes
19:16	Original Buffer 0 Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	Yes
15:0	Original Buffer 0 Pointer MSB	The 16 MSBs of the 48-bit original buffer pointer	No

Table 10-15. Host Packet Descriptor Extended Packet Info Block Word 0 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Timestamp Info	This field contains an application specific timestamp which can be used for traffic shaping in a QoS enabled system.	Configurable

Table 10-16. Host Packet Descriptor Extended Packet Info Block Word 1 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Software Info 0	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

Table 10-17. Host Packet Descriptor Extended Packet Info Block Word 2 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Software Info 1	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

Table 10-18. Host Packet Descriptor Extended Packet Info Block Word 3 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Software Info 2	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

Table 10-19. Host Packet Descriptor Protocol Specific Word N (Optional)

31:0	Protocol Specific Data N	This field stores information which varies depending on the block and packet type.	Configurable

10.1.2.2.2 Host Buffer Descriptor

The Host Buffer Descriptor is identical in size and organization to a Host Packet Descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol specific information. Host Buffer Descriptors are designed to be linked onto a Host Packet Descriptor or another Host Buffer Descriptor to provide support for unlimited scatter/gather type operations. Host Buffer Descriptors provide information about a single corresponding data buffer.

Every Host buffer descriptor stores the following information:

1. Pointer to the first valid byte in the data buffer
2. Length of the data buffer
3. Pointer to the next buffer descriptor in the packet

Note

A Host Buffer Descriptor must start on a 64 Byte Boundary

Host Buffer Descriptors always contain 48 bytes of required information. Since it is a requirement that it is possible to convert a Host descriptor between a Buffer Descriptor and a Packet Descriptor (by filling in the appropriate fields) in practice, Host Buffer Descriptors will be allocated using the same sizes as Host Packet Descriptors.

The Host Buffer Descriptor layout is shown below.

Buffer Reclamation Info (16 bytes)
Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)

A Host Packet Descriptor and zero or more Host Buffer Descriptors may be linked together using the Next Descriptor Pointer fields to form packets. The last descriptor in a packet has a zero Next Descriptor Pointer. Each Host Buffer descriptor also points to a single data buffer.

The contents of the Host Buffer Descriptor words are detailed in [Table 10-20](#) through [Table 10-31](#).

Table 10-20. Host Buffer Descriptor Reserved Word 0 (BD Word 0)

Bits	Name	Description	Rx Overwrite
31:0	RESERVED	Reserved	No

Table 10-21. Host Buffer Descriptor Reserved Word 1 (BD Word 1)

Bits	Name	Description	Rx Overwrite
31:0	RESERVED	Reserved	No

Table 10-22. Host Buffer Descriptor Buffer Reclamation Info (BD Word 2)

Bits	Name	Description	Rx Overwrite
31:18	RESERVED		No
17	Early Return	This field indicates that each buffer pointer should be immediately returned to the specified queue when data transfer is started from the packet instead of waiting for the entire buffer to be emptied. This flag is used to enable in-place reception of packets on a Receive Channel while the source packet is in the process of being transferred on a Transmit Channel. 0 = Buffer/Packet descriptor pointers should only be returned after all reads have been completed 1 = Buffer/Packet descriptor pointers should be returned immediately upon fetching the descriptor and beginning to transfer data.	No
16	Return Push Policy	This field indicates how a Transmit or Receive DMA should return the descriptor pointers to the free queues. This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. The Rx DMA will only use this field when an error occurs during reception and the DMA must return descriptors back to the free queue from which they came. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator.	No
15:0	Packet Return Queue Num	This field indicates the ring number within the Ring Accelerator that the descriptor is to be returned to after transmission is complete.	No

Bits	Name	Description	Rx Overwrite
31:28	RESERVED		No
27:0	Original Buffer 0 Length	The Buffer Length field indicates the original size of the buffer in bytes. Data bytes are in the buffer. This value will not be overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the host at initialization. Since the buffer length in BD Word 8 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.	No

Table 10-30. Host Buffer Descriptor Original Buffer Info Word 1 (BD Word 10)

Bits	Name	Description	Rx Overwrite
31:0	Original Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will not be overwritten during reception. This value is read by the RX DMA to determine the actual buffer location as allocated by the host at initialization. Since the buffer pointer in BD Words 6/7 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information. This field contains the 32 LSBs of the 48-bit original buffer pointer	No

Table 10-31. Host Buffer Descriptor Original Buffer Info Word 2 (BD Word 11)

Bits	Name	Description	Rx Overwrite
31:20	RESERVED		Yes
19:16	Original Buffer 0 Pointer Address Space Select	Effectively bits 51:48 of the address – treated special by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	Yes
15:0	Original Buffer 0 Pointer MSB	The 16 MSBs of the 48-bit original buffer pointer	No

10.1.2.2.3 Monolithic Packet Descriptor

The Monolithic Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a Monolithic Packet Descriptor

- Source and Destination Tags
- Packet Type
- Packet Length
- Packet Error Indicator
- Packet Return Information
- Protocol Specific Region Size
- Protocol Specific Region Offset
- Protocol Specific Control/Status Bits
- Packet Data

Note

A Monolithic Packet Descriptor must start on a 64 Byte Boundary.

The maximum size of a Monolithic Packet Descriptor is 4 MB. Of this, Monolithic Packet Descriptors always contain 16 bytes of required information and may also contain 16 bytes of software specific tagging information and up to 128 bytes (indicated in 4 byte increments) of protocol specific information. How much protocol specific information (and therefore the allocated size of the descriptors) is application dependent.

The Monolithic Packet descriptor layout is shown below.

Packet Info (16 bytes)
Extended Packet Info Block (Optional) Includes Timestamp, and software Data Words (16 bytes)
Protocol Specific Data (Optional) (0 to M bytes where M is a multiple of 4)
Null Region (0 to 511 bytes)
Packet Data (0 to 4M – 1)
Other software Data (Optional and User Defined)

The 'Other software Data' portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store private data. This region is not used in any way by the hardware components in a UDMA system and these modules will not modify any bytes within this region.

The contents of the Monolithic Packet Descriptor words are detailed in [Table 10-32](#) through [Table 10-41](#)

Table 10-32. Monolithic Packet Descriptor Word 0

Bits	Name	Description	Rx Overwrite
31:30	2'd2	Monolithic Packet Descriptor type.	Yes
29	Extended Packet Info Block Present	This field indicates the presence of the Extended Packet Info Block in the descriptor. 0 = EPIB is not present 1 = 16 byte EPIB is present	Yes
28	RESERVED		Yes
27:22	Protocol Specific Valid Word Count	This field indicates the valid number of 32-bit words in the protocol specific region. This is encoded in increments of 4 bytes as follows: 0 = 0 bytes 1 = 4 bytes ... 16 = 64 bytes ... 32 = 128 bytes 33-63 = RESERVED	Yes
21:0	Packet Length	The length of the packet in bytes. The valid range for the packet length is 0 to 4M-1 bytes. If the packet length is set to 0, the port will not actually transmit any information. Instead, the port will perform buffer/descriptor reclamation as instructed in the return information in word 2.	Yes

Table 10-33. Monolithic Packet Descriptor Word 1

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
27:24	Protocol Specific Flags	This field contains protocol specific flags/information that can be assigned based on the packet type.	Yes
23:14	Packet ID	Unique Packet ID for packet within FlowID	Yes
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

Table 10-34. Monolithic Packet Descriptor Word 2

Bits	Name	Description	Rx Overwrite
31:27	Packet Type	This field indicates the type of this packet and is encoded as follows: 0-31 = To Be Assigned	Yes
26:18	Data Offset	This field indicates the byte offset from byte 0 of this descriptor to the location where the valid data begins. On Rx, this value is set equal to the value for the SOP offset given in the Rx DMA channel's Monolithic control register. When a monolithic packet is processed, this value may be modified in order to add or remove bytes to from the beginning of the packet. The value for this field can range from 0-511 bytes. Note that the value of this field must always be greater than or equal to 4 times the value given in the Protocol Specific Valid Word Count field.	Yes
17	Early Return	This field indicates that each buffer pointer should be immediately returned to the specified queue when data transfer is started from the packet instead of waiting for the entire buffer to be emptied. This flag is used to enable in-place reception of packets on a Receive Channel while the source packet is in the process of being transferred on a Transmit Channel. 0 = Buffer/Packet descriptor pointers should only be returned after all reads have been completed 1 = Buffer/Packet descriptor pointers should be returned immediately upon fetching the descriptor and beginning to transfer data.	No
16	Return Push Policy	This field indicates how a Transmit DMA should return the descriptor pointers to the free queues. This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator.	No
15:0	Packet Return Queue Num	This field indicates the queue number that the descriptor is to be returned to after transmission is complete.	No

Table 10-35. Monolithic Packet Descriptor Word 3

Bits	Name	Description	Rx Overwrite
31:24	Source Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_hi_sel field in the flow configuration table entry.	Configurable
23:16	Source Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_lo_sel field in the flow configuration table entry.	Configurable
15:8	Dest Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_hi_sel field in the flow configuration table entry.	Configurable
15:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_lo_sel field in the flow configuration table entry.	Configurable

Table 10-36. Monolithic Extended Packet Info Word 0 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Timestamp Info	This field contains an application specific timestamp which can be used for traffic shaping in a QoS enabled system.	Configurable

This word is only present if the Extended Packet Info Block present bit is set in Word 0.

Table 10-37. Monolithic Extended Packet Info Word 1 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Software Info 0	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

This word is only present if the Extended Packet Info Block present bit is set in Word 0.

Table 10-38. Monolithic Extended Packet Info Word 2 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Software Info 1	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

This word is only present if the Extended Packet Info Block present bit is set in Word 0.

Table 10-39. Monolithic Extended Packet Info Word 3 (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Software Info 2	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

These words if present immediately follow the Software Data Block Information.

Table 10-40. Monolithic Packet Descriptor Protocol Specific Word M (Optional)

Bits	Name	Description	Rx Overwrite
31:0	Protocol Specific Data N	This field stores information which varies depending on the packet type.	Configurable

The payload data follows the protocol specific words at an offset specified in the data offset field of Word 0.

Table 10-41. Monolithic Packet Descriptor Payload Data Words 0-N

Bits	Name	Description	Rx Overwrite
31:0	Packet Data N	These words store the packet payload data.	Yes

This field is endian specific. In other words, this is the only field in the descriptor which changes based on the endianness of the system.

10.1.2.2.4 Transfer Request Descriptor

The Transfer Request Descriptor contains the following information:

- Indicator which identifies the descriptor as a TR Descriptor
- Source and Destination Tags (Not Applicable to BCDMA)
- Packet Error Indicator (Not Applicable to BCDMA)
- Packet Return Information (Not Applicable to BCDMA)
- Set of one or more Transfer Request Records
- Set of one or more Transfer Response Records

Note

A Transfer Request Packet Descriptor must start on a 64 Byte Boundary.

Transfer Request Packet Descriptors always contain 16 bytes of required information and a variable number of Transfer Request/Transfer Response Records (request and response counts match).

The Transfer Request descriptor layout is shown below.

Packet Info (16 bytes)
Null (0-102 bytes to bring start of TR request array into natural alignment for memory fetch efficiency)
Array of Transfer Request Records (M bytes)
Array of Transfer Response Records (4 bytes per)

Table 10-42. Transfer Request Packet Descriptor Word 0

Bits	Name	Description	Rx Overwrite	
			UDMA/UTC	BCDMA
31:30	2'd3	TR Packet Descriptor type.	Yes	No
29	RESERVED		Yes	No
28:20	Reload Count	Specifies what to do when the last entry is processed in this packet. This field specifies how many times to return to the Reload Index upon reaching the Last Entry. When an internal count is incremented to this value and the TR indicated by the Last Entry has been processed, this packet will be considered complete. For UDMA/UTC, the descriptor will be placed back on the return queue specified in Word 2. For BCDMA, the descriptor will be placed back on ring and the reverse occupancy counter increased. A value of 0x1FF indicates that a perpetual loop is desired. In this case, the loop count is considered infinite and the internal count will not be incremented. A teardown operation on the channel will cause the loop to be broken at the nearest iteration boundary.		No
19:14	Reload Index	Specifies the value to set the current processing index to when the last entry is processed and the Reload Enable is set to 1. This is basically an absolute index to jump to on the 2 nd and following passes through the TR packet.		No
13:0	Last Entry	Specifies the index of the last valid entry in this packet	Yes	No

Table 10-43. Transfer Request Packet Descriptor Word 1

Bits	Name	Description	Rx Overwrite	
			UDMA/UTC	BCDMA
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type. This field is not supported on BCDMA.	Yes	No
27	RESERVED		Yes	No

Table 10-43. Transfer Request Packet Descriptor Word 1 (continued)

Bits	Name	Description	Rx Overwrite	
			UDMA/UTC	BCDMA
26:24	Transfer Request Nominal Element Size	Specifies the stride between TR entries. The value in this field must be set large enough that any TR in the buffer will fit within the given dimension. TRs are expected to be placed on boundaries as given in this dimension. This field is also used to calculate the location where the Transfer Responses will be written back. This field is encoded as follows: 0 = 16 byte Transfer Request record size 1 = 32-byte Transfer Request record size 2 = 64-byte Transfer Request record size 3 = 128-byte Transfer Request record size 4-7 = RESERVED	Yes	No
23:14	Packet ID	Unique Packet ID for packet within FlowID. This field is not supported on BCDMA.	Yes	No
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers. This field is not supported on BCDMA.	Yes	No

Table 10-44. Transfer Request Packet Descriptor Word 2

Bits	Name	Description	Rx Overwrite	
			UDMA/UTC	BCDMA
31:17	RESERVED		No	Yes
16	Return Push Policy	This field indicates how a Transmit DMA should return the descriptor pointers to the free queues. This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator. This field is not supported on BCDMA.	No	Yes
15:0	Packet Return Queue Num	This field indicates the queue number that the descriptor is to be returned to after transmission is complete. This field is not supported on BCDMA.	No	Yes

Table 10-45. Transfer Request Packet Descriptor Word 3

Bits	Name	Description	Rx Overwrite	
			UDMA/UTC	BCDMA
31:24	Source Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_hi_sel field in the flow configuration table entry. This field is not supported on BCDMA.	Configurable	No

Table 10-45. Transfer Request Packet Descriptor Word 3 (continued)

Bits	Name	Description	Rx Overwrite	
			UDMA/UTC	BCDMA
23:16	Source Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_lo_sel field in the flow configuration table entry. This field is not supported on BCDMA.	Configurable	No
15:8	Dest Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_hi_sel field in the flow configuration table entry. This field is not supported on BCDMA.	Configurable	No
15:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_lo_sel field in the flow configuration table entry. This field is not supported on BCDMA.	Configurable	No

Table 10-46. Transfer Request Packet Descriptor Payload Words 0-N

Bits	Name	Description	Rx Overwrite
31:0	Transfer Control Record Array	Transfer Control Records. This is an array of records which encapsulate the Transfer Request and Transfer Response messages which are used by the UTC/ BCDMA	Yes (partial)

10.1.2.3 Transfer Request Record

10.1.2.3.1 Overview

This section describes the standard transfer request (TR) format to initiate a DMA transfer. The TRs can support both half and full duplex with multiple dimensions as well as cache wars. The UTC (Universal Transfer Controller)/ BCDMA (Block-Copy DMA) does not have to support all types of TRs. Each TR will also generate a TR response. A TR can be sent to the UTC either through a PSI-L interface or an optionally supported Direct TR submission (previously QDMA) which will have Memory Mapped TR submission registers that can be written. The Memory Mapped TR submission registers further be classified by submission type either a single burst (atomic write) or multiple burst (non-atomic). The non-atomic TR will be sent when the submission register with word 0 is written.

A TR can be sent to the BCDMA either through a TR descriptor using a pass-by-reference ring or as a Direct TR submission using a pass-by-value ring.

Table 10-47. Terms and Definitions

Term	Definition
TR	A transfer request to move data.
CR	A cache operation request. A request to send messages to a specified cache controller to prepare the cache for a future operation.
UTC	Universal Transfer Controller the module in the UDMA architecture that handled the actual movement of data requested in the TR.

10.1.2.3.2 Addressing Algorithm

For a basic TR request the same algorithm is used. The innermost loop always consumes physically contiguous elements from memory. Its implicit dimension is 1 byte, this can be changed if the TR contains the formatting flags field and it is supported by the UTC. The pointer itself moves from fetch to fetch on the maximum byte alignments specified for the UTC/ BCDMA, in increasing order. In each level outside the inner loop, the loop moves the pointer to a new location based on the size of that loop level's dimension.

10.1.2.3.2.1 Linear Addressing (Forward)

The following code illustrates the basic algorithm for a 4-level loop nest block move. This model assumes that it transfers data 1 byte at a time and the input and output block are the same size in all dimensions.

```
// sptr is a byte pointer.
// dptr is a byte pointer.
// Source address is indirect
if (TR_ISA) {
    sptr = *sptr;
}
// Destination address is indirect
if (TR_IDA) {
    dptr = *dptr;
}
// TR_TRIGX can be selected to come from Global events, Local event, or none.
// Check for trigger of TYPE0
if (TR_TRIG0_TYPE == TYPE0) while(!TR_TRIG0);
if (TR_TRIG1_TYPE == TYPE0) while(!TR_TRIG1);
for (i3 = 0; i3 < ICNT3; i3++)
{
    sptr3 = sptr; // save current position before entering next level
    dptr3 = dptr; // save current position before entering next level
    // Check for trigger of TYPE1
    if (TR_TRIG0_TYPE == TYPE1) while(!TR_TRIG0);
    if (TR_TRIG1_TYPE == TYPE1) while(!TR_TRIG1);
    for (i2 = 0; i2 < ICNT2; i2++) {
        sptr2 = sptr; // save current position before entering next level
        dptr2 = dptr; // save current position before entering next level
        // Check for trigger of TYPE2
        if (TR_TRIG0_TYPE == TYPE2) while(!TR_TRIG0);
        if (TR_TRIG1_TYPE == TYPE2) while(!TR_TRIG1);
        for (i1 = 0; i1 < ICNT1; i1++) {
            sptr1 = sptr; // save current position before entering next level
            dptr1 = dptr; // save current position before entering next level
            // Check for trigger of TYPE3
            if (TR_TRIG0_TYPE == TYPE3) while(!TR_TRIG0);
            if (TR_TRIG1_TYPE == TYPE3) while(!TR_TRIG1);
            for (i0 = 0; i0 < ICNT0; i0++) {
                // UTC/BCDMA can combine these in optimized burst aligned accesses.
                *dptr = *sptr;
                sptr = sptr++;
                dptr = dptr++;
            }
            // Update based on saved pointer for this level
            sptr = sptr1 + SDIM1;
            dptr = dptr1 + DDIM1;
        }
        // Update based on saved pointer for this level
        sptr = sptr2 + SDIM2;
        dptr = dptr1 + DDIM2;
    }
    // Update based on saved pointer for this level
    sptr = sptr3 + SDIM3;
    dptr = dptr1 + DDIM3;
}
```

This form of addressing allows programs to specify regular paths through memory in a small number of parameters. Additionally, it allows for various stall points through the loop to allow for hardware or software induced pausing of the transfer. The following table defines these parameters more explicitly.

Table 10-48. Addressing Parameters for a Basic Stream

Parameter	Definition
ICNT0	Number of iterations for the innermost loop dimension, loop level 0. That is, DIM0 = BYTES.
ICNT1	Number of iterations for the first level above the innermost loop, loop level 1.
SDIM1	Number of bytes between the starting points for consecutive iterations of loop level 1 for the source.
DDIM1	Number of bytes between the starting points for consecutive iterations of loop level 1 for the destination.
ICNT2	Number of iterations for loop level 2.

Table 10-48. Addressing Parameters for a Basic Stream (continued)

Parameter	Definition
SDIM2	Number of bytes between the starting points for consecutive iterations of loop level 2 for the source.
DDIM2	Number of bytes between the starting points for consecutive iterations of loop level 2 for the destination.
ICNT3	Number of iterations for loop level 3.
SDIM3	Number of bytes between starting points for consecutive iterations of loop level 3 for the source.
DDIM3	Number of bytes between the starting points for consecutive iterations of loop level 3 for the destination.

10.1.2.3.3 Transfer Request Formats

The Transfer Request format builds on the same structure adding fields to the TR to give more configuration options. The structure in [Table 10-49](#) shows the 512-bit data structure that makes up the maximum sized UTC/BCDMA Transfer request.

Table 10-49. Transfer Request Template

word 15		word 14		word 13		word 12	
DICNT3	DICNT2	DICNT1	DICNT0	DDIM3		DDIM2	
word 11		word 10		word 9		word 8	
DADDR				DDIM1		FMTFLAGS	
word 7		word 6		word 5		word 4	
DIM3		DIM2		ICNT3	ICNT2	DIM1	
word3		word 2		word 1		word0	
ADDR				ICNT1	ICNT0	FLAGS	

The UTC/BCDMA defines a four-level loop nest for addressing elements within the TR, using the algorithms described in the Addressing algorithm. Most of the fields in the TR template map directly to the parameters in those algorithms.

Table 10-50. Transfer Request Fields

Field Name	Description	Size (bits)
FLAGS	TR flags that specify type of TR and how the TR should be handled. It also supports the TR triggering and output events.	32
ICNT0	Total loop iteration count for level 0 (innermost)	16
ICNT1	Total loop iteration count for level 1	16
ADDR	Starting address for the source data or destination data if it is a half-duplex write	64
DIM1	Signed dimension for loop level 1 for the source data	32
ICNT2	Total loop iteration count for level 2	16
ICNT3	Total loop iteration count for level 3 (outermost)	16
DIM2	Signed dimension for loop level 2	32
DIM3	Signed dimension for loop level 3	32
FMTFLAGS	Flags that tell how the data is formatted either between the input and the output or if the data should use different addressing schemes or sizes. These flags are OPTIONAL and only specific features may be supported by a given DMA implementation. The UDMA/UTC capabilities register specifies which features are supported. This field is not supported on BCDMA.	32
DDIM1	Signed dimension for loop level 1 for the destination data	32
DADDR	Starting address for the destination of the data	64
DDIM2	Signed dimension for loop level 2 for the destination data	32
DDIM3	Signed dimension for loop level 3 for the destination data	32
DICNT0	Total loop iteration count for level 0 (innermost) used for destination	16

Table 10-50. Transfer Request Fields (continued)

Field Name	Description	Size (bits)
DICNT1	Total loop iteration count for level 1 used for destination	16
DICNT2	Total loop iteration count for level 2 used for destination	16
DICNT3	Total loop iteration count for level 3 used for destination	16

The TR assumes all iteration counts as unsigned integers, and all dimensions as signed integers representing byte offsets.

The template above fully specifies the type of elements, length, and dimensions of the transfer.

Since all transfers will not require all the fields the TRs have the type field which allow the number of words required to be sent for the TR to be reduced.

10.1.2.3.4 Flags Field Definition

[Table 10-51](#) expands the 32-bit FLAGS field. The numbers above each field here indicate bit numbers within the field.

Table 10-51. Transfer Request Template FLAGS Field

31								24				23								16							
CONFIGURATION SPECIFIC FLAGS												CMD ID															
15		14		13		12		11		10		9		8		7		6		5		4		3		0	
TRIGGER1_TY PE				TRIGGER1				TRIGGER0_TY PE				TRIGGER0				EVENT_SIZE				WAIT		STATI C		TYPE			

The flags field fills in the remaining details about the stream, as follows:

Table 10-52. FLAGS Field Descriptions

Bit	Field	Description
0-3	TYPE	The TYPE of TR that is being sent 0: One dimensional data move 1: Two dimensional data move 2: Three dimensional data move 3: Four dimensional data move 4: Four dimensional data move with data formatting 5: Four dimensional Cache Warm 6-7: Reserved 8: Four Dimensional Block Move 9: Four Dimensional Block Move with Repacking 10: Two Dimensional Block Move 11: Two Dimensional Block Move with Repacking 12-14: Reserved 15: Four Dimensional Block Move with Repacking and Indirection
4	STATIC	This field is only valid on Type 8 and type 9 TRs The TR is static and will continually reload into the channel upon completion of the TR until a channel tear down. This field is not supported on BCDMA.

Table 10-52. FLAGS Field Descriptions (continued)

Bit	Field	Description
5	WAIT	This field is only valid on Type 15 TRs. This field indicates whether or not this TR should ensure it completes before allowing the next TR to start on this channel. The encoding is as follows: 0 = Allow next TR to start immediately 1 = Wait for this TR to complete before allowing next TR to start When set, the next TR will not be considered triggered (regardless of any other trigger conditions) until all write status responses for the current TR have landed.
6-7	EVENT_SIZE	This is how often the TR will generate an output event. 0: Event is only generated with the TR is complete 1: Event is generated when the second inner most loop (ICNT1) is decremented by 1. 2: Event is generated when the third inner most loop (ICNT2) is decremented by 1. 3: Event is generated when the outer most loop (ICNT3) is decremented by 1.
8-9	TRIGGER0	This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER0_TYPE Field. 0: No Trigger 1: Global Trigger 0 for the channel 2: Global Trigger 1 for the channel 3: Local Event for the channel
10-11	TRIGGER0_TYPE	This is the type of data transfer that will be enabled by receiving a trigger. 0: The second inner most loop (ICNT1) will be decremented by 1. 1: The third inner most loop (ICNT2) will be decremented by 1. 2: The outer most loop (ICNT3) will be decremented by 1. 3: The entire TR will be allowed to complete.
12-13	TRIGGER1	This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER1_TYPE Field. 0: No Trigger 1: Global Trigger 0 for the channel 2: Global Trigger 1 for the channel 3: Local Event for the channel This field is reserved for a Direct TR.
14-15	TRIGGER1_TYPE	This is the type of data transfer that will be enabled by receiving a trigger. 0: The second inner most loop (ICNT1) will be decremented by 1. 1: The third inner most loop (ICNT2) will be decremented by 1. 2: The outer most loop (ICNT3) will be decremented by 1. 3: The entire TR will be allowed to complete.

Table 10-52. FLAGS Field Descriptions (continued)

Bit	Field	Description
16-23	CMD ID	The Command ID for the TR. This will be sent back with the response for the Channel controller to identify the specific TR. For a Direct TR this is the event number that will be generated based on the event trigger. This field is not supported on BCDMA.
24-31	Configuration Specific Flags	These are flag bits that can be specified by the specific UTC/ BCDMA configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific UTC/ BCDMA implementation.

The following sections expand on each of these fields.

10.1.2.3.4.1 Type: TR Type Field

The TR Type field gives the size of the TR and which fields are expected in the TR. Based on the type the number of words required to be sent to complete the TR can be decreased. The tables below show the minimum size for each TR as well if any fields will be treated as reserved.

Table 10-53. Transfer Request Minimum Size Type 0 One Dimensional Transfer

w 0	w 1	w 2	w 3	w 4	w 5	w 6	w 7	w 8	w 9	w 10	w 11	w 12	w 13	w 14	w 15
FLAGS	ICNT0	ADDR		RESERVED/NOT REQUIRED											

Table 10-54. Transfer Request Minimum Size Type 1 Two Dimensional Transfer

w 0	w 1	w 2	w 3	w 4	w 5	w 6	w 7	w 8	w 9	w 10	w 11	w 12	w 13	w 14	w 15

10.1.2.3.4.2 STATIC: Static Field Definition

The static field is used to allow for a single TR to be reused repeatedly. If the static bit is set then the UTC upon completing the specified TR will restart the TR with the same values as were in the initial TR. This TR will stay active until the channel is torn down. The initiating of a tear down of the channel will clear the STATIC field in the active TR and it will be removed from the channel FIFO after the TR completion.

Note

If a TR is submitted to a channel FIFO with the STATIC field set then any TRs placed in the FIFO after that will NOT be run until the teardown has been initiated.

10.1.2.3.4.3 EVENT_SIZE: Event Generation Definition

The UTC/BCDMA allows for an event to be generated at specified intervals for each TR. As the TR passes through the various loops in the addressing algorithm it will generate an event that then can be routed to other event receivers, such as other channels or interrupts to processors.

Table 10-64. Event Size Encoding

Value	Event Type	When it Fires
0	Completion Event	When the TR is complete and all status for the TR has been received.
1	ICNT1 Decrement	Type 0: When the last data transaction is sent for the TR. Type 1-11: When ICNT1 is decremented
2	ICNT2 Decrement	Type 0 – 1,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT2 is decremented
3	ICNT3 Decrement	Type 0 – 2,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT3 is decremented

10.1.2.3.4.4 TRIGGER INFO: TR Triggers

The TR allows for two different triggers to be set to allow for the data transfer to be prevented or halted through the process of transferring the data. The triggers are specified by selecting a type of trigger and the size of the transfer that can be allowed for the receipt of a given trigger. The triggers themselves in the UTC/BCDMA are collected on a per channel basis and for each of three sources. Anytime the trigger event is received the internal

counter is incremented. The trigger event will not be cleared until the specified block has started its transfer and it will **only** clear the triggers that are active.

CAUTION

This does allow for one TR in the channel to use global event 0 and the next TR to use global event 1. If while the first TR is running global event 0 can increment and will decrement each time the TR reaches the specified level. At the same time global event 1 will be incremented whenever it is received but it will not decrement until the next TR runs. If the global event 1 counter reaches overflows then an error event will NOT be generated but the event will be lost.

10.1.2.3.4.5 TRIGGERX_TYPE: Trigger Type

The trigger type sets the value of TR_TRIGX as shown in the addressing algorithm description. The TR_TRIGX value allows for the temporary halting of the TR until the expected event has been received. After the given loop has been entered the selected trigger will be decremented.

10.1.2.3.4.6 TRIGGERX: Trigger Selection

The TR is able to select up to 2 of 3 trigger sources for a given TR. The events can come from the dedicated local event on the UTC/BCDMA itself or from two assigned global events that come from the PSI-L interface on the UTC/BCDMA. The trigger counters are always enabled so that events can be received prior to the TR getting loaded. The trigger counters are only decremented when the trigger is active and the TR has scheduled the first transfer of the transaction.

10.1.2.3.4.7 CMD ID: Command ID Field Definition

The command ID is used as a unique identifier for the TR. The value is not used during the data transfer but is only used by the TR Completion Response to allow for hardware and software to identify the specific TR.

10.1.2.3.4.8 Configuration Specific Flags Definition

The configuration specific flags are specific to a given TR type. If a TR type does not require additional flags the field should be filled with 0's. Currently only Types 0-4 and Type 15 support the following configuration specific flags:

Table 10-65. Configuration Specific Flags

Bit	Field	Description
0	ISA	Indirect Source Address 0: Source address in TR is a directly usable pointer to the data 1: Source address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
1	IDA	Indirect Destination Address 0: Destination address in TR is a directly usable pointer to the data 1: Destination address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
2	SUPR_EVT	Suppress Event Output: 0 = Output events will be generated according to FLAGS.EVENT_SIZE field 1 = No output events will be generated for the duration of this TR execution This field is only valid on split and type 15 TRs (Type 0-3,15)
3	Reserved	Reserved for Future use.

Table 10-65. Configuration Specific Flags (continued)

Bit	Field	Description
6:4	EOL	<p>This field is only valid on split TRs (Type 0-3).</p> <p>On source (Read) split TRs, this field specifies whether or not the EOL delimiters should be produced on the Tx PSI-L bus. The encodings of this field for source split TRs is as follows:</p> <p>0 = SOL/EOL match SOP/EOP 1 = SOL/EOL boundaries are each ICNT0 bytes 2 = SOL/EOL boundaries are each ICNT0×ICNT1 bytes 3 = SOL/EOL boundaries are each ICNT0×ICNT1×ICNT2 bytes 4 = SOL/EOL boundaries are each ICNT0×ICNT1×ICNT2×ICNT3 bytes</p> <p>On destination (Write) split TRs, this field specifies how to handle EOL delimiters when they are encountered on the Rx (write) side of a TR. EOL delimiters can be produced from the Tx (read) side of a block copy operation or from a remotely paired peripheral when operating in split TR mode. The encodings of this field are as follows:</p> <p>0: Ignore EOL 1: Line length is icnt0 bytes. Clear any remaining ICNT0 bytes and increment ICNT1 by 1 2: Line length is icnt0×icnt1 bytes. Clear any remaining ICNT0/1 bytes and increment ICNT2 by 1 3: Line length is icnt0×icnt1×icnt2 bytes. Clear any remaining ICNT0/1/2 bytes and increment ICNT3 by 1 4: Line length is icnt0×icnt1×icnt2×icnt3 bytes. Move on to next TR 5-7: RESERVED</p>
7	EOP	<p>This TR should generate an EOP on the streaming interface for any downstream packet oriented consumers to denote that a 'packet' of data is complete</p> <p>0: No EOP flag will accompany the last PSI-L data phase associated with transfers from this TR 1: On egress the DMA will set the EOP flag coincident with transferring the last of the data for this TR. If the TR data does not complete an entire PSI-L data phase then the remaining bytes in the data phase will be skipped and the internal FIFO pointer will be updated to begin packing new data on a new data phase boundary.</p>

10.1.2.3.5 TR Address and Size Attributes

The fields described below all describe the data transfer that needs to be made as described in the Linear Memory Addressing Block Move Algorithm.

10.1.2.3.5.1 ICNT0

The ICNT0 is the number of elements to transfer in the inner loop of the TR. If the TR type does not contain a FMTFLAGS field then this count is assumed to be the number of bytes to transfer. If the FMTFLAGS field is included in the types then the number of bytes to be transferred will be ICNT0 times the Element size rounded up to the nearest byte.

10.1.2.3.5.2 ICNT1

The ICNT1 field is the loop count for the second innermost loop count as defined in the Addressing algorithm.

10.1.2.3.5.3 ADDR

The address location is the initial address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register.

While the ADDR field is 64 bits wide, the usable extent of the address on a K3 system is 48 bits of absolute offset plus a 4-bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the ADDR field is given in [Table 10-66](#).

Table 10-66. ADDR Field Format

Bits	Subfield	Description
63:52	Reserved	Reserved

Table 10-66. ADDR Field Format (continued)

Bits	Subfield	Description
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.
47:0	Address	The 48-bit source or source/destination starting address for the transfer. This address will be interpreted to be either physical, virtual, or intermediate physical based on the tx_atype or rx_atype field in the DMA Tx/Rx channel's Configuration Register. The actual width implemented for the address field on any given DMA instance may be adjusted to the needs of each specific K3 SoC. 48 bits is just the maximum size which is envisioned to be supported. Some systems may have address widths as low as 32 or 36 bits. The HW implementation may choose to provide address width configurability in order to reduce costs

10.1.2.3.5.4 DIM1

This is the offset of the address from the initial address for the first access of the second loop. This will be added to the address from the loop before. This is a signed value so that the address can be both above and below the initial address.

10.1.2.3.5.5 ICNT2

This is the count for the third innermost loop in the addressing algorithm.

10.1.2.3.5.6 ICNT3

This is the count for the outermost loop in the addressing.

10.1.2.3.5.7 DIM2

This is the offset of the address from the initial address to the next address in the third innermost loop. This is a signed vales so that the address can be both above and below the previous address.

10.1.2.3.5.8 DIM3

This is the offset of the address from the initial address to the next address in the outermost loop. This is a signed values so that the address can be both above and below the previous address.

10.1.2.3.5.9 DDIM1

This is the offset of the destination address from the initial destination address for the first access of the second loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

10.1.2.3.5.10 DADDR

The destination address location is the initial destination address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register

While the DADDR field is 64 bits wide, the usable extent of the address on a K3 system is 48 bits of absolute offset plus a 4 bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the DADDR field is given as follows:

Table 10-67. DADDR Field Format

Bits	Subfield	Description
63:52	Reserved	Reserved

Table 10-67. DADDR Field Format (continued)

Bits	Subfield	Description
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.
47:0	Address	The 48-bit starting destination address for the transfer. This address will be interpreted to be either physical, virtual, or intermediate physical based on the tx_atype field in the DMA Tx channel's Configuration Register. The actual width implemented for the address field on any given DMA instance may be adjusted to the needs of each specific K3 SoC. 48 bits is just the maximum size which is envisioned to be supported. Some systems may have address widths as low as 32 or 36 bits. The HW implementation may choose to provide address width configurability in order to reduce costs

10.1.2.3.5.11 DDIM2

This is the offset of the destination address from the initial destination address for the first access of the third loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

10.1.2.3.5.12 DDIM3

This is the offset of the destination address from the initial destination address for the first access of the outer loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

10.1.2.3.5.13 DICNT0

This is the number of elements to use in the destination if the TR is repacking the data. This number reflects the number of elements to be transferred.

10.1.2.3.5.14 DICNT1

This is the number of times to execute the second loop to use in the destination transfer.

10.1.2.3.5.15 DICNT2

This is the number of times to execute the third loop to use in the destination transfer.

10.1.2.3.5.16 DICNT3

This is the number of times to execute the fourth loop to use in the destination transfer. The value of DICNT0 × DICNT1 × DICNT2 × DICNT3 must equal ICNT0 × ICNT1 × ICNT2 × ICNT3. If any of the values are zero they are NOT included in the multiplication.

10.1.2.3.6 FMTFLAGS

The format flags are used to specify special formatting of the transfer. [Table 10-68](#) shows the definition of the sub-fields in the FMTFLAGS field.

Table 10-68. Transfer Request Template FMTFLAGS Field

31										16
AMODE SPECIFIC										
15	14	13	12	11	8	7	4	3	2	0
RESERVED		SECTR		DFMT		ELTYPE		DIR	AMODE	

The flags field fills in the remaining details about the stream, as follows:

Table 10-69. FMTFLAGS Field Descriptions

Bit	Field	Description
16-31	AMODE SPECIFIC	This 16-bit field is defined based on the addressing mode used as selected in the AMODE field.
14-15	Reserved	Reserved for Future use
12-13	SECTR	A secondary TR is required and the format of the secondary TR.
8-11	DFMT	The data reformatting function to apply in the middle of the TR
4-7	ELTYPE	The type of element and its size and potential output size for the innermost loop. If this is not specified in the TR then a byte is the assumed element.
3	DIR	For a block type transfer does the addressing mode apply for source or destination. The other one will use linear. If it is a non-block type TR then this field is ignored
0-2	AMODE	The Addressing Mode of TR that is being sent 0: Linear Addressing 1: Circular Addressing 2-7: Reserved for future use

10.1.2.3.6.1 AMODE: Addressing Mode Definition

The addressing mode field allows for different algorithms to be used other than the default linear addressing mode described in the Addressing algorithm.

10.1.2.3.6.1.1 Linear Addressing

This is the addressing that is used if there is no FMTFLAGS field in the TR.

10.1.2.3.6.1.2 Circular Addressing

Circular addressing modifies how the UTC performs address arithmetic so that addresses remain within a power-of-2 sized window. Circular addressing works by holding upper address bits constant during an address update, while allowing the lower address bits to vary. This contrasts with the default—linear addressing—which allows all of the address bits to vary.

The UTC TR provides address mode selection for each level of loop nest. Each level can select between linear addressing or circular addressing with one of two circular block sizes.

Conceptually, selectable addressing mode support replaces all address arithmetic with a function similar to the following.

```
enum addr_mode_t
{
    LINEAR, // Linear addressing mode
    CIRC0, // Circular addressing with block size 0
    CIRC1, // Circular addressing with block size 1
};
uint64_t circ_mask_0; // Circular addressing mask for block size 0
uint64_t circ_mask_1; // Circular addressing mask for block size 1
uint64_t address_add( uint64_t base, int32_t offset, addr_mode_t mode )
{
    uint64_t new_addr = base + offset;
    if ( mode == LINEAR )
        return new_addr;
    // Look up address mask based on selected circular buffer size.
    // Mask contains 1s for bits that remain fixed, and 0s elsewhere.
    uint64_t addr_mask = mode == CIRC0 ? circ_mask_0 : circ_mask_1;
    return ( base & addr_mask ) | ( new_addr & ~addr_mask );
}
```

The address_add primitive then takes the place of plain addition for all TR address computations in this mode. The following example illustrates address_add.

```
for ( i3 = 0; i3 < ICNT3; i3++)
{
    ptr3 = ptr; // save current position before entering next level
```

```
for (i2 = 0; i2 < ICNT2; i2++)
{
    ptr2 = ptr; // save current position before entering next level
    for (i1 = 0; i1 < ICNT1; i1++)
    {
        ptr1 = ptr; // save current position before entering next level
        for (i0 = 0; i0 < ICNT0; i0++)
        {
            fetch( ptr, ELEM_BYTES );
            ptr = address_add( ptr, ELEM_BYTES, addr_mode_0 );
        }
        // Update based on saved pointer for this level
        ptr = address_add( ptr1, DIM1, addr_mode_1 );
    }
    // Update based on saved pointer for this level
    ptr = address_add( ptr2, DIM2, addr_mode_2 );
}
// Update based on saved pointer for this level
ptr = address_add( ptr3, DIM3, addr_mode_3 );
}
```

The values for the circular addressing can be selected by using the 16 bits of the AMODE specific Field as described in the AMODE SPECIFIC Addressing Mode Field.

10.1.2.3.6.2 DIR: Addressing Mode Direction Definition

This field is used if the TR TYPE specifies the TR is for a block move if the addressing mode specified in the AMODE field applies to the source addressing or the destination addressing. A value of 0 means the source addressing will use the method selected in the AMODE field and the destination address will use the default linear addressing. A value of 1 means that the destination addressing will use the method selected in the AMODE field and the source addressing will use the default linear addressing. If the TR TYPE is not a block transfer then this field will be ignored.

10.1.2.3.6.3 ELTYPE: Element Type Definition

The Element Type field allows the user to specify the basic unit that is used for the innermost loop. If the FMTFLAGS field is not present then the UTC will assume a value of 0 which is a byte size element. The element type also allows for the some expansion or contraction of the element size from the source to the destination.

Table 10-70. ELTYPE Encoding

Encoding	Definition
0	1 Byte per element
1	1.5 Bytes(12 bits) per element
2	2 Bytes per element
3	3 Bytes per element
4	4 Bytes per element
5	8 Bytes per element
6	16 Bytes per element
7	32 Bytes per Element
8	1 Byte per Input Element 2 Bytes per Output Element
9	1.5 Bytes per Input Element 2 Bytes per Output Element
10	2 Bytes per Input Element 1 Byte per Output Element
11	2 Bytes per Input Element 1.5 Bytes per Output Element
12-15	Reserved for Future Use

10.1.2.3.6.4 DFMT: Data Formatting Algorithm Definition

The Data Formatting Algorithm is a method to specify a manipulation of the data between how it is read and how it is sent. If the TR Type is not a block operation TR then this field will be ignored. Otherwise [Table 10-71](#) specifies what the encodings meaning.

Table 10-71. DFMT Encoding

Encoding	Definition
0	No Change. The input and output block will remain identical
1	Constant Copy. The input block is not an address but the address is up to a 64-bit constant
2	Transpose. The inner and second most inner loops are swapped so that rows become columns and columns become rows.
3	Reverse. The data in the row will be accessed in the reverse of the order that it is read. So the largest address read in a row will be the first address written.
4	Reverse Transpose. The data will be written in the reverse of the order that is read as well as transposed. So the largest address read in a row will be the address in the first line being written out.
5-15	Reserved for Future Use

10.1.2.3.6.5 SECTR: Secondary Transfer Request Definition

The Secondary Transfer Request field allows the user to specify if the TR requires an additional TR located in memory. If this is used then the address given in the TR is the pointer to the Secondary TR and the secondary TR will have a pointer to the actual final TR.

Table 10-72. Secondary Transfer Request Format

Encoding	Size	Definition
0	0	The TR does not require a secondary TR
1	64 bytes	The TR will fetch a 64-byte Secondary TR prior to the initial read.
2	128 bytes	The TR will fetch a 128-byte Secondary TR prior to the initial read.
3	TBD	Reserved for future use

10.1.2.3.6.5.1 Secondary TR Formats

The secondary TR format is a TR that is fetched by the UTC when it is executing a TR to fill in additional information that does not fit in the original TR. It is not included in the standard TR as the information required in it is not required until execution time and is kept separate so the Channel FIFO space can be minimized. The first four words of the Secondary TR are always the real start address of the transfer followed by a Secondary TR Flags field. The remaining words in the secondary TR are defined by the Secondary TR TYPE from the Secondary TR Flags field.

Table 10-73. Secondary Transfer Request Template for 64-Byte Secondary TR

Type Specific	SECONDARY TR FLAGS		ADDR

10.1.2.3.6.5.2 Secondary TR FLAGS

The next diagram expands the generic 32-bit Secondary TR FLAGS field. The numbers above each field here indicate bit numbers within the field.

Table 10-74. SECONDARY TR FLAGS Field Definition

31	SEC_TR_TYPE_SPECIFIC			16
15	4	3	0	

Table 10-74. SECONDARY TR FLAGS Field Definition (continued)

SEC_TR_TYPE_SPECIFIC	SEC_TR_TYPE
----------------------	-------------

The flags field fills in the remaining details about the stream, as follows:

Table 10-75. FLAGS Field Descriptions

Bit	Field	Description
31-4	SEC_TR_TYPE_SPECIFIC	Reserved for the SEC_TR_TYPE to define based on its requirements
3-0	SEC_TR_TYPE	The TYPE of SEC_TR 0: Multiple Buffer Interleave 1-15: Reserved

The following sections expand on each of these fields.

10.1.2.3.6.5.2.1 SEC_TR_TYPE: Secondary TR Type Field

The Secondary TR Type field is used to state the purpose of the secondary TR. This can be defined

10.1.2.3.6.5.2.2 Multiple Buffer Interleave

The multiple buffer interleave is used to have a single TR plus Secondary TR that can define a fetch where a single line is selected from multiple buffers and then sent as a single buffer. This can be used along with transpose mode of the data to present data in slices optimal for processing the same algorithm on different data sets at the same time. An example of this can be seen in [Figure 10-4](#).

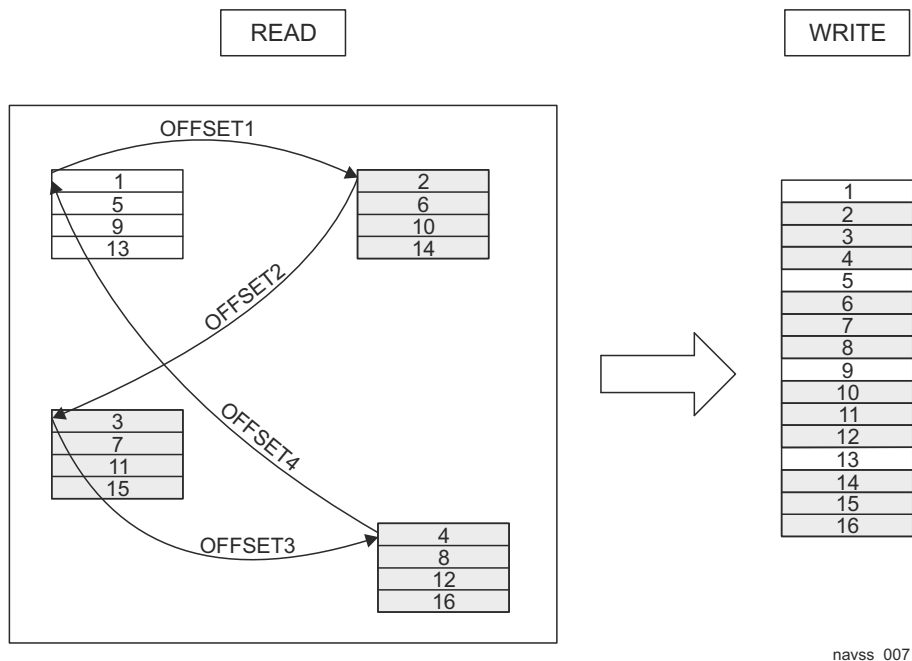

Figure 10-4. Example of Multiple Buffer Interleaving Read with 4 Offsets

The case above provides the ability to minimize the number of TRs submitted to make the transfer but the interleaved Read main advantage comes when used with the transpose mode enabled. [Figure 10-5](#) shows the advantage of the interleaved mode along with the transpose mode to allow for maximum size transfer on both read and write transactions.

navss_008

Figure 10-5. Example of Interleaved Read with 4 Offsets and Transpose Enabled

As the figure shows the data that is written out now contains one element from each block of memory and can be read in directly to processing units.

Table 10-76. SECONDARY TR FLAGS Field Definition

RESERVED	SECONDARY TR FLAGS	ADDR	

Multiple Buffer Interleave will work by setting the SECTR field in the TR presented to the channel to be either 64 or 128 bytes depending on the number of offsets required. An offset number of 4 or 8 will require 64 bytes while 16 offsets will require 128 bytes. When the channel becomes active it will see that the SECTR field is nonzero and fetch the SECTR of the size specified. The first access from the channel will be a read of the secondary TR as specified in the address field of the TR. Upon receiving the Secondary TR the channel will parse the type field and seeing that it is a Multiple Buffer interleave will load the offset index fields for the channel. Additionally it will load the ADDRESS field from the secondary TR into the Address of the actual TR to allow it to process as normal.

The first address fetch will then be to this SEC_TR_ADDRESS. After finishing the inner loop the next address will be SEC_TR_ADDRESS + OFFSET0.

Note

ICNT1 should be equal to the height of the transfer blocks times the number of offsets.

10.1.2.3.6.6 AMODE SPECIFIC: Addressing Mode Field

The AMODE Specific Fields are defined based upon the Addressing Mode being used as specified in AMODE: Addressing Mode Definition.

10.1.2.3.6.6.1 Circular Address Mode Specific Flags

If the circular addressing mode is selected in AMODE the definition of the upper 16 bits of the FMTFLAGS field are used to select the type of addressing for each entry in the loop and to define 2 unique masks that can be used for the circular buffering.

The following example code shows the method used to compute the masks referred to by the address_add function described in the 'Address Arithmetic with Selectable Linear/Circular Addressing Modes' section.

```
// Circular addressing masks.
// 1 bits in the mask indicate address bits that remain fixed.
// 0 bits in the mask indicate address bits that are allowed to vary.
uint64_t circ_mask_0; // mask for circular addressing block 0
uint64_t circ_mask_1; // mask for circular addressing block 1
void compute_circular_address_masks( int cbk0, int cbk1 )
{
    int block_size_0 = cbk0 + 9; // power-of-2 of block size in bytes
    int block_size_1 = cbk0 + cbk1 + 10;
    if ( block_size_1 > 31 ) block_size_1 = 32; // clamp to 4GB maximum size
    circ_mask_0 = (~0ULL) << block_size_0;
    circ_mask_1 = (~0ULL) << block_size_1;
}
```

Example 3-4 Circular Address Mask Computation

24-25	AM0	The address mode to use with ICNT0 loop
26-27	AM1	The address mode to use with ICNT1 loop
28-29	AM2	The address mode to use with ICNT2 loop
30-31	AM3	The address mode to use with ICNT3 loop

10.1.2.3.6.6.1.1 CBK0 and CBK1: Circular Block Size Selection

The CBK0 and CBK1 fields set the circular block sizes for circular addressing. CBK0 directly determines the circular block size for block 0. CBK1 combines with CBK0 to determine the circular block size for block 1. Specifically, the streaming engine sets block 1's size according to $CBK0 + CBK1 + 1$. Therefore, circular block 1 is always larger than circular block 0.

The following table illustrates the resulting valid block sizes for circular block 0 and 1. For circular block 0, the use the value of CBK0 directly. Circular block 0 supports block sizes ranging from 512 bytes to 16M bytes. For circular block 1, use the value of $CBK0 + CBK1 + 1$. Circular block 1 supports sizes ranging from 1K bytes to 4G bytes.

Table 10-81. Circular Block Size Decoding

Encoded Block Size	Decoded Block Size	Encoded Block Size	Decoded Block Size	Encoded Block Size	Decoded Block Size	Encoded Block Size	Decoded Block Size
0	512	8	128K	16	32M	24	Reserved
1	1K	9	256K	17	64M	25	Reserved
2	2K	10	512K	18	128M	26	Reserved
3	4K	11	1M	19	1M	27	Reserved
4	8K	12	1M	20	1M	28	Reserved
5	16K	13	1M	21	1M	29	Reserved
6	32K	14	1M	22	1M	30	Reserved
7	64K	15	1M	23	1M	31	Reserved

10.1.2.3.6.6.1.2 Amx: Addressing Mode Selection

The fields AM0 through AM3 control the addressing modes for each of the 4 dimensions. The UTC supports the following addressing modes:

Table 10-82. AMX Address Mode Selection Encoding

AMX	Meaning
00b	Linear addressing
01b	CKB0 (Circular Buffer 0 is used)
10b	CKB1 (Circular Buffer 1 is used)
11b	Reserved

Each dimension has its own addressing mode, independent of the other dimensions. This permits any mixture of linear and circular addressing among the 4 dimensions.

When a given dimension selects linear addressing, the UTC uses unmodified two's complement arithmetic to update addresses for that loop level.

When a given dimension selects circular addressing via CBK0 or CBK1, the UTC uses the circular address arithmetic described above in the Address Arithmetic with Selectable Linear/Circular Addressing Modes section.

10.1.2.3.6.7 Cache Flags

If the TR type is a cache warm the format flags field is replaced with a Cache Flags field.

[Table 10-83](#) shows the breakdown of the 32 bit Cache Flags field.

Table 10-83. Transfer Request Template CACHEFLAGS Field

31	24	23	16
CACHE OPERATION		RESERVED	
15	8	7	0
RESERVED		CACHE ID	

The flags field fills in the remaining details about the stream, as follows:

Table 10-84. FMTFLAGS Field Descriptions

Bit	Field	Description
24-31	Cache Operation	0: Prewarm the Cache 1: Prewarm MMU 2-255: Reserved for future use
8-23	Reserved	Reserved for future use
0-7	Cache ID	The Cache number to perform the operation on. 0-254: Cores. 255: L3 Cache

10.1.2.4 Transfer Response Record

Upon completing a TR the UTC will send back a TR Response to the UDMA-C, and the BCDMA will send back a TR Response. The UTC/ BCDMA TR response format is a single 32-bit word as shown in [Table 10-85](#).

Table 10-85. Transfer Request Response Template STATUS FLAGS Field

31	24	23	16
CONFIGURATION SPECIFIC STATUS		CMD ID	
15	8	7	0
RESERVED		STATUS_INFO	STATUS_TYPE

Table 10-86. STATUS FLAGS Field Descriptions

Bit	Field	Description
31:24	Configuration Specific Flags	These are flag bits that can be specified by the specific UTC/ BCDMA configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific UTC/ BCDMA implementation. For UDMA/ BCDMA channels which are capable of interfacing to endpoint peripherals (or via a PDMA) the format of these flags are as follows: 31:28 error_flags – the error_flags field as is provided across PSI-L 27:24 ps_flags – the ps_flags field as is provided across PSI-L
23:16	CMD ID	The Command ID for the TR. This will be sent back with the response for the Channel controller to identify the specific TR. This field is not supported on BCDMA.
15:8	Reserved	Reserved for Future use
7:4	STATUS_INFO	Information that is unique based on the STATUS_TYPE returned
3:0	STATUS_TYPE	The completion status of the TR.

10.1.2.4.1 STATUS Field Definition

The Status field is made up of two sub-fields STATUS_TYPE and STATUS_INFO. A value of 0 means it completed as requested any other value means an error has occurred. [Table 10-87](#) states the legal STATUS_TYPES and the use of the STATUS_INFO in each case.

Note

In all cases the status intends to show the first error received for the TR but due to pipelining and the state machine architecture this might not always be the case. In all cases an error will be generated if the TR does not complete successfully but the error code reported might not be the actual first error. For instance, if a short line is seen in a packet and the packet is also a short frame in some cases the error code will be short packet and not short line even though a short line was the actual first error.

10.1.2.4.1.1 STATUS_TYPE Definition

The STATUS_TYPE field is used to determine what type of status is being returned. Depending on the type of Status it might additionally have information in the STATUS_FIELD to give more details about the specific reason why the status was returned.

Table 10-87. STATUS_TYPE Encoded Values

Value	Error Type	Completion	STATUS FIELD Definition
0	None	Complete	None
1	Transfer Error	None to Partial	CBA Non-Complete Status Received
2	Aborted Error	None to Partial	None
3	Submission Error	None	Submission Error Type
4	Unsupported Feature	None	Feature Type
5	Transfer Exception	Partial	Exception Type
6	Teardown Flush	None	None
7-15	Reserved	Unknown	Reserved

10.1.2.4.1.1.1 Transfer Error

A transfer ERROR occurs anytime that one of the CBA transactions performed by the UTC/ BCDMA returns a status other than complete. The UTC/ BCDMA may continue the transfer or may abort the transfer and return back to an IDLE state. Once the transfer is finished (aborted or complete) the UTC/ BCDMA will send back the TR Response with the STATUS TYPE of Transfer Error. The STATUS FIELD will contain the 3 bit CBA Status field the upper bit specifies if it was a read status (1) or a write status (0).

10.1.2.4.1.1.2 Aborted Error

An aborted error occurs if the PSI-L interface asserts the drop signal prior to the completion of the TR. The UTC/ BCDMA will return back to an IDLE state and send back the TR Response with the STATUS TYPE. If the UTC/ BCDMA receives a transfer error after receiving the abort the transfer error should be reported instead of the Abort Error.

10.1.2.4.1.1.3 Submission Error

A submission error is returned for a TR that is received that cannot be run. The STATUS_INFO field specifies the type of submission errors.

Table 10-88. Submission Error STATUS_INFO Encodings

Value	Submission Error Type
0	ICNT0 was 0
1	Channel FIFO was full when TR received
2	Channel is not owned by the submitter. Either CC submitting to Direct or Direct submitting to a CC channel
3-4	Reserved
5	Bad descriptor type
6-15	Reserved

10.1.2.4.1.1.4 Unsupported Feature

An unsupported feature error is returned for a TR that is received that cannot be run because it specifies a feature that is optional and not supported by the UTC/ BCDMA that received the TR. The STATUS_INFO

specifies the feature that was not supported. If it specifies multiple features that were not supported the UTC/BCDMA implementation can determine which type it wants to return

Table 10-89. Unsupported Feature STATUS_INFO Encodings

Value	Submission Error Type
0	TR Type not supported
1	STATIC not supported
2	EOL not supported
3	CONFIGURATION SPECIFIC not supported
4	AMODE not supported
5	ELTYPE not supported
6	DFMT not supported
7	SECTR not supported
8	AMODE SPECIFIC Field not supported
9-15	Reserved

10.1.2.4.1.1.5 Transfer Exception

A transfer exception is returned for a TR that completed but experienced a known exception during reception. The STATUS_INFO field specifies the type of transfer exception that was encountered.

Table 10-90. Transfer Exception STATUS_INFO Encodings

Value	Transfer Exception Type
0	EOP on incoming data stream was encountered prematurely (short packet)
1	EOP on incoming data stream was encountered late (long packet)
2	The incoming data EOL was encountered prematurely (short line)
3	The incoming data EOL was encountered late (long line)
4-15	Reserved

10.1.2.4.1.1.6 Teardown Flush

Split mode UTC Rx channels (write channels) can respond with a teardown flush in the case that they have received a teardown message, all data has been transferred, and TRs have been prefetched (in anticipation of more data being received). In this case, the UTC will simply return the prefetched TR to the completion queue with the status type set to teardown flush.

10.1.2.5 Channels

Each DMA controller instance contains one or more channels. A channel represents a single thread of strongly ordered operations whose purpose is to move data from one interface to another. Operations between channels are orthogonal and have no assumption of ordering but operations within a channel must be completed in order. The DMA controller uses time division multiplexing to allow work from channels to momentarily use shared data transfer units and data paths.

10.1.2.6 Flows

Each DMA channel will provide one or more flows which allow communication with one or more SW hosts. Each flow contains a single queue pair implemented within a shared circular buffer (ring) in memory. One queue provides uni-directional communication from SW to the DMA while the other queue provides uni-directional communication from the DMA back to SW. Flows are intended to allow traffic which is produced or consumed by a different Host SW process or traffic which is on different priorities to share a single physical DMA channel. A DMA channel will perform time division multiplexing between flows on specific work boundaries. Once a channel is in work on a specific flow, that entire unit of work will be completed before allowing work from a different flow to begin.

10.1.2.7 UDMA/UTC Queues

Queues are used to hold either values or references that need to be passed between components in the system. These components could be software or hardware. Queues are implemented by the Ring Accelerator module.

10.1.2.7.1 Queue Types

10.1.2.7.1.1 Transmit Queues (Pass By Reference)

Tx channels use packet queues referred to as “transmit queues” to store the packets that are waiting to be transmitted. Tx channels require one or more packet queues dedicated to each transmit channel for this purpose. Multiple queues per channel may facilitate Quality of Service (QoS) in some applications. Pass by reference Tx Queues only pass a pointer to a descriptor (and optional information like the packet length). Pass by reference Tx Queues can contain pointers to Host, Monolithic, or TR packet descriptors (depending on Tx channel mode configuration).

10.1.2.7.1.2 Transmit Queues (Pass By Value)

Pass by value Tx Queues are used for direct Transfer Request submission on Tx channels which are configured for 3rd party pass by value mode. Entries on a pass by value Tx Queue include the entire Transfer Request message and optional protocol specific information. Pass by value queues are only supported by the Ring Accelerator.

10.1.2.7.1.3 Transmit Completion Queues (Pass By Reference)

Tx channels also use packet queues referred to as “transmit completion queues” to return packets to the host after they are transmitted. The number of queues required by the channel or system for this purpose is driven by the requirements of the garbage collection software within the driver. Tx completion queues are only used when the packet descriptor indicates that the packet should be returned to a queue instead of directly recycling the descriptors to their queues of origin. Pass by reference Tx Completion Queues only pass a pointer to a descriptor.

10.1.2.7.1.4 Transmit Completion Queues (Pass By Value)

Pass by value Tx Completion Queues are used to pass the Transfer Response messages that are returned when a channel is configured in 3rd Party pass by value mode. Entries on a pass by value Tx Completion Queue include the Transfer Response message. Pass by value queues are only supported by the Ring Accelerator.

10.1.2.7.1.5 Receive Queues

Rx ports use packet queues referred to as “receive queues” to forward completed received packets to the host or another peer port entity. Rx ports may be configured in various ways to forward the received packets onto any number of receive queues. Rx ports may choose to queue their receive packets based strictly on Rx channel, protocol type, priority, direct forwarding requirements (i.e. to another ports Tx queue) or any combination of these and this is application specific. In many cases the receive queue is in fact also a transmit queue for another peer entity. It is just a matter of semantics with respect to which port is referenced in the system.

10.1.2.7.1.6 Free Descriptor Queues

Rx ports use queues referred to as “free descriptor queues” to allocate empty monolithic descriptors. The entries on the Free Descriptor Queues do not have any buffers attached as buffers are allocated as part of the descriptor for monolithic type packets.

10.1.2.7.1.7 Free Descriptor/Buffer Queues

Rx ports use queues referred to as “free descriptor/buffer queues” to allocated empty host type descriptors. The entries on the Free Descriptor/Buffer Queues have pre-attached empty buffers whose size and location are described in the “original buffer information” fields in the descriptor. The host is required to allocate both the descriptor and buffer and pre-link them prior to adding a descriptor to a free descriptor/buffer queue.

10.1.2.7.2 Ring Accelerator Queues Implementation

Work packets which are stored in a pass by reference queue managed by the Ring Accelerator are shown in [Figure 10-6](#).

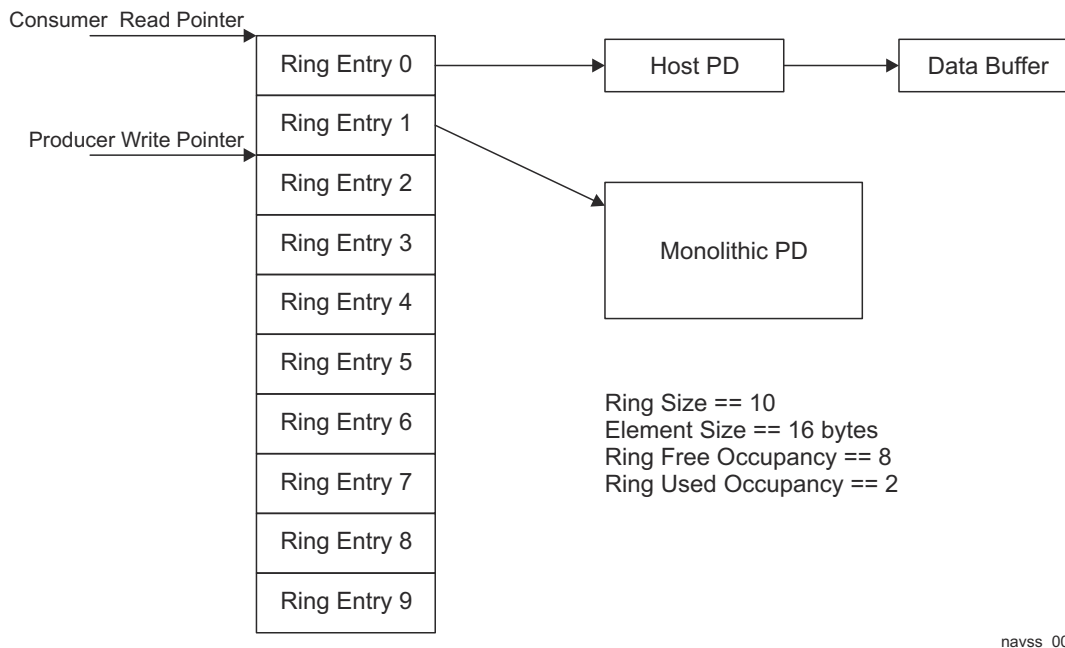

Figure 10-6. Ring Accelerator Based Queue Structure

Work packets stored in a pass by value queue managed by the Ring Accelerator are shown in [Figure 10-7](#).

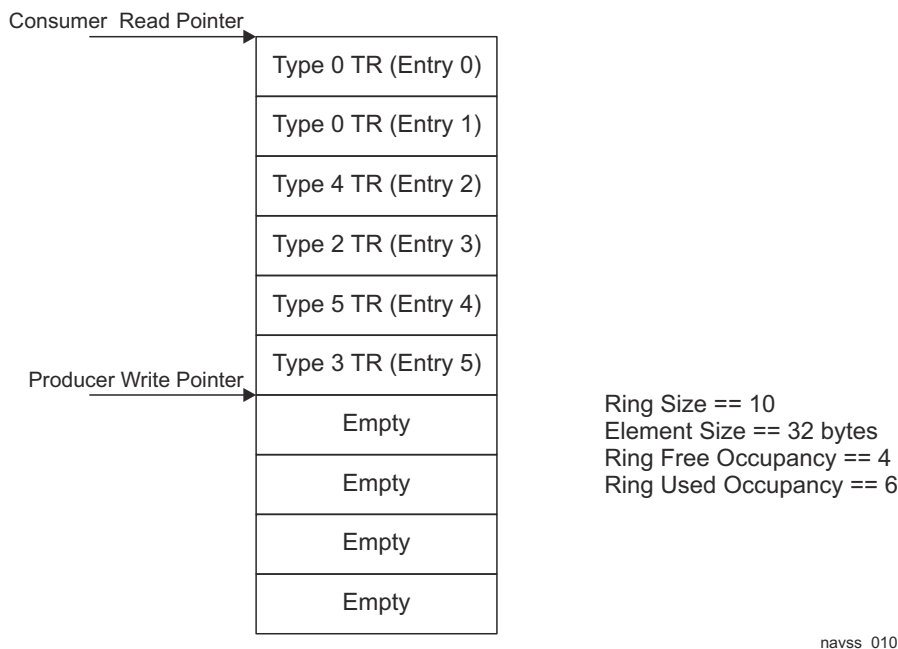

Figure 10-7. Ring Accelerator Based Direct Transfer Request Queue Structure

10.1.2.8 BCDMA Queues

Queues are used to hold either values or references that need to be passed between SW and HW components in the system. Queues are implemented in the BCDMA module using memory mapped rings. Each ring is comprised of a single contiguous memory block which contains an array of elements. Each element is 8 bytes. The size of the ring is selectable from 1 entry up to 64K entries with single entry granularity. Each ring is used to implement a forward and a reverse queue which share the same data elements but which have independent pointers and occupancies. The forward queue is used to pass work from SW to HW and the reverse queue is used to pass completed work back from HW to SW. A doorbell MMR is provided per ring to allow SW to add elements to the forward queue. A separate doorbell MMR is provided per ring to allow SW to acknowledge the

popping of elements from the reverse queue. An occupancy MMR is provided for the reverse queue so that SW can know how many entries are currently completed. Entries are returned on the reverse queue in the exact same order and in the exact same index as the work was provided on the forward queue and because of this, the DMA controllers do not actually modify the ring entry for completion operations (the only exception being for acknowledgement of a teardown operation). Completion is indicated by incrementing of the reverse occupancy only.

10.1.2.8.1 Queue Types

10.1.2.8.1.1 Transmit Queues

Tx channels use packet queues referred to as “transmit queues” to store the packets that are waiting to be transmitted. Tx Queues only pass a pointer to a descriptor. For the BCDMA, pass Tx Queues contain a pointer to a TR packet descriptor. Transmit Queues are implemented as the forward queue on the shared ring structure for a Tx flow.

10.1.2.8.1.2 Transmit Completion Queues

Tx channels also use packet queues referred to as “transmit completion queues” to return packets to the host after they are transmitted. A Tx Completion Queue is provided for each Tx Queue. The DMA controllers do not actually write anything back to completion queues (except for a teardown acknowledgement) but instead just increment the reverse occupancy. Transmit completion queues are implemented as the reverse queue on the shared ring structure for a Tx flow.

10.1.2.8.1.3 Free Descriptor / Buffer Queues

Free descriptor/buffer queues pass an empty list of pre-chained descriptors, each pointing to a single buffer, from SW to the DMA to use for receiving incoming packets. Free Descriptor/Buffer Queues are implemented as the forward queue on the shared ring structure for an Rx flow.

10.1.2.8.1.4 Receive Queues

Rx queues pass a packet which has been received from the DMA back to the SW. Receive queues are implemented as the reverse queue on the shared ring structure for an Rx flow.

10.1.2.8.1.5 Ring Based Queues Implementation

Work packets which are stored in a queue are shown in the following diagram:

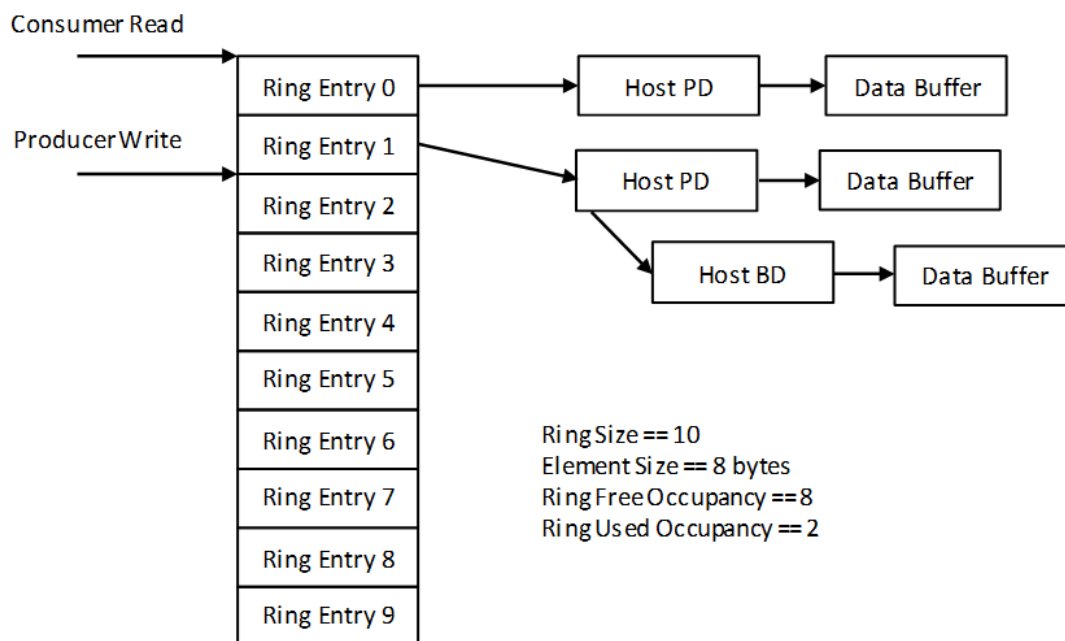

Figure 10-8. Ring Based Queue Structure

10.1.3 Operational Description

10.1.3.1 Resource Allocation

Queues, rings, memory, interrupts, DMA channels, and flow table entries are shared resources within the data movement architecture and their ownership and use must be managed in order to provide stable, safe, and secure operation. The K3 platform provides channelized firewalls which can be used to protect arrayed resources (like queues, rings, channel control registers, etc.) from unwanted/unauthorized use as well as restricted access to the firewall configurations themselves. It is outside the scope of this document to define how the resource management system functions but it is assumed that all of these resources are isolate-able and secure-able.

10.1.3.2 UDMA Ring Accelerator Operation

10.1.3.2.1 Queue Initialization

The base address, size and element size for each ring must be initialized via the provided registers prior to using the ring. Ring initialization is typically done only on channel setup as once initialized the rings can be used indefinitely. Optionally, an internal initialization machine may be provided to set default values for the ring address, size, and element sizes. This capability enables the rings to be used during boot without configuration. Not all rings will necessarily support this feature and if required must be configured at design time. Whether or not this machine is present, all rings are able to be re-configured at run time through the provided registers.

10.1.3.2.2 Queuing packets (Exposed Ring Mode)

Queuing of packets onto a packet queue using the Ring Accelerator is logically equivalent but requires a different set of transactions from queuing packets in queue mode. The producer (entity which is going to queue an entry onto the ring) maintains a current write pointer and a free entry occupancy count for each ring it controls. To queue an entry the producer will write the entry contents (typically a pointer to the Packet Descriptor along with optional sideband information) to the memory location pointed to by the current write pointer and will decrement its free entry occupancy. After the producer has confirmed that the data has actually landed in memory, it will then write to the doorbell register for the ring to increment the used occupancy count for the ring.

More than one entry can be queued with a single doorbell write as the entry count in the doorbell write indicates how many entries have been queued.

10.1.3.2.3 De-queuing packets (Exposed Ring Mode)

The consumer (entity which is going to de-queue an entry from the ring) maintains a current read pointer and a used entry occupancy count for each ring it controls. To de-queue an entry the consumer will read the entry contents from the memory location pointed to by the current read pointer and will decrement its used entry occupancy. The consumer will then write to the doorbell register for the ring to increment the free occupancy count for the ring.

10.1.3.2.4 Queuing packets (Queue Mode)

To queue an entry the producer will write the entry contents (typically a pointer to the Packet Descriptor along with optional sideband information) to the Proxy thread location allocated by the system, with the queue offset for the queue to access. The write within the queue offset to the completion offset (final byte of the data) will cause the entire data to be written to the RA queue.

10.1.3.2.5 De-queuing packets (Queue Mode)

To de-queue an entry the consumer will read the entry contents from the Proxy thread location allocated by the system, with the queue offset for the queue to access. The proxy will read the entry from the RA queue. The consumer can then read the entire contents of the entry. The completion offset (final byte of the data) will cause the proxy to flush that entry (so that it can fetch a new one from the RA upon the next read).

10.1.3.3 UDMA Internal Transmit Channel Setup (All Packet Types)

After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Tx Port DMA State. The host initializes the channel Tx Port DMA State by writing to the Tx Channel Configuration Register A. The Host may choose to write the enable bit in the Tx Channel Configuration Register A at the same time or after it has written all of the channel parameters but note that every write to the Tx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

It should be noted that very little configuration information is required for a UDMA Tx channel compared to previous versions of UDMA. This is because UDMA has transitioned to a full modeless model for channel operation where each packet descriptor specifies the descriptor type, packet type, and the packet return parameters. Packet queues in UDMA may include combinations of host and monolithic descriptors in any order.

After a Transmit channel has been set up, packets can be added to the Queues for the channel to begin the transmit operation. The following sections describe how the transmit operations are performed for the various descriptor types.

10.1.3.4 UDMA Internal Transmit Channel Teardown (All Packet Types)

An Tx channel teardown is initiated by the host by writing the TX_TEARDOWN bit in the Tx Channel N Realtime Control Register. When the host initiates teardown, it can choose to perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the TX_FORCED_TEARDOWN bit in the Tx Channel N Realtime Control Register.

If the TX_FORCED_TEARDOWN bit is clear, a normal teardown has been initiated. In this case, the UDMA will do the following:

1. Stops performing any additional prefetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/TR prefetch has already been performed
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Tx Channel N Realtime Control Register.
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sends a single, 4-byte, teardown complete message to the queue specified in the Tx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	0	Indicates that the teardown was graceful and data was not lost.
30:14	-	0	RESERVED

Bits	Field	Value	Description
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

If the TX_FORCED_TEARDOWN bit is set, a destructive teardown has been initiated. In this case, the UDMA will do the following:

1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
2. Completes any packets which have been prefetched with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation).
3. Clears the channel enable in the Tx Channel N Realtime Control Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Tx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	1	Indicates that the teardown was not graceful. Data was potentially lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not.

The host determines that a teardown is complete by periodically polling the teardown and enable bits for the channel or by waiting to receive the teardown record on the queue specified in the Tx Channel Completion Queue register for the channel.

10.1.3.5 UDMA-P Transmit Channel Pause

Setting the TX_PAUSE bit in the Tx Channel N Realtime Control Register will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overflow conditions from a downstream data sink or upstream data source).

10.1.3.6 UDMA-P Transmit Operation (Host Packet Type)

After a channel has been set up it can begin to be used to transmit packets. Packet transmission in Host mode involves the following steps:

1. The Host is made aware of one or more chunks of data in memory that need to be transmitted as a packet. This may involve directly sourcing data from the Host or it may involve data which has been forwarded from another data source in the system.
2. The Host allocates and populates a host packet descriptor. The host will initialize the following fields within the packet descriptor:
 - a. Descriptor Type (set to Host)
 - b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
 - c. Source Tag
 - d. Destination Tag (application specific)
 - e. Packet Type
 - f. Any protocol specific flags for the given packet type
 - g. Buffer Pointer with the byte aligned address of the first chunk of buffer data
 - h. Buffer Length with the number of bytes in the first chunk of buffer data
 - i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.

- j. The Next Descriptor Pointer with the address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero
- k. Any protocol specific descriptor sections that are required for the given packet type or system configuration
3. The Host allocates and populates host buffer descriptors as necessary to point to any remaining chunks of data that belong to this packet. The host will initialize the following fields within the host buffer descriptor:
 - a. Buffer Descriptor reclamation policy fields (if the intention is to have the DMA automatically recycle the buffer descriptors as they are transmitted).
 - b. Buffer Pointer with the byte aligned address of the given chunk of buffer data
 - c. Buffer Length with the number of bytes in the given chunk of buffer data
 - d. The Next Descriptor Pointer with the address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero
4. The Host writes queues the packet onto one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
5. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
6. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
7. The DMA controller reads the packet descriptor pointer from the Ring Accelerator
8. The DMA controller reads the packet descriptor from memory
9. Step 9:
 - If the return policy bit (PD Word 2, bit 15) is cleared, the DMA controller empties each buffer in sequence by transmitting the contents in one or more block data moves. As each buffer is emptied, the DMA will read the next buffer descriptor to obtain the pointer and size of the data buffer as well as the pointer to the next descriptor in the chain.
 - If the return policy bit is set, the DMA controller empties each buffer in sequence by transmitting the contents in one or more block data moves.
10. Step 10:
 - If the return policy bit (PD Word 2, bit 15) is cleared, when all data for the packet has been transmitted as specified in the packet size field, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
 - If the return policy bit is set, as each buffer is emptied the DMA will write the buffer descriptor pointer to the queue specified in the return queue number field of the buffer descriptor. The DMA will also read the next buffer descriptor to obtain the pointer and size of the data buffer, the return queue information for the descriptor, as well as the pointer to the next descriptor in the chain.
11. Step 11:
 - If the return policy bit (PD Word 2, bit 15) is cleared, after the Packet Descriptor pointer has been written, the Ring Accelerator will indicate the status of the Tx Completion Queue by sending an up event .
 - If the return policy bit is set, when all data for the packet has been transmitted as specified in the packet size field, if the current buffer is not marked as end of packet (via a null next descriptor pointer), the DMA will continue to walk the list returning buffer descriptors to the appropriate queues as described in step 10.
12. Step 12:
 - If the return policy bit (PD Word 2, bit 15) is cleared, the Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
 - If the return policy bit is set, when all buffers have been returned, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
13. If the return policy bit (PD Word 2, bit 15) is cleared, host responds to status change from the Ring Accelerator (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.
14. If the return policy bit (PD Word 2, bit 15) is cleared, once the garbage collection causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register and potentially de-assert the interrupt line.

If the return policy bit (PD Word 2, bit 15) is cleared, the complete process is illustrated on [Figure 10-9](#).

If the return policy bit is set, the complete process is illustrated on [Figure 10-10](#).

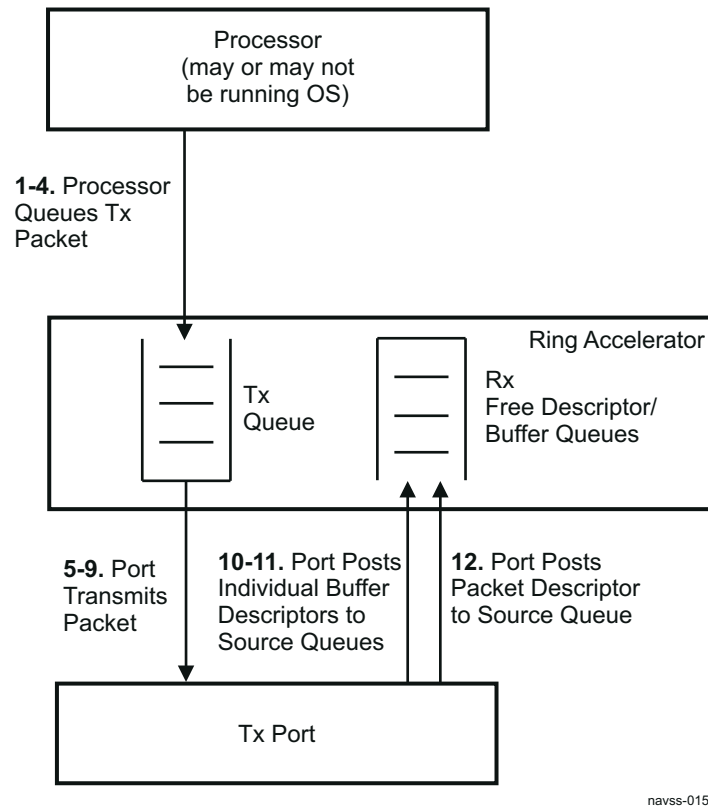

[Figure 10-9](#) shows a diagram of the host packet transmit operation – complete packet return.

navss-014

Figure 10-9. Host Packet Tx Operation – Complete Packet Return

[Figure 10-10](#) shows a diagram of the host packet transmit operation – automatic buffer recycling packet return.

navss-015

Figure 10-10. Host Packet Tx Operation – Automatic Buffer Recycling Packet Return

10.1.3.7 UDMA-P Transmit Operation (Monolithic Packet)

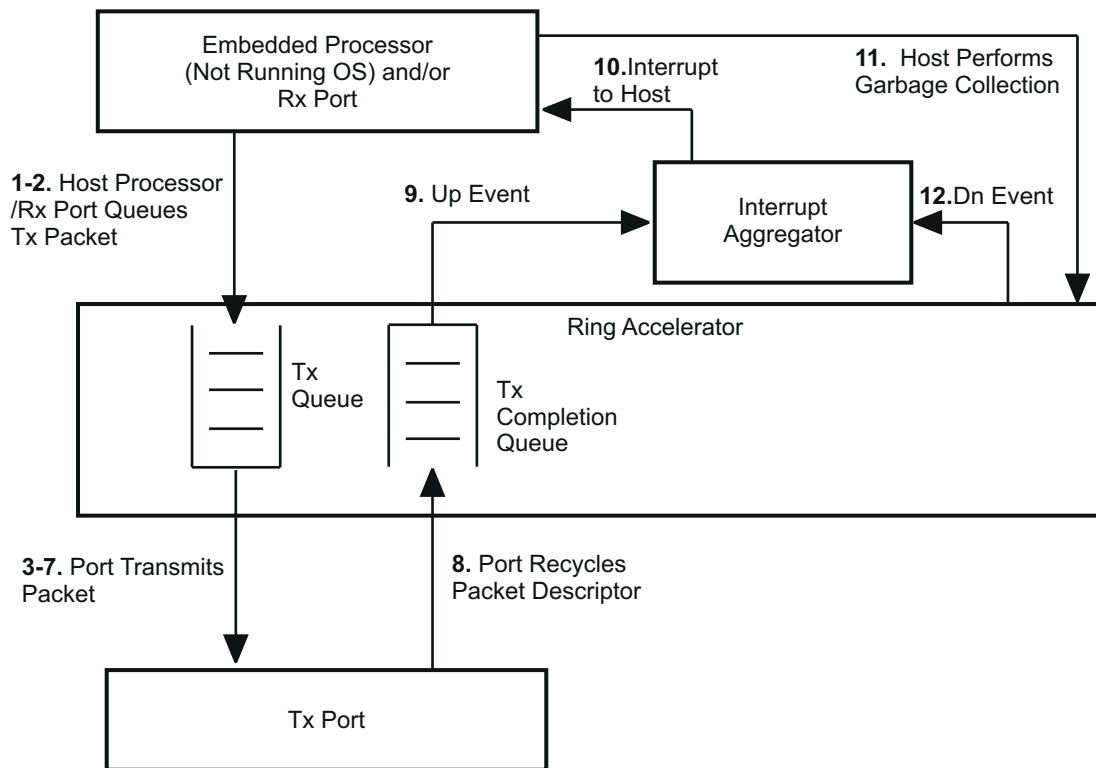

Packet transmission in Monolithic mode involves the following steps:

1. The Host allocates and populates a monolithic packet descriptor. The host will initialize the following fields within the packet descriptor:
 - a. Descriptor Type (set to Monolithic)
 - b. Packet Length indicating the total number of bytes in the packet
 - c. Source Tag
 - d. Destination Tag (application specific)
 - e. Packet Type
 - f. Any protocol specific flags for the given packet type
 - g. Offset to payload data
 - h. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
 - i. Networking Stack Information (application specific and optional)
 - j. Any protocol specific words that are required for the given packet type
2. The Host queues the packet onto one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the Ring Accelerator.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by transmitting the contents in one or more block data moves. The size of these blocks is application specific. The DMA controller module specification is intended to document the block size used by a given implementation.

8. When all data for the packet has been transmitted as specified in the packet size field, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
9. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

Whether or not any further processing is required on the packet at this point depends on the nature of the queue that the packet was returned to. The most common case is that the monolithic descriptor will be returned to the Rx Free Descriptor queue that it was allocated from originally. If this is the case, the Tx processing is complete at this point. Alternatively, the queue may also be a Tx Completion Queue in which case, the following optional steps may also be performed:

10. While most types of peer entities and embedded processors are able to directly and efficiently use these level sensitive status lines, cached processors may require a hardware block to convert the level status into pulsed interrupts and to perform some level of aggregation of the descriptor pointers from the completion queues into lists.
11. Host responds to status change from Ring Accelerator and performs garbage collection as necessary for packet.
12. Ring Accelerator sends down event when ring is empty

navss_011

Figure 10-11. Monolithic Packet Tx Operation

10.1.3.8 UDMA Transmit Operation (TR Packet)

Packet transmission in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
 - a. Descriptor Type (set to TR)
 - b. Reload Enable to 1 if looping is required, otherwise 0
 - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
 - d. Last Entry to TR count minus 1
 - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer

- f. Packet ID to a value that can be used to correlate the packet when it is placed back on the Tx completion queue
 - g. Source Tag
 - h. Destination Tag (application specific)
 - i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
 - j. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Transmit Queues for the desired UDMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
 3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
 4. The DMA controller is eventually brought into context for the corresponding Tx channel and begins to process the packet.
 5. The DMA controller reads the packet descriptor pointer from the RA.
 6. The DMA controller reads the packet descriptor from memory
 7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. These contents are then transmitted either to an internal UTC (in the case of a UDMA-P) or via PSI-L to a remote UTC (in the case of a UDMA-C).
 8. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of reads (for single ended transfers) or reads and corresponding writes (for block copy transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
 9. The UDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the UDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.
 10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the UDMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
 11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

10.1.3.9 UDMA Transmit Operation (Direct TR)

If the rings are configured in pass by value mode individual Transfer Request and Response records can be passed between software and hardware without any higher level data structures. This mode allows for the UDMA to be prompted to do a transfer by just writing memory mapped locations with a source address, destination address and byte count (in the simplest case). Direct TR is accomplished as follows:

1. The Host writes a valid Transfer Request record to the Tx Queue of the desired UDMA channel.
2. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
3. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
4. The DMA controller reads the Transfer Request record from the ring via the RA in a single nominal TR sized block data move. These contents are then transmitted either to an internal UTC (in the case of a UDMA-P) or via PSI-L to a remote UTC (in the case of a UDMA-C).
5. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of reads (for single ended transfers) or reads and corresponding writes (for block copy transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
6. When a Transfer Response is returned for the Transfer Request record the UDMA will write the response into the next entry in the Transmit Completion Ring. Since the Transfer Responses come back from the UTC strongly ordered each response will be written into the ring strongly ordered as well.

7. After the Transfer Response has been written, the Ring Accelerator indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

10.1.3.10 UDMA Transmit Error/Exception Handling

There are 3 specific errors which may be encountered during Tx operation and which are trapped by the UDMA. The following table lists the errors and how the UDMA will process them:

Table 10-91. UDMA Tx Error/Exception Handling

Condition	Channel Mode	Pauses Channel	Error Flag Set in Channel	Data Transfer	TR Flush	Outputs Transfer Events
TR null icnt0	All UTC	Selectable ⁽¹⁾	Yes	No	Just that TR	No
Unsupported TR Type	All UTC	Selectable ⁽¹⁾	Yes	No	Just that TR	No
Bus Errors	All	Selectable ⁽¹⁾	Yes	Yes	No	Yes

(1) If PAUSE_ON_ERROR bit is set in channel configuration

10.1.3.10.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and is unproductive wrt completion of any useful work. The Tx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.10.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Tx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.10.3 Bus Errors

If a bus error is encountered during transmit the DMA will log the error by asserting the TX_ERROR bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

10.1.3.11 UDMA Receive Channel Setup (All Packet Types)

After a reset or a previous teardown operation but before receiving packets on a channel the host must initialize the channel's Rx Port DMA State. The host initializes the channel Rx Port DMA State by writing to the Rx Channel Configuration Registers. The Host may choose to write the enable bit in the Rx Global Channel Configuration Register at the same time or after it has written all of the channel parameters but note that every write to the Rx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

10.1.3.12 UDMA Receive Channel Teardown

A Rx channel teardown is intended to be initiated at the data source (the source thread). Initiation is commanded by the host by writing the teardown bit in the PSI-L source thread register 0x408. This will cause the source of the data to gracefully terminate any packet that is in flight and send a PSI-L data phase with the tdown signal asserted. When the UDMA receives a data phase with the tdown attribute asserted it will immediately set the internal RX_TEARDOWN bit in the Rx Channel N Realtime Control Register.

Upon seeing the RX_TEARDOWN bit asserted the port can perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the RX_FORCED_TEARDOWN bit in the Rx Channel N Realtime Control Register.

If the RX_FORCED_TEARDOWN bit is clear, a normal teardown has been initiated. In this case, the UDMA will do the following:

1. Stops performing any additional prefetches for the channel (TR mode channels)

2. Completes any packets normally which may be pending in the ingress port buffers (what the port considers as pending packets is application specific).
3. Clears the channel enable in the Rx Channel Global Configuration Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Rx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	0	Indicates that the teardown was graceful and data was not lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

If the RX_FORCED_TEARDOWN bit is set, a destructive teardown has been initiated. In this case, the UDMA will do the following:

1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
2. Completes any packets which may be pending in the ingress port buffers with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation) . Packets will be drained from the Rx FIFO either using 'null' write transfers or real transfers and the Packet Descriptors will be returned with an accurate accounting of actual bytes transferred.
3. Clears the channel enable in the Rx Channel N Realtime Control Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Rx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	1	Indicates that the teardown was not graceful. Data was potentially lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not. The normally intended method of issuing a teardown on a packet mode or single ended TR mode channel is to initiate the teardown at the remote PSI-L data source and allow it to flow into the UDMA. If that is not possible, the host may write the RX_TEARDOWN bit directly to a 1.

The Host determines that a teardown is complete by periodically polling the teardown and enable bits for the channel or by waiting to receive the teardown record on the queue specified in the Tx Channel Completion Queue register for the channel.

10.1.3.13 UDMA-P Receive Channel Pause

Setting the RX_PAUSE bit in the Rx Channel N Realtime Control Register will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overrun conditions from a downstream data sink or upstream data source).

10.1.3.14 UDMA-P Receive Free Descriptor/Buffer Queue Setup (Host Packets)

The Host is ultimately responsible for providing all of the free descriptors and buffers that the port uses as it receives packets. For Rx Free Descriptor/Buffer queues, descriptors are allocated in a large block by the Host and then initialized and linked with buffers before being given matched pairs where the Host initializes the

descriptor to point to its corresponding buffer before being pushed onto a Receive Free Descriptor/Buffer queue. Once the host has allocated both a descriptor and a buffer, it adds them to an Rx Free Descriptor/Buffer Queue by writing the pointer to the descriptor to the Rx Free Descriptor/Buffer Queue register D for the desired queue.

Before the Host adds each Rx buffer descriptor to the queue, it must first initialize the Rx buffer descriptor values as follows:

- Write the Original Buffer Pointer with the byte aligned address of the buffer data
- Write the Original Buffer Size
- Write the Return Queue Number field in the descriptor to appropriate values (required if auto-recycling is intended)
- Write the On Chip/ Off Chip indicator in the descriptor

Depending on the software architecture, the Host may also desire to write the return policy bit in the descriptor at this point as well. The DMA will not overwrite any of these listed fields (including return policy) during reception.

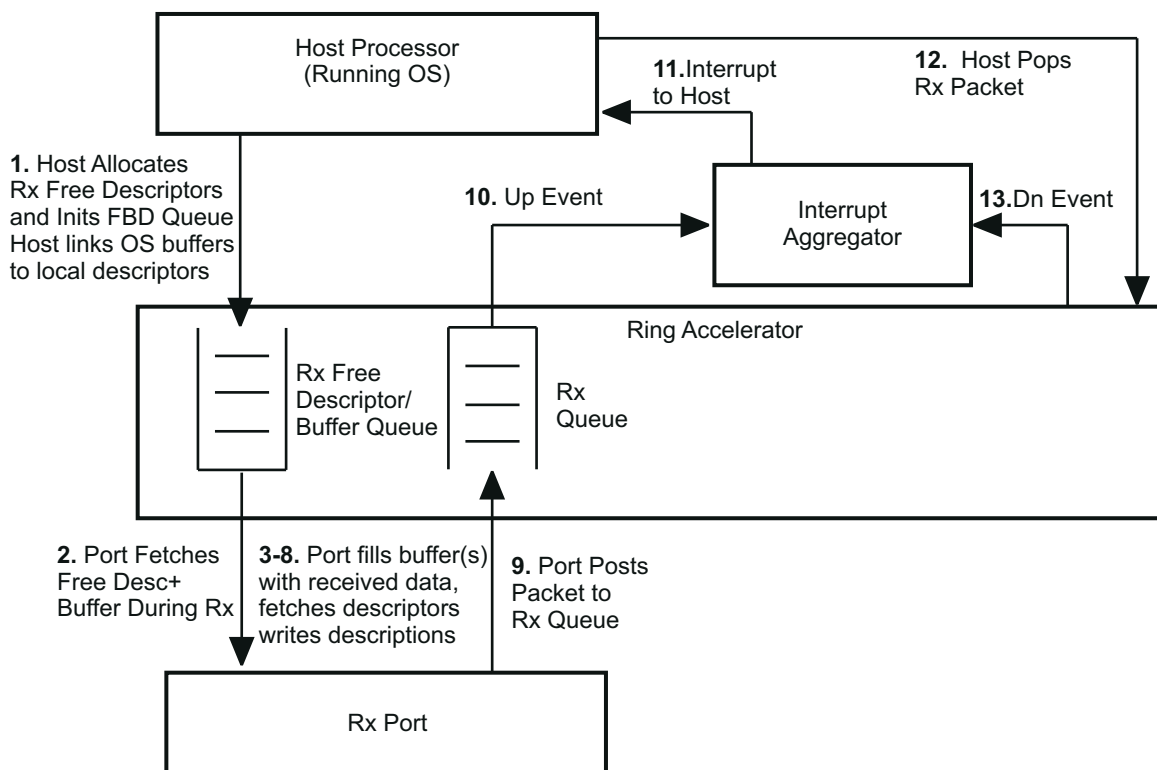

All other fields in the Descriptor do not need to be initialized as they will be overwritten by the Port on reception.

10.1.3.15 UDMA-P Receive FlowID Firewall Operation

Each incoming packet that enters the UDMA-P will either include an explicitly specified FlowID contained in the info words or it will have an implicitly specified default FlowID which is the same as the channel number. The Rx FlowID firewall checks the incoming FlowID on the received packet to verify that it is either the corresponding default FlowID for the channel or that the FlowID falls within the range specified in the Rx Channel Flow Range register. If the received flowID is not the channel number and it does not fall within the legal range as specified then the packet is dropped, the error is trapped in the Rx Flow ID Firewall Status register, and an optional output event is generated as specified in the Rx Flow ID Firewall Output Event Steering Register.

10.1.3.16 UDMA-P Receive Operation (Host Packet)

Figure 10-12 shows a diagram of the overall Receive operation for Host flow mode.

navss_012

Figure 10-12. Host Packet Receive Operation

When packet reception begins on a given channel, the port will begin by fetching the first descriptor + buffer from the Ring Accelerator using the Free Descriptor/Buffer Queue 0 Index that was initialized in the Rx Flow Table for the flow which is being used by the channel. If the SOP Buffer Offset in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port will then continue filling that buffer and will fetch additional descriptors + buffers as needed using the Free Descriptor/Buffer Queue 1, 2, and 3 indexes for the 2nd, 3rd, and remaining buffers in the packet.

A detailed summary is as follows:

1. Host allocates, populates, and places pointers to free descriptor/buffer structures onto Rx Free Descriptor/Buffer Queues
2. UDMA-P fetches packet descriptor pointer from RA
3. UDMA-P reads the packet descriptor to obtain the packet info, buffer pointer, and size
4. UDMA-P fills the buffer with received data
5. If packet is not complete, UDMA-P fetches next buffer descriptor pointer from RA
6. UDMA-P fills the buffer with received data

If the RX_DESC_TYPE field in the Rx Flow Register A is set to 0 (Normal Rx Host Mode), Steps 5-7 continue until all packet data is received at which point the Rx engine proceeds to step 8. If the RX_DESC_TYPE is set to 1 (Single Buffer Packet Host Mode) the Rx engine will proceed to step 8 skipping step 7.

7. UDMA-P writes previous buffer descriptor to memory. This includes the following fields:
 - a. Buffer information
 - b. Buffer Pointer with the byte aligned address of the chunk of buffer data
 - c. Buffer Length with the number of bytes in the chunk of buffer data
 - d. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.

If the RX_DESC_TYPE field in the Rx Flow Register A is set to 0 (Normal Rx Host Mode), Steps 5-7 continue until all packet data is received at which point the Rx engine proceeds to step 8. If the RX_DESC_TYPE is set to 1 (Single Buffer Packet Host Mode) the Rx engine proceeds to step 8 as soon as the first buffer is full. Any remaining data in the packet from the line is then received into one or more additional packets each exactly one Host buffer long.

The UDMA-P performs the following operations when the entire packet has been received:

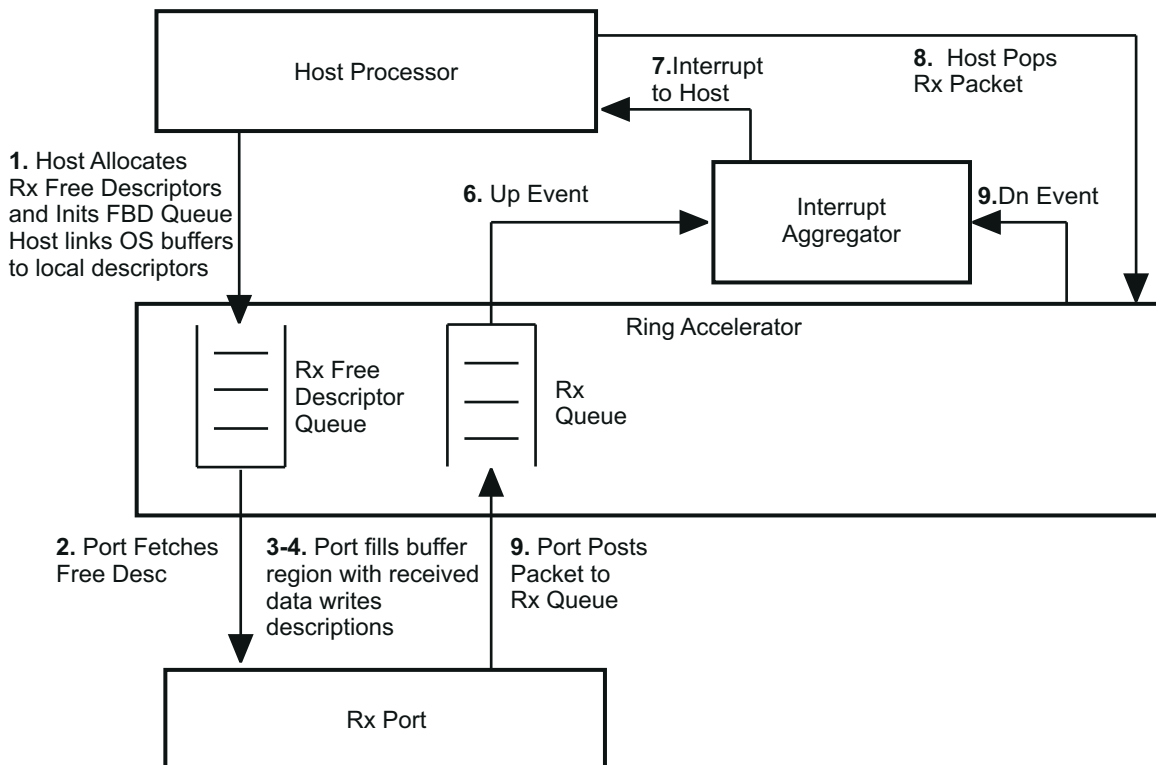

8. UDMA-P writes the packet descriptor to memory. This includes the following fields:
 - a. Descriptor Type (set to Host)
 - b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
 - c. Source Tag
 - d. Destination Tag (application specific)
 - e. Packet Type
 - f. Any protocol specific flags for the given packet type
 - g. SOP buffer information
 - i. Buffer Pointer with the byte aligned address of the chunk of buffer data
 - ii. Buffer Length with the number of bytes in the chunk of buffer data
 - h. Any protocol specific words that are required for the given packet type
 - i. Networking Stack Information (application specific and optional)
 - j. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.
9. UDMA-P writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the rx_dest_qnum field in the Rx Flow Table entry or will be a queue which was provided via the PSI-L destination queue number override field.
10. Once the packet pointer is written to the Ring Accelerator it will send an up event to the Interrupt Aggregator
11. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host
12. The Host will pop the packet pointer from the Rx Queue

13. If the pop causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

The Ring Accelerator is responsible for indicating the status of the Receive Queues to other ports/embedded processors using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

10.1.3.17 UDMA-P Receive Operation (Monolithic Packet)

Figure 10-13 shows a diagram of the overall Receive operation for a monolithic descriptor type.

navss_013

Figure 10-13. Monolithic Packet Receive Operation

The following sequence is a detailed summary of the Monolithic Packet Reception process:

1. The Host initializes free Descriptors and places them on an Rx Free Descriptor Queue
2. The UDMA-P fetches a single descriptor for the packet from the Ring Accelerator using the Monolithic Type Free Descriptor Queue Index that was initialized in the Rx Flow Table entry that is being used for the packet.
3. If the RX_SOP_OFFSET field in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the payload portion of the monolithic descriptor. The port will then continue filling the payload portion of the descriptor until the entire packet has been received.

The port performs the following operations when the entire packet has been received:

4. Writes the packet descriptor to memory. This includes the following fields:
 - a. Descriptor Type (set to Monolithic)
 - b. Packet Length indicating the total number of bytes in this packet.
 - c. Source Tag
 - d. Destination Tag (application specific)
 - e. Packet Type
 - f. Any protocol specific flags for the given packet type
 - g. Networking Stack Information (application specific and optional)
 - h. Any protocol specific words that are required for the given packet type

5. Writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the rx_dest_qnum fields in the Rx Flow Entry or can be overridden by the value in the PSI-L destination queue override field.
6. Once the packet pointer is written to the Ring Accelerator it will send an up event to the Interrupt Aggregator
7. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host
8. The Host will pop the packet pointer from the Rx Queue
9. If the pop causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

The Ring Accelerator is responsible for indicating the status of the Receive Queues to other ports/processors using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

10.1.3.18 UDMA Receive Operation (TR Packet)

Packet reception in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
 - a. Descriptor Type (set to TR)
 - b. Reload Enable to 1 if looping is required, otherwise 0
 - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
 - d. Last Entry to TR count minus 1
 - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
 - f. Packet ID to a value that can be used to correlate the packet when it is placed back on the Tx completion queue
 - g. Source Tag
 - h. Destination Tag (application specific)
 - i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
 - j. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Rx TR Queues for the desired UDMA channel. Channels may provide more than one Rx TR Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the RA.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. These contents are then transmitted to an internal UTC.
8. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of writes (for single ended transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
9. The UDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the UDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the UDMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.

11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

10.1.3.19 UDMA Receive Operation (Direct TR)

If the rings are configured in pass by value mode individual Transfer Request and Response records can be passed between software and hardware without any higher level data structures. This mode allows for the UDMA to be prompted to do a transfer by just writing memory mapped locations with a source address, destination address and byte count (in the simplest case). Direct TR is accomplished as follows:

1. The Host writes a valid Transfer Request record to the Rx TR Queue of the desired UDMA channel.
2. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
3. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
4. The DMA controller reads the Transfer Request record from the ring via the RA in a single nominal TR sized block data move. These contents are then transmitted to an internal UTC (in the case of a UDMA-P).
5. All of the data transfers specified in a TR will be completed as a series of writes (for single ended transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
6. When a Transfer Response is returned for the Transfer Request record the UDMA will write the response into the next entry in the Transmit Completion Ring. Since the Transfer Responses come back from the UTC strongly ordered each response will be written into the ring strongly ordered as well.
7. After the Transfer Response has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

10.1.3.20 UDMA Receive Error/Exception Handling

Several types of errors/exceptions may be encountered during reception of data. The following table outlines the various errors and exceptions that can occur:

Table 10-92. UDMA Rx Error/Exception Handling

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Descriptor Starvation	All Packet	Exception	No	No	Option	Option	-	No
Protocol Errors	All Packet	Info	No	No	Normal	No	-	No
Drop	Host – normal	Exception	No	No	Partial ⁽²⁾	Until EOP	-	No
	Host – single buffer	Error	Selectable ⁽¹⁾	Yes	Partial ⁽²⁾	Until EOP ⁽³⁾	-	No
	Mono	Exception	No	No	Partial ⁽²⁾	Until EOP	-	No
	UTC–single ended	Exception	No	No	Partial ⁽²⁾	Until EOP	Until EOP ⁽⁴⁾	Yes
	UTC- block copy	Illegal	-	-	-	-	-	-
EOL Asserted Prematurely	All Packet	Error	Selectable ⁽¹⁾	Yes	No	Yes	-	No
	UTC – single ended	Exception	No	No	Normal	No	No	Yes
	UTC – block copy	Illegal	-	-	-	-	-	-
EOP Asserted Prematurely (Short Packet)	UTC – single ended	Exception	No	No	Normal	No	Until EOP ⁽⁴⁾	Yes
EOP Asserted Late (Long Packet)	UTC – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All UTC	Error	Selectable ⁽¹⁾	Yes	No	No	Just that TR	No

Table 10-92. UDMA Rx Error/Exception Handling (continued)

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Unsupported TR Type	All UTC	Error	Selectable ⁽¹⁾	Yes	No	No	Just that TR	No

- (1) If PAUSE_ON_ERROR bit is set in channel configuration
- (2) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.
- (3) EOP will only occur when in single buffer mode when teardown is initiated. The data is a (never ending) stream. Drop is never supposed to be asserted during this mode of operation.
- (4) EOP on TR is true for all PBV TRs, the final TR in a PBR, or if the user specified EOP in the TR flags

10.1.3.20.1 Error Conditions

The following sections describe items which fall under an error severity when encountered by the UDMA on Rx:

10.1.3.20.1.1 Bus Errors

If a bus error is encountered during receive the DMA will log the error by asserting the RX_ERROR bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

10.1.3.20.1.2 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and it unproductive towards completion of any useful work. The Rx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.20.1.3 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Rx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.20.2 Exception Conditions Exception Conditions

There are a few cases which can occur when processing incoming packets which are not considered errors but which will require handling in order to avoid locking up the UDMA packet or TR mode write engines.

Packet mode channel exceptions include:

- Descriptor Starvation
- Protocol Errors
- Dropped Packets

Since the TR mode engine performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following sections outline these scenarios.

TR mode channel exceptions include:

- Reception of EOL delimiter
- Short Packets
- Long Packets

10.1.3.20.2.1 Descriptor Starvation

Descriptor starvation occurs when the Port attempts to fetch a free descriptor from an Rx Free Descriptor Queue or Rx Free Descriptor/Buffer Queue and none are available. When no descriptor is available, the Ring Accelerator will return a value of 0x0 for the descriptor pointer (Optionally, some ports may contain internal counters for the free queues which indicate how many elements are currently queued. In this case, no access to the RA is required and starvation is directly detected via a zero element count). When the port detects that

descriptor starvation has occurred it will react based on the value of the RX_ERROR_HANDLING bit which was programmed into the Rx Flow N Configuration Register A.

- If the RX_ERROR_HANDLING bit is cleared:

The Port will assert a descriptor starvation indicator and will then return any descriptors that it has already used in the reception of the current packet back to the appropriate Free Descriptor or Free Descriptor/Buffer queue that they were fetched from. This is performed by writing the pointers for each descriptor to the Rx Free Descriptor Queue N Register in sequence using the queue indexes in the Rx DMA state. The port may choose to implement a counter that counts the number of packets that were dropped due to descriptor starvation and may also desire to distinguish between whether the starvation occurred on the packet descriptor (SOP) or on a buffer starvation.

- If the RX_ERROR_HANDLING bit is set:

The Port will assert a descriptor starvation indicator (which may cause an interrupt to the Host) and will then behave as if it had not performed the current data block transfer which caused the starvation. The Port is required to pause its current processing saving the state of the transfer. The next time that the channel comes into context it will again try to allocate a descriptor with the intention being that if buffers/descriptors have been added that the operation will complete successfully on a subsequent retry.

10.1.3.20.2.2 Protocol Errors

Protocol errors occur when the port logic detects that the received packet did not pass protocol specific criteria that was checked during reception of the packet. Examples of protocol errors include packet length errors, CRC errors, or alignment errors.

When protocol errors are detected, the port may choose whether or not it will drop the packet. The mechanism that is used to determine which packets to drop and which to forward is application specific. If the port determines that it needs to forward the packet to the Host, it will set the Packet Error bit in the Descriptor indicating that this is a packet which experienced a protocol related error. The type of protocol related error is generally indicated in either the Protocol Specific bits in the Host or Monolithic descriptor or in the Protocol Specific bytes region. The packet length information and certain portions of the Protocol Specific region may not be correct for packets which encounter errors.

10.1.3.20.2.3 Dropped Packets

Packets can be dropped within an Rx Port for any number of reasons which with the exception of the starvation case which was covered above are application specific.

If a split TR mode channel receives instruction to drop a packet on the PSI-L interface, the UDMA/UTC will continue executing the TRs but without data transfer up until a TR is completed for which the EOP condition was set. Events will be generated as normal although data may not be actually transferred.

10.1.3.20.2.4 Reception of EOL Delimiter

If an end of line delimiter is received by the Rx (write) side of the UTC the EOL_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

10.1.3.20.2.5 EOP Asserted Prematurely (Short Packet)

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and then to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

10.1.3.20.2.6 EOP Asserted Late (Long Packets)

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

10.1.3.21 UTC Operation

A UTC accepts Transfer Request records from the UDMA-C and performs a sequence of transactions as specified in the TR record in accordance with the address generation algorithm that is specified in the Transfer Request format specification. The UTC will wait until an optional triggering event has occurred to load the channel state into one of its read or write engines so that the data movement operations can be completed. The UTC will complete the specified transactions until it either has transferred a pre-set number of bytes or until it has reached a point in the sequence where the TR indicates that a trigger is required to continue execution. When either of these two conditions is met, the UTC will save off the current state of the channel and will wait until the channel is re-triggered at which point the TR execution will continue. Once the entire Transfer Request specified sequence of data transfers has completed, the UTC will wait to ensure that all outstanding writes have landed at their respective destination endpoints and will then return a Transfer Response message back to the UDMA-C indicating the success or failure of the Transfer Request. The UTC processes Transfer Request operations on a given channel with strong ordering such that all Transfer Response operations will be returned in an order corresponding to the exact order that Transfer Request operations were issued.

10.1.3.22 UTC Receive Error/Exception Handling

Several types of errors/exceptions may be encountered during reception of data. The following table outlines the various errors and exceptions that can occur:

Table 10-93. UTC Rx Error/Exception Handling

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Drop	UTC—single ended	Exception	No	No	Partial ⁽²⁾	Until EOP	Until EOP ⁽³⁾	Yes
	UTC- block copy	Illegal	-	-	-	-	-	-
EOL Asserted Prematurely	UTC – single ended	Exception	No	No	Normal	No	No	Yes
	UTC – block copy	Illegal	-	-	-	-	-	-
EOP Asserted Prematurely (Short Packet)	UTC – single ended	Exception	No	No	Normal	No	Until EOP ⁽³⁾	Yes
EOP Asserted Late (Long Packet)	UTC – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All UTC	Error	Selectable ⁽¹⁾	Yes	No	No	Just that TR	No
Unsupported TR Type	All UTC	Error	Selectable ⁽¹⁾	Yes	No	No	Just that TR	No

(1) If pause_on_error bit is set in channel configuration

(2) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.

(3) EOP on TR is true for all PBV TRs, the final TR in a PBR, or if the user specified EOP in the TR flags

10.1.3.22.1 Error Handling

If an error occurs during the processing of a Transfer Request, the UTC will discontinue any further operations on the TR and will wait for all outstanding transactions to complete. At that point, the Transfer Response record will be returned to the UDMA-C with the appropriate codes indicating the type of failure as specified in the Transfer Response Format specification.

Depending on the value of the PAUSE_ON_ERROR bit in the UTC configuration register, the UTC will next do one of the following:

If the PAUSE_ON_ERROR bit is clear the channel will move on to the next Transfer Request record that it received from the UDMA-C.

If the PAUSE_ON_ERROR bit is set the channel will halt from processing any new Transfer Request records in order to allow the Host to examine the current channel state in order to determine the potential cause of the failure. The UTC is required to preserve as much of the channel state as possible as soon as a failure is determined. Note that the state will not necessarily provide exact details or a 'smoking gun' as the UTC implementation allows for large scale transaction pipelining and error status returns from the bus can occur well after the machine has moved on to other channel tasks.

10.1.3.22.1.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and it unproductive towards completion of any useful work. The Rx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.22.1.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Rx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.22.2 Exception Conditions

There are a few cases which can occur when processing TRs which are not considered errors but which will require handling in order to avoid locking up the UTC read or write engines. Since the UTC performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following outline these scenarios.

10.1.3.22.2.1 Reception of EOL Delimiter

If an end of line delimiter is received by the Rx (write) side of the UTC the EOL_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

10.1.3.22.2.2 EOP Asserted Prematurely (Short Packet)

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and the to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

10.1.3.22.2.3 EOP Asserted Late (Long Packets)

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

10.1.3.23 BCDMA - Ring Operation

10.1.3.23.1 Queue Initialization

The base address and size for each ring must be initialized via the provided MMRs prior to using the ring. Ring initialization is typically done only on channel / flow setup as once initialized the rings can be used indefinitely.

10.1.3.23.2 Queueing Entries

Entries can only be queued by SW onto the forward queue of a ring. To queue an entry the producer will write the entry contents (typically a pointer to the Packet Descriptor or a TR) to the memory location pointed to by the current write pointer and will decrement its internally maintained free entry occupancy. After the producer has confirmed that the data has actually landed in memory, it will then write to the forward doorbell register (RINGRT[a]_RT_FDB) for the ring to increment the pending forward occupancy count for the ring.

More than one entry can be queued with a single doorbell write as the entry count in the doorbell write indicates how many entries have been queued.

10.1.3.23.3 De-queueing Entries

Entries can only be de-queued by SW from the reverse queue of a ring. The consumer (entity which is going to de-queue an entry from the ring) maintains a current read pointer for each ring it controls. To de-queue an entry the consumer will read the occupancy from the reverse occupancy register (RINGRT[a]_RT_ROCC) and will then read the entry contents from the memory location pointed to by the current read pointer. The consumer will then write a decrement value to the reverse doorbell register (RINGRT[a]_RT_ROCC) for the ring to decrement the waiting occupancy count for the reverse queue within the ring and will increment its internally maintained free entry occupancy for the ring.

10.1.3.24 BCDMA - Output Event Generation

Each channel and flow within a DMA has the ability to generate specific types of events which can be routed to the IA in the system and from there re-routed to any event consumer. Events are output from the DMA controllers using a simple integer encoding. Up to 4 events can be generated from any given channel but only event types which have functional value are supported on each specific type of channel. The DMA channel event types are listed as follows:

Table 10-94. Per-Channel/Flow Event Support and Encoding

Name	Description	Per	BCDMA Tx	BCDMA Rx
Ring Entry Zero/Non-zero	Asserts an up event anytime the ring transitions to a non-zero occupancy / teardown state. Asserts a down event anytime the ring transitions to a zero occupancy / teardown state.	Flow	X	X
Channel Error	Asserts an up event anytime an error occurs on the channel. Asserts a down event when the channel error bit is cleared.	Channel	First flow in channel only	First flow in channel only
Rx Starvation	Asserts an up event when starvation occurs on a flow. Asserts a down event when entries are added to the ring for that flow.	Flow		

Table 10-94. Per-Channel/Flow Event Support and Encoding (continued)

Name	Description	Per	BCDMA Tx	BCDMA Rx
RX Flow FW Error	Asserts an up event when a flow id arrives on the RX interface that is not between the flowid_start and flowid_end values for the channel. Asserts a down event when the RX Flow ID Firewall Status Register pend bit is cleared	Pktdma		
Data Events	Asserts an up event when the selected loop counter has decremented. If the suppress event bit is not set in the TR	Channel	X	X

Each BCDMA instance will provide an event transport-lane (ETL) interface to pass outgoing events. The index field on this ETL will be calculated based on the event type and channel or flow offset. Each BCDMA instance is configured with base values to which a channel or flow index is added for each type of event which can be generated. These base index values are listed in the specification for that specific instantiation of each DMA and are named as follows:

Table 10-95. BCDMA Event Base Index Parameters

DMA	Event Base Parameter Name	Function	Offset
BCDMA	tcomp_evtbase	Base index for split Tx flow reverse ring completion events	Tx flow number
	rcomp_evtbase	Base index for split Rx flow reverse ring completion events	Rx flow number
	terr_evtbase	Base index for split Tx channel error events	Tx channel number
	rerr_evtbase	Base index for split Rx channel error events	Rx channel number
	tdcomp_evtbase	Base index for Tx channel TR data completion events	Tx channel number
	rdcomp_evtbase	Base index for Rx channel TR data completion events	Tx channel number

Example:

The producer event map is set up so that the Tx flows from a BCDMA instance are to start at 64 and proceed upward from there. The tcomp_evtbase for that BCDMA instance is set to 64. In this configuration, the reverse ring entry completion event for flow 0 will produce an event on index 64, flow 1 will produce an event on index 65, etc. The terr_evtbase for the same BCDMA instance is set to 128. In this configuration, error events for channel 2 would produce events with an index of 130.

10.1.3.25 BCDMA - Split Transmit Channel Setup

This section describes the setup procedure for split Tx channels within the BCDMA. After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Tx Port DMA State. The host initializes the channel Tx Port DMA State by configuring all of the Tx flow entries for the channel and then writing to the Tx Channel Configuration Register A (TCHANRT[a]_TRT_CTL). The Host may choose to write the enable bit in the Tx Channel Configuration Register A (<TCHANRT[a]_TRT_CTL> [31] TX_ENABLE) at

the same time or after it has written all of the channel parameters but note that every write to the Tx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

After a Transmit channel has been set up, packets can be added to the Queues for the channel to begin the transmit operation. The following sections describe how the transmit operations are performed for the various descriptor types.

10.1.3.26 BCDMA - Split Transmit Operation Pause

Setting the pause bit in the Channel N Control Register (<TCHANRT[a]_TRT_CTL> [29] TX_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potentially overflowing trigger events).

10.1.3.27 BCDMA - Split Transmit Channel Teardown

This section describes the teardown procedure for split mode Tx channels within the BCDMA. A Tx channel teardown is initiated by the host by writing the tx_teardown bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]_TRT_CTL> [30] TX_TEARDOWN). When the host initiates teardown, it can choose to perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the tx_forced_teardown bit in the Tx Channel N Real-time Control Register (<TCHANRT[a]_TRT_CTL> [28] TX_FORCED_TEARDOWN).

If the tx_forced_teardown bit is clear, a normal teardown has been initiated. In this case, the DMA will do the following:

1. Stops performing any additional descriptor fetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/TR fetch has already been performed
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Tx Channel N Global Configuration Register (<TCHANRT[a]_TRT_CTL> [31] TX_ENABLE).
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sets bit 31 of the Tx Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
7. If the current Tx reverse ring occupancy is 0, issues a Tx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
8. If the current TX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
9. If the tx_forced_teardown bit is set (only valid on BCDMA), a destructive teardown has been initiated. In this case, the BCDMA will do the following:
