 1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
 2. Completes any packets which have been prefetched with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation).
 3. Clears the channel enable in the Tx Channel Global Configuration Register (<TCHANRT[a]_TRT_CTL> [31] TX_ENABLE).
 4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
 5. Sets bit 31 of the Tx Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
 6. If the current Tx reverse ring occupancy is 0, issues a Tx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not.

The Host determines that a teardown using either of the following methods:

1. Periodically polling the teardown and enable bits for the channel

2. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (RINGRT[a]_RT_ROCC) for the channel.

10.1.3.28 BCDMA - Split Transmit Operation (TR Packet)

Packet transmission in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
 - a. Descriptor Type (set to TR)
 - b. Reload Enable to 1 if looping is required, otherwise 0
 - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
 - d. Last Entry to TR count minus 1
 - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
 - f. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Transmit Queues for the desired BCDMA channel. Channels may provide more than one Queue (1 queue per provided flow) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The BCDMA internally provides a level sensitive status signal for the queue which indicates if any work is currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding read channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the ring in memory.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller sequentially empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. As a TR is read from the descriptor, it is stored in the internal state of the DMA channel until it is completed.
8. All of the data transfers specified in a TR will be completed as a series of reads.
9. The BCDMA will wait until data returns for each read operation that has been initiated. When the final read operation is returned within each TR, the BCDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the BCDMA will increment the reverse occupancy for the channel / flow.
11. After the occupancy is incremented, the BCDMA will indicate the status of the Tx Completion Queue by sending an up event.
12. The Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register (VINT[a]_ENABLE_SET) as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
13. The Host responds to the status change from the BCDMA (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.
14. During garbage collection the Host will write to the reverse queue Doorbell register (RINGRT[a]_RT_RDB) for the channel/flow to acknowledge the popping of those completed packets. The doorbell writes eventually cause the queue to become empty.
15. The BCDMA will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register (VINT[a]_STATUS) and potentially de-assert the interrupt line.

10.1.3.29 BCDMA - Split Transmit Error / Exception Handling

There are 3 specific errors which may be encountered during Tx split operation and which are trapped by the BCDMA. The following table lists the errors and how the BCDMA will process them:

Table 10-96. BCDMA Tx Error / Exception Handling

Condition	Pauses Channel	Error Flag Set in Channel	Data Transfer	TR Flush	Outputs Transfer Events
TR null icnt0	Selectable ⁽¹⁾	Yes	No	Just that TR	No
Unsupported TR Type	Selectable ⁽¹⁾	Yes	No	Just that TR	No
Bus Errors	Selectable ⁽¹⁾	Yes	Yes	No	Yes

(1) If pause_on_error bit is set in channel configuration

10.1.3.29.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and is unproductive wrt completion of any useful work. The Block Copy engine in the BCDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.29.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Block Copy engine in the BCDMA will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

10.1.3.29.3 Bus Errors

If a bus error is encountered during transmit the BCDMA will log the error by asserting the tx_error bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

10.1.3.30 BCDMA - Split Receive Channel Setup

After a reset or a previous teardown operation but before receiving packets on a channel the host must initialize the channel's Rx Port DMA State. The host initializes the channel Rx Port DMA State by writing to the Rx Channel Configuration Registers. The Host may choose to write the enable bit in the Rx Global Channel Configuration Register (<RCHANRT[a]_RRT_CTL > [31] RX_ENABLE) at the same time or after it has written all of the channel parameters but note that every write to the Rx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

10.1.3.31 BCDMA - Split Receive Channel Pause

Setting the pause bit in the Channel N Control Register (<RCHANRT[a]_RRT_CTL > [29] RX_PAUSE) will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potentially overflowing trigger events).

10.1.3.32 BCDMA - Split Receive Channel Teardown

An Rx channel teardown is intended to be initiated at the data source (the source thread). Initiation is commanded by the host by writing the teardown bit in the PSI-L source thread register 0x408. This will cause the source of the data to gracefully terminate any packet that is in flight and send a PSI-L data phase with the tdown signal asserted. When the BCDMA receives a data phase with the tdown attribute asserted it will immediately set the internal rx_teardown bit in the Rx Channel N Real-time Control Register (<RCHANRT[a]_RRT_CTL > [30] RX_TEARDOWN).

Upon seeing the rx_teardown bit asserted the port can perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the rx_forced_teardown bit in the Rx Channel N Real-time Control Register (<RCHANRT[a]_RRT_CTL > [28] RX_FORCED_TEARDOWN).

If the rx_forced_teardown bit is clear, a normal teardown has been initiated. In this case, the BCDMA will do the following:

1. Stops performing any additional prefetches for the channel (TR mode channels)
2. Completes any packets normally which may be pending in the ingress port buffers (what the port considers as pending packets is application specific).
3. Clears the channel enable in the Rx Channel Global Configuration Register (<RCHANRT[a]_RRT_CTL > [31] RX_ENABLE).
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sets bit 31 of the Rx Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
6. If the current Rx reverse ring occupancy is 0, issues an Rx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.
7. If the current RX Reverse ring occupancy is not 0 then a write to the doorbell with a negative value of the current occupancy will clear any remaining work but the forward ring pointer will remain the same. If the ring pointer needs to be reset then perform a write to any of the ring configuration registers.
8. If the rx_forced_teardown bit is set, a destructive teardown has been initiated. In this case, the BCDMA will do the following:
 - a. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
 - b. Completes any packets which may be pending in the ingress port buffers with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation) . Packets will be drained from the Rx FIFO either using 'null' write transfers or real transfers and the Packet Descriptors will be returned with an accurate accounting of actual bytes transferred.
 - c. Clears the channel enable in the Rx Channel Global Configuration Register (<RCHANRT[a]_RRT_CTL > [31] RX_ENABLE).
 - d. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
 - e. Sets bit 31 of the Rx Flow Reverse Ring Occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) to indicate that a teardown has completed.
 - f. If the current Rx reverse ring occupancy is 0, issues an Rx reverse ring completion up event which is then routed to an IA and can be further routed to any event consumer.

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not. The normally intended method of issuing a teardown on a packet mode channel is to initiate the teardown at the remote PSI-L data source and allow it to flow into the BCDMA. If that is not possible, the host may write the rx_teardown bit directly to a 1.

The Host determines that a teardown using either of the following methods:

1. Periodically polling the teardown and enable bits for the channel
2. Waiting for an interrupt and observing the teardown complete bit is set in the channel's default flow (first flow in channel) reverse occupancy register (<RINGRT[a]_RT_ROCC> [31] TDOWN_COMPLETE) for the channel.

10.1.3.33 BCDMA - Split Receive Operation (TR Packet)

Packet reception in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
 - a. Descriptor Type (set to TR)
 - b. Reload Enable to 1 if looping is required, otherwise 0
 - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
 - d. Last Entry to TR count minus 1
 - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
 - f. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Rx TR Queues for the desired BCDMA channel. Channels may provide more than one Rx TR Queue (one per flow) and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller / scheduler implementation.

3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the ring in memory.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves.
8. All of the data transfers specified in a TR will be completed as a series of writes and a Transfer Response will be returned indicating the completion and status of the transfer.
9. The BCDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the BCDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the DMSS will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports / processors / prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard interrupts.

10.1.3.34 BCDMA - Split Receive Error / Exception Handling

Several types of errors/exceptions may be encountered during reception of split Rx data. The following table outlines the various errors and exceptions that can occur:

Table 10-97. Rx Error / Exception Handling

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Descriptor Starvation	All Packet	Exception	No	No	Option	Option	-	No
Protocol Errors	All Packet	Info	No	No	Normal	No	-	No
Drop	Host – normal	Exception	No	No	Partial ⁽¹⁾	Until EOP	-	No
EOP Asserted Late (Long Packet)	BCDMA – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All BCDMA	Error	Selectable ⁽¹⁾	Yes	No	No	Just that TR	No
Unsupported TR Type	All BCDMA	Error	Selectable ⁽¹⁾	Yes	No	No	Just that TR	No

- (1) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.

10.1.3.34.1 BCDMA Exception Conditions

Since the TR mode engine performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following sections outline these scenarios.

TR mode channel exceptions include:

- Reception of EOL delimiter
- Short Packets
- Long Packets
- Descriptor Starvation

10.1.3.34.1.1 Reception of EOL Delimiter

If an end of line delimiter is received by the Rx (write) side of the BCDMA the EOL_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

10.1.3.34.1.2 EOP Asserted Prematurely (Short Packet)

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and the to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

10.1.3.34.1.3 EOP Asserted Late (Long Packets)

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

10.1.3.34.1.4 Descriptor Starvation

Descriptor starvation occurs when the Port receives enough data for a burst but the ring for the channel is currently empty. This causes push back on the receive port and can cause lost data.

The Port will assert a starvation bit in the RX Receive Channel Status register (RCHANRT[a]_RRT_STATUS[1-0]). When the doorbell register (RINGRT[a]_RT_DB) is written to populate the ring the starvation bit will clear. Note that the intention is that the port will wait for an entry to be added to the ring. It is assumed that if data loss is not desired that the host will guarantee that a descriptor is present.

10.2 Navigator Subsystem (NAVSS)

This chapter describes the features and functions of the Navigator Subsystem (NAVSS) hardware modules in the device.

The SoC device contains two NAVSSes:

- Main NAVSS (NAVSS0) – See [Section 10.2.1](#), *Main Navigator Subsystem (NAVSS)*
- MCU NAVSS (MCU_NAVSS0) – See [Section 10.2.2](#), *MCU Navigator Subsystem (MCU NAVSS)*.

10.2.1 Main Navigator Subsystem (NAVSS)

This section describes the top-level integration of the main Navigator Subsystem (NAVSS) in the device.

10.2.1.1 NAVSS Overview

Main SoC Navigator Subsystem (NAVSS0) consists of DMA/Queue Management components – UDMA and Ring Accelerator (UDMASS), Peripherals (Module subsystem [MODSS]), Virtualization translation (VirtSS), and a North Bridge (NBSS).

UDMASS – UDMASS is the essential part of the *TI Data Movement Architecture* (see [Section 10.1](#)). UDMASS consists of:

- Unified DMA Controller – [Section 10.2.3](#)
- Ring Accelerator – [Section 10.2.4](#)
- Packet Streaming Interface (PSI-L) – [Section 10.2.8](#)
- Block Copy DMA Controller – [Section 10.2.11](#)

MODSS – Module subsystem is a collection of peripherals with different system-level functions, for example, interprocessor communication and time sync, among others. NAVSS0 contains the following modules:

- Mailbox – [Section 7.1](#)
- Spinlock – [Section 7.2](#)
- Two Timer Managers (Timer banks) – [Section 11.2](#)
- Time Stamp Module (CPTS) – [Section 11.1](#)
- Infrastructure components such as:
 - CBASS – *System Interconnect*
 - Proxies – [Section 10.2.5](#), [Section 10.2.6](#)
 - Interrupt aggregators – [Section 10.2.7](#)
 - Interrupt router – *NAVSS Interrupt Router Configuration*

NBSS – North bridge – [Section 10.2.10](#)

VirtSS – Virtualization sub-system provides all the translation components supported in K3 for virtualization:

- Peripheral Virtualization Units (PVU) – [Section 8.3](#)

ECC aggregators – [Section 12.10.6](#)

NAVSS0 hardware components and their integration are shown on [Figure 10-14](#).

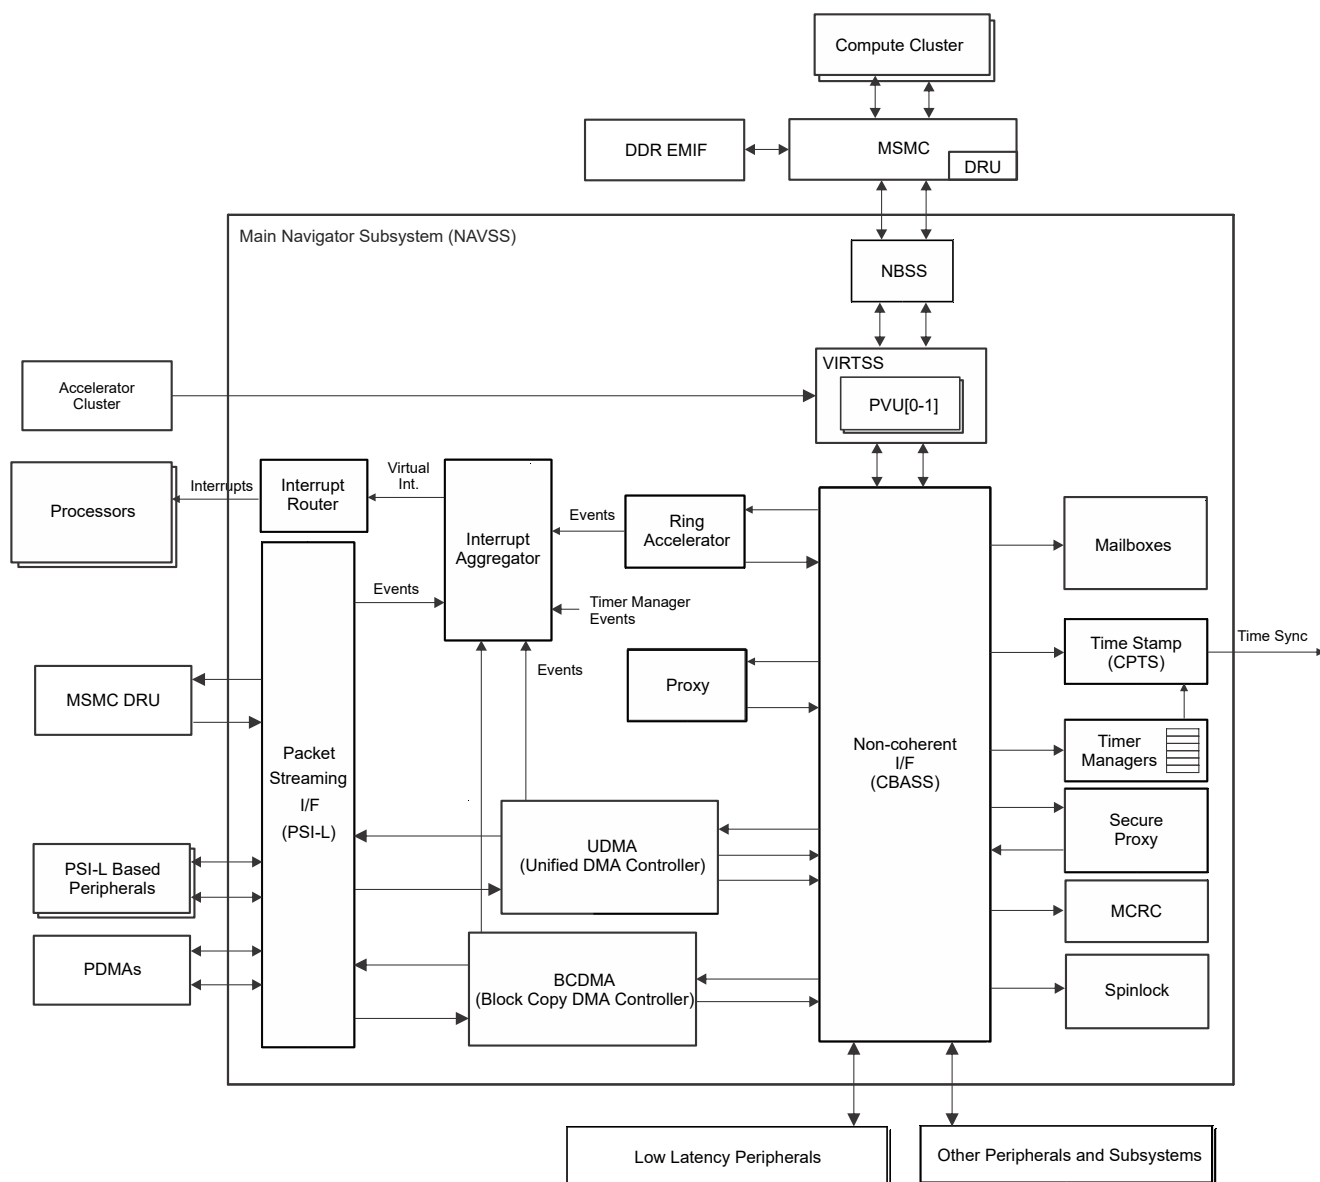

Figure 10-14. NAVSS0 Top-Level Block Diagram

Note

MCU NAVSS functionality is similar to that of main NAVSS, however it is composed of fewer peripherals and has reduced bandwidth.

10.2.1.2 NAVSS Functional Description

See [Section 10.1](#), *DMA Architecture*, for the *TI K3 Data Movement (DMA) Architecture* specification.

See the following sections for the respective module description:

UDMASS:

- Unified DMA Controller – [Section 10.2.3](#)
- Ring Accelerator – [Section 10.2.4](#)
- Packet Streaming Interface (PSI-L) – [Section 10.2.8](#)
- Block Copy DMA Controller – [Section 10.2.11](#)

MODSS:

- Mailbox – [Section 7.1](#)
- Spinlock – [Section 7.2](#)
- Two Timer Managers (Timer banks) – [Section 11.2](#)
- Time Stamp Module (CPTS) – [Section 11.1](#)
- Infrastructure components:
 - CBASS – *System Interconnect*
 - Proxies – [Section 10.2.5](#)
 - Interrupt aggregators – [Section 10.2.7](#)
 - Interrupt router – *NAVSS Interrupt Router Configuration*

NBSS – North bridge – [Section 10.2.10](#)

ECC aggregators – [Section 12.10.6](#)

VirtSS – Virtualization sub-system provides all the translation components supported in K3 for virtualization:

- Peripheral Virtualization Units (PVU) – [Section 8.3](#)

10.2.1.3 NAVSS Interrupt Configuration

This section describes the actions needed to configure interrupts within the NAVSS. The information provided is applicable to either the NAVSS or MCU_NAVSS subsystems.

Table 10-98 are module-specific hardcoded parameters required to properly configure the NAVSS interrupt support.

Table 10-98. NAVSS Parameters

Parameter	Value NAVSS0	Value MCU_NAVSS0	Description
RA_RING_CNT	1024	286	Number of total rings supported
IA_SEVI	4608	1536	UDMA Interrupt Aggregator Source Event Input (SEVI) count
IA_VINTR	256	256	UDMA Interrupt Aggregator Virtual Interrupt (VINTR) count
IR_IBASE	See NAVSS Interrupt Router Configuration	See MCU NAVSS Interrupt Router Configuration	Interrupt Router input interrupt base number for given module (hardcoded values in interrupt router)
EO	See Global Event Map	See Global Event Map	Event offset (hardcoded offsets in NAVSS)

Table 10-99 lists software-configurable variables used in the examples and descriptions.

Table 10-99. NAVSS Software Variables

Variable	Valid Range	Description
R#	0 – RA_RING_CNT-1	Ring number
E#	0 – (destination module specific)	Event number
GE#	= EO + E#	Global event number
SB#	0 – IA_SEVI-1	Interrupt aggregator status bit number
VI#	0 – IA_VINTR-1	Virtual interrupt number
OI#	0 – NAVSS0_INTR_OUTL_CNT - 1	Interrupt router output CPU interrupt number. See corresponding NAVSS Interrupt Router Configuration

10.2.1.3.1 NAVSS Event and Interrupt Flow

Figure 10-15 illustrates the event and interrupt flow within the NAVSS and output interrupts to a CPU. Information that flows between NAVSS modules is also indicated (in this case, Global Event (GE) information flows between ring accelerator and the PSILSS).

Figure 10-15. NAVSS Interrupt Flow

10.2.1.3.1.1 NAVSS Interrupts Description

This section describes the interrupt-related information that flows within NAVSS and how this information is configured or generated.

1. Ring Number (R#)

- Data is read from and written to a specific Ring Accelerator ring using direct ring-mode, proxy, or secure proxy accesses
- The Ring Accelerator has specific ring number ranges for specific purposes. The R# must match the intended purpose of the ring (see *RINGACC Ring Mapping*)

2. Global Event and Event Numbers (GE# and E#)

- GE# = EO + E#

- EO determines the destination module for the event. The PSILSS will route the GE# to the destination module per the NAVSS event mapping, removing EO in the process. The destination module sees only E#. See *Global event Map* for details. Examples:
 - GE# in the range 0x0000 – 0x1FFF (EO = 0x0000, E# = 0x0000 – 0x1FFF) would go to NAVSS0_UDMASS_INTR_AGGR0. The INTR_AGGR sees E#.
 - GE# in the range 0x4000 – 0x47FF (EO = 0x4000, E# = 0x0000 – 0x07FF) would go to NAVSS0_UDMASS_INTR_AGGR0. The INTR_AGGR sees E#.
- For the INTR_AGGR module, E# ranges from 0 to (IA_SEVI - 1)

3. Virtual Interrupt (VI#)

- The INTR_AGGR maps E# (via software configuration) to any SB#
- SB# ranges from 0 to (IA_SEVI - 1)
- Each VI# (0 – (IA_VINTR-1)) is driven by a group of 64 contiguous SB# numbers (VI# driven by SB#'s VI#×64 – (VI#×64)+63)

4. Output Interrupt (OI#)

- The Interrupt Router has a hardwired set of interrupt inputs from various modules (see *NAVSS Interrupt Router Configuration*). Examples:
 - In the NAVSS, 256 interrupt inputs from the NAVSS0_UDMASS_INTR_AGGR0 are hardwired to interrupt inputs 0 – 255. The VI# is zero-relative to this range.
 - In the MCU_NAVSS, 4 event interrupt inputs from the MCRC0 are hardwired to interrupt inputs 256 – 259. The VI# is zero-relative to this range.
- Software configures an interrupt input (based on VI# + IR_IBASE) to an OI#

10.2.1.3.1.2 Application Example

This section uses the following example to illustrate how to configure the NAVSS interrupt support for a specific use-case:

Using NAVSS0, use A72 MPU interrupt 7 for UDMA0 receive ring 16 (assumptions: use up/down event 10, NAVSS0_UDMASS_INTR_AGGR0 for interrupt aggregation, and virtual interrupt 3).

Table 10-100 lists the modules' hardcoded parameters used for this example:

Table 10-100. NAVSS Parameters for the Application Example

Parameter	Value NAVSS0	From Table	Description
RA_UDMAP0_RX	340	<i>RINGACC Ring Mapping</i>	Starting ring number for UDMA0 receive channels
RA_RING_CNT	1024	<i>NAVSS0_RINGACC0 Configuration Parameters</i>	Number of total rings supported
IA_SEVI	4608	<i>Interrupt Aggregators Parameters</i>	NAVSS0_UDMASS_INTR_AGGR0 Steerable Event Input (SEVI) count
IA_VINTR	256	<i>Interrupt Aggregators Parameters</i>	NAVSS0_UDMASS_INTR_AGGR0 Virtual Interrupt (VINTR) count
IR_IBASE	0	<i>NAVSS Interrupt Router Input Mapping</i>	Interrupt-Router-input-interrupt base for NAVSS0_UDMASS_INTR_AGGR0
EO	0	<i>Global event Map</i>	Event offset. Destination is NAVSS0_UDMASS_INTR_AGGR0
CC_IBASE	0	<i>NAVSS0 Hardware Requests</i>	Interrupt-requests-to-CC base

Table 10-101 the variables and their respective calculations for this example.

Table 10-101. NAVSS Software Variables for the Application Example

Variable	Calculations/Value	Description
R#	$= (RA_UDMAP0_RX + 16)$ $= (340 + 16)$ $= 356$	Receive ring 16 translates to ring number
E#	10	Zero-relative event number from PSILSS to NAVSS0_UDMASS_INTR_AGGR0

Table 10-101. NAVSS Software Variables for the Application Example (continued)

Variable	Calculations/Value	Description
GE#	$= (EO + E\#)$ $= (0 + 10)$ $= 10$	Global event number (event 10 to be sent to NAVSS0_UDMASS_INTR_AGGR0)
VI#	$= 3$	VI# = 3 is per example assumptions. VI# could get any value 0 – IA_VINTR-1.
SB#	$= 200$	Must be in the range $(VI\# \times 64) - ((VI\# \times 64) + 63) = 192 - 255$ in order to drive VI# 3. We will use 200 for this example.
OI#	$= (A72_IBASE + 7)$ $= (0 + 7)$ $= 7$	OI# = 7 is per example assumptions. OI# could get any value 0 – 127 to drive an A72 interrupt.

Table 10-102 shows software register writes that will configure the NAVSS to produce the desired interrupt per the example description.

Table 10-102. NAVSS Register Writes for the Application Example

Module	Register	Value to Write	Description
RINGACC0	RING[R#]_EVT (EVENT_j)	RING[]_EVT $= GE\#$ $= 10$	Ring event number must be specified as a global event number
INTR_AGGR0	ENTRY[E#]_INTMAP (IMAP_j)	ENTRY[10]_INTMAP $= (((SB\#/64) \& 0x1FF) < 8) (SB\%64)$ $= (3 < 8) 8$ $= 0x308$	regnum = SB# / 64 bitnum = SB# % 64
INTR_AGGR0	VINT[SB#/ 64]_ENABLE_SET (ENABLE_SET_j)	VINT[3]_ENABLE_SET $= 1 < (SB\% 64)$ $= 1 < 8$ $= 0x100$	Enable interrupt
INTR_ROUTER0	INTERRUPT_CONTR OL[OI#] (MUXCNTL_y)	INTERRUPT_CONTROL[7] $= IR_IBASE + VI\#$ $= 0 + 3$ $= 3$	Route interrupt

10.2.2 MCU Navigator Subsystem (MCU NAVSS)

This chapter describes the integration of the MCU Navigator Subsystem (MCU NAVSS) in the device and internal module parameters.

10.2.2.1 MCU NAVSS Overview

MCU Navigator Subsystem (MCU NAVSS) has a subset of the modules of the main NAVSS and is instantiated in the MCU domain.

MCU Navigator Subsystem consists of DMA/Queue Management components – UDMA and Ring Accelerator (UDMASS), and Peripherals (Module subsystem [MODSS]).

UDMASS – UDMASS is the essential part of the TI Data Movement Architecture. UDMASS consists of:

- Unified DMA Controller
- Ring Accelerator
- Packet Streaming Interface (PSILSS)

MODSS – MODSS is a collection of peripherals with different system-level functions. NAVSS0 contains the following modules:

- Memory CRC module
- Infrastructure components such as CBASS, proxies, interrupt aggregators, and an interrupt router

ECC aggregators – for SEC/DED memory protection.

Figure 10-16 shows the MCU_NAVSS0 top-level block diagram.

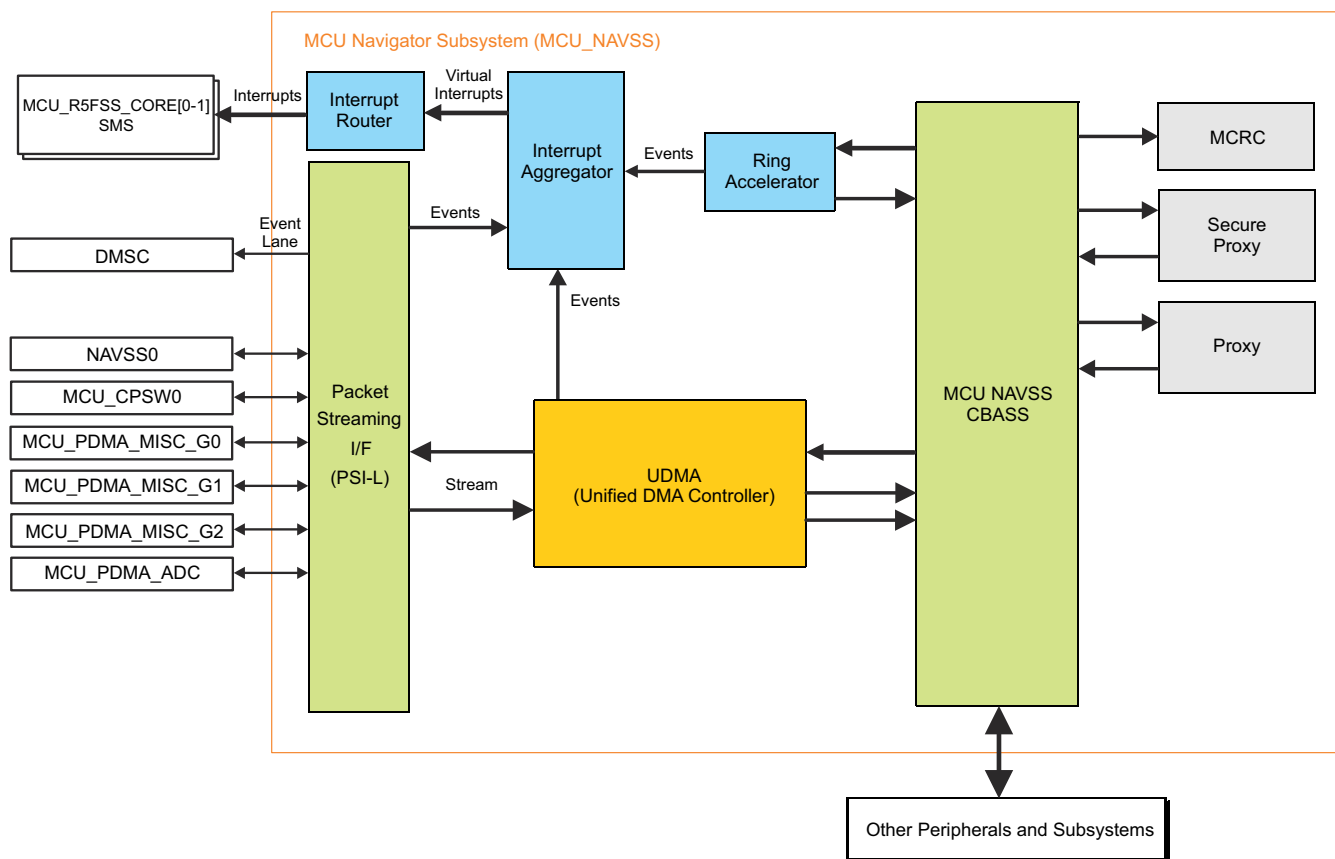

Figure 10-16. MCU NAVSS Top-Level Block Diagram

Note

MCU NAVSS functionality is similar to that of main NAVSS, however it is composed of fewer peripherals and has reduced bandwidth.

10.2.2.2 MCU NAVSS Functional Description

See *DMA Architecture*, for the *TI K3 Data Movement (DMA) Architecture* specification.

See the following sections for the respective module description:

UDMASS:

- Unified DMA Controller – [Section 10.2.3](#)
- Ring Accelerator – [Section 10.2.4](#)
- Packet Streaming Interface (PSI-L) – [Section 10.2.8](#)

MODSS:

- Infrastructure components:
 - CBASS – *System Interconnect*
 - Proxies – [Section 10.2.5](#) and [Section 10.2.6](#)
 - Interrupt aggregator – [Section 10.2.7](#)

ECC aggregators – [Section 12.10.6](#)

10.2.3 Unified DMA Controller (UDMA)

This chapter describes the UDMA controller module, part of NAVSS.

10.2.3.1 UDMA Overview

The UDMA-P is intended to perform similar (but significantly upgraded) functions as the packet-oriented DMA used on previous SoC devices.

Table 10-103. UDMA Allocation Across Device Domains

Module Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_UDMAP0	-	-	✓ (NAVSS)
MCU_NAVSS0_UDMAP0	-	✓ (MCU NAVSS)	-

Figure 10-17 shows a top-level overview of the UDMA module.

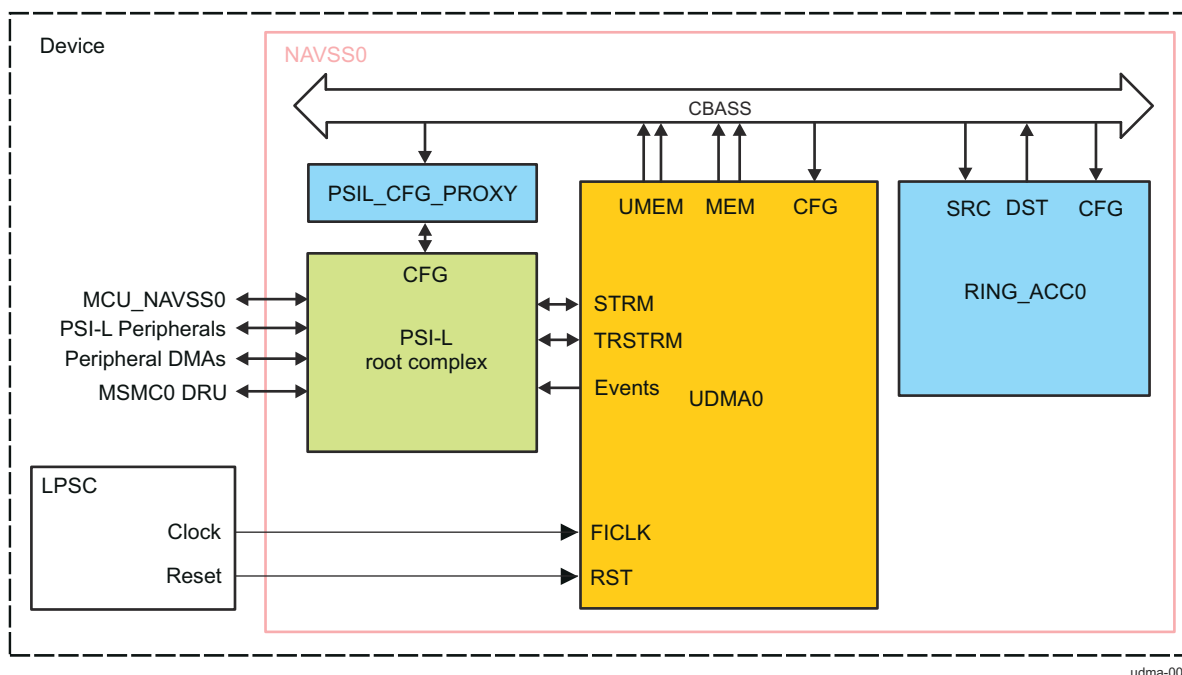

Figure 10-17. UDMA Overview

10.2.3.1.1 UDMA Features

NAVSS0_UDMAP0 controller module supports the following modes and features:

- *TI K3 DMA Architecture* compliant Tx/Rx port implementation (see [Section 10.1, DMA Architecture](#))
- Implements *TI DMA Architecture*-compliant Packet-Oriented DMA Functionality (UDMA-P)
 - Provides internal Tx Packet Oriented DMA processing unit
 - Provides internal Rx Packet Oriented DMA processing unit
 - Supports *rflow_cnt* unique Rx flow table entries
 - Supports 1 transmit queue per data connection
 - Supports 1 receive queue per data connection
 - Supports physical separation of buffer control and payload information
 - Supports host and monolithic descriptor formats
 - Supports unlimited buffer scatter/gather for packets using host descriptor type
 - Supports data buffer sizes up to 4 Mbytes
 - Supports variable first valid byte offset within data buffers
 - Supports packet truncation on transmit
 - Provides per-channel buffering:

- Provides 16 word deep × 128-bit Packet FIFO for each Tx channel
- Provides 4 word deep Packet Info FIFO for each Rx channel
- Provides 8 word deep × 128-bit Packet Data FIFO for each Rx channel
- Supports up to 32 Protocol Specific words for Tx packets
- Supports up to 32 Protocol Specific words for Rx packets
- Implements *TI DMA Architecture* compliant Third Party Channel Controller
 - Channel controller is built as a prefetcher engine
 - Provides the same functionality as a discrete UDMA-C/UTC combination
 - Provides a fully integrated *TI DMA Architecture* Third Party DMA compliant solution
 - Can also fetch TRs and writeback TR responses for up to *echan_cnt* external channels which are transported via the TR PSI-L interface
- Implements *TI DMA Architecture* compliant Unified Transfer Controller
 - Provides a memory read access unit
 - Supports read bursts up to 128 bytes (limited by Tx Per Channel FIFO depth for the channel)
 - Provides a memory write access unit
 - Supports write bursts up to 128 bytes (limited by Tx Per Channel FIFO depth for the channel)
 - Supports Type 0-4, and Type 15 Transfer Request types
- Provides a set of *TI DMA Architecture* compliant Unified DMA channels which all share the execution hardware using time division multiplexing
 - Supports *tchan_cnt* concurrent Tx channels
 - Each Tx channel can be configured at runtime to be:
 - Packet oriented Tx data channel
 - Third party combination source control and data channel (Third Party channel mode)
 - Supports *rchan_cnt* simultaneous Rx (destination) channels
 - Each Rx channel can be configured at runtime to be:
 - Packet oriented Rx data channel
 - Third party combination destination control and data channel (Third Party channel mode)
 - Provides support for three different groups of internal channels:
 - Ultra-high capacity (UHC) channels
 - Quantity specified by: *uchan_cnt*
 - Provide deeper Tx Per Channel FIFOs
 - Provide 16 deep descriptor/TR prefetch buffers
 - UHC channels are the first *uchan_cnt* channels within the Tx and Rx arrays (starting with channel 0 and extending up to channel *uchan_cnt*-1)
 - Tx and Rx UHC channels are specified as a matched pair
 - Still usable as split channels but design must have same number of Tx/Rx UHC channels
 - High-capacity (HC) channels:
 - Quantity specified by: *hchan_cnt* - *uchan_cnt*
 - Provide deeper Tx Per Channel FIFOs
 - Provide 16 deep descriptor/TR prefetch buffers
 - HC channels are the next *hchan_cnt* channels (after any UHC channels) within the Tx and Rx channel arrays (starting with channel *uchan_cnt* and extending up to *uchan_cnt* + *hchan_cnt*-1).
 - Normal capacity (NC) channels:
 - Quantity on Tx specified by: *tchan_cnt* - *uchan_cnt* - *hchan_cnt*
 - Quantity on Rx specified by: *rchan_cnt* - *uchan_cnt* - *hchan_cnt*
 - Provide standard depth Tx/Rx per channel FIFOs
 - Provide 1 deep descriptor/TR prefetch buffers

Note

User can still use ultra-high capacity and high-capacity channels as general normal-capacity channels though may not be taking advantage of the potential DMA throughput advantages.

- Provides per-channel buffering:
 - Provides 16 word deep data FIFO for each NC Tx (source) channel
 - Provides 8 word deep data FIFO for each NC Rx (destination) channel

- Provides single 128-bit read/write VBUSM master interface for prefetcher accesses to RINGACC and memory.
 - Supports up to 16 outstanding reads.
 - Supports up to 16 outstanding writes.
- Provides single 128-bit read/write VBUSM master interface for packet DMA and coherency unit accesses to RINGACC and memory.
 - Supports up to 16 outstanding reads.
 - Supports up to 16 outstanding writes.
- Provides single 128-bit read only VBUSM master interface for payload transfers.
 - Supports up to 16 outstanding reads.
- Provides single 128-bit write only VBUSM master interface for payload transfers.
 - Supports up to 16 outstanding writes.
- Provides 128-bit wide PSI-L compliant source interface for sending data to remote UTCs and remote peripherals
 - Includes 1 outgoing event transport lane
- Provides 128-bit wide PSI-L compliant destination interface for receiving data from remote UTCs and remote peripherals
 - Includes 1 incoming event transport lane
- Provides PSI-L interface for sending Transfer Requests to remote UTC channels and receiving back Transfer Responses
 - Provides 32 entry deep unified Transfer Response FIFO for external channels
- Provides 0 local event input buses

10.2.3.1.2 UDMA Parameters

Table 10-104 shows the UDMA configuration parameters in this SoC.

Table 10-104. UDMA Configuration Parameters

Module Instance	Parameters ⁽¹⁾					
	tchan_cnt ⁽²⁾	rchan_cnt ⁽³⁾	echan_cnt ⁽⁴⁾	hchan_cnt ⁽⁶⁾	uchan_cnt ⁽⁷⁾	rflow_cnt ⁽⁵⁾
NAVSS0_UDMAP0	85	82	256	4	2	224
MCU_NAVSS0_UDMAP0	48	48	0	2	0	96

(1) Parameter values can be read from the capabilities registers. See UDMA_CAP2 and UDMA_CAP3 registers.

(2) Total internal Tx channel count (Normal- + High- + Ultra-high capacities)

(3) Total internal Rx channel count (Normal- + High- + Ultra-high capacities)

(4) External UTC channel count

(5) Rx flow table entry count

(6) High-capacity + Ultra-high capacity channel count

(7) Ultra-high capacity channel count

10.2.3.2 UDMA Functional Description

The UDMA module supports the transmission and reception of various packet types. The UDMA is architected to facilitate the segmentation and reassembly of K3 DMA data structure compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each connected peripheral. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be ongoing. The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware.

An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for Transmit operations. The ordering and rate of Receive operations is indirectly controlled by the order in which blocks are pushed into the DMA on the Rx PSI-L interface.

The UDMA also supports acting as a Unified Channel Controller (UDMA-C)/Unified Transfer Controller (UTC) combined unit which accepts Transfer Request packets from Ring Accelerator and then performs the transfers which the Transfer Request (TR) specifies.

Channels in the UDMA can be configured to be either Packet-based or TR-based Third Party channels on a channel by channel basis.

10.2.3.2.1 Block Diagram

Figure 10-18 shows UDMA main internal components.

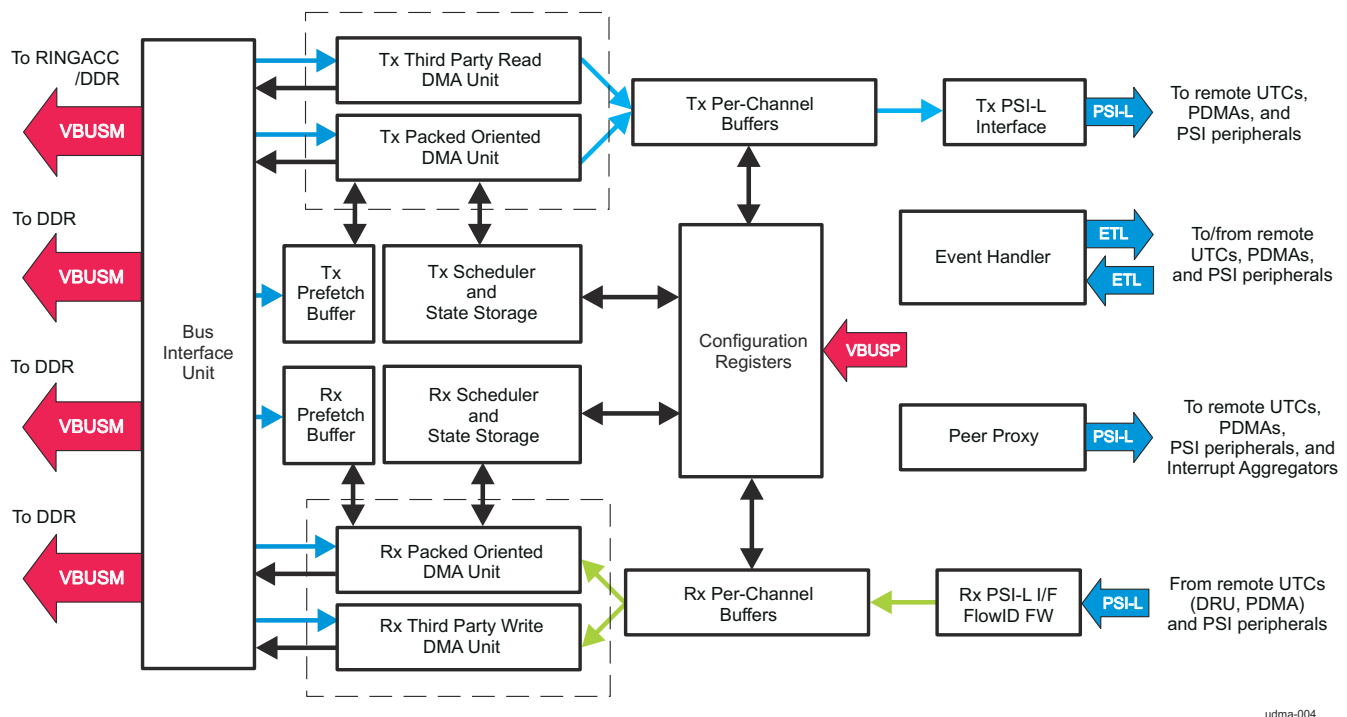

Figure 10-18. UDMA Block-Diagram

Bus Interface Unit

The Bus Interface Unit (BIU) is responsible for merging and buffering all of the transactions that originate from the various master blocks inside the DMA controller into the 4 separate VBUSM master interfaces. Arbitration between the blocks to a given VBUSM interface is round robin within a single priority level. A two word deep retiming buffer is provided on each sub interface of each provided VBUSM bus.

Tx Prefetcher Configuration Registers

The Tx Prefetcher Configuration Registers block is responsible for providing memory mapped registers for configuration of the Tx DMA function, monitoring the fullness level of the Tx prefetch buffers, maintaining Tx

prefetch state information, arbitrating which channel will be allowed to perform prefetch work next, issuing scheduler commands to the Tx Prefetch Units, and writing back the updated state returned from those same prefetch units.

Tx Prefetch Unit(s)

The Tx Prefetch Unit block is responsible for performing a fetch of either a Packet Descriptor (packet mode) or a TR to feed the downstream Tx DMA/Tx Read Units.

Tx Configuration Registers

The Tx Configuration Registers block (*UDMASS_UDMAP0_CFG_TCHAN Registers*) is responsible for monitoring the fullness level of the Tx Per Channel FIFOs, monitoring data transfer work which is pending, maintaining data movement thread state information, arbitrating which channel will be allowed to perform work next, issuing scheduler commands to the Tx Packet and TR based DMA core blocks, and writing back the updated state returned from those same DMA core blocks.

Tx Packet DMA Unit

The Tx Packet DMA Unit block implements all of the state machine functionality necessary to implement the K3 DMA Host and Monolithic Tx protocol. The Tx Packet DMA unit initiates VBUSM transactions in order to read and write descriptor pointers from the Ring Accelerator, read descriptors from memory, and read data from buffers in memory.

Tx Packet Coherency Unit

The Tx Packet Coherency Unit is responsible for ensuring that all control structures and data have been read (and updated if applicable) by the Tx DMA unit(s) prior to returning the packet descriptor pointer to the appropriate return queue in the Ring Accelerator. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Tx queue. This unit is only used on channels which are in Pass-By-Reference mode

Tx TR Coherency Unit

The Tx TR Coherency Unit is responsible for ensuring that all control structures and data have been read prior to allowing the TR response to be written to either the Packet Descriptor or a Pass by Value queue in the Ring Accelerator. This unit ensures that the ordering of TR response writes also directly matches the ordering of Transfer Requests that were processed by the channel. This unit is only used on channels which are in TR mode.

Tx External Channel TR Coherency Unit

The Tx External Channel TR Coherency Unit is responsible for ensuring that TRs received back from remote UTCs are written in strong order to either the Packet Descriptor or a Pass-by-Value queue in the Ring Accelerator. This unit is only used on external UTC channels.

Tx Event Coherency Unit

The Tx Event Coherency Unit is responsible for ensuring that all data transfers have completed before a completion event is issued through the outgoing Event Transport Lane (ETL). This unit is only used on channels which are in TR mode.

Tx Per Channel Buffers

The Tx Per Channel Buffers implement a FIFO for each Tx DMA channel that is used for buffering packet control and payload data that has been fetched by the Tx Packet DMA units or Tx Third Party Read unit modules. The buffers are byte oriented on write so that the data from the DMA units which may not be full words can be packed properly. The buffers are block oriented on read in accordance with the transport mechanism outlined in the PSI-L Interface specification. Each Tx (source) channel in the UDMA controller maps directly onto a thread in the Tx PSI-L interface. The Tx Per Channel Buffer block outputs queue fullness information to the Tx Scheduler block which it then uses to determine when it must initiate DMA opportunities to backfill the buffers. The Tx Per Channel Buffer will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status

of all of the threads and will perform a round robin arbitration between the different threads for the use of the Transmit PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

Rx FlowID Firewall

The Rx FlowID firewall checks the incoming flowID on the received packet from the Rx PSI-L interface to verify that it is either the corresponding flowID for the channel (that is, the default flow ID for the channel which is the same as the channel number) or that the flowID falls within a programmed range that is considered legal for the channel. If the received flowID does not fall within the legal range then the packet is dropped and the error is trapped.

Rx Per Channel Buffers

The Rx Per Channel Buffers implement a FIFO for each Rx DMA channel that is used for buffering packet control and payload data that has been pushed into the DMA from the Rx PSI-L interface. The Rx Per Channel Buffers also includes an arbitration unit which determines which Rx DMA channel must be serviced next

Rx Configuration Registers

The Rx Configuration Registers block (*UDMASS_UDMAP0_CFG_RCHAN Registers*) is responsible for providing memory mapped registers for configuration of the Rx DMA functions including the default settings for the free descriptor and destination queues. For modularity and high speed pipelining reasons, the Rx traffic is looped through the Rx Configuration Registers block where the original stream information is merged with information from the configuration registers on its way to the Rx DMA unit module. This prevents the Rx DMA Core from having to spend cycles accessing the channel configuration information for the channel.

Rx Packet DMA Unit

The Rx Packet DMA Unit block implements all of the state machine functionality necessary to implement the K3 DMA Rx protocol for Host and Monolithic descriptor types. The Rx Packet DMA Unit initiates VBUSM transactions in order to read descriptor pointers from the Ring Accelerator, read buffer descriptor information, write descriptors to memory, and write data to buffers in memory.

Rx Packet Coherency Unit

The Rx Packet Coherency Unit is responsible for ensuring that all control structures and data have been written by the Rx DMA unit(s) prior to returning the packet descriptor pointer to the appropriate return queue in the Ring Accelerator. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Rx free queues. Writes are not considered complete by this unit until the entire write status has been returned for all outstanding transactions for a given packet ID. This unit is only used on channels which are in Pass By Reference mode

Rx TR Coherency Unit

The Rx TR Coherency Unit is responsible for ensuring that all control structures have been read and all data has been written prior to allowing the TR response to be written to either the Packet Descriptor or a Pass by Value queue in the Ring Accelerator. This unit ensures that the ordering of TR response writes also directly matches the ordering of Transfer Requests that were processed by the channel. This unit is only used on channels which are in TR mode.

Rx Event Coherency Unit

The Rx Event Coherency Unit is responsible for ensuring that all data transfers have completed before a completion event is issued through the outgoing ETL. This unit is only used on channels which are in TR mode.

Third Party Read Unit

The Third Party Read Unit(s) are responsible for sequencing all of the Tx side channel control and data transfers. The Third Party Read Unit is responsible for performing the actual data read operations including sequential address generation and nested loop control. Like the Tx Packet DMA Unit, the Third Party Read Unit receives state information from the Tx Configuration Registers and returns that state when a transfer opportunity is complete. The Third Party Read Unit will perform as much data transfer as is specified in the Transfer Request

up until either a fixed number of bytes have been transferred, the transfer is completed, or the transfer has reached a point which requires an input trigger event to proceed.

Third Party Write Unit

The Third Party Write Unit(s) are responsible for sequencing all of the Rx side channel data transfers. The Third Party Write Unit is responsible for performing the actual data write operations including sequential address generation and nested loop control. Like the Rx Packet DMA Unit, the Third Party Write Unit receives state information from the Rx Configuration Registers and returns that state when a transfer opportunity is complete. The Third Party Write Unit will perform as much data transfer as is specified in the Transfer Request up until either a fixed number of bytes have been transferred or the transfer is completed or the transfer has reached a point which requires an input trigger event to proceed.

Event Handler

The Event Handler block is responsible for accepting and logging channel triggering events and for generating channel completion and error events.

PSI-L Real Time Proxy

The PSI-L Real Time Proxy block is responsible for allowing tunneled VBUSP transactions to the Real Time Remote Peer registers to generate PSI-L configuration transactions to the paired remote peer for each Tx and Rx channel.

10.2.3.2.2 General Functionality

This section is applicable to all UDMA modes.

10.2.3.2.2.1 Operational States

At any given time the UDMA can be in one of three different states as described in [Table 10-105](#).

Table 10-105. Operational States

Operational State	Description
Init	This is the initial state of UDMA during and immediately after reset. During this state, all of the RAMs inside the UDMA will be initialized to known values including the ECC redundant parity bits. While in the Init state, the DMA will de-assert all ready signals on all applicable slave interfaces and will de-assert all request signals on all applicable master interfaces. The UDMA will automatically transition out of the Init state into the Idle state when all of the RAM initialization has been completed.
Idle	Once the UDMA leaves the Init state, it enters the Idle state whenever no outstanding transactions are pending on any of the UDMA interfaces (master or slave). The Idle state is generally a transient state and is used by the UDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. As channels have work queued on them and transactions begin flowing into the system, the UDMA transitions to the Active state. When no more work is pending, or when the host pauses/disables active channels, or when the SoC power management desires to shut down the UDMA, the UDMA will account for any outstanding transactions and will re-enter the Idle state. The UDMA leaves the Idle state anytime it generates or receives a transactions that requires a return response as those protocols dictate that the clock must remain running to avoid faulting the handshaking protocol.
Active	The UDMA enters the Active state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent) the UDMA transitions to the Idle state.

10.2.3.2.2.2 Tx Channel Allocation

In NAVSS0, a total of *tchan_cnt* Packet Tx channels are provided within the DMA for concurrent data transfers between memory mapped space and the Tx Per Channel Buffers. Each of these channels can be configured to operate as a packet oriented channel (uses queues/rings/descriptors/buffer) or as a Third Party DMA source channel (uses Transfer Request packets to control read operations). Depending on which channel mode is selected, when a Tx channel comes into context the work for that channel will either be dispatched to a Tx Packet DMA Unit or a Third Party Read Unit respectively.

A total of *echan_cnt* external UTC channels are also provided. These channels only perform fetches and transfers of Transfer Requests to remote UTC channels and writeback of returned Transfer Responses to TR

descriptors (pass by reference) or RINGACC rings (pass by value). The external channels are at channel numbers immediately above the internal channels.

The Tx channels are allocated as shown in [Table 10-106](#).

Table 10-106. Internal Tx Channel Allocation

DMA Channel	Function	Tx Queue (Ring)
0	Tx Channel	0 (Starting queue number in RINGACC for Tx channel 0)
...
<i>tchan_cnt</i> - 1	Tx Channel	<i>tchan_cnt</i> - 1

10.2.3.2.2.3 Rx Channel Allocation

In NAVSS0, a total of *rchan_cnt* Rx channels are provided within the DMA for concurrent transfers between the Rx Per Channel Buffers and memory mapped space. Each of these channels can be configured to operate as a packet oriented channel (uses rings/descriptors/buffer) or as a Third Party DMA destination channel (uses rings/ Transfer Request packets or TR standalone records to control read operations). Depending on which channel mode is selected, when a Tx channel comes into context the work for that channel will either be dispatched to an Rx Packet DMA Unit or a Third Party Write Unit respectively. The Rx channels are allocated as shown in [Table 10-107](#).

Table 10-107. Rx Channel Allocation

DMA Channel	Function	Src Tag
0	Rx Channel	0
...
<i>rchan_cnt</i> - 1	Rx Channel	<i>rchan_cnt</i> - 1

10.2.3.2.2.4 Tx Teardown

As is specified in the *TI DMA Architecture* specification, the host initiates a Tx DMA channel teardown operation by writing to the TDOWN bit in the TCHANRT UDMA_TRT_CTL_j register. Once a channel teardown is requested, the appropriate Tx DMA unit will complete any packet/TRs that the channel has prefetched or is currently in the process of transferring and will then clear the EN bit, will send a Teardown packet out the outbound Payload Data PSI-L interface, and will push a Teardown Completion Record onto the Tx Default Queue for the channel. If the Tx DMA engine is not currently in a packet/TR for the channel, it will immediately clear the EN, send the Teardown packet, and push the Teardown Completion Record. Once the teardown is complete, no further packet processing will occur until the host software re-enables the channel.

10.2.3.2.2.5 Rx Teardown

As is specified in the *TI DMA Architecture* specification, the host initiates an optimal Rx DMA channel teardown operation by shutting down the incoming payload stream at its source (a remote peer peripheral or the Tx side of a block copy channel). Once teardown is initiated at the source, data will eventually drain from the incoming PSI-L stream and when all data is complete, the remote peer entity will send a Teardown packet (either a standalone packet or tdown asserted with eop on the last data phase of the last packet). When the UDMA receives a teardown message, the TDOWN bit will be set in RCHANRT UDMA_RRT_CTL_j. In the case where a remote peer cannot generate a teardown message, the host must ensure that all data has stopped flowing from the remote peer and will then directly set the TDOWN bit. Once the UDMA sees the TDOWN asserted it will wait for any existing packets which are currently held in the Rx Per Channel FIFO to be completed and will then de-assert the EN bit in RCHANRT UDMA_RRT_CTL_j. If the back end application continues to allow new packets to be pushed into the Rx PC FIFO, the DMA will continue to delay marking the channel as torn down as long as the Rx PC FIFO never reaches an empty state

10.2.3.2.2.6 Tx Clock Stop

The Tx clock stop interface allows the Tx portion of the UDMA to be gracefully commanded to shut down its operations and enter into an IDLE state so that the main clock (FICLK) can be stopped. When the tcs_clkstop_req input is asserted, the Tx portion of the UDMA will stop processing transmit packets/TRs for

each channel at the next packet/TR boundary. Once all of the Tx channels have gracefully stopped transmission, the UDMA will assert the `tcs_clkstop_ack` output. Once the UDMA Tx engine has entered the IDLE state, it will remain there until the `tx_clockstop_req` is de-asserted.

10.2.3.2.2.7 Rx Clock Stop

The Rx clock stop interface allows the Rx portion of the UDMA to be gracefully commanded to shut down its operations and enter into an IDLE state so that the main clock (FICLK) can be stopped. When the `rsc_clkstop_req` input is asserted, the Rx portion of the UDMA will stop processing receive packets for each channel at the next packet boundary. Once all of the Rx channels have gracefully stopped reception, the UDMA will assert the `rsc_clkstop_ack` output. Once the UDMA Rx engine has entered the IDLE state, it will remain there until the `rx_clockstop_req` is de-asserted.

10.2.3.2.2.8 Rx Thread Enables

PSI-L threads must first be enabled in order to transfer commands or data. Threads are enabled or disabled by setting or clearing the enable bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

10.2.3.2.2.9 Events

Events are used in the *TI DMA Architecture* for triggering hardware or software (by being turned into interrupts) processes. Physical (or local) events in the *TI DMA Architecture* are implemented as active-high, single-cycle, long, synchronous pulses which are strobed to communicate that a particular condition has occurred. Virtual (or global) events are implemented as a value which is passed across a shared bus (ETL) - one value per cycle. Physical (local) events can be used by the UDMA to communicate with some local peripherals. Virtual (global) events are used by the UDMA to communicate with remote peripherals, the interrupt aggregator, and other DMA instances in the system.

10.2.3.2.2.9.1 Local Event Inputs

There are no local events routed to the UDMA local event inputs in the current NAVSS implementation.

10.2.3.2.2.9.2 Inbound Tx PSI-L Events

The Tx PSI-L interface includes a single inbound event transport lane (ETL) which allow events to be received from other UDMA/UTC/PDMA instances for synchronization and triggering purposes. Events passed in from this event transport lane will already have been decoded as destined for some event destination index for this particular UDMA. The appropriate LSBs of each event number are extracted and the specified event is asserted.

The event map for inbound events to the UDMA is shown in [Table 10-108](#).

Table 10-108. Inbound Event Map

Event Number	Target
0	Tx Channel 0 Global Trigger 0
1	Tx Channel 0 Global Trigger 1
2	Tx Channel 1 Global Trigger 0
3	Tx Channel 1 Global Trigger 1
...	...
169	Tx Channel 84 Global Trigger 1
170	Rx Channel 0 Global Trigger 0
171	Rx Channel 0 Global Trigger 1
172	Rx Channel 1 Global Trigger 0
173	Rx Channel 1 Global Trigger 1
...	...
333	Rx Channel 81 Global Trigger 1

10.2.3.2.2.9.3 Outbound Rx PSI-L Events

The Rx PSI-L interface includes a single outbound event transport lane (ETL) which allows internal events to be sent to other UDMA/UTC/PDMA instances on the device for synchronization and triggering purposes. The destination event number is programmed for each event source within the UDMA. See registers:

- TCHAN UDMA_TOES_J
- TCHAN UDMA_TEOES_J
- RCHAN UDMA_ROES_J
- RCHAN UDMA_REOES_J

10.2.3.2.2.10 Emulation Control

The emulation control input and register bits (SOFT and FREE in the UDMA_EMU_CTRL register) allow DMA operation to be suspended. When the emulation suspend state is entered, the DMA will stop processing receive and transmit packets for each channel at the next packet boundary. Any packet currently in reception or transmission will be completed normally without suspension. Emulation control is implemented for compatibility with other peripherals. [Table 10-109](#) shows the operations of the emulation control input and register bits.

Table 10-109. Emulation Behavior Control

Emulation Control Input	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

10.2.3.2.3 Packet Oriented Transmit Operation

Packet transmission is accomplished within the UDMA by moving data from structures that are located in memory via the VBUSM Memory Interfaces onto the Transmit Packet Data PSI-L Interface. This movement of data is performed in blocks whose size is specified by the Tx DMA scheduler.

10.2.3.2.3.1 Packet Mode VBUSM Master Interface Command ID Selection

The UDMA keeps a transaction command scoreboard for each specific direction for the Packet Mode VBUSM Master interface. The scoreboard tracks which command indexes are currently outstanding from the DMA on that interface. When a read or write is requested by one of the internal master agents in the UDMA, the scoreboard corresponding to the specified interface and for the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*). The index values for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

10.2.3.2.4 Packet Oriented Receive Operation

Packet reception is accomplished within the UDMA by moving data from the Receive PSI-L Interface to data structures that are located in memory accessible via the VBUSM Memory Interface(s).

10.2.3.2.4.1 Rx Packet Drop

The Rx PSI-L Interface master may assert the *rstrmp_drop* signal co-incident with the transfer of any data phase of a packet. When this signal is sampled asserted by the UDMA, the drop condition will be latched into a flag for that thread and the Rx Packet DMA unit will be notified that the packet is to be flushed and recycled rather than passed to the host. The drop signal is only required to be asserted with a single data phase and will only cause the current packet to be dropped from packet stream. The UDMA will drop all data given to it until the EOP is found on the thread and then the internal drop flag will be cleared. When the UDMA drops a packet on a channel configured for Packet mode there is no notification to the host.

10.2.3.2.4.2 Rx Starvation and the Starvation Timer

As described in the *TI DMA Architecture* specification, whenever the Rx DMA engine needs to read a Free Descriptor Pointer from the Ring Accelerator, it is possible that the queue may be empty. When this occurs it is

referred to as buffer starvation. The Ring Accelerator provides a message interface to the UDMA which provides increment and decrement information so that the UDMA can keep a local occupancy counter for each ring that it can access from the RINGACC. When the Rx engine requires a free descriptor it will first check to see if the local occupancy for that ring is non-zero. If the occupancy is zero, starvation has occurred. When starvation occurs the Rx DMA will respond in one of two ways depending on the value of the `rx_error_handling` bit in Rx Flow Table entry that is currently being used for that particular packet reception opportunity. If the `rx_error_handling` bit is 0, the Rx DMA will drop the packet and will return any descriptors which it may have previously allocated for that packet to the respective queues from which they were allocated. If the `rx_error_handling` bit is set, the Rx DMA is required to retry checking to see if a Free Descriptor is available at a later time.

A timer is provided in order to control the rate at which the retry attempts will occur. All channels share the same timer and the period of the timer is set using the `TIMEOUT_CNT` field in the `UDMA_PERF_CTRL` register. The `TIMEOUT_CNT` field specifies in clock cycles the minimum delay between subsequent attempts to check if a Free Descriptor is available on each individual channel.

Example: If the `TIMEOUT_CNT` is set to 256 and channel 1 finds its Free Descriptor queue empty on cycle 10, it will be required to wait until at least cycle 266 before it can make another attempt check the queue again. The actual number of cycles which will be waited by the DMA will typically be larger than the `TIMEOUT_CNT` value and this is not intended to be a highly precise operation. The critical requirement is that the DMA will not attempt to bring a channel into context to check if a buffer is available at a more frequent rate than is allowed.

10.2.3.2.5 Third Party Mode Operation

10.2.3.2.5.1 Events and Flow Control

The following sections describe the mechanisms that are provided for supporting flexible flow control between peripherals, the UDMA and other DMA instances.

10.2.3.2.5.1.1 Channel Triggering

Channels which are configured in Third Party mode must be triggered in order for them to perform work. Triggering can be configured to be immediate, one-shot, or periodic at different levels of TR completion and is specified in the TR itself. Each channel in the UDMA is capable of being triggered by two separate events which are mapped at specific offsets in a global event target map (just like an address map for memory mapped slaves). The UDMA maps its channel triggers with Tx side channels first followed by Rx side channels as described in [Table 10-108, Inbound Event Map](#).

10.2.3.2.5.1.2 Internal TR Completion Events

Each TR which is processed, provides the ability to assert 1 of 4 possible output events at specific completion levels for the TR. Since the output event is specified directly in the TR and the TRs are written by potentially untrusted software processes, channels are only able to assert *virtual events* when they complete various portions of the TR. These virtual events are then mapped to actual destination events in the global event map by the `TCHAN_UDMA_TOES_j` or `RCHAN_UDMA_ROES_j` event steering registers. These registers are programmed statically by a trusted software process that has determined the channels that should have access to the specified event destination slots.

10.2.3.2.5.2 Transmit Operation

10.2.3.2.5.2.1 Transfer Request

After reset, all channels that are configured in Third Party transfer mode will be idle and waiting for work to be assigned to them. In order to initiate Third Party channel operation, the host software places work in the form of either a Transfer Request Descriptor or an individual Transfer Request record onto the Tx Queue of the channel. The exact mechanisms which are used and the contents of both the Transfer Request Descriptor and the Transfer Request record are given in the *TI DMA Architecture* specification.

10.2.3.2.5.2.2 Transfer Response

At the completion of each set of operations which fulfill a Transfer Request record, the UDMA will return a Transfer Response record to either the original Transfer Request Descriptor or the Tx Completion Queue, depending on the mechanism which was used to provide the Transfer Request record. If the Transfer Request record originated in a Transfer Request Descriptor then a corresponding slot in the Transfer Request Descriptor will be overwritten with the response status. If the Transfer Request record originated in a pass by value Tx Ring,

the Transfer Response record will be placed in a pass by value Tx Completion Ring. The Transfer Response record will only contain a completion code which indicates if the transfer was a success or if a particular type of failure occurred. The exact mechanisms which are used and the contents of the Transfer Response Record are given in the *TI DMA Architecture* specification.

10.2.3.2.5.2.3 Data Transfer

Packet transmission is accomplished within the UDMA by moving data from structures that are located in memory via the VBUSM Memory Interface(s) onto the Transmit PSI-L Interface. On the Tx side of the UDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx Per Channel Buffer for that channel. At a later time, the data is moved from the Tx Per Channel FIFO to a remote peer DMA entity via the Tx PSI-L interface.

10.2.3.2.5.2.4 Memory Interface Transactions

The sequence of control transactions that are performed by the UDMA on the Read/Write VBUSM interface during transmit is to read a Transfer Request record from a logical work queue and to then return a corresponding Transfer Response record to a separate logical work queue when all the transfers in the request have been completed. This sequence repeats for as long as Transfer Request records are provided on the work queue. The exact details of the operations that are involved are covered in the *TI DMA Architecture* specification (see [Section 10.1](#)).

The sequences of data transactions that are performed by the UDMA on the Read Only VBUSM interface during transmit can be described as a sequence of piecewise linear read transfers whose starting addresses are each sequentially calculated based on loops and offsets given in the Transfer Request record. A TR can have up to 4 levels of nested transfer sets where each set can have a different element count and stride between elements. TR record formats are described in detail in the Transfer Request format specification.

10.2.3.2.5.2.5 Error Handling

In the case that an error occurs during any Tx operation, the UDMA will stop processing the TR at that point and will return an appropriate error code in the Transfer Response message as specified in the *TI DMA Architecture* specification. The PAUSE_ON_ERR bit in the TCHAN UDMA_TCFG_j registers controls whether or not the DMA will pause operation on that channel if an error or exception occurs. If the PAUSE_ON_ERR bit is set to 1 the channel will be paused so that the host can optionally read the channel state to determine where in the transfer the channel execution was. If the PAUSE_ON_ERR bit is 0 the DMA will flush the current Transfer Request record for channels in pass by value mode and will flush the current Transfer Request Descriptor for channels in pass by reference mode.

10.2.3.2.5.3 Receive Operation

10.2.3.2.5.3.1 Transfer Request

After reset, all channels that are configured in Third Party mode will be Idle and waiting for work to be assigned to them. In order to initiate Third Party channel operation, the Host places work in the form of either a Transfer Request Descriptor or an individual Transfer Request record onto the Rx TR Queue of the channel. The exact mechanisms which are used and the contents of both the Transfer Request Descriptor and the Transfer Request record are given in the *TI DMA Architecture* specification.

10.2.3.2.5.3.2 Transfer Response

At the completion of each set of operations which fulfill a Transfer Request, the UDMA will send a Transfer Response message back to either the Packet Descriptor (pass by reference channel mode) or to the completion queue in the Ring Accelerator (pass by value channel mode). The contents of this message are described in detail in the *TI DMA Architecture*.

10.2.3.2.5.3.3 Error Handling

In the case that an error occurs during any Rx operation, the UDMA will stop processing the TR at that point and will return an appropriate error code in the Transfer Response message as specified in the *TI DMA Architecture* specification. The PAUSE_ON_ERR bit in the RCHAN UDMA_RCFG_j registers controls whether or not the DMA will pause operation on that channel if an error or exception occurs. If the PAUSE_ON_ERR bit is set to 1 the channel will be paused so that the host can optionally read the channel state to determine where in

the transfer the channel execution was. If the PAUSE_ON_ERR bit is 0 the DMA will flush the current Transfer Request record for channels in pass by value mode and will flush the current Transfer Request Descriptor for channels in pass by reference mode.

10.2.3.2.5.4 Data Transfer

Third Party mode packet reception is accomplished within the UDMA by unpacking and moving data from the Rx Per Channel FIFOs which were filled via the Rx PSI-L Interface to specified memory mapped address ranges via the write only VBUSM master interface. On the Rx side of the UDMA, these transfers are always writes. Each write transfer which is performed by the Third Party Write Unit is to a destination address and of a size as calculated from parameters specified in the Transfer Request packet which was previously received to control the channel behavior.

10.2.3.2.5.4.1 Memory Interface Transactions

The sequence of control transactions that are performed by the UDMA on the Read/Write VBUSM interface during transmit is to read a Transfer Request record from a logical work queue and to then return a corresponding Transfer Response record to a separate logical work queue when all the transfers in the request have been completed. This sequence repeats for as long as Transfer Request records are provided on the work queue. The exact details of the operations that are involved are covered in the *TI DMA Architecture* specification (see [Section 10.1](#)).

The sequences of data transactions that are performed by the UDMA on the Write Only Memory interface during receive can be described as a sequence of piecewise linear write transfers whose starting addresses are each sequentially calculated based on loops and offsets given in the Transfer Request record. A TR can have up to 4 levels of nested transfer sets where each set can have a different element count and stride between elements. TR record formats are described in detail in the Transfer Request format specification.

10.2.3.2.5.4.2 Rx Packet Drop

The Rx PSI-L Interface master may assert the rstmr_drop signal co-incident with the transfer of any data phase of a packet. When this signal is sampled asserted by the UDMA, the drop condition will be latched into a flag for that thread and the Third Party write unit will be notified that the packet is to be flushed and no further writes are to be performed. The drop signal is only required to be asserted with a single data phase and will only cause the current packet to be dropped from packet stream. The UDMA will drop all data given to it until the EOP is found on the thread and then the internal drop flag will be cleared. When the UDMA drops the packet on a channel that is in Third Party mode, a 'dropped by source' error code will be placed in the Transfer Response packet which is returned to the Packet Descriptor or completion queue.

10.2.4 Ring Accelerator (RINGACC)

This chapter describes the RINGACC module, part of the NAVSS.

10.2.4.1 RINGACC Overview

The Ring Accelerator (RINGACC or RA) provides hardware acceleration to enable straightforward passing of work between a producer and a consumer. There is one RINGACC module per NAVSS.

Table 10-110. RINGACC Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_RINGACC0	-	-	✓ (NAVSS)
MCU_NAVSS0_RINGACC0	-	✓ (MCU NAVSS)	-

Figure 10-19 shows a top-level overview of the RINGACC module.

Figure 10-19. RINGACC Overview

10.2.4.1.1 RINGACC Features

NAVSS0_RINGACC0 supports the following features:

- Supports independent memory-mapped ring structures. See ring count in [Table 10-111](#), *RINGACC Configuration Parameters*.
- Supports various modes for each ring based on usage and compatability
- Provides single-word deep shared incoming Transfer Response FIFO
- Provides bit-wide source VBUSM read/write slave interface for accesses from DMA controller entities.
 - Provides 2 word deep command FIFO
 - Provides 2 word deep write data FIFO
 - Provides 2 word deep read data FIFO
 - Provides 2 word deep write status FIFO
- Provides bit-wide destination VBUSM read/write master interface for accesses to ring structures in memory
- Supports up to 16 outstanding writes
- Supports up to 16 outstanding reads

- Source interface provides an array of 1024 × 512-byte long address windows (four for each ring) which are packed into a single contiguous address range
 - Read and write addresses which target a specific window are translated, in order to redirect the read or write transaction, to an effective address calculated from the base address for the ring plus current ring offset
 - Each read or write access presented on VBUSM slave interface is modified and bridged onto the VBUSM master interface

10.2.4.1.2 RINGACC Not Supported Features

- Queue manager mode, which makes the queue act like a traditional queue-manager (QM) queue, is not supported.
- Peeks from tail

10.2.4.1.3 RINGACC Parameters

Table 10-111 shows the RINGACC configuration parameters in this SoC.

Table 10-111. RINGACC Configuration Parameters

Module Instance	Parameters		
	Ring Count	Number of Monitors	Proxy Target Base
NAVSS0_RINGACC0	1024	32	0x000038000000
MCU_NAVSS0_UDMASS_RINGACC0	286	32	0x00002B000000

Table 10-112 shows the MSRAM configuration parameters set during SoC design. MSRAM0 is accessible only from the ring accelerator (DST port).

Table 10-112. MSRAM Configuration Parameters

Module Instance	Parameters		
	Depth	Width	Base Address
NAVSS0_MSRAM0	4096	128	0x000030000000
MCU_NAVSS0_UDMASS_MSRAM0	3594	64	0x000028000000
MCU_NAVSS0_UDMASS_MSRAM1	4096	64	0x000028010000

10.2.4.2 RINGACC Functional Description

The Ring Accelerator (RINGACC) converts constant-address read and write accesses to equivalent read or write accesses to a circular data structure in memory. The RINGACC eliminates the need for each DMA controller which needs to access ring elements from having to know the current state of the ring (base address, current offset). The DMA controller performs a read or write access to a specific address range (which maps to the source interface on the RINGACC) and the RINGACC replaces the address for the transaction with a new address which corresponds to the head or tail element of the ring (head for reads, tail for writes). Since the RINGACC maintains the state, multiple DMA controllers or channels are allowed to coherently share the same rings as applicable. The RINGACC serves a very similar function to the Queue Manager in the earlier SoCs. The RINGACC uses less memory and is able to place data which is destined towards software into cached memory directly.

10.2.4.2.1 Block Diagram

Figure 10-20 shows ring accelerator's main internal components.

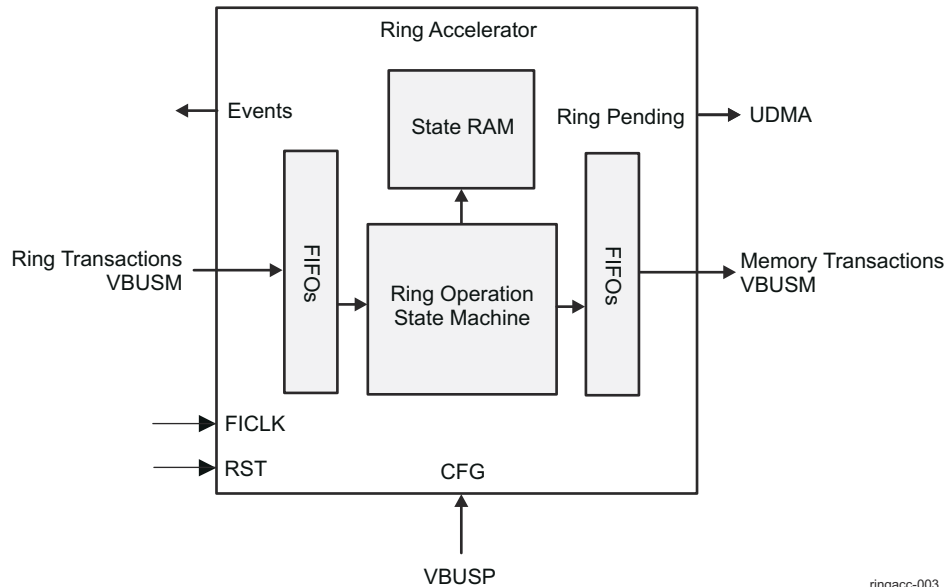

Figure 10-20. Ring Accelerator Block-Diagram

10.2.4.2.1.1 Configuration Registers

The Configuration Registers block is responsible for providing memory mapped registers for configuration of the RINGACC functions. The configuration registers are divided into:

- Static configuration fields (NAVSS0_UDMASS_RINGACC0_CFG Registers), which are typically initialized and then left at specified values for long time periods (or until a reset occurs)
- Real-time (RT) registers (NAVSS0_UDMASS_RINGACC0_CFG_RT Registers), which are modified frequently during runtime.

Configuration registers are listed and described in *RINGACC Register Manual*.

10.2.4.2.1.2 Source Command FIFO

The Source Command FIFO buffers VBUSM command phases which are accepted from the VBUSM source interface.

10.2.4.2.1.3 Source Write Data FIFO

The Source Write Data FIFO buffers VBUSM write data phases which are accepted from the VBUSM source interface.

10.2.4.2.1.4 Source Read Data FIFO

The Source Read Data FIFO buffers VBUSM read data phases which have been returned from the VBUSM destination interface (via the main state machine) and which are to be output on the VBUSM source interface.

10.2.4.2.1.5 Source Write Status FIFO

The Source Write Status FIFO buffers VBUSM write status data phases which have been returned from the VBUSM destination interface and which are to be output on the VBUSM source interface.

10.2.4.2.1.6 Main State Machine

The Main State Machine (MSM) block implements all of the control logic which is necessary to accept a command from the source interface, perform a lookup into the ring state RAM, determine the effective address for the destination interface transaction, modify the address (and byte count for reads) for the transaction, and place that modified transaction into the outgoing destination FIFOs. The MSM block is also responsible for updating the ring index and occupancy values and for producing output status to indicate changes to the ring state. The MSM also modifies the ring state whenever the read data or write status for a previous ring transaction return and forwards those responses back to the originating master.

10.2.4.2.1.7 Destination Command FIFO

The Destination Command FIFO stores VBUSM transaction commands which are output from the MSM as modified versions of transactions that were popped from the Source Command FIFO. The Destination command FIFO allocates a new command ID for each read or write command that is pushed to the FIFO. Read IDs are allocated from a scoreboard maintained in the Destination Read Data FIFO. Write IDs are allocated from a scoreboard maintained in the Destination Write Status FIFO. When a new command is allocated, the Destination Command FIFO also pushes the original *cid* and *crouteid* values from the source side transaction into a scoreboard in either the Destination Read Data or Destination Write Status FIFOs depending on the applicable transaction direction. The read interface of the Destination Command FIFO directly drives commands onto the destination VBUSM command interface.

10.2.4.2.1.8 Destination Write Data FIFO

The Destination Write Data FIFO stores write data phases for write commands that are passing through the RINGACC towards memory. The write interface of the Destination Write Data FIFO is directly connected to the read interface of the Source Write Data FIFO and the read interface directly drives write data onto the destination VBUSM write data interface.

10.2.4.2.1.9 Destination Read Data FIFO

The Destination Read Data FIFO provides a read command translation scoreboard and also stores read data phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Read Data FIFO is directly connected to the destination VBUSM read data interface. As read data passes through the Destination Read Data FIFO, the *rid* and *rrouteid* are changed back to their original values using information which was stored in read command translation scoreboard.

10.2.4.2.1.10 Destination Write Status FIFO

The Destination Write Status FIFO provides a write command translation scoreboard and also stores write status phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Writes Status FIFO is directly connected to the destination VBUSM write status interface. As write status words pass through the Destination Write Status FIFO, the *sid* and *srouteid* are changed back to their original values using information which was stored in the write command translation scoreboard.

10.2.4.2.2 RINGACC Functional Operation

10.2.4.2.2.1 Queue Modes

Each ring or queue can be in one of four modes that determines how it must be accessed and the compatibility it has with hardware and software.

10.2.4.2.2.1.1 Ring Mode

Ring mode is used when software owns one side of the ring, and hardware or another software owns the other side. This mode allows the software that owns a side of the ring to control that side including accessing

the memory directly rather than going through hardware, and software updates the hardware on any changes through the Doorbell registers. These doorbell accesses indicate when software has pushed or popped entries, allowing the entity on the other side of the ring to know when there are elements ready. The ring mode has limitations that the exposed side of the ring is completely under software control, and any atomicity needed must also be performed by software, which is why the exposed side of a ring is usually owned by a single thread of software. This limitation also means that any hardware configuration that would normally access the same ring for both pushes and pops cannot use ring mode as hardware cannot access the exposed side of the ring, such as free queues that are normally read by hardware but could also be pushed by hardware on an error.

When software is popping from the ring, it must guarantee that it never pops more elements through the Doorbell register (RINGACC_DB_j) than what is valid in the Ring Occupancy (RINGACC_OCC_j) register, which holds how many elements are ready for software consumption. There could be some elements which have data written to memory but have not received status back from memory and those are not considered ready to pop yet as the ring status has not fully updated. Therefore, just reading from memory to determine the number of elements to pop is not sufficient. If software attempts to pop more than the RINGACC_OCC_j register value, then the occupancies could go negative resulting in missed down events and spurious interrupts. An optimization for software is to read the RINGACC_OCC_j register less frequently and keep a local copy which guarantees the maximum number of allowed pops. When the software copy of RINGACC_OCC_j reaches 0, or periodically, the software can read the register to refresh the value. This must reduce the frequency of register reads instead of reading the register for every software pop.

10.2.4.2.2.1.2 Messaging Mode

Messaging mode requires that all accesses to the queue must go through RINGACC so that all accesses to the memory are controlled and ordered. RINGACC then controls the entire state of the queue, and software has no direct control, such as through doorbells and cannot access the storage memory directly. This is particularly useful when more than one software or hardware entity can be the producer and/or consumer at the same time. Software must access the data through bus accesses to the RINGACC. As with the earlier example, if there are free queues that need the hardware to both push and pop, then they must be configured as at least messaging mode (or a later mode) and not ring mode.

10.2.4.2.2.1.3 Credentials Mode

Credentials mode adds per element credentials storage to messaging mode. This allows multiple producers with their own credentials to have those credentials stored with the element. This allows the consumer to inherit the credentials of each element rather than a single set for the entire queue, such as for DMA TR credential inheritance. This mode requires each operation to use two elements of storage since the credentials are stored in the second element, so the element count must be scaled appropriately. The credentials field is located in the same location as all modes, the word just before the first word of the message.

10.2.4.2.2.1.4 Queue Manager Mode

Queue manager mode makes the queue act like a traditional queue-manager (QM) queue in previous devices.

Note

Queue Manager mode is no longer supported in this device. This section was left for completeness only.

10.2.4.2.2.1.5 Peek Support

All modes except ring mode allow the peek operations so that software can view the next element without actually popping it from the queue. This is done by reading from a different offset from the normal pop operation. All the same fields are read but the element is not actually popped off of the queue. This is useful for algorithms that need to know about the overall queue and head element to make decisions but have not yet decided to pop from the queue.

10.2.4.2.2.1.6 Index Register Operation

In ring mode, the Index (RINGACC_INDX_j) register follows the software control of the ring through the doorbell registers, while the hardware index (RINGACC_HWINDX_j) register follows the hardware access of

the ring through bus transactions. It works for a ring in either direction as the doorbell register update indicates whether elements were produced or consumed. But in the other queue modes, there is no simple manner to determine which index is for software or hardware since they both use bus transactions which the module cannot differentiate. So for these other queue modes, the index register is always the read index, and the hardware index register is the write index.

10.2.4.2.2.2 VBUSM Slave Ring Operations

Each ring contains four memory spaces on the VBUSM slave bus for access, each of which is 512 bytes long, with a total of 4 kB per ring. Each ring space starts immediately after the preceding ring. The allocation per ring is as in [Table 10-113](#).

Table 10-113. Ring Memory Partition

Offset	Operation	Supported Ring Modes
0x0 - 0x1FF	Reads pop from head. Writes push to head.	Read supported in all modes, write supported in all modes except Ring mode
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.	Write supported in all modes, read supported in all modes except Ring mode
0x400 - 0x5FF	Reads peek from head. Writes ignored.	All modes except for Ring mode.
0x600 - 0x7FF	Reserved	Peeks from tail are not supported in this device
0x800 - 0xFFF	Reserved	Reserved

Within each 512-byte (0x200) space, the message data is right justified so that the last byte is always the 511-th byte. The element size of the ring defines which words are valid. The word just before the first valid message word is the credentials field. Access must not be made before the credentials register .

10.2.4.2.2.3 VBUSM Master Interface Command ID Selection

The RINGACC keeps a transaction command scoreboard for reads and writes. Each scoreboard tracks which command indexes are currently outstanding from the RINGACC and which are free to use. When a read or write is requested by the Main State Machine, the scoreboard corresponding to the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*) for the outgoing transaction on the destination interface. 15 is the maximum index value for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

10.2.4.2.2.4 Ring Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective write address using *ring base + ring_index*
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments hardware index and hardware occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid*, *cid*, and *ring number* into scoreboard
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and *ring number* from scoreboard
2. RINGACC increments software index and occupancy for ring
3. RINGACC pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

10.2.4.2.2.5 Ring Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective read address using ring base + ring_index
4. RINGACC increments hardware index and decrements hardware occupancy for ring
5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC increments software index and decrements software occupancy for ring
3. RINGACC pushes restored *routeid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

10.2.4.2.2.6 Host Doorbell Access

The following sequence will occur for each VBUSP write to the doorbell register (RINGACC_DB_j) for a ring:

1. RINGACC extracts ring number from config address
2. RINGACC looks up ring state using ring number
3. RINGACC adds doorbell ring value to both hardware and software occupancies for ring
4. RINGACC re-evaluates pending bit for ring

10.2.4.2.2.7 Queue Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective write address using ring base + ring_index
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments WR index and RD- and WR-occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid*, *cid*, and ring number into scoreboard
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

10.2.4.2.2.8 Queue Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective read address using *ring base* + *ring_index*
4. RINGACC increments RD index and decrements RD- and WR-occupancy for ring
5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC pushes restored *rrouteid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

10.2.4.2.2.9 Mismatched Element Size Handling

When less data is written than defined by the element size for the ring for RING or MESSAGE modes, only the written data is stored in the memory and any remaining bytes maintain their old values. The index and *occ* are still incremented normally, and any special fields that are unwritten are assumed to be 0.

Writing less data for CREDENTIALS mode is illegal, as those types need the full data to append the additional words to the correct offsets in memory.

When more data is written than defined by the element size for the ring, it will be an error and the write will be ignored and no index or *occ* increments occur. The only exception is for writes to an 8-byte element size ring, where the additional fields up to another 8 bytes are allowed but not written (for old Queue Manager compatibility).

When less data is read than defined by the element size for the ring, only the read data is fetched from memory, and any remaining bytes are lost. The index and *occ* are still incremented normally.

When more data is read than defined by the element size for the ring, it will be an error and the read will not affect the ring, the read data will be 0s, and no index or *occ* decrements occur. Access beyond the credentials word must not be attempted and can result in unpredictable behavior.

All accesses must be for multiples of 32-bit words, and partial bytes are not supported for all ring modes.

10.2.4.2.3 Events

The module outputs events about queue levels that can be used by an external module for statistics or interrupts.

Each queue has

- an up event when the queue goes from 0 elements to 1 or more elements
- and a down event when the queue goes from 1 or more elements to 0 elements.

The event number is programmable per queue in the RINGACC_EVENT_j register. This event occurs when the state machine updates the final occupancy for the queue. In ring mode this is when the response from the memory access returns, while in other queue modes this is when the operation is processed.

An event number programmed to 0xFFFF indicates to not produce an event for that ring when an event is not necessary. The register event number fields reset to 0xFFFF, so they must be programmed to a valid value before events will be generated. This applies to the monitor event number fields as well.

10.2.4.2.4 Bus Error Handling

If a bus error is detected on a response to a ring memory transaction, an error event is triggered to alert software. Since the ring contents may be corrupted as the push or pop was not completed correctly, software should consider resetting the ring and any software or hardware elements using the ring. A log register (RINGACC_ERROR_LOG) captures the ring that had the error and whether it was from a push or pop, and an error up event is sent to the programmed event number. After an error is logged, another will not be captured until the first is read out. When read, if an error is pending an error down event is sent to clear any interrupt, and then the next bus error log can be captured. A read of the RINGACC_ERROR_LOG register when there is no error log pending will not produce any down events. The event that is triggered is also programmable. Only legal push and pop operations will capture this error, and not for any peek, emudbg read, flush command, or any operations that is illegal and causes the resulting memory access to be flushed.

10.2.4.2.5 Monitors

Monitors can be configured that allow various functions to be tracked of programmed queues. Each monitor is programmed to monitor a particular queue, the function to provide, and the data source to operate on. The supported functions are: to check the queue against programmed thresholds, to keep track of watermarks of the queue, to keep track of starvation occurrences (a read of an empty queue), or statistics capture. The supported data sources are: the queue element count, the head element size value, or the accumulated size value. Each monitor can also be programmed to produce an event should it have a triggering condition.

10.2.4.2.5.1 Threshold Monitor

A threshold monitor uses a programmed low threshold value and a programmed high threshold value to track the data source in the queue and cause an interrupt or status when a threshold is broken, either below the low value or above the high value. This is useful for software to replenish empty buffers when a queue has too few, or for a queue to accumulate enough elements so that software must start processing them, or for debug. The threshold being broken will cause the up or down event.

10.2.4.2.5.2 Watermark Monitor

A watermark monitor tracks the low and high values of the data source since the last read of the monitor. After initial setup or clearing, the watermark values will load the current value of the data source as the low and high. Then for successive operations if the resulting data source of the queue is below the low watermark, or above the high watermark, the associated watermark will be updated. When the monitor value registers are read, the value is cleared and starts tracking again using the current data source value. This can be useful for tracking low and high values of queue element counts or sizes for data tracking, debug or future optimizations, such as allocating items to a queue or buffer sizes based on counts.

10.2.4.2.5.3 Starvation Monitor

A starvation monitor tracks the number of starvation events (a read to an empty queue) that occurred on the queue. The data source is ignored, and the starvation count is always incremented whenever there is a read to the queue and the queue is empty. The count is cleared when the monitor value is read. This can be useful to trigger if any starvation event occurs, or to track how many of these events occur in a timeframe, and can be used for future optimizations or debug.

10.2.4.2.5.4 Statistics Monitor

The statistics monitor can track some simple statistics on the queue operations. The data source is ignored. The first value is the count of the number of writes to the queue, and the second value is the count of the number of reads from the queue. The counts are cleared when the monitor values are read. This can be useful to track the activity on a queue, and can be used for future optimizations or debug.

10.2.4.2.5.5 Overflow

RINGACC provides an overflow function where a push to a full ring will result in a push to a special overflow ring, rather than just losing the pushed data. The overflow ring is defined through the RINGACC_OVRFLOW register, and that ring must be defined with a large enough element size to cover the element size of any other ring, as well as enough elements to hold enough overflow data (as an overflow to the overflow ring will be lost). When there is a push to a full ring, there will be two elements written to the overflow ring, first the push data, and then the ring number that was full. A supervisor entity can own the overflow ring and perform what actions are needed from the overflow data. The size of the overflow ring must be an even number since two elements will be pushed for each overflow event. The overflow ring must be configured in *ring* or *message* modes.

10.2.4.2.5.6 Ring Update Port

To enhance performance for DMAs, the RINGACC provides a bus that indicates when ring updates occur, allowing the DMA to track their own rings and detect updates before the responses arrive. The bus will go valid whenever there is an update to the state of a ring, which can be from a push, pop, or doorbell write. It will not go valid for a peek, a emudbg pop, a push to a full ring, as those do not update the ring state. When the bus is valid, the other signals are valid and indicate whether the operation was a push or a pop, whether the resulting state of the ring is empty, the ring number, and the number of elements updated to the ring (the push determines whether it is subtracted or added to the current count). One special case is a pop from an empty ring, which indicates an update but the element count is 0 since no items were actually popped, but a DMA using the cnt to add or subtract must handle this correctly by default. The bus will go valid once the operation command has been completed, and not after the response has been received, even for ring mode rings, allowing the DMA to see the update as soon as it is known by the RINGACC even before it is known to software.

10.2.4.2.5.7 Tracing

This module provides a trace output of all operations so that the traffic can be viewed at a later time. The trace uses a simple write-only 32-bit VBUSP bus, with a defined packet header. The *msgtype* field defines the type of operation, and the message data is simply the data involved in the operation. It is likely the trace output will be

read slower than new operations could provide data, so there will be a trace buffer able to hold two complete messages plus trace headers. If a new operation starts while the trace buffer does not have enough space, then that trace message will not be sent. And RINGACC_TRACE_CTL register controls whether to enable the trace output, whether to trace a single queue or all queues, and whether to include the message data in the trace output.

Table 10-114 shows the trace message for a push.

Table 10-114. Trace Message for a Push

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x1	Msgtype for push
1	8:0	0x009	Standard Trace Header
2	31	push_to_head	Push to head flag, 0 = to tail, 1 = to head
2	30:16	0x0	Unused
2	15:0	queue	Queue for push
3-N	31:0	message data	Optional message data for push, length dependent on message size

Table 10-115 shows the trace message for a pop.

Table 10-115. Trace Message for a Pop

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x2	Msgtype for pop
1	8:0	0x009	Standard Trace Header
2	31	empty	empty pop, 0 = valid message, 1 = empty
2	30:16	0x0	unused
2	15:0	queue	queue for pop
3-N	31:0	message data	Optional message Data for pop, length dependent on message size

Table 10-116 shows the trace message for a peek.

Table 10-116. Trace Message for a Peek

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x3	Msgtype for peek
1	8:0	0x009	Standard Trace Header
2	31	empty	empty peek, 0 = valid message, 1 = empty
2	30:16	0x0	unused
2	15:0	queue	queue for peek
3-N	31:0	message data	Optional message Data for peek, length dependent on message size

10.2.5 Proxy

This chapter describes the Proxy module in a NAVSS.

10.2.5.1 Proxy Overview

The Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses.

Figure 10-21 shows a top-level overview of the Proxy module.

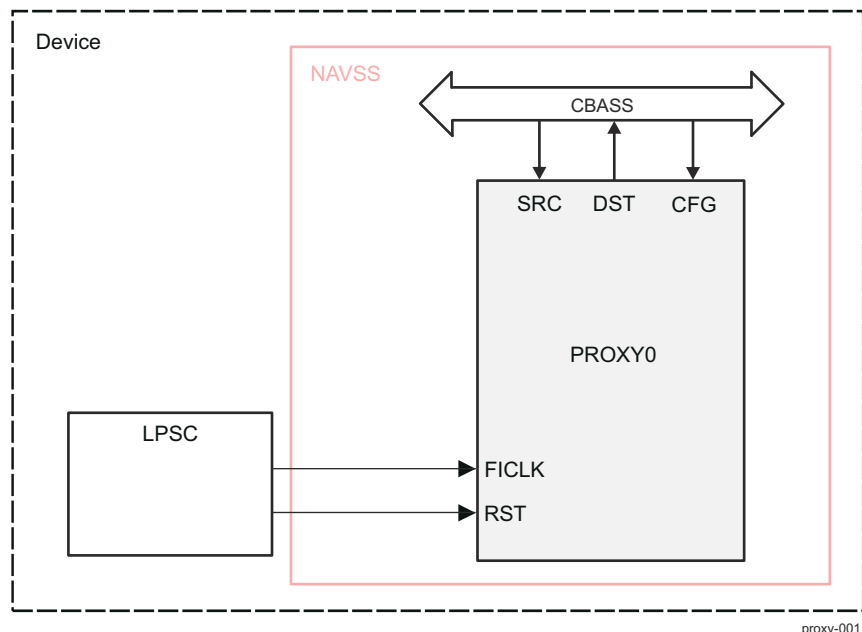

Figure 10-21. Proxy Overview

Table 10-117. Proxy Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_PROXY0	-	-	✓ (NAVSS)
MCU_NAVSS0_PROXY0	-	✓ (MCU NAVSS)	-

10.2.5.1.1 Proxy Features

Each Proxy supports the following features:

- Provides proxy buffers to store large data bursts that a host can only access in smaller amounts.
- Keeps the large data coherent until the complete data has been accessed.
- Allows for interleaved access between multiple hosts using multiple proxies.
- Each target has pre-configured number of channels, size of each channel, and address offset. See [Table 10-118](#).

10.2.5.1.2 Proxy Parameters

Table 10-118 shows the Proxy configuration parameters set during SoC design.

Table 10-118. Proxy Configuration Parameters

Module Instance	Parameters				
	Proxies ⁽¹⁾	Buffer Size ⁽²⁾	Target	Channels ⁽³⁾	Sizes ⁽⁴⁾
NAVSS0_PROXY0	64	256	NAVSS0_RINGACC0	1024	4096
MCU_NAVSS0_PROXY0	64	256	MCU_NAVSS0_RINGACC0	286	4096

(1) Number of proxy threads supported. Can be read off from the PROXY_CONFIG read-only register

- (2) Number of bytes per proxy buffer
- (3) Number of channels for the target
- (4) Number of bytes per channel supported for the target

10.2.5.1.3 Proxy Not Supported Features

The following features are not supported by the module:

- Does not support proxy sharing. Each host must use its own proxy within the module.

10.2.5.2 Proxy Functional Description

This module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are for large Message Manager messages, Queue Manager data that is more than a pointer, or DMA Transfer Requests Messages. All of these require larger data sets, from 12 to 128 bytes, and the modules require the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as hardware registers, and the largest CPU access is typically 8 bytes. So the proxy provides the ability to access the module with a single burst, and at the same time allows the CPU to access the same data in smaller accesses. The proxy itself does not contain the resources, but it stays in front of other module (target module) that does contain the resources. The proxy will access the target module with the entire data in a single burst, once the host has completed the data.

10.2.5.2.1 Targets

10.2.5.2.1.1 Ring Accelerator

The RINGACC provides four distinct offsets to use per ring/queue shown in [Table 10-119](#), totaling 4 kB space per ring/queue. Each channel has access modes (enabled via PROXY_CTL_j[17-16] MODE field):

- head access
- tail access
- peeks from head

Table 10-119. RINGACC Offsets per Ring/Queue

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.
0x400 - 0x5FF	Reads peek from head. Writes ignored.
0x600 - 0x7FF	Reads peek from tail. Writes ignored. This mode is not supported in this device.
0x800 - 0xFFFF	Reserved

10.2.5.2.2 Proxy Sizes

The number of proxies in the module is configured during SoC design. See [Table 10-118](#). Each proxy has its own address space to the module and determining which proxy is being accessed is simply based on the address bits above the final size of each proxy space. The size of the proxy space is always 4 KB. This is enough to contain the data message, along with controls for which channel, access mode, and element size for the access.

10.2.5.2.3 Proxy Interleaving

Each proxy must have a single owner, as each proxy only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy. Then they will have their own buffer and each can access a different resource at the same time. Each proxy is completely independent and kept coherent regardless of accesses to other proxies or regardless of the order of accesses. So the proxies support interleaving of multiple hosts' accesses.

10.2.5.2.4 Proxy Host States

Each individual proxy per host uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy is in use or not, but also for error detection. The proxy always stays in idle state, when there is no activity. There is a write state for when the proxy has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy has read data from a resource

and that entire data has not been fully read by the host. When a proxy access completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

10.2.5.2.5 Proxy Host Channel Selection

The host must program the PROXY_CTL_j (where j = 0h to 3Fh) prior to accessing the PROXY_DATA_j_y (where j = 0h to 3Fh, y = 0h to 7Fh) unless the previous values are to be reused. This sets the channel within the target, the access mode (head, tail, peek), and the element size. These values will be used when writing the full message to the target, or reading a new message from the target. The target address used will be based on the target base address, the programmed channel, the programmed access mode (for the offset within the 4 kB of the target channel), and the element size (for the offset within the 512 Bytes max size message).

$$\text{target address} = \text{target base} + (\text{channel} \times 4\text{KB}) + (\text{mode} \times 512\text{B}) + (512 - \text{element size in bytes})$$

, for element size in bytes length.

The proxy will detect an error if these fields are changed while in the middle of a message.

10.2.5.2.6 Proxy Host Access

A proxy begins in an idle state, where there is no data in the buffer. In this state the proxy will accept any access to a new resource. If the proxy is in another state, representing a resource is in progress, and the host attempts to access another target or resource, or switches from read to write, then the proxy will detect that as an error and flush the buffer with no final target access and the data is lost and the proxy goes back to idle state.

10.2.5.2.6.1 Proxy Host Writes

The first write to an idle proxy puts the proxy into write mode for the selected target and channel. Further legal writes are stored in the buffer for the enabled bytes and position within the buffer. A write to a previously written location will overwrite the previous data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy is then put back into idle state.

10.2.5.2.6.2 Proxy Host Reads

When in idle state, the first read to the proxy will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data is returned, and the proxy is put back into idle state.

10.2.5.2.7 Permission Inheritance

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target. This will copy the secure, debug, priv, privid, and virtid signals so that they can be firewalled during the target access for the resource.

10.2.5.2.8 Buffer Size

Buffer size is shown in [Table 10-118](#). An attempt to access a larger message will result in the proxy going into error mode. Software must only create messages up to the supported target size.

10.2.5.2.9 Error Events

Each proxy can produce an event when it has detected an error. This error occurs when the host changes the target, resource, or access direction before completing the previous data. An error can also occur for an access to an illegal target, illegal offset within a target, such as beyond the target size or buffer size, or if the access spans multiple channels. This error does not include accessing reserved register locations within the proxy thread, as that results in normal reserved register behavior of ignoring write data and reading 0s. There is a separate status bit per proxy for these errors. The event number is programmed via PROXY_EVT_REG_j (where j = 0h to 3Fh) for each proxy. The event will not be sent if the event is programmed to 0xFFFF.

10.2.5.2.10 Debug Reads

Since debug reads with emudbg=1 must not cause any side effects or bus errors, any debug read will just read the buffer and never cause a target read. It will also not return any bus errors.

10.2.6 Secure Proxy

This chapter describes the Secure Proxy module in NAVSS.

10.2.6.1 Secure Proxy Overview

The Secure Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses. Secure Proxy is a modified version of the Proxy module in NAVSS.

Table 10-120. Secure Proxy Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_SEC_PROXY0	-	-	✓ (NAVSS)
MCU_NAVSS0_SEC_PROXY0	-	✓ (MCU NAVSS)	-

10.2.6.1.1 Secure Proxy Features

Secure Proxy supports the following features:

- Provides proxy function to store large data bursts that a host can only access in smaller amounts
- Supports a number of threads, where each has their own independent proxy function
- Keeps the large data burst coherent until the complete data has been accessed
- Allows for interleaved access between multiple hosts or tasks using multiple proxy threads
- Supports a programmable fixed queue for each proxy thread
- Supports multiple producers all writing to the same queue
- Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
- Supports programmable thresholds for when to generate events.

10.2.6.1.2 Secure Proxy Parameters

Table 10-121 shows the Secure Proxy configuration parameters set during SoC design.

Table 10-121. Secure Proxy Configuration Parameters

Module Instance	Parameters				
	Proxies ⁽¹⁾	Message Size ⁽²⁾	Target	Channels ⁽³⁾	Sizes ⁽⁴⁾
NAVSS0_SEC_PROXY0	370	64	NAVSS0_RINGACC0	110	4096
MCU_NAVSS0_SEC_PROXY0	90	64	MCU_NAVSS0_RINGACC0	30	4096

(1) Number of proxy threads supported. Can be read off from the SEC_PROXY_CONFIG read-only register

(2) Number of bytes for message. Can be read off from the SEC_PROXY_CONFIG read-only register

(3) Number of channels for the target

(4) Number of bytes per channel supported for the target

10.2.6.1.3 Secure Proxy Not Supported Features

The following features are not supported by the module:

- Does not support proxy thread sharing. Each host or task must use its own proxy thread within the module if they can access simultaneously or independently. This includes when the task can be interrupted by another task that also uses the proxy
- In the system, a proxy must be the only method to access messages that use the same set of queues (to keep credits local), which means all hosts using the same set of message queues must also use the same proxy for access and not local proxys
- Does not support multiple proxy threads reading from the same queue. For tracking purposes, there can be only 1 consumer proxy thread per queue.

10.2.6.2 Secure Proxy Functional Description

This module provides proxy functions for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are:

- large messages (for power control, security control, or IPC)

- data descriptors that are more than a pointer
- DMA Transfer Requests (TR)

All of these require larger data sets, from 12 to 128 bytes, and the storage hardware requires the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as registers, and the largest CPU access is typically 8 bytes. Therefore the proxy provides the ability to access the hardware with a single burst, and at the same time allows the CPU to access the same data in smaller accesses.

Figure 10-22 describes Secure Proxy major building blocks.

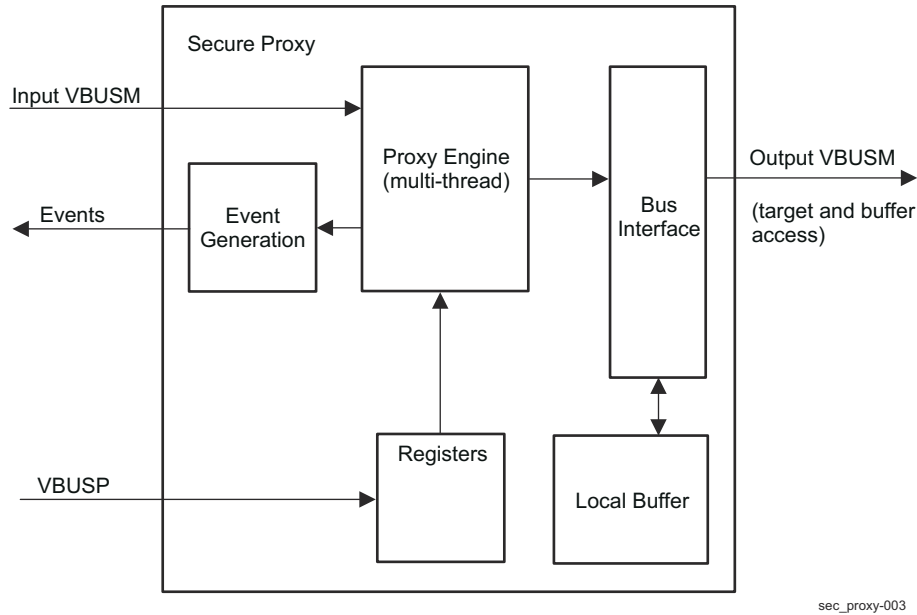

Figure 10-22. Secure Proxy Block Diagram

10.2.6.2.1 Targets

10.2.6.2.1.1 Ring Accelerator

The RING_ACC provides four distinct offsets to use per ring/queue shown in Table 10-122, totaling 4 KB space per ring/queue.

Secure Proxy always writes to tail, which is the offsets from 0x200 to 0x3FF. Secure Proxy always reads from the head, which is the offsets from 0x000 to 0x1FF. The latter two offsets in RING_ACC are not used by this proxy. And if the proxy message size is less than 512 bytes, then it always access the upper bytes of those regions, so that the message always ends on the last byte of each region, byte 511.

Table 10-122. RING_ACC Offsets per Ring/Queue

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.
0x400 - 0x5FF	Reads peek from head. Writes ignored. Not used by Secure Proxy
0x600 - 0x7FF	Reads peek from tail. Writes ignored. Not used by Secure Proxy
0x800 - 0xFFF	Reserved

This means that target writes will use the following calculation:

$$\text{target base address} + (\text{queue} \times 4\text{KB}) + 0x400 - \text{msg_size} \quad (17)$$

,and burst until offset 0x3FF.

And target reads will use the following calculation:

target base address + (queue × 4KB) + 0x200 - msg_size (18)

,and burst until offset 0x1FF.

10.2.6.2.2 Buffers

The proxy does not store all the buffers internally. It is programmed with a buffer base address (SEC_PROXY_BUFFER_L, SEC_PROXY_BUFFER_H), and all accesses to the buffer are made through the output VBUSM port using that base. The external buffer must be enough to store one *msg_size* per proxy thread. The proxy only includes a small temporary buffer to save one entire message when accessing the target. Otherwise all host accesses are made to the external buffer. This buffer storage must be considered private for the proxy hardware, so any other access can cause unpredictable results.

10.2.6.2.2.1 Proxy Credits

To support outbound proxy limits, the proxy will use internal credits for tracking resource usage. SEC_PROXY_CTL_j register sets the max credits each outbound proxy thread contains. When a proxy thread sends a message, the current credit count (SEC_PROXY_STATUS_j) decrements by 1. If the current credit count is 0, then the proxy thread is not allowed to send any more messages, and they just remain inside the proxy (so that the host can come back later when a credit has become available and quickly send the same message). When a message that was send by this proxy thread is read by an inbound proxy thread then the credit is returned to this proxy thread and the current credit count increments by 1.

For inbound proxy threads, the credits are used to track pending messages. When an outbound proxy thread sends a message that is read by this proxy thread, then the current credit count of this proxy thread is incremented by 1. A current credit count that is non zero indicates a message is pending and can be read. When the proxy thread completes the read of a message the current credit count is decremented by 1. If the current credit count is zero, then the proxy thread will read an empty message where all the data is 0s. The credit count saturates at 255, so if there can be more messages in the system for that proxy thread than 255 then multiple proxy threads should be used, or the count can become mismatched after a saturate.

10.2.6.2.2.2 Proxy Private Word

To support tracking of credits from each proxy thread, the proxy will extract the first word from the total message size for private tracking usage. This will include saving the proxy thread ID used within the proxy. This is necessary so that when a proxy reads a new message from the target it can inspect this word and return the credit to the source proxy thread. This allows the outbound proxy threads to have a set number of message credits, which decrement when a new message is written, and increment when a message from that proxy thread is read, thus keeping the credits in the system coherent. Any data written to this first word of the message will be ignored, so software should not write to the first word of messages through the proxy. Consumer software can use the first word to identify the source proxy thread of the message (SEC_PROXY_DATA_j).

10.2.6.2.2.3 Completion Byte

The proxy completes a message when the completion byte is accessed. This completion byte is the final byte in the full size of the message. This byte can be written by any size access, whether byte, 32-bit, or 64-bit word. The write of a message is not complete until this final byte of the message is written, and only then will the message be sent to the target. The read of a message is not complete until this final byte of the message is read by the host, and only then will reading a new message be allowed. Even if the final byte of the message is not needed, it must be accessed to complete the message inside the proxy hardware.

10.2.6.2.3 Proxy Thread Sizes

There are a configurable number of proxy threads in the module. Each thread has its own address space to the module and determining which proxy thread is being accessed is simply based on the address bits above the final size of each proxy thread space. Since each proxy thread will be programmed to a single resource, the only space requirement is that for using 4 KB to match typically used MMU page sizes. Only the first N bytes, matching the target channel size, is usable.

10.2.6.2.4 Proxy Thread Interleaving

Each proxy thread must have a single owner, as each proxy thread only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy thread. Then they

will have their own buffer and each can access a different resource at the same time. Each proxy thread is completely independent and kept coherent regardless of accesses to other proxy threads or regardless of the order of accesses. So the proxy support interleaving of multiple hosts' accesses.

10.2.6.2.5 Proxy States

Each proxy thread uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy thread is in use or not, but also for error detection. The proxy thread always starts in idle state, when there is no currently activity. There is a write state for when the proxy thread has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy thread has read data from a resource and that entire data has not been fully read by the host. When a proxy thread access completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

10.2.6.2.6 Proxy Host Access

A proxy thread begins in an idle state, where there is no data in the buffer. In this state the proxy thread will accept an access to the resource.

10.2.6.2.6.1 Proxy Host Writes

The first write to an idle proxy thread puts the proxy thread into write mode for the selected channel. Further legal writes are stored in the buffer for the enabled bytes and offset within the buffer. A write to a previously written location will overwrite the previous data. The buffer is not cleared initially, so if a byte is not written, the message will include previous buffer data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy thread is then put back into idle state. A write completion when there are no credits available results in the message not being written to the resource and the proxy thread remains in write mode (so that the message can be quickly completed when a credit becomes available).

10.2.6.2.6.2 Proxy Host Reads

When in idle state, the first read to the proxy thread will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data is returned, and the proxy thread is put back into idle state. If an initial read is made and there are no pending messages, the proxy thread will return an empty message, where the data is all 0s.

10.2.6.2.6.3 Buffer Accesses

Each read or write will actually trigger a read or write to the external buffer space allocated for that proxy thread, where the real message data is stored. In addition, when a write message completes, the external buffer will be read for the entire message for that proxy thread so that it can then be written to the target. Similarly, after a read causes a read from the target to get a new message, the entire message is written to the external buffer to store the message to the buffer.

10.2.6.2.6.4 Target Access

After the write has completed and the external buffer read for the entire message, the entire message is then written to the target as a single burst. Similarly, for a read that needs a new message, the target is read for a full message as a single burst.

10.2.6.2.6.5 Error State

If an error is detected in a proxy thread, the proxy will put that proxy thread into error state, and the current buffer will be lost. A status bit will be set that indicates the proxy thread is in error. All accesses to that proxy thread will be ignored until the status bit is cleared. Once cleared the proxy thread is put back into idle state. Errors are: an access to an offset beyond the length of the message, or a mismatch in the direction of access against what was programmed such as reading an outbound thread or writing an inbound thread.

10.2.6.2.7 Permission Inheritance

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target.

10.2.6.2.8 Resource Association

Each proxy thread has a register (SEC_PROXY_CTL_j) to define the resource within the target that the proxy thread is mapped to. The host has no ability to access any other resource in the target. This allows the setup of the proxy to determine the resources that all the hosts use.

10.2.6.2.9 Direction

Each proxy thread has a register (SEC_PROXY_CTL_j) to define the direction for access. It can either be an outbound proxy thread for writing messages to resources. Or it can be an inbound proxy thread for reading messages from resources. The host must match the direction programmed or it will result in a proxy thread error.

10.2.6.2.10 Threshold Events

Each proxy thread can produce events based on the state of the resource it uses. For outbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to write. For inbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to read. These threshold values are programmed in SEC_PROXY_EVT_MAP_j, allowing the host to determine how often it gets events. Programming the count values while the threshold is set to 0 will not trigger events, but if the threshold is not 0 then programming the counts will trigger events based on whether the threshold is reached or not. No event is generated if the event is programmed to 0xFFFF.

10.2.6.2.11 Error Events

Each proxy thread can produce an event when it has detected an error. This error occurs when the host violates the programmed setup of the proxy thread or accesses beyond the message size. There is a separate status bit per proxy thread for these errors. No event is generated if the event is programmed to 0xFFFF.

10.2.6.2.12 Bus Errors and Credits

If a target read for a message returns a bus error, this indicates the read was bad and the data is corrupt and usually 0s. Because the private word is contained in the message, if the private word is corrupted then the source proxy thread is not valid and the credit return will not be correct. Since the data is usually 0, this means the credit would be returned to proxy thread 0 incorrectly most of the time. And the credit will be lost for the actual source proxy thread of the message that was not read correctly. The hardware has no way to correct for this, as the message from the target is corrupt so it does not know the correct owner of the credit. If software detects that a read message is corrupt, it can attempt to correct the situation by resetting the affected proxy threads using that queue, to restore their credit counts back to the default. Software may also want to reset proxy thread 0 since it may be getting extra credits.

10.2.6.2.13 Debug

When the transaction has the *emudbg* set for a read, all side effects will not occur. This means that the read will not cause a target read since that would affect the target, and instead current buffer will be read even if the previous message has completed.

10.2.7 Interrupt Aggregator (INTR_AGGR)

This chapter describes the INTR_AGGR module, part of NAVSS.

10.2.7.1 INTR_AGGR Overview

The Interrupt Aggregator (INTR_AGGR or INTA) provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane (ETL) bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

Table 10-123. INTR_AGGR Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_INTR_AGGR0	-	-	✓ (NAVSS)
NAVSS0_INTR_AGGR1	-	-	✓ (NAVSS)
NAVSS0_UDMASS_INTR_AGGR0	-	-	✓ (NAVSS)
MCU_NAVSS0_UDMASS_INTR_AGGR0	-	✓ (MCU NAVSS)	-

10.2.7.1.1 INTR_AGGR Features

NAVSS0_INTR_AGGR0 supports the following features:

- 64-bit VBUSP slave using 64-bit registers
- Provides a set of *TI Interrupt Architecture* compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks.
 - Maps a collection of "DMA Messaged Events" which are input through an Event Transport Lane (ETL) into specific bit locations in one or more interrupt cause registers
 - Mapping is performed based on a programmable table which provides a single location for each ordinal input event number (0 through sevt_cnt-1)
 - Table specifies a specific bit in a specific cause register that the event should set or clear depending on the type of event (up vs down)
 - Tracks a single 'event up'/'event down' condition. There is no event counting. (The 'cnt' field of the ETL is ignored)
 - Tracked status interrupts are presented to the user through a standard interrupt register interface
 - Provides separate 'enable set' and 'enable clear' registers
 - Provides both masked and unmasked interrupt status
 - Interrupt status bits can be manually cleared using 'write 1 to clear'
- Provides a set of Global Event Input (GEVI) counters which can count events which were delivered via an ingress Event Transport Lane (ETL)
 - Each counted event provides an register by which the count can be read and an register by which a specified amount can be decremented by the host
 - Each counted event generates a egress Global event on a zero to non-zero and non-zero to zero transition, controllable through a mapping register
- Provides a set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
 - Each ingress event index provides a configurable 'pulse' or 'rising edge' bit, plus the configurable index of the generated Global event
- Provides a set of Global Event Input (GEVI) 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces.

10.2.7.1.2 INTR_AGGR Parameters

Table 10-124 shows the MODSS Interrupt Aggregators 0 and 1, and UDMASS Interrupt Aggregator 0 parameters set during design time. 4 local (LEVI) interrupts are from the MCRC0 module.

Table 10-124. Interrupt Aggregators Parameters

Module Instance	Parameters				
	VINTR ⁽¹⁾	SEVI ⁽²⁾	GEVI ⁽³⁾	LEVI ⁽⁴⁾	MEVI ⁽⁵⁾
NAVSS0_INTR_AGGR0	64	1024	0	0	0
NAVSS0_INTR_AGGR1	64	1024	0	0	0
NAVSS0_UDMASS_INTR_AGGR0	256	4608	512	132	512
MCU_NAVSS0_UDMASS_INTR_AGGR0	256	1536	256	12	128

- (1) VINTR – Number of Virtual Interrupt outputs. These are connected to the interrupt router inputs. Value can be read from INTA_INTCAP/UDMA_INTA_INTCAP register.
- (2) SEVI – Number of Main (Steerable) Events. Value can be read from INTA_INTCAP/UDMA_INTA_INTCAP register.
- (3) GEVI – Number of Countable Events. Value can be read from INTA_AUXCAP/UDMA_INTA_AUXCAP register.
- (4) LEVI – Number of Local Event inputs. Value can be read from INTA_AUXCAP/UDMA_INTA_AUXCAP register.
- (5) MEVI – Number of Multicast Events. Value can be read from INTA_AUXCAP/UDMA_INTA_AUXCAP register.

10.2.7.2 INTR_AGGR Functional Description

The Interrupt Aggregator provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Both the signaling and content of K3 system events are incompatible with standard interrupt controllers. The INTR_AGGR provides mechanisms which convert the TI proprietary system events to standard level sensitive pending bits which can be used by the Interrupt Router and all downstream interrupt infrastructure. Events can be presented to the INTR_AGGR in two different forms:

- Events may be active high pulses, or clock synchronous rising edges, which are input on separate orthogonal pins. These are called 'Local Events'.
 - Local event signals that are used in pulse counting mode must be sourced by the same clock as the interrupt aggregator.
 - Local event signals that are used in edge counting mode must be sourced by pseudo-synchronous sources (and be a slower clock multiple) to the interrupt aggregator clock, and they must remain high for at least 1 'slow' clock cycle.
- Events may be messages which are input in time division multiplexed sequential order from an Event Transport Lane. These are called 'Global Events'.

In both cases, these events need to be conditioned to transition them from a transient indicator that something occurred to a persistent and reliable indication of the current state of the system. The INTR_AGGR is architected to perform this conversion in an efficient and cost effective manner.

10.2.7.2.1 Submodule Descriptions

10.2.7.2.1.1 Status/Mask Registers

The Status and Mask Registers block is responsible for providing persistent storage for the interrupt status and mask bits and for formatting those in a way that is compliant to the *TI Interrupt Architecture* requirements. These requirements include the ability to set and clear bits orthogonally and to provide a masked version of the status register that corresponds to the supplied bit mask for each register.

10.2.7.2.1.2 Interrupt Mapping Block

The Interrupt Mapping Block accepts ordinally numbered events (0-N) and converts those ordinal event numbers into a status register number and bit number pair that is then used to manipulate the specified bit in the Status Registers block.

10.2.7.2.1.3 Global Event Input (GEVI) Counters

The GEVI Counters block is responsible for accepting an Event Transport Lane events and summing the total message counts for each received event index. The module creates global egress events for zero to non-zero count up' events and non-zero to zero 'count down' events. The egress global event index is configured via GEVI UDMA_INTA_MCMAP_j register, so count status egress events can optionally be fed back into the INT_AGGR, via the ETL switch fabric.

10.2.7.2.1.4 Local Event Input (LEVI) to Global Event Conversion

The Local to Global event block is responsible for accepting an array of input pins and independently counting the number of cycles for which those pins are asserted high, or by counting individual clock synchronous rising edge events. The counting mode is configurable on a 'per pin' basis. The events are converted to egress Global events on an egress ETL. Global events can optionally be fed back into the INT_AGGR, via the ETL switch fabric.

10.2.7.2.1.5 Global Event Multicast

The Global event multicast block takes an ingress global event from an ingress ETL, and maps it into two egress Global events on two egress ETL interfaces. Global events can optionally be fed back into the INT_AGGR, via the ETL switch fabric.

10.2.7.2.2 General Functionality

10.2.7.2.2.1 Event to Interrupt Bit Steering

Each time an event message is received on the Main Event Transport Lane interface, the interrupt mapping block performs a direct lookup into an SRAM using the event number as the address. The SRAM stores a corresponding raw interrupt status register and bit number within that register which are to be manipulated anytime a message is received indicating something occurred on that specific event. When an *up* event is received, the specified bit in the *j* Status register will be set. When a *down* event is received, that same bit will be cleared. This block is what allows flexible aggregation of various system events into an array of bits in the interrupt status registers. It is intended that this mapping is essentially static - set up when a resource is allocated and left untouched until the resource is no longer needed. Note that the 'cnt' field of the ETL is ignored and no interrupt counting is performed here. When 'UpDn=1', the interrupt flag bit is set, and when 'UpDn=0', the flag bit is cleared.

10.2.7.2.2.2 Interrupt Status

The event messages which are generated from the event to interrupt bit steering logic are input to the Interrupt Status registers. Each time an event is received, the interrupt status registers machine will assert or de-assert the specified bit in the specified register. The assertion and de-assertion in the interrupt status register is unaffected by the interrupt enable state. When an up event is received, the corresponding bit is set and when a down event is received, the corresponding bit is cleared. Some sources of input events will not include the ability to send a down event. In these cases, the interrupt router provides the ability to clear the status bits through the Interrupt Source Clear register. The host will write a one to the specific bit in the register which is to be cleared and the interrupt status machine will clear the bit internally. It is not intended that the Host directly clear bits which are automatically cleared via down events from the source itself.

10.2.7.2.2.3 Interrupt Masked Status

Interrupt enable bits are used in conjunction with the interrupt status bits to create the interrupt masked status register values. The interrupt masked status register (INTA_STATUSM_j) contains the value of the interrupt status ANDed with the value of the interrupt enable register. Each time a new event message is received from the event to interrupt bit steering logic or the interrupt enable register is modified, the interrupt masked status register is re-evaluated.

10.2.7.2.2.4 Enabling/Disabling Individual Interrupt Source Bits

Separate (INTA_ENABLE_SET_j and INTA_ENABLE_CLEAR_j) registers are provided to allow individual enable bits to be enabled or disabled without the need for a read-modify-write operation. When the INTA_ENABLE_SET_j register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be set. When the INTA_ENABLE_CLEAR_j register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be cleared.

10.2.7.2.2.5 Interrupt Output Generation

Each interrupt masked status register (INTA_STATUSM_j) is accompanied by a single pending bit which indicates if any enabled interrupt source within the corresponding interrupt status register is currently asserted. These pending bits from the interrupt masked status registers are collectively output from the INTR_AGGR as the VINTR_PEND bus. The interrupt status outputs will always be updated to reflect the current values of the INTA_STATUSM_j register. This is accomplished by triggering output updates on write operations to the internal RAM that holds the current raw status and enable masks.

10.2.7.2.2.6 Global Event Counting

When enabled, the INTR_AGGR will provide a set of counters which will track how many outstanding messages have been observed for each ingress event index from the ingress Counted Global Event Transport Lane (ETL) interface. For each message received where the 'UpDn' flag is set, the corresponding counter will be incremented by value of the 'cnt' field of ingress message. Events where the 'UpDn' flag is cleared are ignored. The counter is made visible to software in the UDMA_INTA_COUNT_j register. When software has read the count, it can acknowledge that count has been seen and processed by writing back an integer value specifying the amount by which the counter should be decremented, and the counter will subtract that value from the current count (which may have updated since it was read). The count will saturate at a value of 0xFFFFFFFF. Writing a count 'ack' value higher than the one read is not supported and will produce non-deterministic results.

When a count transitions from zero to a non-zero value, a Global Up 'UpDn=1' event is sent out an egress ETL interface. When a count transitions from a non-zero value to zero, a down 'UpDn=0' event will be sent. The index of the Global event is mappable on a 'per-counter' basis, using the UDMA_INTA_MAP_j register. The event may be mapped such that it then re-enters INTR_AGGR's 'Event to Interrupt Bit Steering Block' to generate an interrupt to the host. The event routing is handled by an external event switch fabric. Note that writing a new egress event index via the UDMA_INTA_MAP_j register does not alter the stored event count for the ingress event register index.

10.2.7.2.2.7 Local Event to Global Event Conversion

When enabled, the INTR_AGGR will provide a set of Local to Global event conversion registers. Local events may be discrete clock synchronous pulses or clock synchronous rising edges. The counting mode is configurable on a 'per pin' basis. In pulsed mode, the module will track how many outstanding clock cycle long pulses have been observed on each of the provided LEVI interface pins. For each cycle in which a LEVI input pending bit is asserted the corresponding counter will be incremented by 1. In 'rising edge' mode, the number of rising edge transitions on the pin is counted.

The module will generate egress Global events on its egress ETL, with a different global index configured for each ingress LEVI pin. The LEVI pins numbers (1-N) are converted to arbitrary global event indices via the global event mapping UDMA_INTA_MAP_j registers. The egress Global events can themselves be mapped to re-enter the INTR_AGGR's Global Event Counting block, so that the counts can then be made visible to software in the GEVI count registers as described in [Section 10.2.7.2.1.3](#). The event routing is handled by an external event switch fabric.

10.2.7.2.2.8 Global Event Multicast

In UDMASS_INTR_AGGR0, the INTR_AGGR will provide a set of Global event multicast (UDMA_INTA_MCMAP_j) registers. These registers allow an ingress Global event on its ingress ETL interface to be mapped into two egress Global events on two separate egress ETL interfaces. A set of registers map the ingress Global event index (1-N) into two arbitrary egress event indices.

10.2.8 Packet Streaming Interface Link (PSI-L)

This section describes the Packet Streaming Interface Link (PSI-L) for the device.

10.2.8.1 PSI-L Overview

PSI-L is a packet based protocol used to transfer data between several device modules. Each transaction is routed based on thread ID value instead of physical address. All PSI-L interfaces are point to point direct connections to NAVSS0 or MCU_NAVSS0. All switching functions among the PSI-L based interfaces are done inside NAVSS0 and MCU_NAVSS0.

The PSI-L also has an event interface referred to as ETL, which is purely used to transfer event information. Only MCU_NAVSS0 has such event interface. It is connected to WKUP_ and allows MCU_NAVSS0 to send event information to the interrupt aggregator inside WKUP_.

[Figure 10-23](#) shows an overview of all PSI-L connections within the device.

Figure 10-23. PSI-L Overview

10.2.8.2 PSI-L Functional Description

10.2.8.2.1 PSI-L Introduction

The PSI-L is used to transfer words of packet data and control information between two peer entities via direct connection. There are credits used for flow control to guarantee that blocking does not occur between threads. Multiple packet transfers can be ongoing simultaneously across a PSI-L interface each on a separate logical thread but all sharing a single datapath through time division multiplexing. Each packet which is transferred is accompanied by a destination thread ID which indicates the logical destination thread to which the packet is being sent.

There is low level hardware handshake between PSI-L master and slave used for transferring data. As it is blocking by nature, a higher level protocol is also used in which credits are maintained for each thread connection. Moments of non-readiness are allowed on the interface but there is no possibility that one thread can block another for an indefinite time since a thread must have credit for the destination before it is allowed to use the interface.

Figure 10-24 illustrates the point to point PSI-L connection.

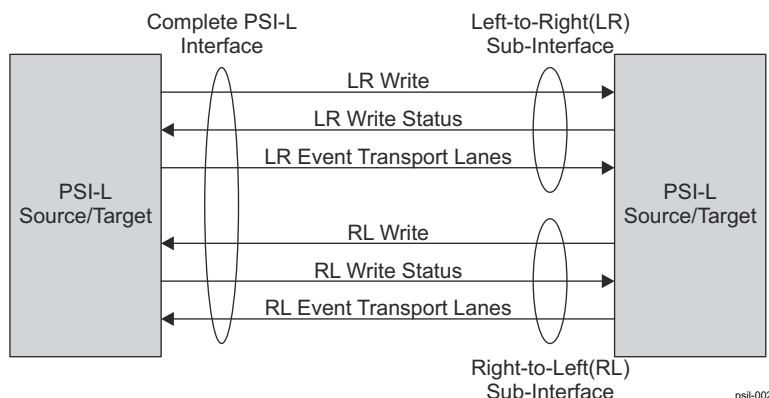

Figure 10-24. PSI-L Connection

PSI-L is intended to be a versatile interface which can carry various types of communications. Table 10-125 describes several types of threads which have been defined.

Table 10-125. Types of PSI-L Threads

Type	Description	Example Endpoints
Queue Management (QM) Messaging	Provides transport for queue push, pop, and divert messages to support distributed queue based work passing	Centralized queue manager or message manager and distributed DMA clients
Direct IO	Allows for tunneling CBASS compatible bus transactions through a PSI interconnect	Module which has no CBASS master to a remote proxy block
DMA Control Transport	Provides transport for DMA transfer descriptions from a source thread to a destination thread	DMA channel controller to DMA transfer controller
DMA Data Transport	Provides transport for packed data from a source thread to a destination thread	Packet oriented module like networking adapters to or from centralized DMA

Each thread on PSI-L is established between a single thread master and a single thread slave using a connection oriented transfer mechanism. A thread master and a thread slave are "paired" to create a logical connection between them referred to as a thread. Pairing is accomplished using a Pair Configuration Message which is valid in all thread types. Pairing can only occur between a thread master and a thread slave of the same type.

10.2.8.2.2 PSI-L Operation

The PSI-L allows multiple independent streams of packet data (threads) to share a single interface using data phase granularity time division multiplexing. This time division multiplexing is accomplished by dividing each stream into single data transfers. In this way a stream is comprised of a sequence of strongly ordered data

transfers but packet transfers between different streams are allowed to be interleaved. Each data phase is qualified with a type identifier which indicates whether the data is packet info, direct IO write or read info, timestamp, software info, control data, payload data, or status.

10.2.8.2.2.1 Event Transport

PSI-L provides a mechanism by which events can be transported within one or more optional sub-interfaces on a link. These sub-interfaces are referred to as event transport lanes (ETLs) and are independent of any PSI-L packet or message transfers which may be ongoing on the other interfaces within the PSI-L. A maximum of one event can be transferred on each event transport lane in each clock cycle. The event transport protocol is a simple request-ready type of hardware handshake.

10.2.8.2.2.2 Threads

A thread is a complete flow-controlled stream of communication. The PSI-L thread space is divided into a 32K contiguous region representing all of the source threads (0x0000 - 0x7FFF) and a 32K contiguous region representing all of the destination threads (0x8000 - 0x8FFF).

Source threads are responsible for sending request transactions, accepting response transactions, and sending data transfer transactions. Destination threads are responsible for accepting request transactions, sending response transactions, and accepting data transfer transactions. A given thread generally performs only a single class of transactions (see [Table 10-125](#)). Both source and destination threads may act as masters for transfers on one of the PSI-L write sub-interfaces but in this case source threads are actually initiating data transfers while destination threads are only responding to a previous request issued by a source request. Source threads only transfer to destination threads and destination threads only transfer to source threads. Transfers between same thread types do not occur.

The following types of message transfers always originate from source threads and terminate in destination threads:

- Configuration write message
- Configuration read message
- QM push message
- QM pop message
- QM divert message
- Direct read operation message
- Direct write operation message
- DMA transfer request message
- DMA data message

The following types of message transfers always originate in destination threads and terminate in source threads:

- Configuration write response message
- Configuration read response message
- QM push response message
- QM pop response message
- QM divert response message
- DMA transfer response message

10.2.8.2.2.3 Arbitration Protocol

On each cycle, an arbiter built into the master side of each interface decides on which thread to transfer data in the next clock cycle. Both forward (from source threads) and reverse (from destination threads) direction transfers can occur across the same physical interface so the arbiter must ensure that sustained blocking of any thread can occur.

The decision about which thread to allow using the interface is based on the following factors:

1. Whether data is ready at the source to be sent
2. Whether credit exists for the thread such that it is guaranteed there is a place for the data to land in the destination endpoint. For reverse direction transfers (response messages), it is assumed that credit always exists.

3. The relative priority of the traffic that the thread is carrying for the given packet duration
4. Whether the transfer is for a forward or reverse direction thread (requests versus responses).

No thread can be considered for inclusion in arbitration unless both data is available and credit exists in the destination endpoint. For each thread which can be considered in the current arbitration cycle, the arbiter should then pick the thread with the highest priority. Reverse transfers should be considered higher priority than forward transfers.

10.2.8.2.2.4 Thread Configuration

Each source thread has programmable registers for configuring the pairing with a corresponding destination thread and for enabling data flow. Each destination thread has programmable registers for reporting the buffering capability of the thread and for enabling data flow. These registers are accessed using configuration read and write messages from a configuration host.

Each configuration write message sent from a configuration host is acknowledged with a configuration write response message from the addressed endpoint. Each configuration read message sent from a configuration host is acknowledged with a configuration read response message from the addressed endpoint.

10.2.8.2.2.4.1 Thread Pairing

Depending on the type of traffic that each source thread carries it may or may not have a fixed pairing with a destination thread.

10.2.8.2.2.4.1.1 Configuration Transaction Pairing

Configuration write and read transactions are only initiated by a special module called configuration proxy (CFG_PROXY). Each configuration proxy in the system uses a single source thread which can initiate configuration write and read transactions to the configuration registers of every other source and destination thread in the PSI-L system. The CFG_PROXY registers are described in *PSI-L CFG_PROXY Registers*.

Each source thread routes to a single target thread and this pairing is specified by programming a required pairing register set for each thread. A source has no ability to change what target thread it talks to. If a source must be able to talk to different targets (or target threads), then it can either have multiple threads or a streaming switch that can be programmed to route the transfers appropriately based on specific packet fields.

10.2.8.2.2.4.2 Configuration Registers Region

The configuration registers region contains static configuration information including the settings for linking a thread source to a thread destination. These registers are described in *PSI-L Configuration Registers*. The thread ID mapping is shown in *Navigator Subsystem (NAVSS)*.

10.2.9 PSIL Subsystem (PSILSS)

This chapter describes the PSIL subsystem (PSILSS) in the device.

10.2.9.1 PSILSS Overview

The PSILSS is a PSI-L compliant hardware switch that makes the connection between PSI-L master and slave endpoints. The SoC implements the following PSILSS instances:

- PDMA_USART_PSILSS0
 - [4:1] switch
 - Master endpoint: NAVSS0
 - Slave endpoints: PDMA_USART_G0, PDMA_USART_G1, PDMA_USART_G2 and PDMA_MCAN
- PDMA_CPSW_PSILSS0
 - [4:1] switch
 - Master endpoint: NAVSS0
 - Slave endpoints: CPSW2G, PDMA_SPI_G0 and PDMA_SPI_G1
- PDMA_DEBUG_PSILSS0
 - [2:1] switch
 - Master endpoint: NAVSS0
 - Slave endpoints: PDMA_DEBUG_G0 and PDMA_DEBUG_G1
- SA2_CPSW_PSILSS0
 - [2:1] switch
 - Master endpoint: NAVSS0
 - Slave endpoints: CPSW9G and SA2_UL
- CSI_PSILSS0
 - [5:1] switch
 - Master endpoint: NAVSS0
 - Slave endpoints: CSI_TX_IF0, CSI_TX_IF1, CSI_RX_IF0, CSI_RX_IF1 and CSI_RX_IF2
- DMPAC_VPAC_PSILSS0
 - [5:1] switch
 - Master endpoint: NAVSS0
 - Slave endpoints: VPAC0_TC0, VPAC0_TC1, VPAC1_TC0, VPAC1_TC1 and DMPAC

Table 10-126. PSILSS Modules Allocation within Device Domains

PSILSS Instance	Domain		
	WKUP	MCU	MAIN
PDMA_USART_PSILSS0	–	–	✓
PDMA_CPSW_PSILSS0	–	–	✓
PDMA_DEBUG_PSILSS0	–	–	✓
SA2_CPSW_PSILSS0	–	–	✓
CSI_PSILSS0	–	–	✓
DMPAC_VPAC_PSILSS0	–	–	✓

10.2.9.1.1 PSILSS Features

Each PSILSS module supports the following features:

- Implements a PSI-L 1.2 compliant interconnect
- Integrates the configured endpoints, either master or slave, and applies clock, data width or protocol conversion when necessary
- Integrates a single level CBASS for switching traffic between multiple masters and slaves using VBUSP
 - It uses the configured data width, clock and reset for the main SCR
- Provides full connectivity between all master and all slave endpoints
- Transactions are routed based on the configured thread map to the defined slave endpoint
- Events are routed based on the configured event map to the defined slave endpoints, or the default event output for an event aggregator

- Support event endpoints that are not PSI-L but still connect to the event interconnect

10.2.9.2 PSILSS Functional Description

10.2.9.2.1 PSILSS Basic Operation

The PSILSS implements a PSI-L 1.2 interconnect between endpoints. Each endpoint connects to a CBASS that provides a CBA 4.0 VBUSP transport which is used to transport the PSI-L streams. The CBASS can implement any bridging needed for clock conversion, but any data width conversion is handled in the PSILSS as data width conversion in PSI-L requires special bridges for packing and unpacking data. In this context, a master endpoint is one that creates streams that go into the PSILSS, and a slave endpoint is one that consumes streams from the PSILSS and returns status.

The PSILSS converts the PSI-L signals to VBUSP signals in order to use the CBASS to perform the routing based on the thread maps and the requested destination thread. The CBASS performs the routing and switching of the traffic from a number of masters to a number of slaves. The masters send transactions to the CBASS. The CBASS decodes which slave is being accessed based on the signals and the map. The CBASS routes that transaction to the slave. The CBASS also arbitrates for a slave when there are multiple transactions being requested simultaneously, which can be based on transaction priority. Once a transaction is selected, the CBASS sends the transaction to the slave.

10.2.9.2.2 PSILSS Event Routing

The PSIL events are also routed based on the event number. An event map defines which event number range maps to the destination ETL events of that endpoint. All source events from endpoints will be routed to a destination endpoint based on this event map. When the event number does not map to any endpoint, then it is routed to a default output event interface that connects to an event aggregator to map them to interrupts.

In addition to PSI-L endpoints, event endpoints are supported. These events connect to the same event interconnect as the PSI-L endpoints and pass events in the same way. An event endpoint can be a producer or consumer of events, and the same event mapping can apply to an event or PSI-L endpoint.

10.2.9.2.3 PSILSS Link Down Detection

The PSILSS provides MMRs that show the current link status of all the PSIL endpoints. It also tracks and provides status MMRs of any links that went down, from being active and running to a down state when the PSILSS is not in reset. This detection can generate an event so that software can remedy the situation. The hardware does not cleanup the traffic, so software must take care to idle any traffic before an endpoint is reset, which causes the link to go down, as well as to cleanup any connections after an endpoint has gone down. Software must guarantee the endpoint link is up again before setting up new connections.

10.2.9.2.4 PSILSS Configuration

Table 10-127 shows the thread numbers for the PSILSS slave endpoints.

Table 10-127. PSILSS Endpoint Thread Map

PSILSS Instance	Endpoint	Thread Number
PDMA_DEBUG_PSILSS0	PDMA_DEBUG_0	0x4300
	PDMA_DEBUG_1	0x4304
PDMA_CPSW_PSILSS0	PDMA_SPI_G0	0x4600
	PDMA_SPI_G1	0x4620
	CPSW2G	0x4640
	SPARE	0x4658
	PDMA_USART_PSILSS0	0x4700
PDMA_USART_PSILSS0	PDMA_USART_G0	0x4700
	PDMA_USART_G1	0x4702
	PDMA_USART_G2	0x4704
	PDMA_MCAN	0x470A
DMPAC_VPAC_PSILSS0	VPAC0_TC0	0x4820
	VPAC0_TC1	0x4840
	VPAC1_TC0	0x4880
	VPAC1_TC1	0x48A0
	DMPAC	0x48E0

Table 10-127. PSILSS Endpoint Thread Map (continued)

PSILSS Instance	Endpoint	Thread Number
CSI_PSILSS0	CSI_TX_IF0	0x4900
	CSI_TX_IF1	0x4920
	CSI_RX_IF0	0x4940
	CSI_RX_IF1	0x4960
	CSI_RX_IF2	0x4980
SA2_CPSW_PSILSS0	CPSW9G	0x4A00
	SA2_UL	0x4A40

Table 10-128 through Table 10-133 provide further details about the source (src) and destination (dst) configuration parameters for the various PSILSS instances, including number of threads per endpoint. Note that the last two columns in each table present the associated source and destination thread numbers in decimal value.

Table 10-128. PDMA_DEBUG_PSILSS0 Configuration Parameters

Endpoint	Data Width (Src / Dst)	ETL Count (Src / Dst)	Thread Count (Src / Dst)	Source Thread Map	Destination Thread Map

10.2.10 NAVSS North Bridge (NB)

This section describes the North Bridge (NB) in the main Navigator Subsystem.

10.2.10.1 NB Overview

The North bridge bridges between CBA 4.0 compliant VBUSM interfaces and a three-threaded CBA 4.0 compliant VBUSM.C interface.

Figure 10-25. NB Overview

10.2.10.1.1 Features Supported

- Implements a CBA 4.0 VBUSM to/from VBUSM.C compliant bridge
- Implements CBA 4.0 VBUSM compliant slave interface(s) to receive traffic from a VBUSM source
- Implements a CBA 4.0 VBUSM compliant master interface to create traffic to a VBUSM destination
- Implements a CBA 4.0 VBUSM.C compliant interface to receive and create traffic to and from a VBUSM.C endpoint using 3 threads
- Can optionally support fragmentation of VBUSM write commands into defined burst aligned sizes
- Can optionally support fragmentation and reassembly of VBUSM read commands into defined burst aligned sizes
- Can optionally support synchronous or asynchronous clock conversion
- Can optionally support data width conversion
- Can optionally support using the CBA 4.0 VBUSM credit interface for the VBUSM interfaces
- Allows for priority escalation through the bridge, either for higher priority pending commands inside the bridge or requesting into the bridge
- Supports the K3 clkstop idle signal
- Can optionally support a maximum outstanding read byte count to limit the total read data
- Can optionally insert memory attributes for commands
- Can optionally maintain VBUSM order based on orderid
- Allows programming the mapping of the VBUSM source interfaces to VBUSM.C threads

10.2.10.1.2 NB Parameters

North Bridges are implemented in the SoC with the parameters shown in [Table 10-134](#) and [Table 10-135](#).

Table 10-134. NB0 Configuration

Parameter	Value	Description
Number of sources	2	The number of VBUSM source interfaces
Source 0	CBASS MSMC_SLV to MSMC0	Source 0
Source 1		Source 1
start64k	0x0060000000	This defines the starting address of the memory in VBUSM.C that uses the 64-KB table.
num64k	8192	This defines the number of entries in the 64-KB table.

Table 10-135. NB1 Configuration

Parameter	Value	Description
Number of sources		The number of VBUSM source interfaces
Source 0	CBASS MSMC_DDR_ to MSMC1	Source 0
Source 1	CBASS MSMC_DDR_ to MSMC1	Source 1
start16m[0]	0x0080000000	This defines the starting address of the memory in VBUSM.C that uses the 16-MB table. The index is for each of the 16-MB regions.
start16m[1]	0x0800000000	
num16m[0]	128	This defines the number of entries in the 16-MB table. The index is for each 16-MB region.
num16m[1]	8192	

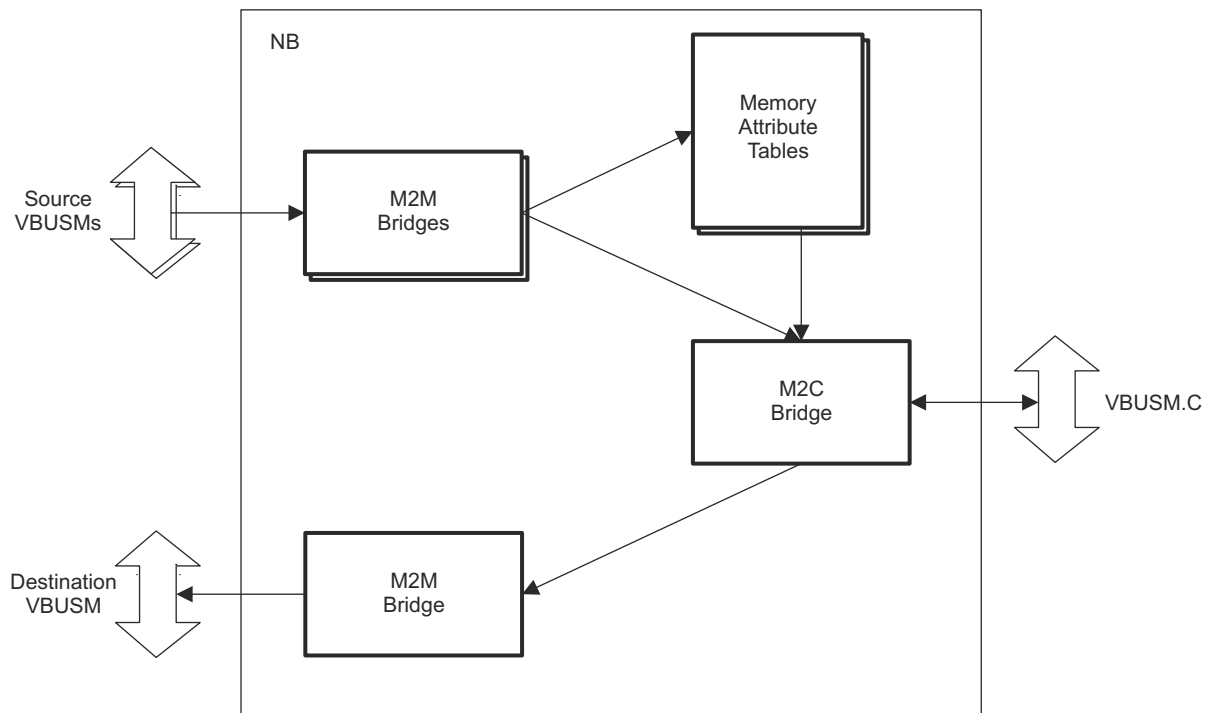

10.2.10.1.2.1 Compliance to Standards

The module is compliant to the CBA 4.0 VBUSM specification and VBUSM.C annex.

10.2.10.1.2.2 Features Not Supported

- Does not support fragmentation of VBUSM.C commands
- Does not support VBUSM.C coherence traffic

10.2.10.2 NB Functional Description

navss-020

Figure 10-26. NB Block Diagram

The CBA 4.0 North bridge, NB, bridges between CBA 4.0 compliant VBUSM interfaces and a three threaded CBA 4.0 compliant VBUSM.C interface. This is achieved by using M2M bridges to support all the M2M features and then an M2C bridge to convert the VBUSM interfaces to a VBUSM.C interface, which support duplex traffic. The M2M bridges allow for clock frequency conversion, data width conversion and fragmentation for the Source M2M bridge(s). This allows the M2C bridge to remain simple and operate at the VBUSM.C clock frequency and data width, as well as assume all required burst limitations have already been handled. Some additional features needed for the north bridge are implemented, including: adding memory attributes to source VBUSM transactions, and forcing a maximum outstanding read data limit.

10.2.10.2.1 VBUSM Slave Interfaces

The slave interfaces on the bridge is the source VBUSM port to receive commands and return data and status. These ports have the defined prefix, smX (SoC Master, input to bridge), to identify them, where the X is the number to identify each port starting from zero. The number of these interfaces and bridges is shown in [Table 10-134](#) and [Table 10-135](#).

10.2.10.2.2 VBUSM Master Interface

The master interface on the bridge is the destination VBUSM port to send commands and receive data and status. These ports have the defined prefix, ss (SoC Slave, output of bridge), to identify them.

It is important to note that any feature not supported in the optional signals for this bus that is supported on the VBUSM.C interface will not be corrected inside the bridge. Examples are excluding the emudbg pin on this bus but expecting VBUSM.C transactions with emudbg set to not create bus status errors on this VBUSM bus outside the bridge (as the bridge will just pass the returned status which could be an error if it does not support the emudbg pin).

10.2.10.2.3 VBUSM.C Interfaces

The pair of interfaces on the bridge is the VBUSM.C port to send and receive commands and send and receive data and status. These ports will have the defined prefix, mm (Memory Master, output of bridge) and ms (Memory Slave, input to bridge), to identify them. These interfaces support three threads for sending and receiving traffic.

10.2.10.2.3.1 Multi-Threading

The VBUSM.C interfaces use multi-threading to support both input and output traffic on the same data signals. The threads are used to separate that traffic. Thread 0 is used for commands to VBUSM.C, thread 1 is used for commands from VBUSM.C, and thread 2 is used for realtime commands to VBUSM.C. Any responses due to commands must use the same thread when returned.

10.2.10.2.3.2 Write Command Crediting

VBUSM.C interfaces use credits for sending data phases. For writes and read responses to the MSMC (VBUSM.C consumer), there is a requirement that all credits for the write, including the command and all data phases, should be available before sending the command. Since the VBUSM.C data width is always half the max burst size on VBUSM.C, the write command must wait for a TAC credit available and 1 or 2 TDC credits available before the write can be sent.

10.2.10.2.3.3 Early Credit Response

The VBUSM.C interfaces use the credit mechanism available. They do not check for full burst available credits before sending any piece of the burst (command or data). To prevent deadlocks, the connected VBUSM.C device must support sending early credit responses, before the entire burst is received.

10.2.10.2.3.4 Priority Escalation

The VBUSM.C interface does not natively define a mechanism for priority escalation, since the cepriority signal is only valid when a command is sent, and can otherwise be ignored. To support this feature this bridge supports updating the cepriority output even if there is no valid command, so identify the highest priority of any pending commands when the bridge cannot sent a command, such as due to a lack of credits. The VBUSM.C consumer can assume the cepriority output from this bridge is always valid every cycle, and use the cepriority along with the priorities of all pending commands. When there are no pending commands, the cepriority output will be the lowest priority, 7.

10.2.10.2.4 Source M2M Bridges

The source M2M bridges perform all the usual bridging functions from the source VBUSM interface to an internal VBUSM interface running at the same clock frequency and data width of the VBUSM.C interface. It also performs the fragmentation to sizes the VBUSM.C interface requires. It additionally performs full read data reassembly, orderid based ordering, and read data cacheline conversion.

10.2.10.2.5 Destination M2M Bridge

The destination M2M bridge performs all the usual bridging functions to the destination VBUSM interface from an internal VBUSM interface running at the same clock frequency and data width of the VBUSM.C interface.

10.2.10.2.6 M2C Bridge

The M2C bridge performs the protocol conversion and multi-threading of the VBUSM.C interface from the internal VBUSM interfaces. It also handles the cacheline conversion of the write data.

A VBUSM.C write with a dtype of 1 (CPU instruction) will be converted to a VBUSM write with a dtype of 0 (CPU data), as this condition is allowed in VBUSM.C but not in VBUSM.

10.2.10.2.7 Memory Attribute Tables

The bridge can optionally include a memory attribute lookup table to add the coherence memory attributes required for VBUSM.C for VBUSM commands missing them. It is implemented using up to 4 tables, a table of 64-KB regions and 1 to 3 tables of 16-MB regions. The first table is meant to cover an internal memory with smaller granularity, while the second to fourth tables are meant to cover the external memory with a much larger size and larger granularity. The external memory has one to three regions as its address space might be

fragmented in the SoC memory map. Starting address and number of table entries for each region are shown in [Table 10-134](#) and [Table 10-135](#).

When a command without memory attributes, an `atype = 0`, is input to the M2C bridge, this table performs the lookup in parallel and returns the memory attributes to the M2C bridge in the next cycle. If the `atype` is another value, it is assumed the memory attributes on the VBUSM interface are valid. The lookup is performed by matching the address against the starting addresses, assuming the successive regions always starts at later address, including that the up to three 16-MB regions are given in increasing order. Then the offset from the starting address of the region and the region size, 64-KB or 16-MB, is used to calculate the entry of attributes for that address. Then a memory is read to retrieve the attributes and return them to the M2C bridge. An output FIFO is implemented to capture the attributes if they are not accepted immediately.

There is a memory attribute table module for each VBUSM slave interface. If the MAT is enabled, at least one of the 64-KB region and/or the first 16-MB region must be populated, or both. The second and third 16-MB regions are optional.

10.2.10.2.8 Outstanding Read Data Limiter

If a param defines a maximum outstanding read data byte count, then this function will track the requested read bytes against the limit. If a read command does not violate the total read bytes outstanding limit then the read is allowed to the VBUSM.C, otherwise it is stalled. When read data arrives from the VBUSM.C the outstanding count is reduced, allowing more read commands to be sent.

10.2.10.2.9 Ordering

Ordering becomes a concern due to the fact that the VBUSM commands are fragmented and not guaranteed to be returned in order by the VBUSM.C interface. This violates the CBA ordering rules for a single slave endpoint. So the bridge will force read data ordering based on the `orderid` signal across all masters, as a balance between cost and performance. This means that each read command received from the VBUSM interface with a particular `orderid` value will have their read data returned in exactly the same order. This means that even if the reads are from different masters, the data will still be returned in order, to reduce the amount of tracking the bridge has to perform. But, if the reads use different `orderid` values then that read data can be returned in any order, whichever is received first on the VBUSM.C interface.

10.2.10.2.10 Quality of Service

To support quality of service, QoS, the north bridge allows for configuring multiple VBUSM source interfaces. This not only allows defining particular sources to be realtime to achieve better qos, but also to load balance and effectively utilize any extra bandwidth provided by the VBUSM.C interface. There are registers (`NB_THREADMAP`) allowing programming of which source interfaces map to which of the two VBUSM.C threads, normal or realtime traffic. All traffic on the source will always map to the defined thread.

Any sources mapped to the realtime thread will be arbitrated first, before any sources mapped to the normal thread, to provide the QoS. If there are multiple sources mapped to the same thread then they are arbitrated based on priority and if they are the same priority then by round robin.

To route return traffic from the VBUSM.C back to the correct VBUSM source, the `orderid` is used. As such, each source mapped to each thread must use a different `orderid` value in the SoC. This would mean that if there are 8 sources total, with 4 mapped to each thread, then each group of 4 should not share the same `orderid` for any traffic routed to it in the SoC to keep their `pathid` values unique. The bridge is configured to identify which VBUSM source uses which `orderid` value(s).

10.2.10.2.11 IDLE Behavior

The north bridge IDLE output is a combination of all the IDLE outputs from the components. These are combined and registered as the NB IDLE on the Destination VBUSM bus clock.

10.2.10.2.12 Clock Power Management

The north bridge provides internal clock power management for all major components: bridges and register modules. Each component will track its own activity and shut off the clock tree when there has been no activity for 12 cycles. There is a 1 cycle latency for starting up the clock once off, so bus transactions may be initially

stalled. The bus early wakeup signals can be used to wakeup the clocks before the transactions arrives to remove some of the latency impact.

10.2.11 Block Copy DMA (BCDMA)

The Block Copy DMA is intended to perform similar functions as an Embedded DMA (EDMA) and the UDMA-P/UTC. The BCDMA module moves data from a memory mapped source address set to a corresponding memory mapped address. The BCDMA maintains state information for each of the channels which allows data copy operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

A block diagram of the Block Copy DMA Controller is shown below:

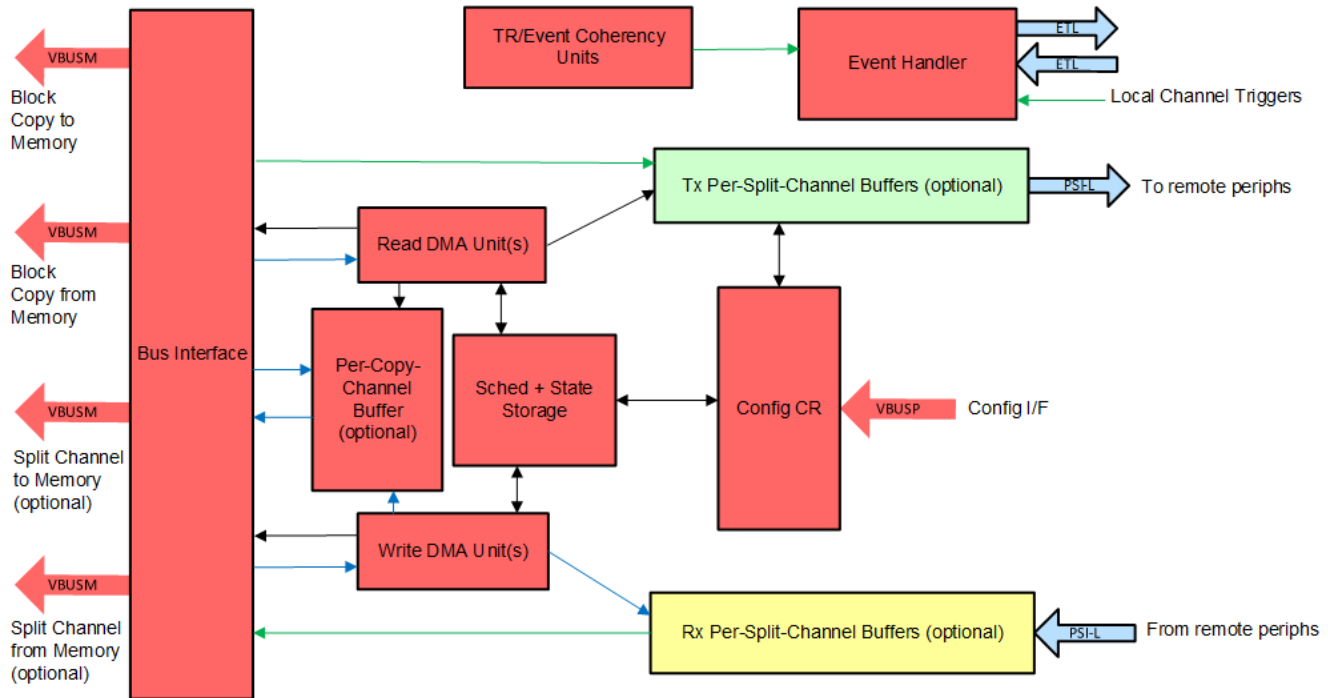

Figure 10-27. Block Copy DMA Block Diagram

10.2.11.1 BCDMA Submodule Descriptions

10.2.11.1.1 Bus Interface Unit

The Bus Interface Unit is responsible for merging and buffering all of the transactions that originate from the various controller blocks inside the DMA controller into the 4 separate VBUSM controller interfaces. Arbitration between the blocks to a given VBUSM interface is round robin within a single priority level. A 2 word deep retiming buffer is provided on each sub interface of each provided VBUSM bus.

10.2.11.1.2 Config CR

The function of the Config CR is to switch transactions which arrive on the configuration interface to the various configuration targets within the DMA. The Config CR also provides a retiming buffer on the configuration bus primary interface ports.

10.2.11.1.3 Configuration Registers

The Configuration Registers block is responsible for monitoring the fullness level of the Per Channel FIFOs, monitoring data transfer work which is pending, maintaining data movement thread state information, arbitrating which channel will be allowed to perform work next, issuing scheduler commands to the Read and Write DMA units, and writing back the updated state returned from those same DMA units.

The Configuration Registers block is also responsible for providing memory mapped registers for configuration of the DMA channels.

10.2.11.1.3.1 BCDMA Mapping Table

Table 10-136 applies to TX, RX and BC Mapping.

Table 10-136. BCDMA Mapping Table (continued)

Total Bits	Bits	Register Offset	Field	Description
399	15	0xB0	sot	

10.2.11.1.4 Read Unit(s)

The Read Units implement all of the state machine functionality necessary to perform the read transfers defined in the SW supplied Transfer Request records. The read DMA unit initiates VBUSM transactions in order to read descriptor pointers from memory mapped rings, read descriptors, Transfer Request records, and payload data from memory.

10.2.11.1.5 TR Coherency Unit

The TR Coherency Unit is responsible for ensuring that all control structures and data have been read (and updated if applicable) by the BCDMA unit(s) and all prior TRs have completed prior to incrementing the reverse ring occupancy for the flow/channel.

10.2.11.1.6 Per-Copy-Channel Buffers

The Per-Copy-Channel Buffers implement a FIFO for each BCDMA generic block copy channel and is used for buffering payload data that has been fetched by read DMA unit modules. The write DMA units issue write transfers from the Per Channel Buffers to specified addresses in memory. The buffers are byte oriented on both write and read so that the data from the DMA units which may not be full words can be packed and unpacked properly. This unit is optional and is only present if one or more generic block copy channels are configured in the BCDMA instance.

10.2.11.1.7 Tx Per-Split-Channel Buffers

The Tx Per-Split-Channel Buffers implement a FIFO for each BCDMA Tx split mode channel and is used for buffering payload data that has been fetched by read DMA unit modules. Data is transferred from the buffer to the remote peripheral via a PSI-L interface. This unit is optional and is only present if one or more Tx split mode channels are configured in the BCDMA instance.

10.2.11.1.8 Rx Per-Split-Channel Buffers

The Rx Per-Split-Channel Buffers implement a FIFO for each BCDMA Rx split mode channel and is used for buffering payload data that has been received from remote peripherals via a PSI-L interface. Data is read from these FIFOs and written out to memory as directed by the write DMA unit modules. This unit is optional and is only present if one or more Rx split mode channels are configured in the BCDMA instance.

10.2.11.1.9 Write Unit(s)

The Write Units implement all of the state machine functionality necessary to perform the write transfers defined in the SW supplied Transfer Request records. The write DMA unit initiates VBUSM transactions in order to read descriptor pointers from memory mapped rings, read descriptors and/or Transfer Request records from memory mapped rings, read descriptor and Transfer Request records, and write payload data to memory.

10.2.11.1.10 Event Coherency Unit

The Event Coherency Unit is responsible for ensuring that all writes have completed prior to signaling an output event for a channel/flow.

10.2.11.1.11 Event Handler

The Event Handler block is responsible for generating channel completion and error events and for accepting and tracking channel triggering.

10.2.11.2 Channel Classes

Not all channels within a DMA controller require the same performance capabilities. Raw bandwidth and latency tolerance requirements will vary greatly between data transfers at various points in the system. Due to area concerns, several different classes of DMA channels are provided in the BCDMA and are described as follows:

Class Name	Description
Normal Capacity	Provides baseline amount of descriptor and TR prefetch and Tx/Rx control and data buffering. Suitable for most peripheral transfers which are communicating with on-chip memories and DDR
High Capacity	Provides an elevated amount of descriptor and TR prefetch and custom Tx/Rx control and data buffering. Suitable for applications which require moderate per-channel bandwidth with significantly increased latency (ex. Transferring data to/from PCIe)
Ultra-High Capacity	Provides identical descriptor and TR prefetch as High Capacity but with increased Tx data buffering to allow for more read data in flight. Suitable for applications requiring high per-channel bandwidth with significantly increased latency (ex. 16+Gbps transfers to/from PCIe).

BCDMA instances may provide support for any or all of the above channel classes through design time configuration parameters.

10.3 Peripheral DMA (PDMA)

This chapter describes the PDMA architecture in the device.

10.3.1 PDMA Controller

10.3.1.1 PDMA Overview

The Peripheral DMA is a simple DMA which has been architected to specifically meet the data transfer needs of peripherals, which perform data transfers using memory mapped registers (MMRs) accessed via a standard non-coherent bus fabric. The PDMA module is located close to one or more peripherals which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only statically configured Transfer Request (TR) operations.

The PDMA is only responsible for performing the data movement transactions which interact with the peripherals themselves. Data which is read from a given peripheral is packed by a PDMA source channel into a PSI-L data stream which is then sent to a remote peer UDMA-P destination channel which then performs the movement of the data into memory. Likewise, a remote UDMA-P source channel fetches data from memory and transfers it to a peer PDMA destination channel over PSI-L which then performs the writes to the peripheral.

The PDMA architecture is intentionally heterogeneous (UDMA-P + PDMA) to right size the data transfer complexity at each point in the system to match the requirements of whatever is being transferred to or from. Peripherals are typically FIFO based and do not require multi-dimensional transfers beyond their FIFO dimensioning requirements, so the PDMA transfer engines are kept simple with only a few dimensions (typically for sample size and FIFO depth), hardcoded address maps, and simple triggering capabilities.

Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs round-robin scheduling between channels in order to share the underlying DMA hardware.

The PDMA is linked to the UDMA-P (NAVSS) either through a direct PSI-L connection, or through a PSI-L switch (PSILSS).

10.3.1.1.1 PDMA Features

10.3.1.1.1.1 MCU_PDMA0 (MCU_PDMA_MISC_G0) Features

The MCU_PDMA0 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access units (write unit 0)
 - Provides a 32-bit wide VBUSP write only master interface for peripheral accesses
 - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0):
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 7 simultaneous destination (Tx) channels
- Supports up to 7 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.2 MCU_PDMA1 (MCU_PDMA_MISC_G1) Features

The MCU_PDMA1 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
 - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.

- Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 8 simultaneous destination (Tx) channels
- Supports up to 8 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.3 MCU_PDMA2 (MCU_PDMA_MISC_G2) Features

The MCU_PDMA2 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
 - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
 - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 4 simultaneous destination (Tx) channels
- Supports up to 4 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.4 MCU_PDMA3 (MCU_PDMA_ADC) Features

The MCU_PDMA3 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 0 memory write access units
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 0 simultaneous destination (Tx) channels
- Supports up to 4 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.5 PDMA5 (PDMA_MCAN) Features

The PDMA5 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
 - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
 - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 54 simultaneous destination (Tx) channels
- Supports up to 54 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports MCAN transfer mode only (does not support X-Y and AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals
- Provides ECC support

10.3.1.1.1.6 PDMA6 (PDMA_MCASP_G0) Features

The PDMA6 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
 - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
 - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to simultaneous destination (Tx) channels
- Supports up to simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.7 PDMA9 (PDMA_SPI_G0) Features

The PDMA9 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
 - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
 - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 16 simultaneous destination (Tx) channels
- Supports up to 16 simultaneous source (Rx) channels

- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals
- Provides ECC support

10.3.1.1.1.8 PDMA10 (PDMA_SPI_G1) Features

The PDMA10 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
 - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
 - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 16 simultaneous destination (Tx) channels
- Supports up to 16 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals
- Provides ECC support

10.3.1.1.1.9 PDMA13 (PDMA_USART_G0) Features

The PDMA13 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
 - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
 - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 2 simultaneous destination (Tx) channels
- Supports up to 2 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.1.10 PDMA14 (PDMA_USART_G1) Features

The PDMA14 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):

- Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
- Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 2 simultaneous destination (Tx) channels
- Supports up to 2 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.1.11 PDMA15 (PDMA_USART_G2) Features

The PDMA15 module supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
 - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
 - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
 - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
 - Supports read burst up to 64 bytes (on selected channel types)
 - Supports 1 outstanding read
- Supports up to 6 simultaneous destination (Tx) channels
- Supports up to 6 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
 - Provides 8×128-bit word deep data FIFO for each destination channel
 - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

10.3.1.2 PDMA Functional Description

10.3.1.2.1 PDMA Functional Blocks

Figure 10-28 shows the PDMA block diagram.

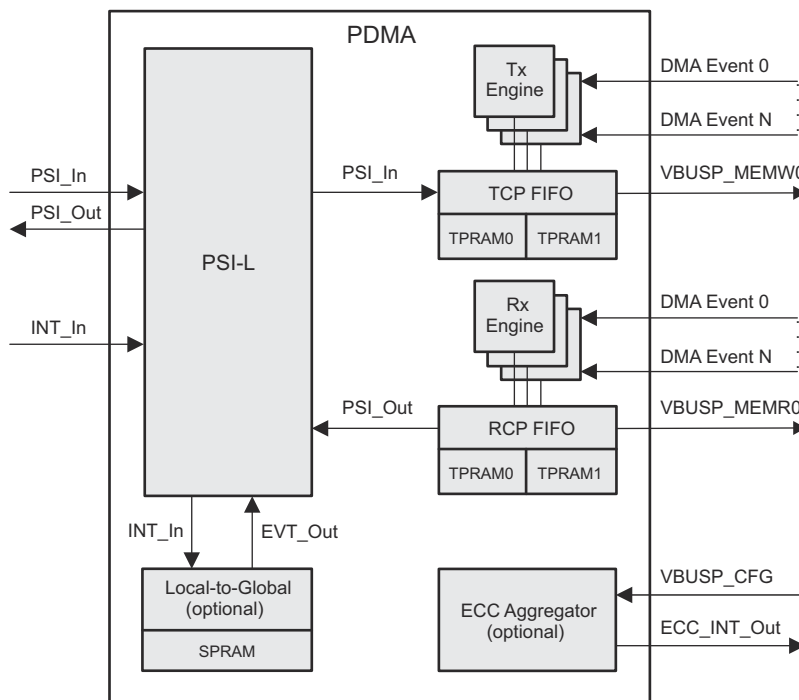

Figure 10-28. PDMA Block Diagram

Note

For detailed description of the PSI-L interface, see *Packet Streaming Interface Link (PSI-L)*.

10.3.1.2.1.1 Scheduler

The scheduler block is responsible for monitoring the fullness level of the various FIFOs, monitoring input DMA triggering events, maintaining channel state information, and issuing credits to the Tx and Rx DMA units when it is time to perform each low-level read or write operation.

10.3.1.2.1.2 Tx Per-Channel Buffers (TCP FIFO)

The Tx per-channel buffers implement channelized FIFOs for each DMA channel. A single logical data FIFO is provided for each destination DMA channel that is used for buffering payload data that has been pushed into the PDMA from the Tx PSI-L interface. The Tx per-channel buffers are always written with full Tx PSI-L wide words (except for EOL/EOP data phases) but are read on byte granularity from the Tx DMA units.

10.3.1.2.1.3 Tx DMA Unit (Tx Engine)

The Tx DMA unit block implements all of the state machine functionality necessary to implement static TR type UTC destination channels. The Tx DMA unit waits until it is triggered by an incoming DMA event and then writes data from the Tx per-channel data FIFO associated with the channel to an external memory mapped target via a VBUSP controller interface. The number and width of the writes that are performed is in accordance with the parameters, which have been programmed via PSI-L into the static TR for the channel.

10.3.1.2.1.4 Rx Per-Channel Buffers (RCP FIFO)

The Rx per-channel buffers implement a logical FIFO for each source DMA channel that is used for buffering payload data that has been fetched by the Rx DMA units. The buffers are byte-oriented on write so that the data from the Rx DMA units, which may not be full words, can be packed properly. The buffers are word-oriented on

read in accordance with the transport mechanism outlined in the PSI-L interface specification. Each channel in the Rx DMA controller maps directly onto a thread in the Rx PSI-L interface.

The Rx per-channel buffers block outputs queue fullness information to the scheduler block, which it then uses to determine when it should initiate DMA opportunities to backfill the buffers. The Rx per-channel buffers will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round-robin arbitration between the different threads for the use of the Rx PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

10.3.1.2.1.5 Rx DMA Unit (Rx Engine)

The Rx DMA unit block implements all of the state machine functionality necessary to implement static TR type UTC source channels. The Rx DMA unit waits until it is triggered by an incoming DMA event and then reads data from an external memory mapped source via a VBUSP controller read interface into the Rx per-channel data FIFO associated with the channel. The number and width of the writes that are performed is in accordance with the parameters, which have been programmed via PSI-L into the static TR for the channel.

10.3.1.2.2 PDMA General Functionality

10.3.1.2.2.1 Operational States

At any given time the PDMA can be in one of three different states as follows:

- **INIT:** This is the initial state of the machine during and immediately after reset. During this state, all of the RAMs inside the PDMA will be initialized to known values including the ECC redundant parity bits. While in the INIT state, the DMA will de-assert all 'ready' signals on all applicable target interfaces and will de-assert all 'request' signals on all applicable controller interfaces. The PDMA will automatically transition out of the INIT state into the IDLE state when all of the RAM initialization has been completed.
- **IDLE:** Once the PDMA leaves the INIT state, it enters the IDLE state whenever no outstanding transactions are pending on any of the PDMA interfaces (controller or target). The IDLE state is generally a transient state and is used by the PDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. As channels have work queued on them and transactions begin flowing into the system, the PDMA transitions to the ACTIVE state. When no more work is pending, or when the host pauses/disables active channels, or when the power management complex on the SoC desires to shut down the PDMA and asserts 'clock stop request', the PDMA will account for any outstanding transactions and will re-enter the IDLE state. The PDMA leaves the IDLE state anytime it generates or receives a transactions that requires a return response as those protocols dictate that the clock must remain running to avoid faulting the handshaking protocol.
- **ACTIVE:** The PDMA enters the ACTIVE state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent), the PDMA transitions to the IDLE state.

10.3.1.2.2.2 Clock Stop

The clock stop interface is a request/acknowledge interface used to coordinate the handshaking of properly stopping the main clock to the IP. Before attempting to perform a clock stop operation, software is required to teardown all active channels (via 'real time' registers in the BCDMA/PKTDMA, or PSIL register 0x408 in PSIL based peripherals), and after this is complete, also clear the global enable bit for all channels (via PSIL register 0x2 in BCDMA/PKTDMA and PSIL based peripherals). Attempting a clock stop on the IP without first performing the channel teardowns or clearing of global enable bits will result in IP specific behavior that may be UNDEFINED.

The PDMA will not drive clock stop IDLE or clock stop ACK while the global enable (PSIL register 0x2) is set for any channel.

10.3.1.2.2.3 Emulation Control

The emulation control input (EMUSUSP) and the per-channel emulation control FREE bit allow PDMA operation to be suspended on a per-channel basis. When the emulation suspend state is entered, the PDMA will stop

processing receive and transmit TRs for each channel at the next TR boundary. Any TR currently in reception or transmission will be halted at its next FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR.

Emulation control is implemented for compatibility with other peripherals. Each source and destination channel can be configured to either honor the suspend signal, or to 'free run' without regard to suspend. This is controlled via the PDMA_PSILCFG_TX_RT_ENABLE / PDMA_PSILCFG_RX_RT_ENABLE[0] FREE bit.

10.3.1.2.3 PDMA Events and Flow Control

The following sections describe the simplified mechanism that is provided on the PDMA for triggering and completion event generation.

10.3.1.2.3.1 Channel Types

Each channel in the PDMA is configured at design time (and cannot be changed by software) to be either standard X-Y FIFO mode or MCAN channel or AASRC channel. Either of these two sections provide information about the channel type support in the device: *PDMA Features* and *PDMA Sources*.

When reading the sections below, ignore any information that concerns unsupported channel type.

10.3.1.2.3.1.1 X-Y FIFO Mode

Most peripherals which are serviced by the PDMA follow the pattern of transferring 'X' bytes from a fixed, non-changing address in a burst 'Y' times for each triggering event that is received. The 'X' parameter is typically 1-16 bytes and the 'Y' parameter can be any integer up to 2048.

10.3.1.2.3.1.2 MCAN Mode

The MCAN module is found to require a few minor differences than standard X-Y mode. First, buffer ownership on transmit is different in that the PDMA will start out owning the TX buffer space (instead of waiting for an initial DMA event from the MCAN). There is also a requirement to perform a write of a fixed value to a fixed address after each DMA event is serviced to pass ownership of a buffer back to the MCAN. Finally, there is an MCAN packet fragmentation requirement to place an 8-byte header on each 64-byte chunk that is transmitted and to remove the header from each 64-byte chunk (other than the first block) that is received.

10.3.1.2.3.1.3 AASRC Mode

The AASRC mode of the PDMA is similar to the X-Y mode in that X specifies the sample width, any Y specifies the number of FIFO samples to transfer per DMA request, but in addition to this, a programmable FIFO list is supplied that allows a single PDMA channel to transfer data to multiple FIFOs. The FIFO list specifies which FIFOs to access, and in which order to access them. Both AASRC 'stream' and 'group' modes are supported in terms of DMA signalling and the FIFO memory map. When in AASRC mode, the entire PDMA operates exclusively in this mode. AASRC channels do not share the same PDMA as do XY and MCAN channels.

The following additional details apply to the PDMA in AASRC mode:

- Main features:
 - Up to 16 independent RX channels and 16 TX channels
 - Each channel represents a different data stream to either the paired-DMA or a McASP PDMA
 - Each channel can be configured to read or write any of the AASRC FIFOs in any order
 - Packing support for 1, 2, 3, and 4 byte samples
 - Can directly talk to a McASP using any McASP data format
 - Packing sample size is fixed for a given channel
 - Supports both 'group' and 'stream' AASRC signaling and FIFO memory maps
 - There is a single stream/group mode setting for each PDMA channel
- Additional details:
 - Each channel has a 'mask' of which DMA requests must fire to activate the channel
 - In stream mode, the mask specifies the all the FIFO DMA requests that must fire
 - In group mode, the mask specifies the one group DMA request that must fire
 - Each channel specifies an ordered list of how FIFOs should be accessed

- All channels use a common list, specifying a range of entry indices within that list
 - This allow each channel to use a varying number of list elements
- The order list can be processed multiple times per DMA request
 - The number of samples to be transferred per request must match the configured threshold for the DMA request in the AASRC
- All FIFOs are specified by index only
 - In the TX ordering table, the indices are assumed to be TX FIFOs
 - In the RX ordering table, the indices are assumed to be RX FIFOs
 - If a DMA channel is in group mode, the PDMA assumes the indices referenced by that channel represent group mode FIFOs; otherwise, it assumes stream mode FIFOs
- The PDMA has configured base addressed and inter-FIFO spans such that is can always convert from a FIFO index to the proper Stream or Group mode FIFO address

10.3.1.2.3.2 Channel Triggering

Channels must be triggered in order for them to perform work. A local event input bus is provided on the PDMA and each bit in the input bus corresponds to the trigger for the channel with the same channel index as the bit index in the bus (bit 0 triggers channel 0, bit 1 triggers channel 1, etc.).

The PDMA provides a 2-bit counter per event input to accommodate startup latency in the channel.

10.3.1.2.3.3 Completion Events

All transfers on PDMA are split TRs in that they have a paired-DMA half and a (static) PDMA half. Completion events are designed to be triggered from the paired-DMA half of the split TR.

10.3.1.2.4 PDMA Transmit Operation

10.3.1.2.4.1 Destination (Tx) Channel Allocation

A total of N destination channels are provided within the PDMA for concurrent transfers from Tx per-channel buffers to the various attached peripherals, where N is a design-time configurable paramater. Each Tx channel requires a single PSI-L thread. See *PDMA Sources* for Tx channel allocation for each PDMA.

10.3.1.2.4.2 Destination (Tx) Channel Out-of-Band Signals

Table 10-137 shows how PSIL signals are handled for destination channels.

Table 10-137. Tx Channel Out-of-Band Signals

PSI-L Signal	XY/AASRC Mode	MCAN Mode
SOP	Ignored	Ignored
EOP	Ignored	Closes current MCAN packet
SOL	Ignored	Ignored
EOL	Ignored	Ignored
DROP	Ignored	Ignored
PKT_ERROR	Ignored	Ignored
PAUSE	Ignored	Ignored
TDOWN	Reflect in status; teardown when data marker reached	Reflect in status; teardown when data marker reached

10.3.1.2.4.3 Destination Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will need to first pair the channel with a remote data source (normally a paired-DMA channel), setup the static TR for the channel, and enable the thread.

10.3.1.2.4.3.1 PSI-L Destination Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The host will pair each destination PDMA channel with (typically) a corresponding source channel in the paired-DMA. The PDMA thread is configured to point to the paired-DMA thread and the paired DMA thread is configured to point to the PDMA thread. Once paired, the source channels in the paired-DMA will send all their data to the destination channel in the PDMA and

the destination channel in the PDMA will never see any data other than data from the source channel in the paired-DMA.

The following PSI-L registers are related to destination thread pairing:

- PDMA_PSILCFG_TX_ENABLE
- PDMA_PSILCFG_TX_CAPABILITIES
- PDMA_PSILCFG_TX_BYTE_COUNT
- PDMA_PSILCFG_TX_RT_ENABLE

Refer to their descriptions for further details.

10.3.1.2.4.3.2 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will send configuration transactions across PSI-L and will setup the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of 'X' and 'Y' parameters, but the field interpretation varies somewhat. The following PSI-L register bit fields are used to setup the static TR:

- PDMA_PSILCFG_TX_STATIC_TR[26-24] X
- PDMA_PSILCFG_TX_STATIC_TR[11-0] Y

Refer to their descriptions for further details.

10.3.1.2.4.3.3 PSI-L Destination Thread Enables

PSI-L destination threads must first be enabled in order to accept data. Threads are enabled or disabled by setting or clearing the ENABLE bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of write transactions.

10.3.1.2.4.4 Data Transfer

Packet transmission is accomplished within the PDMA by unpacking and moving data from the Tx per-channel FIFOs which were filled via the transmit PSI-L interface to specified memory mapped address ranges via the VBUSP controller interfaces. On the Tx side of the PDMA, these transfers are always writes. Each write transfer which is performed by the Tx DMA unit is to a destination address that is hardcoded in the channel at design time and of a size as specified in the static transfer request.

The sequences of logical transactions that are performed by the PDMA on the memory interface during transmit is dependent on the channel type. The following sections describe what will happen for the two different channel types.

10.3.1.2.4.4.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter writes of 'X' parameter bytes to the data FIFO address specified for the channel. Each write that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the Tx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

10.3.1.2.4.4.1.1 X-Y FIFO Burst Mode

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. So for example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting the PDMA_PSILCFG_TX_STATIC_TR[31] BURST bit enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address will increment throughout the burst
- Bursts will be sub-divided to fit into a 64 byte transfer window
- One sample is transferred for every bus data phase
 - Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
 - Cannot burst 64-bit samples on a 32-bit bus (configure for 2×32-bit samples instead)
- PDMA will 'gap' the byte enables on writes as needed

10.3.1.2.4.4.2 MCAN Mode Channel

The PDMA channel will remain idle until data is received from the paired-DMA over the PSIL interface. At this time, the PDMA will immediately start copying packet bytes into the MCAN TX buffer corresponding the PDMA/MCAN channel. The number of bytes copied is smaller of the remaining bytes in the packet or the value of the 'Y' parameter. Once a TX buffer has been filled, the PDMA will transfer ownership of the buffer to MCAN by performing an MCAN register write. The PDMA will then wait to regain ownership of the TX buffer by waiting for the corresponding MCAN TX event. At this time, the PDMA will continue with refilling the TX buffer for the next packet fragment. On subsequent fills (until the end of packet is reached), the PDMA will skip over the 8-byte MCAN header, leaving the original contents from the initial fragment copy in place.

10.3.1.2.4.4.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

10.3.1.2.4.4.3 AASRC Mode Channel

The AASRC channel is controlled primarily via the PDMA_PSILCFG_TX_AASRC_TX_FIFO_CONFIG register for the channel. This register holds three basic pieces of information:

- Whether the channel uses AASRC stream mode or group mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the PDMA_PSILCFG_TX_AASRC_TX_FIFO_CONFIG setting. The pulses for the individual events are latched and held by the PDMA until they all arrive. Once the channel activates, it will start reading FIFO index values from TX order table (PDMA_PSILCFG_TX_AASRC_TX_ORDER_TABLE0, PDMA_PSILCFG_TX_AASRC_TX_ORDER_TABLE1), starting at the configured FIRSTSLOT and ending with the LASTSLOT. The actual FIFO indices used are obtained from the ordering table. For example, say FIRSTSLOT=3 and LASTSLOT=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs written for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width written to the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel. Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

10.3.1.2.4.5 Tx Pause

The host initiates a channel pause by setting the PDMA_PSILCFG_TX_RT_ENABLE[9] PAUSE bit. The paused channel can be resumed by clearing the register bit.

10.3.1.2.4.6 Tx Teardown

The host initiates a channel teardown by setting the TDOWN bit in the paired-DMA (BCDMA/PKTDMA) channel that is paired with the PDMA. The paired-DMA communicates the teardown state through the PSI-L data channel, to ensure that the teardown is not seen by the PDMA until all the previous paired-

DMA data for the channel has been flushed. At this time, the teardown state will be reflected in the PDMA_PSILCFG_TX_RT_ENABLE[30] TDOWN bit. Note that a non-synchronized teardown can also be initiated by directly clearing the PDMA_PSILCFG_TX_RT_ENABLE[31] ENABLE.

Once all data has been flushed from the PDMA to the peripheral, the enable state of the PDMA channel will be cleared in the PDMA_PSILCFG_TX_RT_ENABLE register, but the teardown bit will remain high. Upon completion, no further packet processing will occur until the host re-configures the channel. If the channel fails to teardown because the peripheral has stopped responding, or if the paired-DMA transmission stops on a data boundary that is not compatible with the static TR configuration, the PDMA_PSILCFG_TX_RT_ENABLE[28] FLUSH bit can be set to guarantee that all data can be properly flushed from the internal pipe.

10.3.1.2.4.7 Tx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully, even with flush enabled. If this occurs, the channel may be reset by clearing the PDMA_PSILCFG_TX_ENABLE[31] ENABLE bit. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the paired-DMA peer. Resetting the paired-DMA peer is also required before re-initializing and re-pairing the channel.

10.3.1.2.4.8 Tx Debug/State Registers

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. These registers appear on the PSI-L bus, near the static TR registers. For transmit, they are defined as follows:

- PDMA_PSILCFG_TX_DEBUG_1
- PDMA_PSILCFG_TX_DEBUG_2

Refer to their descriptions for further details.

10.3.1.2.5 PDMA Receive Operation

10.3.1.2.5.1 Source (Rx) Channel Allocation

A total of M destination channels are provided within the PDMA for concurrent transfers from the various attached peripherals into the Rx per-channel buffers and on to the PSI-L Rx Interface, where M is a design-time configurable parameter. Each Rx channel requires a single PSI-L thread. See *PDMA Sources* for Rx channel allocation for each PDMA.

10.3.1.2.5.2 Source Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will need to first pair the channel with a remote data source (normally a paired-DMA channel), setup the static TR for the channel, and enable the thread.

10.3.1.2.5.2.1 PSI-L Source Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The host will pair each source PDMA channel with (typically) a corresponding destination channel in the paired-DMA. The PDMA thread is configured to point to the paired-DMA thread and the paired-DMA thread is configured to point to the PDMA thread. Once paired, the source channels in the PDMA will send all their data to the source channel in the paired-DMA and the destination channel in the paired-DMA will never see any data other than data from the source channel in the PDMA.

Refer to their descriptions for further details.

10.3.1.2.5.2.2 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will send configuration transactions across PSI-L and will set up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of 'X', 'Y', and 'Z' parameters, but the field interpretation varies somewhat. The following PSI-L register bit fields are used to setup the static TR:

- PDMA_PSILCFG_RX_STATIC_TR[26-24] X
- PDMA_PSILCFG_RX_STATIC_TR[11-0] Y

- PDMA_PSILCFG_RX_STATIC_TR_Z[11-0] Z

Refer to their descriptions for further details.

10.3.1.2.5.2.3 PSI-L Source Thread Enables

PSI-L source threads must be enabled in order to process peripheral DMA requests and send data. When disabled, DMA requests are ignored.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of read transactions.

10.3.1.2.5.3 Data Transfer

Packet reception is accomplished within the PDMA by moving data from structures that are located in memory accessible via the VBUSP Memory Interface(s) onto the receive PSI-L interface. On the Rx side of the PDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx per-channel buffer for that channel. At a later time, the data is moved from the Rx per-channel FIFO to a remote peer DMA entity via the Rx PSI-L interface.

The sequences of logical transactions that are performed by the PDMA on the memory interface during receive is dependent on the channel type. The following sections describe what will happen for the two different channel types.

10.3.1.2.5.3.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter reads of 'X' parameter bytes from the data FIFO address specified for the channel. Each read that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the Rx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same read unit.

10.3.1.2.5.3.2 MCAN Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. The DMA event pins are mapped from the CAN filter event bits. The event bits determine the channel and one of two CAN buffers to use for the RX operation. This allows the RX buffers on the CAN to be configured in a ping/pong fashion, preventing the loss of CAN packet data. When an event is received, the PDMA will start copying bytes out of the corresponding CAN buffer. The number of bytes copied is equal to the value of the 'Y' parameter in the channel configuration. Once all data has been copied from the buffer, the PDMA transfers ownership of the buffer back to the CAN by writing a CAN register. It then waits for another RX DMA event. The PDMA can copy multiple CAN RX buffers to the same CPPI packet. It will not close out the CPPI packet until it has copied out a number of RX buffers equal to the 'Z' parameter in the channel configuration. On subsequent RX buffer copies, the MCAN will skip the first 8 bytes of the RX buffer, which is the MCAN packet header.

The mapping of MCAN filter events to MCAN channels and buffer is important for properly configuring the DMA. The mapping is defined as shown in [Table 10-138](#).

Table 10-138. Mapping of MCAN Filter Events to MCAN Channels

CAN FE2	CAN FE1	CAN FE0	Description
0	0	0	Not used
0	0	1	Not used
0	1	0	PDMA CAN channel offset 0, RX buffer 0
0	1	1	PDMA CAN channel offset 0, RX buffer 1
1	0	0	PDMA CAN channel offset 1, RX buffer 2
1	0	1	PDMA CAN channel offset 1, RX buffer 3
1	1	0	PDMA CAN channel offset 2, RX buffer 4
1	1	1	PDMA CAN channel offset 2, RX buffer 5

By using two filter entries in the CAN, software can setup a ping-pong buffer for a particular RX packet ID. For example, the following two filter entries will setup a ping-pong using RX buffers 0 and 1 for packet ID = 5 on CAN RX channel 0 (Table 10-139).

Table 10-139. Ping-Pong Buffer Example in MCAN Mode

Filter Entry	Packet Match ID	Filter Event Bits
0	5	0x2
1	5	0x3

10.3.1.2.5.3.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

10.3.1.2.5.3.3 AASRC Mode Channel

The AASRC channel is controlled primarily via the PDMA_PSILCFG_RX_AASRC_RX_FIFO_CONFIG register for the channel. This register holds three basic pieces of information:

- Whether the channel uses AASRC stream mode or group mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the PDMA_PSILCFG_RX_AASRC_RX_FIFO_CONFIG setting. The pulses for the individual events are latched and held by the PDMA until they all arrive. Once the channel activates, it will start reading FIFO index values from RX order table (PDMA_PSILCFG_RX_AASRC_RX_ORDER_TABLE0, PDMA_PSILCFG_RX_AASRC_RX_ORDER_TABLE1), starting at the configured FIRSTSLOT and ending with the LASTSLOT. The actual FIFO indices used are obtained from the ordering table. For example, say FIRSTSLOT=3 and LASTSLOT=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs read for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width read from the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel. Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

10.3.1.2.5.4 Rx Pause

The host initiates a channel pause by setting the PDMA_PSILCFG_RX_RT_ENABLE[29] PAUSE bit. The paused channel can be resumed by clearing the register bit.

10.3.1.2.5.5 Rx Teardown

The host initiates a RX channel teardown by setting the PDMA_PSILCFG_RX_RT_ENABLE[30] TDOWN bit for the target RX channel. The PDMA communicates the teardown state to the paired-DMA through the PSI-L data channel, to ensure that the teardown is not seen by the paired-DMA until all the previous PDMA data for the channel has been flushed.

The PDMA will not stop reading peripheral data until it reaches a FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR. It will always attempt to complete the 'Y' count for the current event being processed. Upon reaching a stopping point, the PDMA will then clear the ENABLE bit in the pairing register, however the TDOWN bit will remain set. No further packet processing will occur until the host re-configures the channel. The teardown process will propagate to the paired-DMA and its final status can be checked there.

10.3.1.2.5.6 Rx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully. If this occurs, the channel may be reset by clearing the PDMA_PSILCFG_RX_ENABLE[31] ENABLE bit. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the paired-DMA peer. Resetting the paired-DMA peer is also required before re-initializing and re-pairing the channel.

10.3.1.2.5.7 Rx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. These registers appear on the PSI-L bus, near the static TR registers. For receive, they are defined as follows:

Refer to their descriptions for further details.

10.3.1.2.6 PDMA ECC Support

The PDMA optionally integrates an ECC aggregator module that consolidates the ECC configuration and status bits for all the ECC-supported memories within the PDMA. The ECC aggregator provides a single end-of-interrupt (EOI) handshake based interrupt to the host (for both single and double error detections), and a standard 32-bit VBUSP interface for configuring and querying the various ECC wrappers via their respective register set.

In this device, only PDMA5, PDMA9 and PDMA10 include an ECC aggregator.

For detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of PDMA ECC aggregators, see *PDMA Registers*.

10.3.1.3 PDMA Registers

10.3.1.3.1 PDMA PSI-L RX Configuration Registers

Table 10-141 lists the PDMA PSI-L RX configuration registers (PDMA_PSILCFG_RX). These registers are not memory mapped and are accessed indirectly via CFG_PROXY modules in NAVSS.

Table 10-140. PDMA_PSILCFG_RX Instances

Instance	Base Address
PDMA_PSILCFG_RX	N/A

Table 10-141. PDMA_PSILCFG_RX Registers

Offset	Acronym	Register Name	PDMA_PSILCFG_RX Physical Address

Table 10-155. PDMA_PSILCFG_RX_DEBUG_2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	INEVENT	R/W	0h	When set, the PDMA is in the middle of processing a FIFO event.
30	TDOWN	R/W	0h	When set, the PDMA is processing a teardown operation. This bit is set simultaneously with the teardown bit in the source (RX) RT enable register. This bit will clear when the teardown is complete, regardless as to if the teardown bit in the pairing register is cleared or not. The teardown will propagate to the UDMA-P and its full completion status can be checked there.
29	PAUSE	R/W	0h	When set, the PDMA is stopped in a paused state. This bit will clear if the channel is unpaused or disabled.
28	SPACE	R/W	0h	When set, there is a non-zero amount of internal FIFO space available to hold new read data.
27	XSPACE	R/W	0h	When set, there is enough internal FIFO space available to start servicing a peripheral DMA event.
26	BUFFER	R/W	0h	This is the current RX buffer (0/1) for the current MCAN receive operation.
25-24	RESERVED	R	0h	Reserved
23-20	STATE	R/W	0h	This code reflects the current state of the PDMA channel, and is specific to the current implementation.
19-16	EVENTCNT	R/W	0h	This field holds the number of backlogged DMA events yet to be serviced.

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

Table 10-165. PDMA_PSILCFG_RX_RT_ENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ENABLE	R/W	0h	When set, the RX channel is enabled. When cleared, the RX channel is disabled. When disabled, the channel ignores all DMA events from the peripheral. It maintains proper data transfers with the UDMA-P such that the credit handshake is not disrupted. However, unlike teardown, it does not close out the current open packet. Thus the TDOWN bit should always be used to disable an RX channel instead of manually clearing this bit. Failing to use teardown may result in stale data remaining in the internal RX FIFO, which would also prevent the channel from going idle without a channel reset. Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.
30	TDOWN	R/W	0h	When set, the channel will commence a RX channel teardown procedure. It will stop on the next FIFO boundary. It then clears the DMA event count and ignores all future DMA events from the peripheral. After stopping peripheral reads, the PDMA sends a teardown message to the UDMA-P that also closes the current packet with an EOP. If no packet is open at the time of the teardown, the message also includes SOP. The EOP teardown message may or may not contain final packet data. Once the channel teardown is complete and ready to be reused, the ENABLE bit is cleared.

Table 10-165. PDMA_PSILCFG_RX_RT_ENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
29	PAUSE	R/W	0h	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals but will not act on them. The PAUSE bit can be cleared and data will resume. Pause will not stop teardown from completing.
28-2	RESERVED	R	0h	Reserved
1	IDLE	R	0h	This is a read-only bit that signifies that the paused or disabled channel is also idle. It can only become set if PAUSE is set or ENABLE is cleared.
0	FREE	R/W	0h	When cleared, the channel honors the debug suspend signal. When set, the channel will 'free run', regardless of the value of debug suspend.

10.3.1.3.1.13 PDMA_PSILCFG_RX_DEBUG_3 Register (Offset = 40Fh) [reset = 0h]

PDMA_PSILCFG_RX_DEBUG_3 is shown in [Figure 10-41](#) and described in [Table 10-167](#).

Return to [Summary Table](#).

Debug/State Register 3. The debug/state registers give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations.

Table 10-175. PDMA_PSILCFG_TX_STATIC_TR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26-24	X	R/W	0h	<p>X-Y FIFO mode static TR: Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0h = 8 bits; 1h = 16 bits; 2h = 24 bits; 3h = 32 bits; 4h = 64 bits; 5h-7h = RESERVED.</p> <p>MCAN mode static TR: Not used.</p> <p>AASRC mode static TR: Element size. This field specifies how much data is transferred in each write which is performed by the DMA. This field is encoded as follows: 0h = 8 bits; 1h = 16 bits; 2h = 24 bits; 3h = 32 bits; 4h = 64 bits; 5h-7h = RESERVED.</p>
23-12	RESERVED	R	0h	Reserved
11-0	Y	R/W	0h	<p>X-Y FIFO mode static TR: Element count. This field specifies how many elements to transfer each time a trigger is received on the channel.</p> <p>MCAN mode static TR: Buffer Size. This field specifies how many bytes should be written to an MCAN TX buffer. This field includes the 8-byte MCAN header on the initial packet fragment. The PDMA will break up the source packet into fragments of this buffer size, copying the 8-byte MCAN header for the initial fragment, and then skipping it for each additional fragment and thus reusing the header from the first fragment. A buffer size less than 16 is treated as 16, and a buffer size greater than 72 is treated as 72.</p> <p>AASRC mode static TR: FIFO element count. In AASRC mode, a channel can service multiple FIFOs using a list supplied in its FIFO configuration. This field specifies how many times to service the FIFO list, hence how many elements to transfer from each FIFO, each time a trigger is received on the channel. Note for each loop specified by the value of Y, the entire list is processed. For example, if the FIFO list is 0, 1, 2, 3, and Y is set to 2 loops, the FIFOs are serviced in the order: 0, 1, 2, 3, 0, 1, 2, 3.</p>

10.3.1.3.2.4 PDMA_PSILCFG_TX_DEBUG_1 Register (Offset = 402h) [reset = 0h]

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

Table 10-189. PDMA_PSILCFG_TX_RT_ENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ENABLE	R/W	0h	When set, the TX channel is enabled. When cleared, the TX channel is disabled. When disabled, it discards all held data. It clears DMA event counts and ignores all future DMA events from the peripheral. It maintains data exchange with the UDMA-P so that credit handshake is not disrupted. A 'hard teardown' can be performed by directly clearing this bit. Note that this bit cannot be changed from 0 to 1 if the global enable bit in the peer enable register is 0.
30	TDOWN	R/W	0h	When set, the channel will commence a TX channel teardown procedure. To perform a TX teardown, the teardown bit should be set in the UDMA-P and it will automatically propagate to this register bit with the normal flow of peripheral data. Once the channel is fully stopped and ready to be reused (including returning all credits), the ENABLE bit is cleared.
29	PAUSE	R/W	0h	When set, the channel is in a paused state. It will stop on the next FIFO boundary. It continues to accept and count DMA events from the peripherals but will not act on them. The PAUSE bit can be cleared and data will resume.

Table 10-189. PDMA_PSILCFG_TX_RT_ENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	FLUSH	R/W	0h	When set, causes all TX channel data to be discarded instead of being written to the peripheral. It essentially allows the TX engine to 'free run' without DMA requests from the peripheral (it will also override 'pause'). This bit should be set only when a channel fails to complete its teardown procedure normally because a peripheral is no longer functioning or because data flow was halted on a boundary that is not compatible with the static TR configuration.
27-3	RESERVED	R	0h	Reserved
2	ERROR	R/W	0h	When set, the channel has encountered a PSI-L protocol violation. The ERROR bit can only be set by hardware and can only be cleared by software. Once this bit is set, the channel should be fully reset and re-initialized via the PSI-L pairing registers.
1	IDLE	R	0h	This is a read-only bit that signifies that the disabled thread is also idle. This bit is read only and can only become set if the ENABLE bit is cleared.
0	FREE	R/W	0h	When cleared, the channel honors the debug suspend signal. When set, the channel will 'free run', regardless of the value of debug suspend.

10.4 Data Routing Unit (DRU)

This section describes the SoC level Data Routing Units (DRUs) for the device.

Note

There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as described in this section. For the differences between all DRUs, see [Section 10.4.3.8](#).

10.4.1 DRU Overview

The data routing unit (DRU) is a high bandwidth, flexible routing engine with programmable DMA transfer requests. It enables user to perform high speed data transfers between memory mapped slave endpoints, processor caches and shared caches. DRU behaves like a DMA transfer controller, moving data at CPU frequency.

The DRU supports the following features:

- Programmable configuration registers for direct transfer request submission
 - A dedicated atomic register set that requires entire TR sent in a single burst
 - Three nonatomic register sets that allow TR to be written in separate burst and a write to the SUBMIT_WORD0 register triggers the TR
- Read and write command queues
 - Five different queues with a split arbitration between fixed priority and round robin arbitration
 - Each channel can be configured to go to one of these queues
- Programmable priority for each queue
 - Allows setting priority for commands relative to other masters in the system
- One dedicated read port and one dedicated write port to generate independent read and write commands
 - Generates one read command every cycle
 - Generates one write data phase every cycle
 - Moves the data at CPU frequency
 - Optimizes transfers up to 128 byte boundaries
- Support for triggers to gate levels of the DMA loop
 - Supports one dedicated local trigger
 - Supports two dedicated external global triggers from the PSI-L
 - All triggers can be overwritten and controlled by software instead of hardware based event
- Support for region based and channelized firewall
 - Region based firewall intended to protect DRU configuration registers within a programmatically specified range
 - Channelized firewall that protects:
 - The real time configuration registers for each channel
 - The TR submission registers for each channel
 - The data transfers for each channel
- Data formatting networks
 - Circular addressing support for one side of the transfer
- Independent 48-bit address fields for source and destinations
- Up to four dimensional data transfers
 - Has independent source and destination index for up to four dimensional transfers
- Error Handling
 - Debug support through memory mapped registers
 - Data transfer error reports
- Error detection and Correction
 - Full SEC/DED support for the incoming data
 - Full SEC/DED protection each entry in the TR queues
 - Single bit parity support for each 32-bit word in the data buffer

- Parity protection for the address
- PSI-L Interface
 - Receive requests for pre-warm of L2 or L3 Cache
 - Receive TR requests from the UDMA
 - Send response TRs
 - Receive data from a remote UTC
 - Send data to a remote UTC
 - Maintains 2D formatting across PSI-L if requested in TR

10.4.2 DRU Integration

This section describes the SoC level DRUs integration in the device, including information about clocks, resets, and hardware requests.

Note

There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as the SoC level DRUs. For the differences between all DRUs, see [Section 10.4.3.8](#). For integration details about the VPAC0 and DMPAC0 DRUs, see [Section 6.7 Vision Pre-processing Accelerator \(VPAC\)](#) and [Section 6.8 Depth and Motion Perception Accelerator \(DMPAC\)](#).

10.4.3 DRU Functional Description

Note

This section describes the SoC level Data Routing Units (DRUs) for the device. There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as described in this section and its subsections. For the differences between all DRUs, see [Section 10.4.3.8](#).

10.4.3.1 DRU Basic Functionality

Figure 10-52 shows the DRU functional diagram.

Figure 10-52. DRU Functional Diagram

The DRU receives commands to transfer data from one location to another called Transfer Requests (TRs) or to send messages to CPUs or MMUs to pre-warm logic called Cache Requests (CRs). The DRU can receive these commands through the following mechanisms:

- A direct write to the DRU submission registers
- TR submission over PSI-L from external UDMA-C

The previously described mechanisms of receiving TRs and CRs are also referred to as TR submission (see, [Section 10.4.3.1.3](#)). In other words, the DRU memory-to-memory transfers work by receiving TR or CR through TR submission. Then the corresponding request (TR or CR) is placed in a queue to be processed.

Once the TR has been received the Channel Trigger Control block detects if the triggers specified in the TR have been received. If the trigger is not specified (value of 0x0 in the TRIGGER0 or TRIGGER1 fields of the TR FLAGS field), the treatment is as it is always received. Once received the channel is considered active. All active channels are involved in arbitration process for using the subtiler. The channel arbitration is based on the channel queue. There are queues using a fixed priority arbitration - the lowest channel has the highest priority. There are also round robin queues that use the same algorithm as in the fixed priority queue arbitration (lowest channel - highest priority) but on a round robin basis.

The subtiler takes the winning channel (that is, channel with highest priority) and generates the next 1D or 2D transfer (called also sub-TR) based on the trigger size, transfer type and event size specified in the TR. Then the subtiler places that sub-TR into the queue specified for the channel. Once the sub-TR is generated an event control is notified and any active triggers are cleared if the sub-TR crosses the boundary of one of the triggers.

For example, if a TR has a trigger size for a 3D block and the ICNT2 value is 16, then the active triggers are cleared after 16 sub-TRs are sent to the queue. ICNT2 can be specified through one of the following:

- DRU_ATOMIC_SUBMIT_CURR_TR_WORD4_5_j[47-32] ICNT2 field
- DRU_SUBMIT_WORD4_5_j_k[47-32] ICNT2 field
- ICNT2 field of the UDMA-C TR received over PSI-L

Upon reaching the top of the queue the TR is processed. Based on the information in the TR a read of the specified location and size is performed followed by writing the data to the specified destination. Upon sending the last write of the entire TR loop a completion event is generated. The completion event output also places a TR response in the PSI-L response FIFO in case of UDMA-C TR. For information about the TR response format, see *Transfer Response Record* in *DMA Architecture*.

Note

The channel is an independent data flow that can be given requests for data movement. Each channel operates independently of the others but they all share common resources.

The queue is a shared unit between several channels. It holds the order of the channel data movement requests until the shared data engine can perform the actual data move. A channel is assigned a queue where its data movement requests are placed.

Note

The CHRT_SWTRIG register can only be accessed directly through the DRU configuration interface and is used if software wants to control the triggers for the TR.

Figure 10-53 shows the interaction between software and hardware to setup DRU, submit TRs and then release the channel to be used by a different resource. Section 10.4.3.1.1 through Section 10.4.3.1.5 explain in more detail what occurs in each process or decision.

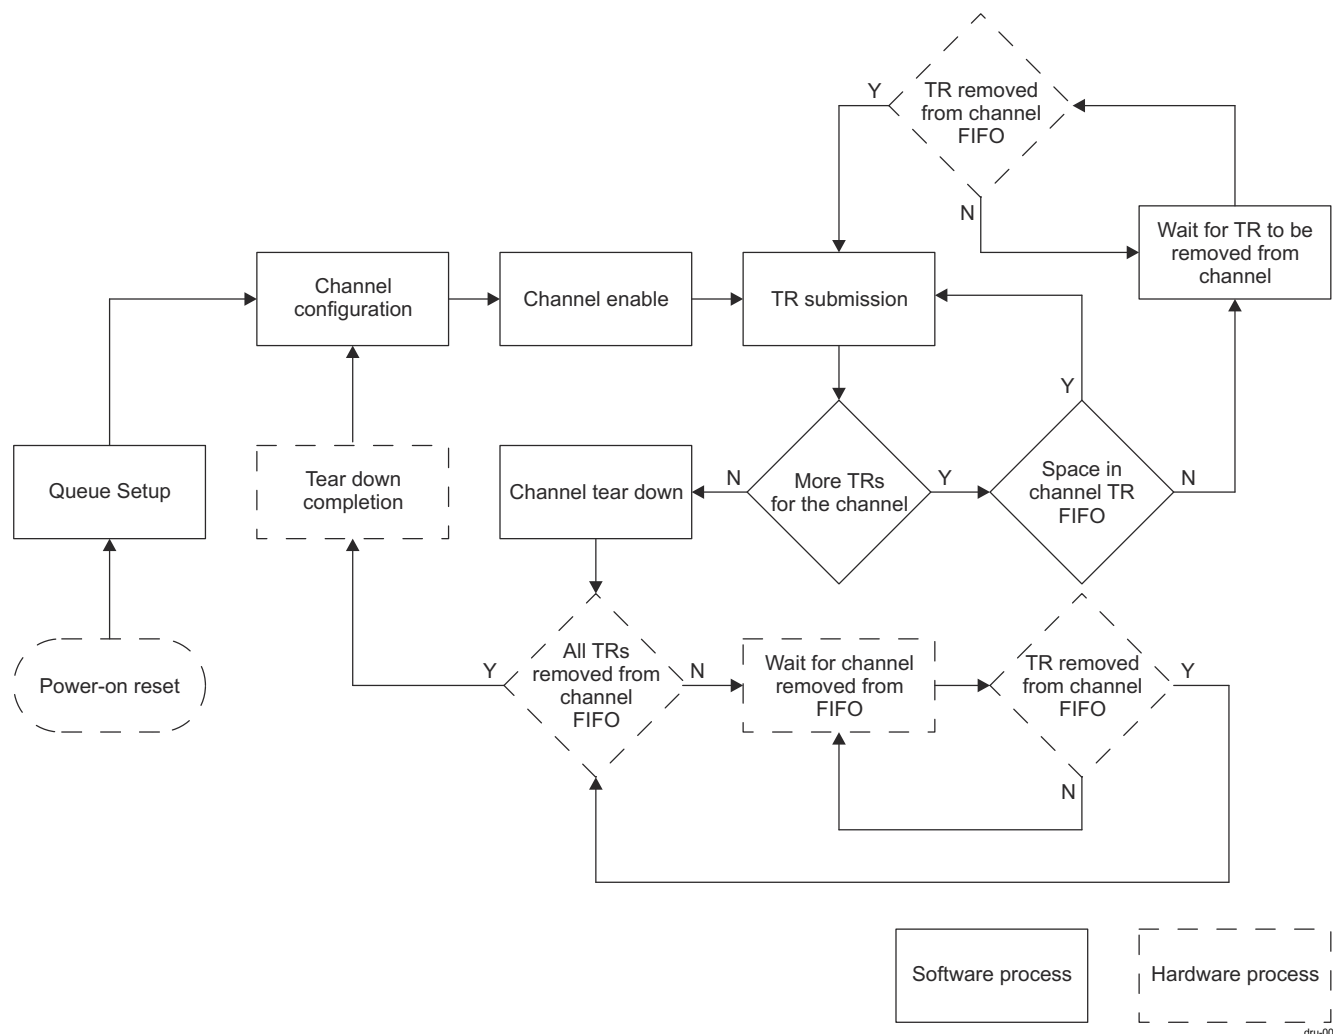

Figure 10-53. DRU Software Managed Flow Diagram

10.4.3.1.1 Queues

Every TR that is active is placed in one of the DRU queues. Each queue operates independently of the others. In a given queue the TRs complete in the order they are placed by the subtiler. Only one read and one write queue may exist at a time. The queues use same resources and need arbitration which is performed based on fixed priority or round robin scheme. In both cases the highest priority queue is the one with the lowest number. The queue priority is specified through the DRU_CFG_y[2-0] PRI field.

Whenever arbitration occurs if there is a TR in a fixed priority queue that TR always goes and the round robin queues are held off. If the fixed priority queues are empty then the round robin queues are arbitrated on a round robin basis, that is, each queue sends its specified number of transactions and then arbitration starts again. On the write side an arbitration ends if the read response has not been received for the next command when the current one completes.

The arbitration happens the last phase of a transfer chunk. A transfer chunk is defined as sending the number of read transactions specified by the DRU_CFG_y[23-16] CONSECUTIVE_TRANS field. After CONSECUTIVE_TRANS number of commands elapse the queue releases the bus and waits for the number of commands specified by the DRU_CFG_y[31-24] REARB_WAIT field before trying to request the bus and involve in arbitration again. Thus software can tune the data flow from each queue to prevent starvation.

If a queue is running and no other queues have a TR then the running one starts its next chunk without stopping. Each time arbitration is performed for round robin queues the queue with the next priority becomes the highest

priority and the current one the lowest priority queue. If a fixed priority queue is active then the current round robin queue remains the highest priority one until the CONSECUTIVE_TRANS count expires or queue is empty.

The DMA bus QoS and order ID attributes for each queue can also be configured through the DRU_CFG_y[10-8] QOS and DRU_CFG_y[7-4] ORDERID fields.

Note

Queue configuration must be done before setting up any channel as queue changes while channels are active can cause unknown behavior.

10.4.3.1.2 Channel Configuration

The DRU operates on having multiple channels that can run in parallel on the shared hardware but are independently triggered by events as needed. Each channel must be configured before it is used. The channel configuration has the following parts:

- Non-realtime configuration intended to be controlled by a single master in the system for all software processes and processors
- Real time configuration controlled by the software process that owns the channel

10.4.3.1.2.1 Non-realtime Channel Configuration

The non-realtime configuration consists of the following:

- Assigning the channel to a submission mechanism via the DRU_CFG_j[19] CHAN_TYPE_OWNER bit
- Assigning the channel via the DRU_CHST_SCHED_j[2-0] QUEUE field to a hardware queue to be used for channel transactions
- Assigning the channel via the DRU_CHOES0_j[15-0] EVT_NUM field to an event to be used for channel notifications

The DRU_CFG_j[31] PAUSE_ON_ERR bit can be used to control the channel behavior in case of error or exception.

The DRU_CFG_j registers must be written to before the channel is enabled via the DRU_CHRT_CTL_j[31] ENABLE bit as once a channel is enabled any write to the DRU_CFG_j, DRU_CHST_SCHED_j and DRU_CHOES0_j registers will result in write failure and an address error. If a channel does not exist an address error is generated upon write too.

10.4.3.1.2.2 Realtime Channel Configuration

Once the non-realtime channel configuration has been done the DRU_CHRT_CTL_j[31] ENABLE bit should be written. It must be written before any TRs can be written. The mechanism to write this bit is based on the ownership of the channel as specified via the DRU_CFG_j[19] CHAN_TYPE_OWNER bit. If the owner is a CPU, than this bit must be written directly through the DRU configuration interface. If the owner is UDMA, than the PSI-L interface must be used to write the ENABLE bit through the PSI-L register configuration write process as described in *PSI-L*.

Note

Once a channel has been enabled the channel configuration registers cannot be modified. The channel can only be disabled through writing 0x1 to the DRU_CHRT_CTL_j[30] TEARDOWN bit.

10.4.3.1.3 TR Submission

The DRU supports the following TR methods:

- A direct write to the DRU submission registers
- TR submission over PSI-L from external UDMA-C

The TR submission checks the following:

- If a legal TR has been submitted
- If the correct submission method has been used
- If there is space in the channel TR FIFO for the new TR

10.4.3.1.3.1 Direct TR Submission

The direct TR submission can be atomic or nonatomic. There is one atomic register set that allows for a TR to be submitted with a single burst write. There are also three nonatomic register sets for nonatomic direct TR submission. Each of these three sets allows direct TR submission without requiring submission in a single burst.

The direct atomic TR submission is handled through DRU register writes to the DRU_ATOMIC_SUBMIT_CURR_TR_WORD0_1_j to DRU_ATOMIC_SUBMIT_CURR_TR_WORD14_15_j registers which require write in a single 64-byte burst. Any write other than this size returns an address error. All burst values are checked if they are legal values and space in the channel FIFO is checked too. Then the TR is pushed into the FIFO and the write status is returned with success. If any of the legal TR format checks or FIFO space check fails or if the channel is not owned and enabled the result is an address error returned.

The direct nonatomic TR submission is handled through DRU register writes to the DRU_SUBMIT_WORD0_1_j_k to DRU_SUBMIT_WORD14_15_j_k registers which are intended to be used for cores not being able to perform a large burst write in a single cycle. There is a single set for each core regardless of the channel number. A write to the DRU_SUBMIT_WORD0_1_j_k register triggers the TR.

Note

The following should be taken into account:

- If a channel is full any write to the DRU_SUBMIT_WORD0_1_j_k register results in an address error.
- The DRU does not check anything to ensure that the same core writes to the same nonatomic register set. Software should perform the check procedure.

10.4.3.1.3.2 PSI-L TR Submission

The DRU PSI-L TR submission is used for TR submissions from an external UDMA-C. The DRU has a single submission thread for each channel. The channel must be configured as UDMA-C type channel before PSI-L pairing.

The PSI-L pairing, TR submission and response follow the mechanisms as described in *PSI-L*. For every TR a TR response is sent. If the TR fails a legal check or channel ownership or FIFO fullness check, an immediate TR response is sent back with the cause of the submission error provided in the response.

10.4.3.1.4 TR Removal from Channel

After all requested write responses are received from a TR the DRU sends completion event for the channel that completed the TR. Software can use this event to determine when a TR can be added to a channel FIFO. Each channel has a small FIFO allowing multiple TRs to be preloaded into a channel thus maximizing the channel throughput. The completion event signifies that an entry has become available in the FIFO.

10.4.3.1.5 Channel Tear Down

A channel must be torn down through setting the DRU_CHRT_CTL_j[30] TEARDOWN bit to 0x1. This allows for channel reconfiguration. Setting the TEARDOWN bit to 0x1 forces the channel to stop sending any new requests not already in the pipeline and when all outstanding requests have been received all other bits in the DRU_CHRT_CTL_j register are cleared. If the DRU_CFG_j[31] PAUSE_ON_ERR bit is set and an error occurs the tear down mechanism can be used to restart the channel. The TEARDOWN bit being set to 0x1 also makes the TR STATIC field in any future reads from the TR memory to be set to 0x0 no matter the value when the TR was submitted. This is the mechanism used to stop a static TR.

10.4.3.1.5.1 Tear Down Completion

The tear down completion process is when software has set the DRU_CHRT_CTL_j[30] TEARDOWN bit to 0x1 so no new TRs can be added to the channel but when previous TRs that had been added to the channel are still running. Once the TR FIFO for the channel is empty hardware clears the DRU_CHRT_CTL_j[30] TEARDOWN and DRU_CHRT_CTL_j[31] ENABLE bits. The channel is now back at the channel configuration process as described in [Section 10.4.3.1.2.1](#) and can be reused as needed by the system.

10.4.3.2 DRU Virtualization

The DRU supports virtual addressing through integrated CMMU along with two uTLBs one for read commands and another for write commands. The CMMU is same as the one associated with C71SS.

The channel configuration adds a bit for ATYPE to choose if the addresses are virtual or physical. If a channel is configured to have virtual addresses the queue sends a request to the uTLB and waits for the status response before it sends the command. If the uTLB returns with a page fault then the TR will fail and all future commands for the TR will be flushed. If the pause on error option is set for the channel then no further TRs will be sent for the channel until it is torn down and setup again. All the attributes for the command are selected based on those returned from the uTLB.

10.4.3.3 DRU Compression and Decompression

The DRU supports compression and decompression of data in line by integrating the Accelerator Framework Compression (AFC) module inside the response buffer path.

The compression logic places the AFC module between the Read Response Buffer and a dedicated write engine for compression and a dedicated write engine of decompression. The read response buffer handles any out of order responses and then the data is pushed into FIFOs inside the AFC module. The AFC module pulls the data out of the FIFOs as 128-bit elements for compression or 128 CDBs for decompression.

Once the 128-bit entry is removed from the FIFO the symbol size specified for the compression is used to split the 128-bit element into the corresponding number of symbols. If the 128-bit does not divide into an even number of symbols then the remain bits are used with the next 128-bit element to create the first symbol. Once each symbol is determined then they are passed into the compression pipeline. The first stage of the compression pipeline is the difference phase. If it is a non-differential compression algorithm then a fixed bias value is subtracted from the symbol. If it is a differential compression algorithm then the symbol is subtracted from a symbol that is from a previous slot. If there was not data at the previous slot selected it will be zero until actual data is present.

The AFC module packs a byte stream into a set of 128-bit CDB that is defined as a super block. At the end of each super block the compression engine will generate a 8-byte write of the CDB information block. These CDB information blocks can then be read back in when decompressing the data to know the size location and decompression information to recreate the original data.

Table 10-211 through Table 10-215 show the templates used to setup the compression and decompression.

Table 10-211. Compression Secondary Transfer Request Template 64 Byte Secondary TR

word 15	word 14	word 13	word 12	
CDB3 Offset from ADDR	CDB3 Format	CDB2 Offset from ADDR	CDB2 Format	
word 11	word 10	word 9	word 8	
CDB1 Offset from ADDR	CDB1 Format	CDB0 Offset from ADDR	CDB0 Format	
word 7	word 6	word 5	word 4	
Max Offset/CDB Table Start Offset	DSTDIM0	SRCDIM0	SB ICNT1	SB ICNT0
word 3	word 2	word 1	word 0	
Compression Flags	SECONDARY TR FLAGS	ADDR of Compressed Data		

Table 10-212. Compression Secondary TR Field Descriptions

Word	Field	Description
0-1	ADDR of Compressed Data	The Location of where the compressed data starts.
2	Secondary TR FLAGS	The Secondary TR Flags that are common for all secondary TRs
3	Compression Flags	The Compression Flags used for the compression
4	SBICNT0 & SBICNT1	The size of the super block for the compression
5	DSTDIM0	The dimension to use for DICNT0 in the original TR after each super block
6	SRCDIM0	The dimension to use for ICNT0 in the original TR after each super block is complete

Table 10-212. Compression Secondary TR Field Descriptions (continued)

Word	Field	Description
7	Max Offset CDB Table Start Offset	For a compression TR this is the maximum offset value that can be written in the CDB table. This means that compressed data will not be written beyond ADDR + Max Offset. For a decompression TR this is the offset from the secondary TR that the first CDB entry should be read from in bytes. It is a signed value.
8	CDB0 Format	This is the format data for the first CDB table value written after the first super block. It will never be used in an initial fetch.
9	CDB0 Offset	This is where the CDB data for this entry begins relative to the ADDR of Compressed data and is always a positive number.

Table 10-213. Multiple Buffer Interleave FLAGS Field Descriptions

Bit	Field	Description
0-3	SEC_TR_TYPE	0: Multiple Buffer Interleave 1: CDB INFO Block and Decompression/Compression Configuration
4-31	SB_DIM0	The dimension to use between lines of the super block. Lower 4 bits are always 0 since minimum element size is 16 byte element.

Table 10-214. Compression FLAGS Field for Non-Differential Algorithms Descriptions

Bit	Field	Description
0-3	Compression Algorithm	0: Zero Based Algorithm 1: Unsigned Golomb 2: Signed Golomb 3-7: Reserved for Future Use 8-15: Differential Type see the Differential Compression Flags Definition
5-4	SB_AM0	The addressing mode to use for the super block during ICNT0 is decrementing. This is only used if the TR is using circular addressing for the direction of the compression engine.
6-7	SB_AM1	The addressing mode to use for the super block when SB_ICNT1 is decremented. This is only used if the TR is using circular addressing for the direction of the compression engine.
8-15	Bias	The constant value subtracted from the symbol before the compression algorithm is applied
16-31	RSVD	Reserved for future use

Table 10-215. Compression FLAGS Field for Differential Algorithms Descriptions

Bit	Field	Description
0-3	Compression Algorithm	0-7: Non-differential algorithms. See Table 10-214 8: Signed Exponential Golomb with differential logic 9-15: Reserved for Future use
5-4	SB_AM0	The addressing mode to use for the super block during ICNT0 is decrementing. This is only used if the TR is using circular addressing for the direction of the compression engine.
6-7	SB_AM1	The addressing mode to use for the super block when SB_ICNT1 is decremented. This is only used if the TR is using circular addressing for the direction of the compression engine.

Table 10-215. Compression FLAGS Field for Differential Algorithms Descriptions (continued)

Bit	Field	Description

30-31	SubSel3	Selection for the subtraction module 0: Current symbol uses the adjacent symbol 1: Current symbol uses the symbol 2 spaces away 2: Current symbol uses the symbol 3 spaces away 3: Current symbol uses the symbol 4 spaces away

10.4.3.4 DRU Output Events

The DRU generates the following events:

- Local output events
- PSI-L global events
- Protocol violation event
- Completion events
- Error completion events

The EVENT_SIZE field of each TR specifies how often a TR generates an output event. That event is provided on the local output event interface as shown in [Figure 10-52](#) and as global event on the PSI-L interface. There is one event per channel. The global event number used by a PSI-L event transport lane can be configured for each channel through the DRU_CHOES0_j[15-0] EVT_NUM field.

As shown in [Table 10-216](#), if the EVENT_SIZE value is in range from 1 to 3, then the output event is generated when the write command for the given loop level (ICNT1, ICNT2 or ICNT3 decremented) has been sent. If EVENT_SIZE = 0, then the output event is generated when all responses have been received.

Table 10-216. EVENT_SIZE Encoding

EVENT_SIZE Value	Event Encoding	Description
0	TR complete	The TR has completed and all responses have been received
1	ICNT1 loop is decremented	The last write command of a row has been sent
2	ICNT2 loop is decremented	The last write command of an array has been sent
3	ICNT3 loop is decremented	The last write command of an array of an array has been sent

For more information about PSI-L interface and its event transport lane, see *PSI-L*.

For more information about the TR EVENT_SIZE field, see *Transfer Request Record* of *DMA Architecture*.

The protocol violation event is not channel associated.

The completion events are defined for each channel. The completion event fires whenever a channel completes a TR successfully. It is only generated when all responses are received from the write portion of the block copy. A single write completion event can occur in a given cycle since it is based on the write responses being received to generate the response.

The error completion events are defined for each channel. The error completion event fires whenever a channel completes a TR with an error and it has flushed out all data related to that TR in the response buffer. Upon determining that a TR is not able to complete successfully, the DRU enters a flush mode to remove all read data received after the error is determined as well as make sure all write responses are received. Once all of this criteria has been matched the write engine fires a completion event. If multiple error completions occur at the same time the DRU will still send them out one at a time using an arbitration scheme used for the original arbitration for the queue, either fixed priority or round robin based on the queue that has the error.

10.4.3.5 DRU Address Fetch Algorithm, TR and CR Formats

The address fetch algorithm, TR and CR formats are defined in *Transfer Request Record* in *DMA Architecture*. It documents all features that can be supported by a Universal Transfer Controller (UTC) like the DRU but it may not support all of them. The DRU_CAPABILITIES register must be read to check what features of the TR are supported by the DRU.

The TR format allows to perform some kinds of data reformatting or to alter from the standard addressing formats. The DRU supports the transpose data reformatting function and the circular buffering alternate addressing algorithm.

10.4.3.5.1 Transpose

Linear streams work for large classes of algorithms, but not all. In some cases it is desired to transpose rows to columns and columns to rows in the data structure. To help in these cases the DRU supports a transpose function.

The transpose type works on element sizes of 32, 64 or 128 bits by sending sub-TRs in the size of 32 elements by 32 lines for 32-bit, 16 elements by 16 lines for 64-bit and 8 elements by 8 lines for 128-bit element. The sub-TR that is being sent always results in the maximum transfer size. For the write requests the data in the response buffer always looks as a buffer aligned to the zeroth offset in the address.

10.4.3.5.2 Circular Buffering

Circular addressing modifies how the DRU performs address arithmetic so that addresses remain within a power-of-two sized window. Circular addressing works by holding upper address bits constant during an address update, while allowing the lower address bits to vary. This contrasts with the default linear addressing which allows all of the address bits to vary.

The TR provides address mode selection for each level of loop nest. Each level can select between linear addressing or circular addressing with one of two circular block sizes.

If circular addressing mode is selected in the AMODE field of the TR, the definition of the upper 16 bits of the FMTFLAGS field of the TR select the type of addressing for each entry in the loop and define two unique masks that can be used for the circular buffering. Additionally, the DIR field in the TR determines if the circular addressing flags apply for the source or the destination of the block move. The other direction always follows the standard linear addressing that is used if AMODE is not set.

For more information about circular buffering and the associated TR fields, see *Circular Address Mode Specific Flags* of *DMA Architecture*.

10.4.3.6 DRU Firewalls

Unlike most of the device modules whose associated firewalls reside on system interconnect (CBASS) level the DRU has its own embedded firewalls. They are the following:

- Region based firewall intended to protect DRU configuration registers within a programmatically specified range.
- Channelized firewall that protects:
 - The real time configuration registers for each channel:
 - DRU_CHRT_CTL_j
 - DRU_CHRT_SWTRIG_j
 - The TR submission registers for each channel:
 - DRU_ATOMIC_SUBMIT_CURR_TR_WORD0_1_j to DRU_ATOMIC_SUBMIT_CURR_TR_WORD14_15_j
 - DRU_SUBMIT_WORD0_1_j_k to DRU_SUBMIT_WORD14_15_j_k
 - The data transfers for each channel

The region based firewall should be configured to cover the range from 0x6D00 4000 to 0x6D0C FFFF. This allows for a single master to control the memory attribute channels and channel ownership. If the region based firewall is configured to overlap the channelized firewall then both firewall checks have to pass for the register update to occur. If the firewall check fails the DRU returns protection error status to the requestor.

Note

Protection error takes precedence over address error. If the address falls into the firewall protected range then a protection error is returned.

Note

Each SoC DRU (DRU0 and DRU1) has both the region based and channelized firewall.

The DRU region based and channelized firewalls are same as the other device firewalls. For more information about their functionality, see *Interconnect Firewalls* in *System Interconnect*. The DRU firewall associated registers are described in the *DRU Registers* sections.

10.4.3.7 DRU Errors

In all error cases the DRU reports the error to the system, ensures that all outstanding commands for the TR have completed and proceeds with the next TR in the queue as if the previous one has finished normally. In most error cases the read transaction completes as normal but the responses are flushed. This ensures that both the read and the write start fresh on the next TR. The error details are logged in the DRU_CHRT_STATUS_DET_j and DRU_CHRT_STATUS_CNT_j registers. The DRU_CAUSE_y registers can be read to check if an error for the corresponding channel has occurred.

10.4.3.8 DRU Configurations

[Table 10-217](#) shows the differences between the SoC level DRUs and the rest DRUs in the device. The rest of the features and functionality is same as described in [Section 10.4.1](#) and [Section 10.4.3](#).

Table 10-217. Differences between DRU Configurations

Feature	SoC Level DRUs	DMPAC.UTC_DRU	VPAC.UTC0_RT_DRU, VPAC.UTC1_NRT_DRU
Cache warm support	Y	Y	N
Atomic direct TR submission	Y	N	N
Nonatomic TR submission register sets	3	0	0
Data reformat functions	Transpose	None	None
Minimum transpose size	32 bits	N/A	N/A
Embedded firewall	Y	Y	N
Event generation	Encoded	Bit vector	Bit vector

11 Time Sync

This chapter describes the time sync modules in the device.

11.1 Time Sync Module (CPTS)	1033
11.2 Timer Manager	1039
11.3 Time Sync and Compare Events	1044

11.1 Time Sync Module (CPTS)

This chapter describes the Time Synchronization (CPTS) module.

11.1.1 CPTS Overview

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations.

11.1.1.1 CPTS Features

Main features of CPTS module are:

- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling
- Supports 8 hardware timestamp push inputs
- Supports timestamp counter compare output
- Supports timestamp counter bit output
- Supports 6 timestamp Generator function outputs
- 32-bit and 64-bit timestamp modes.

11.1.2 CPTS Functional Description

11.1.2.1 CPTS Architecture

Figure 11-1 shows the architecture of the CPTS module.

The CPTS module is used to facilitate host control of time sync operations. The CPTS collects time sync events and then presents them to the host for processing. The types of time sync events are as follows:

- Host Transmit Event
- Ethernet receive event
- Ethernet transmit event
- Time stamp push event
- Time stamp counter rollover event (32-bit mode only)
- Time stamp counter half-rollover event (32-bit mode only)
- Hardware Time Stamp Push Event
- Time Stamp Compare Event

The reference clock used for the time stamp (RCLK) can be derived from several sources.

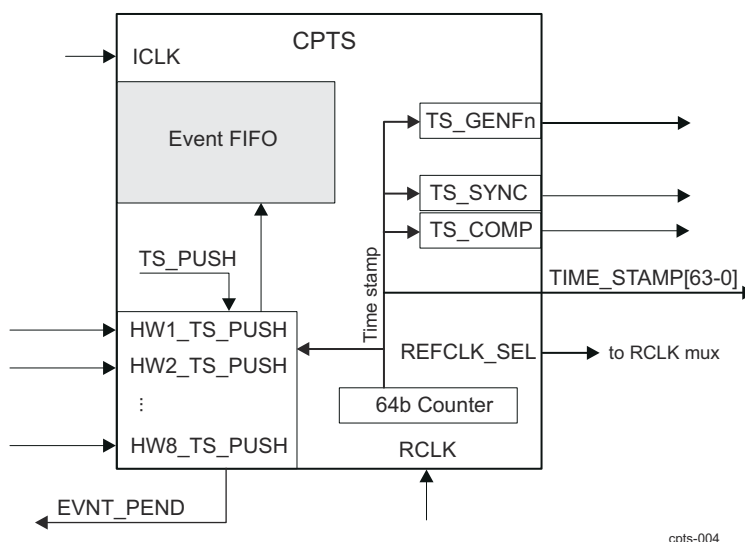

Figure 11-1. CPTS Block Diagram

11.1.2.2 CPTS Initialization

The CPTS module must be configured as follows:

1. Reset the CPTS module

2. Clear the CPTS_EN bit in the CPTS_CONTROL_REG
3. Write the RFTCLK_SEL value in the CPTS_RFTCLK_SEL_REG with the desired reference clock selection
4. Set the CPTS_EN bit in the CPTS_CONTROL_REG
5. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPTS_INT_ENABLE_REG

11.1.2.3 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each RCLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_VAL_REG and CPTS_TS_LOAD_EN_REG).

The TS_INC_VAL[2:0] value must be zero in 32-bit mode. Nudge and PPM adjustments are not supported in 32-bit mode.

11.1.2.4 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each RCLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

64-bit mode is selected via CPTS_CONTROL_REG[5] MODE_64BIT bit set to 1.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_VAL_REG, CPTS_TS_LOAD_HIGH_VAL_REG, and CPTS_TS_LOAD_EN_REG).

The TS_ADD_VAL feature is included to allow 1-ns timestamp operations with an RCLK rate less than 1 GHz. [Table 11-1](#) shows the RCLK and TS_ADD_VAL values for 1-ns operations. The highest RCLK frequency possible should be used as allowed by the silicon technology.

Table 11-1. TS_ADD_VAL

RCLK (MHz)	TS_ADD_VAL
1000	0
500	1
333.33	2
250	3
200	4
166.66	5
142.85714	6
125	7

11.1.2.4.1 64-Bit Timestamp Nudge

The 64-bit TIME_STAMP value can be adjusted by writing the CPTS_TS_NUDGE_VAL_REG[7:0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK clock from the next incremented TIME_STAMP[63:0] value. A nudge value of 0x01 will add one RCLK clock to the next incremented TIME_STAMP[63:0] value. For example, if the current TIME_STAMP value is 0x0F06, and TS_ADD_VAL[2:0]=3, the next incremented timestamp value would be 0x0F0A without a nudge and 0x0F0A +/- TS_NUDGE[7:0] with a nudge. The TS_NUDGE value is cleared to zero when the nudge has occurred.

11.1.2.4.2 64-bit Timestamp PPM

The 64-bit TIME_STAMP can be adjusted by parts per million (PPM) or by parts per hour (PPH). Writing a non-zero value to the TS_PPM[41:0] value enables PPM operations. The adjustment is up or down depending on the TS_PPM_DIR bit. The TIME_STAMP value is increased by the PPM value when TS_PPM_DIR is cleared and decreased by the PPM value when TS_PPM_DIR is set.

- To adjust for 100 parts per million the configured value for TS_PPM[41:0] is:

$$1\,000\,000/100 = 10\,000 \text{ (DEC)}$$

- To adjust for 1 part per hour at 1 GHz RCLK, the configured value for TS_PPM[41:0] is:
 $(1\,000\,000\,000\text{Hz}/1\text{pph}) \times (3600\text{ seconds}/\text{hour}) = 346\,30B8\,A000 \text{ (HEX)}$

11.1.2.5 Event FIFO

All time sync events are push onto the Event FIFO. No overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

11.1.2.6 Timestamp Compare Output

CPTS features one Time Stamp Compare (TS_COMP) output.

Note

64-bit mode operation is identical to 32-bit mode except that all 64 bits of the TIME_STAMP[63-0] are used instead of only the lower 32 bits.

11.1.2.6.1 Non-Toggle Mode

The TS_COMP output is asserted for CPTS_TS_COMP_LEN_REG[23-0] RCLK periods when the TIME_STAMP[31-0] value compares with the CPTS_TS_COMP_VAL_REG[31-0] and the length value is non-zero. The TS_COMP rising edge occurs three RCLK periods after the values compare. A timestamp compare event is pushed into the event FIFO when TS_COMP is asserted. The polarity of the TS_COMP output is determined by the CPTS_CONTROL_REG[2] TS_POLARITY bit. The output is asserted low when the polarity bit is 0.

11.1.2.6.2 Toggle Mode

The TS_COMP output is asserted for CPTS_TS_COMP_LEN_REG RCLK periods when the TIME_STAMP[31-0] value compares with the CPTS_TS_COMP_VAL_REG[31-0] and the length value is non-zero. The TS_COMP toggles thereafter on CPTS_TS_COMP_LEN_REG[23-0] RCLK periods. The length high or low can be adjusted by writing the CPTS_TS_COMP_NUDGE_REG[7-0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK from the CPTS_TS_COMP_LEN_REG value. A value of 0x01 will add one RCLK to the CPTS_TS_COMP_LEN_REG value. Only a single high or low time is adjusted (nudged) and the CPTS_TS_COMP_NUDGE_REG value is cleared to zero when the nudge has occurred. The TS_COMP output is asserted low when the CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit is 0.

No compare events and no CPTS_EVNT interrupts are generated in toggle mode.

The CPTS_CONTROL_REG[6] TS_COMP_TOG bit must be set for toggle mode, and must be set before writing a non-zero value to CPTS_TS_COMP_LEN_REG.

11.1.2.7 Timestamp Sync Output

The TS_SYNC output is a selected bit of the TIME_STAMP counter value. One of the counter bits 17-31 can be selected in CPTS_CONTROL_REG[31-28] TS_SYNC_SEL. The TS_SYNC output is disabled when CPTS_CONTROL_REG[31-28] TS_SYNC_SEL is zero.

If the selected counter bit is 1 at the time when TS_SYNC_SEL value is written then a rising edge will not occur on the TS_SYNC output. A rising edge will occur on the TS_SYNC output upon the next transition-to-1 of the selected counter bit. The TS_SYNC_SEL value must be written to zero before changing to a different non-zero value. No events are generated due to the TS_SYNC operation. The TS_SYNC output is two RCLK periods after the actual count value.

11.1.2.8 Timestamp GENF Output

There are six TS Generate Function (TS_GENFn) outputs (n = 0 to 5). The TS_GENFn outputs have a programmable cycle (frequency) with a PPM feature and a software nudge feature. The TS_GENFn output cycle is CPTS_LENGTH_REG_j[31:0] RCLK periods (which is different than TS_COMP operation).

The TS_GENFn output cycle is CPTS_LENGTH_REG_j[31:0] RCLK periods beginning when the TIME_STAMP[63:0] value compares with the CPTS_COMP_LOW_REG_j[63:0] and the length value is non-

zero. The TS_GENFn output cycle repeats thereafter every CPTS_LENGTH_REG_j[31:0] RCLK periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the TS_GENFn_POLARITY bit is low. No compare events and no CPTS_EVT interrupt are generated.

11.1.2.8.1 GENFn Nudge

The cycle length can be adjusted by writing the CPTS_NUDGE_REG_j[7:0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK clock from the CPTS_LENGTH_REG_j[31:0] value. A value of 0x01 will add one RCLK clock to the CPTS_LENGTH_REG_j value. The CPTS_NUDGE_REG_j value is cleared to zero when the nudge has occurred.

11.1.2.8.2 GENFn PPM

The TS_GENFn output cycle can be adjusted by parts per million (PPM) or by parts per hour (PPH). Writing a non-zero CPTS_PPM_LOW_REG_j/CPTS_PPM_HIGH_REG_j value enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single RCLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPTS_CONTROL_REG_j[0] PPM_DIR bit. When PPM_DIR is set a single RCLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM_DIR is clear a single RCLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

- To adjust for 100 parts per million the configured value for TS_GENFn_PPM[41:0] is:
 $1\,000\,000/100 = 10\,000$ (DEC)
- To adjust for 1 part per hour at 1 GHz RCLK the configured value for TS_GENFn_PPM[41:0] is:
 $(1\,000\,000\,000\text{Hz}/1\text{pph}) \times (3600\text{ seconds}/\text{hour}) = 346\,30B8\,A000$ (HEX)

11.1.2.9 Time Sync Events

Time Sync events are 96-bit or 128-bit (for 32-bit and 64-bit time stamp respectively) values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPTS_EVENT_0_REG through CPTS_EVENT_3_REG hold the data of a time sync event.

11.1.2.9.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPTS_TS_PUSH_REG. The time stamp value is returned in the event, along with a time stamp push event code.

11.1.2.9.2 Time Stamp Counter Rollover Event (32-bit mode only)

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented.

11.1.2.9.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 11-2](#) shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event.

The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

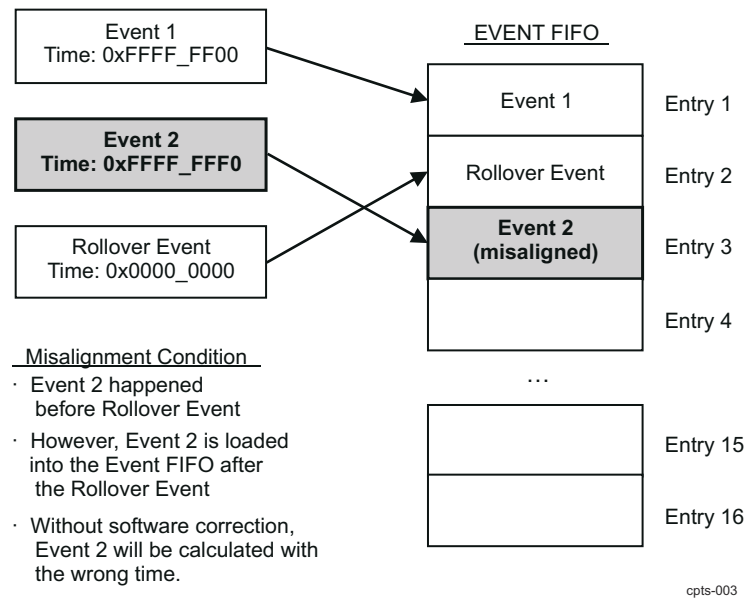

Figure 11-2. Event FIFO Misalignment Condition

11.1.2.9.4 Hardware Time Stamp Push Event

There are eight hardware time stamp inputs (HW[1-8]_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in *CPTS Integration*.

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPTS_EVENT_1_REG register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS_CONTROL_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

11.1.2.10 Timestamp Compare Event

Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode. The TS_COMP output is also asserted when the event is generated. The event is generated when the TIME_STAMP value compares with the CPTS_TS_COMP_VAL_REG/CPTS_TS_COMP_HIGH_VAL_REG and the CPTS_TS_COMP_LEN_REG value is non-zero. The CPTS_TS_COMP_LEN_REG value should be written by software after the CPTS_TS_COMP_VAL_REG/CPTS_TS_COMP_HIGH_VAL_REG is written and should be zero when the comparison value is written.

11.1.2.11 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE_REG.
2. Upon interrupt, read the CPTS_EVENT_0_REG through CPTS_EVENT_3_REG register values.
3. Set the CPTS_EVENT_POP_REG[0] EVENT_POP bit to 1 to pop the previously read value off of the event FIFO.

4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE_REG.
2. Upon interrupt, read the CPTS_EVENT_0_REG through CPTS_EVENT_3_REG register values.
3. Set the CPTS_EVENT_POP_REG[0] bit to 1 to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four RCLK periods plus four ICLK periods.
5. Read the TS_PEND_RAW bit in the CPTS_INTSTAT_RAW_REG register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, proceed to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPTS_INTSTAT_RAW_REG to determine if a valid event is on the event FIFO.

11.2 Timer Manager

This chapter describes the Timer Manager module of the device.

11.2.1 Timer Manager Overview

The Timer Manager module provides timers for timing operations for the processes running on multiple processors in the device.

11.2.1.1 Timer Manager Features

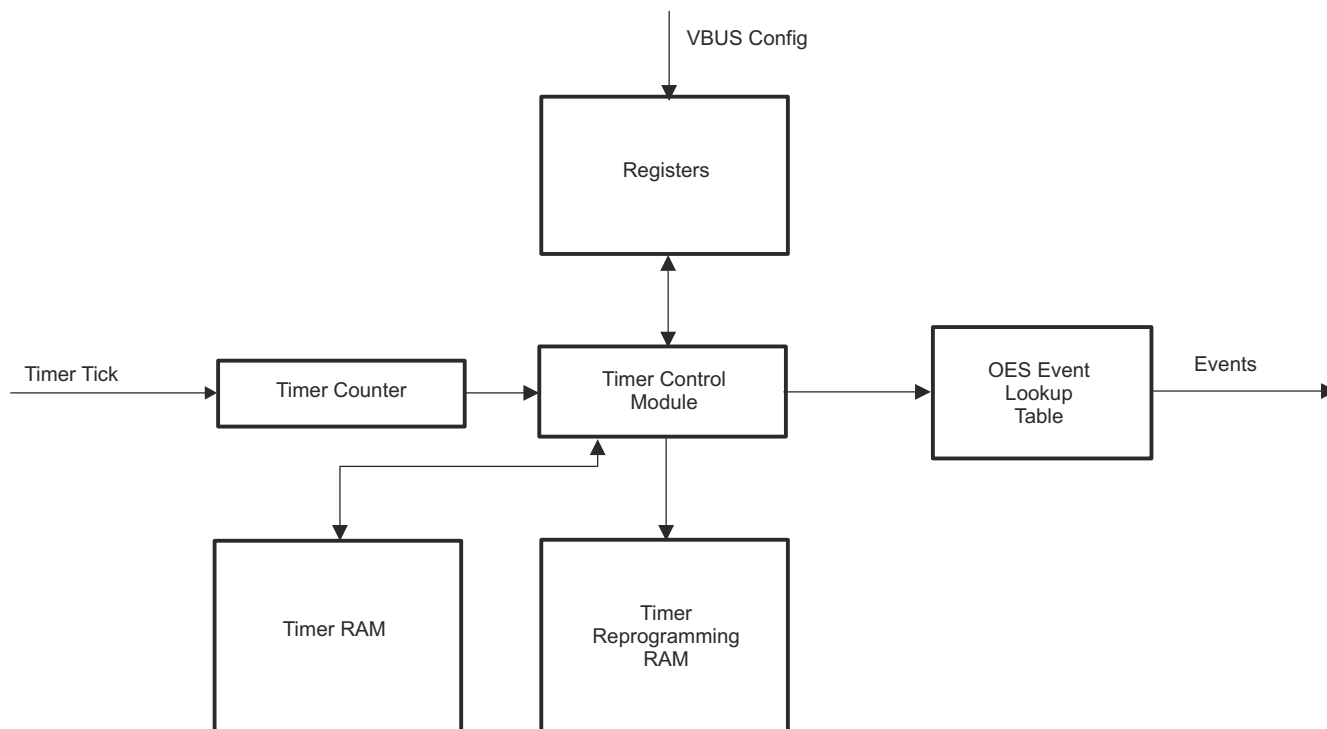

Timer Manager has the following features:

- 1024 × 32-bit RAM-based independent timers
- Host access to determine which timer(s) expired
- 32 registers with individual timeout status (one bit per timer)
- A pair of quick-read registers with the number of timers that have expired and the ids of the first timers to expire
- A bank timeout register with the banks that have expired timers – to avoid having to read all timeout status registers when only a few timers have expired
- Groups of 16 timers separated into pages of 4-K address space
- Timer bits within each page to read expiration status for each timer when software only has access to that page
- 10 μ s time to cycle through all of the timers
- Host access to reset individual timers
 - Reset values are preprogrammed for each timer
 - Timers may all be programmed before the timer manager is enabled, or programmed after enabled.

11.2.2 Timer Manager Functional Description

11.2.2.1 Timer Manager Function Overview

Figure 11-3 shows the Timer Manager diagram.

timer_mgr-004

Figure 11-3. Timer Manager Block Diagram

The 1024 timers in the timer manager are organized as the Timer RAM in [Figure 11-3](#). When the timer manager is enabled, the timer counter will increment with the input timer tick, and the control module continuously loops over the Timer RAM, comparing the values against this timer count. When the timer count is greater than a timer value, the timer control module will generate a timer expiration event.

Based on software writes, the timer control module will update the values in the Timer RAM to setup or cancel active timers. Whenever a new value is written to a `TIMERMGR_SETUP_j_k` memory address, the corresponding timer is touched/setup with the current sum of the timer count and the written value; written values are relative to the current timer count. These values are stored in the Timer Reprogramming RAM, so the software may also write to the `TIMERMGR_CONTROL_j_k` registers to flag a timer for reprogramming, using the previously stored reprogramming value. The latter method is preferred when the timer setup value is not changing, as it does not interrupt the RAM state machine.

11.2.2.2 Timer Counter

The Timer Manager takes an input timer tick to control the timer rate. All timers share a time base. On each rising edge of this tick event, the timer counter increments. The value of the timer counter may be read by software via the `TIMERMGR_COUNTER` register.

11.2.2.2.1 Timer Counter Rollover

A rollover bit is maintained for each timer, such that when reprogrammed, it is the carry bit from the sum of the current time (counter) and the relative reprogramming value for that timer. This has the effect that any timer whose rollover bit is currently set to a 1 will not expire in the current epoch.

When the counter transitions from `0xFFFF FFFF` to `0x0000 0000`, the timer control module changes the rollover bit for all timers from a 1 to a 0. All timers that previously did not have the rollover bit set, will expire when they are next visited by the state machine, as their timeout value was for the previous epoch.

The overall effect is that the timers continue to expire as expected, regardless of when the counter rollover occurs relative to the state machine.

11.2.2.3 Timer Control Module (FSM)

The timer control module controls the RAM accesses for reading and writing. It controls the loops over the timer RAM, checks the values in the RAM to observe expiring timers, flagging timeouts so that events may be triggered and reported. It also takes as input any software-written updates to setup, clear, and touch the timers.

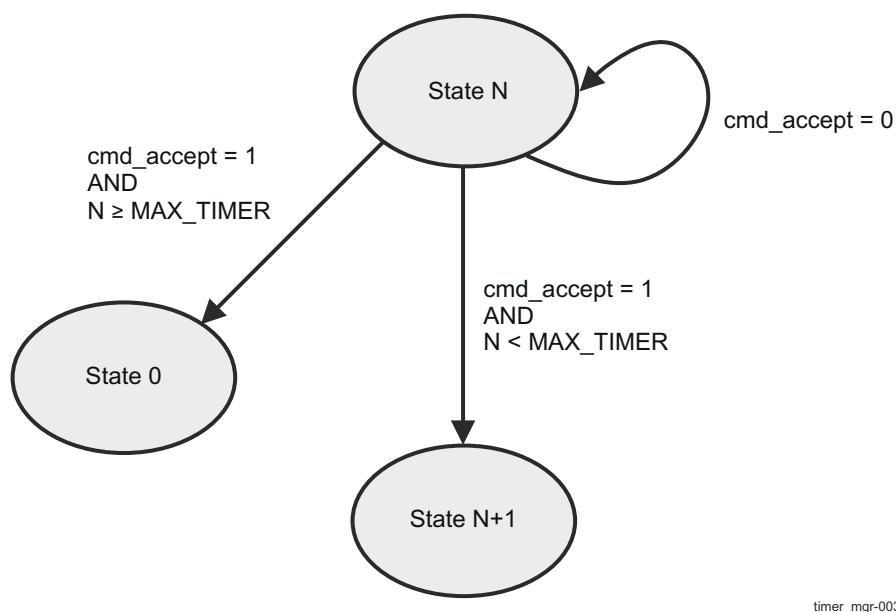

Figure 11-4. Timer State Machine

The timer states are sequential, that is, Timer 0 is checked, then Timer 1 is checked, then Timer 2, and so on. The Timer Control FSM will stall in a given state if the cmd_accept signal from the ksdw_spram_ecc module goes low, and will remain there until the ECC RAM will accept a command.

The timer state always transitions from N to N+1, unless N meets or exceeds the programmed MAX_TIMER value, in which case the system will start over at state 0.

11.2.2.4 Timer Reprogramming

There is a reprogramming module that runs in lock step with the FSM, always one state ahead – the FSM exports its next_state for use by the reprogramming RAM.

This RAM keeps track of the setup values for the timers as programmed by the TIMERMGR_SETUP_j_k memory mapped locations. There is a SET flag for each timer outside of the RAM – if this SET flag is true for the next_state timer, the VBUS ready signals are deasserted; if there is a pending timer setup, there cannot be a read or write to the memory, as this would interrupt the Timer FSM state machine and, with enough accesses, potentially cause the system to exceed the 10-μs window for timer accuracy.

11.2.2.5 Event FIFO

As the subsystem event aggregator requires more than one cycle to process events, there is an internal FIFO to store the generated events. Events may be generated by expiring timers or by activity on the CBA interface, as disabled timers or reset timers must send an event deactivation if the timer was previously expired.

This has an impact on performance, as if there are too many timer expirations in a given window, it potentially violates the 10-μs requirement (this is true without the event FIFO as well, given that the system cannot keep up with a timer expiring every cycle, in the worst case).

11.2.2.6 Output Event Lookup (OES RAM)

The expiring timers must be assigned corresponding event numbers for use in the instantiating system. These lookup values correspond to the 16-bit event number that is output on the event interface when a given timer expires.

The lookup table for timer to event number mapping defaults all timers to the invalid event number (0xFFFF), and any invalid event numbers observed upon lookup for an expiring timer will result in no events being generated by the timer manager – invalid (0xFFFF) events are suppressed and will not result in an event on the event interface.

It is expected that the output event assignments will be programmed once per module reset, and that they are static during operation of the timer manager.

11.2.3 Timer Manager Programming Guide

11.2.3.1 Timer Manager Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

11.2.3.1.1 Initialization Sequence

Initialization of the Timer Manager must include the following steps:

1. Set the number of timers to be used. `TIMERMGR_CNTL[10-1] MAX_TIMER`
 - This controls the loop over the timer RAM and is the highest ID timer that will be used in the operation of the Timer Manager (`MAX_TIMER + 1` is the total number of timers in use)
 - This number must not change during the course of operation; it can only be changed when `TIMERMGR_CNTL[0] ENABLE = 0`. It is assumed that the user will set the `MAX_TIMER` value as required.
 - This step can be skipped if using all timers. `MAX_TIMER` defaults to 1024 (that is, all timers in use).
2. Write output event mapping for all timers to the OES output event lookup table. This must be done before enabling timer manager and must not be done again once the timer manager has been enabled.
3. Write initial setup values to the `TIMERMGR_SETUP_j_k` registers. All timers that will be used initially must have a setup value before the Timer Manager is enabled.
4. Enable individual timers. There are two ways to do this.
 - To enable all timers, use the `TIMERMGR_CNTL[12] MASS_ENABLE` bit. This will enable all timers from 0 to `MAX_TIMER`.
 - Note that `MAX_TIMER` and `MASS_ENABLE` should be set in successive writes, or the previous value of `MAX_TIMER` will be used for `MASS_ENABLE`
 - `MASS_ENABLE` must only be used during initialization.
 - Alternately, individual timers can be enabled or disabled with `TIMERMGR_CONTROL_j_k`
 - It is therefore faster to set the individual `TIMERMGR_CONTROL_j_k` bits if more than half of the in-use timers are to be enabled initially. If more than half of the in-use timers are to be enabled initially, it is faster to use `MASS_ENABLE` and then disable specific timers with the `TIMERMGR_CONTROL_j_k` bits.
5. Enable the timer manager. Set `TIMERMGR_CNTL[0] ENABLE` to 1.

11.2.3.1.2 Real-time Operating Requirements

While running, a CPU can take the following actions to enable, disable, or touch the timers:

11.2.3.1.2.1 Timer Touch

When a timer needs to be updated – indicating that an interface or function is still alive and timeout should be delayed – there are two means of touching a timer:

- If the timer's respective `TIMERMGR_SETUP_j_k` has the appropriate value for its function, the timer can be set again by writing a 1 to the SET bit of the `TIMERMGR_CONTROL_j_k` register.
 - As the timer should remain enabled, this effectively means writing a 3 to the `TIMERMGR_CONTROL_j_k` register for the timer to be touched
- If the timer's respective `TIMERMGR_SETUP_j_k` needs a new value, writing this value has the side effect of also setting the timer – there is no need to also write to the SET bit of `TIMERMGR_CONTROL_j_k`. This should be relatively infrequent during operation, as the setup values for all timers must be written during initialization.

The preferred method for touching timers is using the SET bit of `TIMERMGR_CONTROL_j_k`. It is considerably more efficient. The reprogramming RAM is a single port RAM, and repeated writes to the `TIMERMGR_SETUP_j_k` registers will impact overall timer performance and may result in longer periods before a valid timeout is observed.

11.2.3.1.2.2 Timer Disable

When a timer is no longer in use, the timer should be disabled with the respective `TIMERMGR_CONTROL_j_k` enable bit.

A disabled timer does not stop the time for that timer relative to the counter, and its current value is considered invalid once disabled. A timer should not be disabled and then subsequently re-enabled without reprogramming/re-setting, as it may timeout unexpectedly.

11.2.3.1.2.3 Timer Enable

To enable a timer while the Timer Manager is running, the timer must first be setup again.

- If the current `TIMER_MGR_SETUP_j_k` is appropriate for the timer's intended use, the timer can be re-enabled by writing a 3 to the `TIMER_MGR_CONTROL_j_k` register. (ENABLE = 1, SET = 1)
- If the current `TIMER_MGR_SETUP_j_k` needs to be changed, write to the `TIMER_MGR_SETUP_j_k` before re-enabling the timer. After this value is changed, the timer can be re-enabled by writing 0x3 to the `TIMER_MGR_CONTROL_j_k` register (ENABLE = 1, SET = 1)
 - While `TIMER_MGR_SETUP_j_k` implies SET, it must still be set as the timer is enabled.

11.2.3.1.3 Power Up/Power Down Sequence

The timer manager must be disabled (clear `TIMER_MGR_CNTL[0] ENABLE` to 0) before the timer manager is powered down. The timer manager will only be idle if it is not enabled and the event FIFO is empty – an enabled Timer Manager means the state machine is running and the timer manager is waiting for expired timers.

To power up the Timer Manager if it has been powered down but not reset, the timer values in the timer RAM must be assumed to be invalid. Any timers must either be reprogrammed (`TIMER_SET`) before the timer is re-enabled. If this is not done, the Timer Manager may report timeouts as soon as it is enabled.

Additionally, all timers that have expired must be cleared before disabling the Timer Manager, otherwise there will be no Event Down generated on the event interface to clear the expired timers from the interrupt aggregator. This effectively means that software must disable all timers before writing a 0 to `TIMER_MGR_CNTL[0] ENABLE`.

The event FIFO will continue to drive pending events even if the Timer Manager is disabled, so the remaining Event Down actions will still occur – software only needs to disable the timers to ensure that the Event Down commands are pushed into the event FIFO but does not need to wait for the event FIFO to flush before disabling the timer manager.

11.3 Time Sync and Compare Events

11.3.1 Time Sync Architecture

This section provides a high-level overview of the SoC time synchronization architecture.

11.3.1.1 Time Sync Architecture Overview

[Table 11-2](#) shows the network time synchronization functions supported by the device.

Table 11-2. Network Time Synchronization Functions in the SoC

Interface	Time Sync Functions	Supported by
1×PCIe	Precision time measurement (PTM)	PCIe controller hardware
External input reference clock	External time/clock reference	CPTS

Note

These time sync functions are described in detail in their respective chapters.

Any of these functions can be a time sync master in the system. A sync router (TIMESYNC_INTRTR0) provides flexibility for each time domain to choose its synch master independently. In addition, there is also a router (CMPEVT_INTRTR0) that provides selection of active counter compare events for routing as CPU or DMA events.

11.3.2 Time Sync Routers

11.3.2.1 Time Sync Routers Overview

The timesync event router (TIMESYNC_INTRTR0) and compare event router (CMPEVT_INTRTR0) are instantiations of the generic interrupt router module in the device.

The TIMESYNC_INTRTR0 implements a set of multiplexers to provide selection of active CPTS time sync events for routing to CPTS capable modules. There is one register per output that controls the selection (TIMESYNC_INTRTR0_MUXCNTL_y).

The CMPEVT_INTRTR0 implements a set of multiplexers to provide selection of active CPTS counter compare events for routing as CPU or DMA events. There is one register per output that controls the selection (CMPEVT_INTRTR0_MUXCNTL_y).

Table 11-3 summarizes the configuration details for TIMESYNC_INTRTR0 and CMPEVT_INTRTR0.

Table 11-3. TIMESYNC_INTRTR0 and CMPEVT_INTRTR0 Configuration

Module	Input Interrupt Type
TIMESYNC_INTRTR0	Level
CMPEVT_INTRTR0	Pulse

Refer to *INTRTR Overview* for the general programming sequence that is recommended to be followed for all interrupt routers in the device.

11.3.3 Time Sync Event Sources

See *Interrupt Sources* for Time Sync event mapping.

12.1 General Connectivity Peripherals

This section describes the general connectivity peripherals in the device.

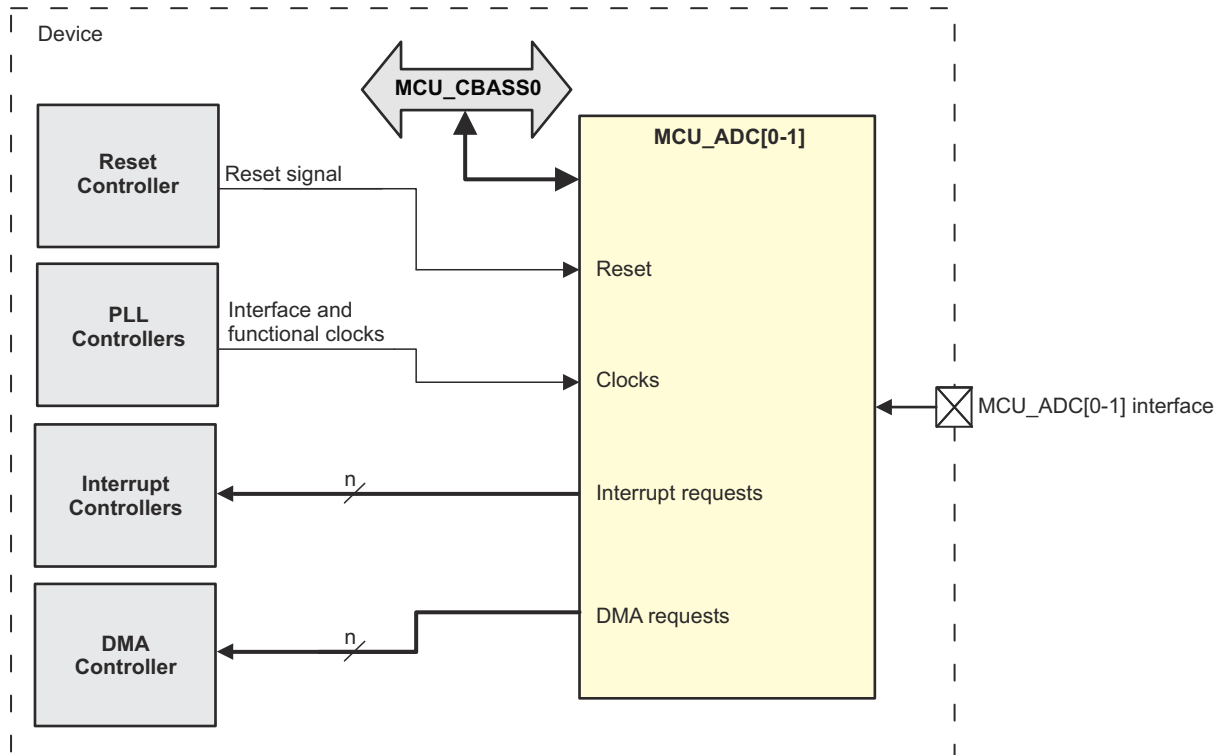

12.1.1 Analog-to-Digital Converter (ADC)

This chapter describes the Analog-to-Digital Converter (ADC) in the device.

12.1.1.1 ADC Overview

The Analog-to-Digital Converter (ADC) module contains a single 12-bit ADC which can be multiplexed to any 1 of 8 analog inputs (channels).

Figure 12-1 presents an overview of the ADC modules.

adc-001

Figure 12-1. ADC Modules Overview

12.1.1.1.1 ADC Features

Each ADC module has the following features:

- 4 MSPS rate with a 60 MHz SMPL_CLK
- Single-ended or differential input options
- Programmable Finite State Machine (FSM) sequencer that supports the following:
 - Software initiated start of conversion
 - Optional hardware start of conversion (SOC), synchronized to external hardware event
 - Single conversion (one-shot mode)
 - Continuous conversions (continuous mode)
 - Sequence through all enabled steps based on a mask
 - Programmable open delay before executing each step
 - Programmable sampling delay for each step
 - Programmable averaging (16, 8, 4, 2, or 1) of input samples for each step
 - Store data in either of two FIFOs – 256-word × 16-bit
 - Option to encode input (channel) number with data

- Support for servicing FIFOs via DMA or processor
- Programmable DMA request event (for each FIFO)
- Support for the following interrupts and status, with masking:
 - Interrupt if AFE fails to return end of conversion (EOC)
 - Interrupt after a sequence of conversions (all non-masked steps)
 - Interrupt for FIFO threshold levels
 - Interrupt if sampled data is out of a programmable range
 - Interrupt for FIFO overflow and underflow conditions
 - Status bit to indicate if ADC is busy converting

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.1.1.1.2 ADC Ports

Table 12-1. MCU_ADC[0-1] Clocks and Resets

Clocks	
Module Clock Input	Description
MCU_ADC_VBUS_CLK	MCU_ADC interface clock
MCU_ADC_SYS_CLK	MCU_ADC system clock
MCU_ADC_CLK	MCU_ADC clock. Output of multiplexer, see <i>ADC Integration</i> . Multiplexer control is provided via CTRLMMR_MCU_ADC_CLKSEL[1-0] CLK_SEL bit field. Default state is HFOSC_CLKOUT.
Resets	
Module Reset Input	Description
MCU_ADC_RST	MCU_ADC reset

Table 12-2. MCU_ADC[0-1] Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCU_ADC_GEN_LEVEL_0	MCU_ADC interrupt request	Level
MCU_ADC_ECC_CORRECTED_ERR_LEVEL_0	MCU_ADC ECC corrected error interrupt request	Level
MCU_ADC_ECC_UNCORRECTED_ERR_LEVEL_0	MCU_ADC ECC uncorrected error interrupt request	Level
DMA Events		
Module DMA Event	Description	Type
MCU_ADC_FIFO0	MCU_ADC receive request line	Pulse
MCU_ADC_FIFO1	MCU_ADC receive request line	Pulse

12.1.1.2 ADC Environment

This section describes the ADC external connections (environment).

[Table 12-3](#) describes the ADC I/O signals.

12.1.1.3 ADC Functional Description

12.1.1.3.1 ADC FSM Sequencer Functional Description

The FSM sequencer supports up to 16 steps that can be configured to perform analog-to-digital conversions. Each of the 16 steps can individually be enabled and configured to operate as software enabled steps or hardware enabled steps. Each step has its own programmable step configuration (ADC_CONFIG_j) and step delay (ADC_DELAY_j) registers that allow users to configure the ADC operation on a per-step basis.

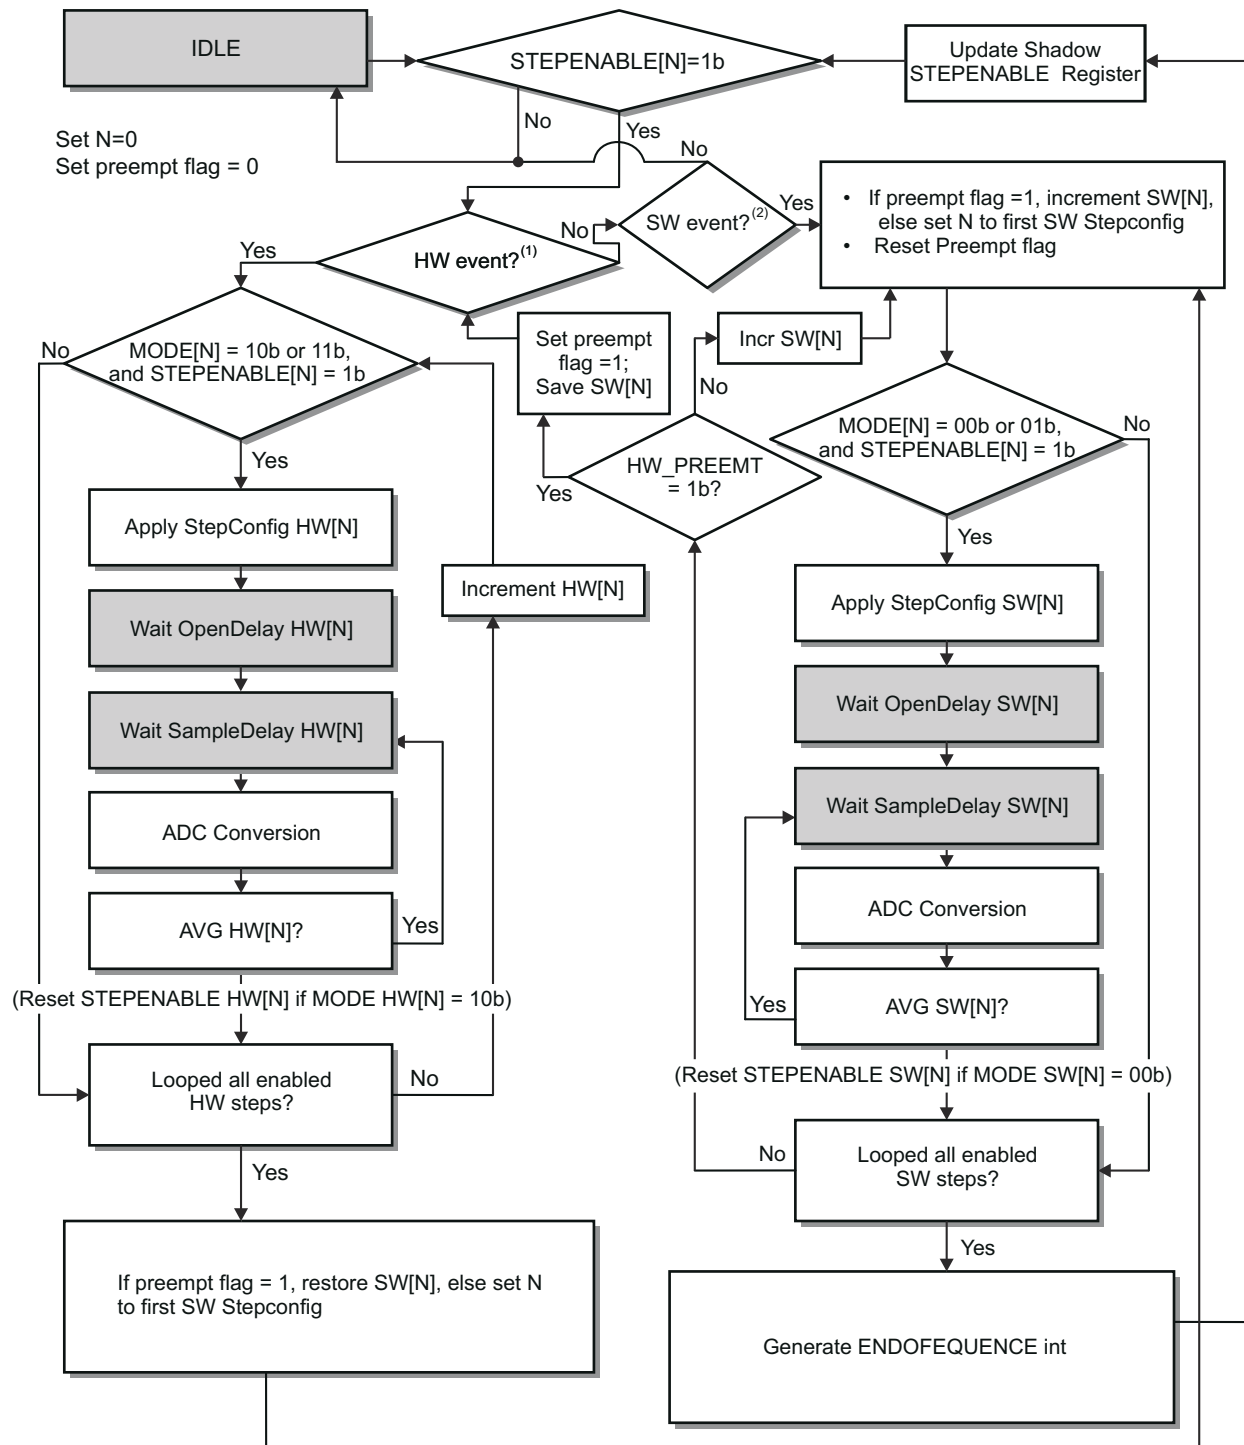

The FSM sequencer enters Idle immediately after the ADC is enabled and remains in Idle while waiting for any of the 16 programmable steps to be enabled. When one or more step is enabled, the FSM sequencer will begin executing or skipping each step starting with the lowest and incrementing up through each step until the highest step has been executed or skipped. The FSM sequencer will execute enabled steps and skip disabled steps. Once all of the steps have been executed or skipped, the FSM sequencer will return to Idle or immediately begin repeating steps configured for continuous mode.

An ENDOSEQUENCE interrupt can be generated after the last enabled step has been executed. If any software enabled steps are configured for continuous operation and they are still enabled when the FSM sequencer has incremented through all the steps, the FSM sequencer will start the sequence again with the first enabled step. Hardware enabled steps are mapped to a hardware event and will need the hardware event to occur before being scheduled.

Figure 12-2 illustrates how the FSM sequencer works. Each shaded box represents a FSM state.

Note

Figure 12-2 does not represent the number of SMPL_CLK cycles required by each state since some states implement user programmable delays that may require more than one SMPL_CLK cycle to complete.

(1) MODE[N] = 10b or 11b, STEPENABLE[N] = 1b, and HW Event = 1

(2) MODE[N] = 00b or 01b and STEPENABLE[N] = 1b

adc-005

Figure 12-2. Sequencer FSM**12.1.1.3.1.1 Step Enable**

A step is enabled or disabled via the ADC_STEPENABLE register. The system software should only write to the ADC_STEPENABLE register when the ADC is disabled or the FSM sequencer is idle. Therefore, it may be necessary to disable the ADC before updating the ADC_STEPENABLE register if the FSM sequencer is executing back-to-back steps where it never enters idle.

12.1.1.3.1.2 Step Configuration

12.1.1.3.1.2.1 One-Shot (Single) or Continuous Mode

Each step can be configured to operate in one-shot or continuous mode via the least significant bit of the MODE bit-field of the respective ADC_CONFIG_j register. Steps configured for one-shot mode will perform a single conversion before being disabled by the FSM sequencer. Steps configured for continuous mode will automatically be re-enabled by the FSM sequencer after each conversion until disabled by software.

12.1.1.3.1.2.2 Software- or Hardware-Enabled Steps

Each step can be configured to operate in SW Enabled mode or HW Enabled mode independently via the most significant bit of the MODE bit-field in the respective ADC_CONFIG_j register. However, the hardware event source is applied globally to all HW Enabled steps and configured via the ADC_CONTROL register.

The user can configure each step to begin immediately after the step is enabled by software (SW Enabled), or wait for a hardware event to occur (HW Enabled).

The EXT_TRIGGER input signal is used by HW Enabled steps. The trigger input has the option of being sourced from a device input pin or several on-device peripherals via a multiplexer controlled by TRIG_SEL of the respective CTRLMMR_MCU_ADC0_CTRL or CTRLMMR_MCU_ADC1_CTRL register. When this option is selected, the hardware event will be triggered after the EXT_TRIGGER input signal transitions from low to high and is held high for a period greater than two cycles of SYS_CLK. This hardware event will only schedule one complete sequence, even for continuous mode. If HW Enabled steps need to be executed again, a new hardware event must be generated after the previously triggered sequence has completed.

SW Enabled steps can be preempted by HW Enabled steps when the HW_PREEMPT bit in the ADC_CONTROL register is set.

12.1.1.3.1.2.3 Averaging of Samples

Each step can be configured, via the respective ADC_CONFIG_j register, to sample an input 1, 2, 4, 8, or 16 times and provide an average data value. If a step is configured to sample more than once, the additional samples are taken back-to-back immediately after the first sample. However, open delay is only applied to the first sample while sample delay is applied to all samples. Once the last sample has been taken the average data value will be stored in the FIFO.

12.1.1.3.1.2.4 Analog Multiplexer Input Select

The AFE contains two 9-to-1 analog multiplexers which are used to select the source connected to the positive input (INP) and negative input (INM) of the ADC. Each step can be configured, via the respective ADC_CONFIG_j register, to select the appropriate input sources. For more information, refer to [Figure 12-4](#) and the ADC_CONFIG_j register field descriptions.

12.1.1.3.1.2.5 Differential Control

The ADC supports differential inputs and each step can be configured, via the respective ADC_CONFIG_j register, to select single-ended input mode or differential input mode.

Note

The ADC INM input must be sourced from REFN for any steps configured to operate in single-ended mode.

12.1.1.3.1.2.6 FIFO Select

The ADC contains two FIFOs and each step can be configured, via the respective ADC_CONFIG_j register, to store its ADC data into either FIFO.

12.1.1.3.1.2.7 Range Check Interrupt Enable

Each step can be configured, via the respective ADC_CONFIG_j register, to compare the value of ADC data to high and low limits programmed in the ADC_RANGE register. The out-of-range interrupt is generated if the value of ADC data is greater than the value of HIRANGE or less than the value of LOWRANGE. Refer to the

ADC_RANGE register field descriptions for information related to setting the high and low limits that trigger an out-of-range interrupt.

12.1.1.3.1.3 Open Delay and Sample Delay

The FSM sequencer provides two programmable delays for each step. The value of OPENDELAY is used to control when the acquisition begins after the step starts and the value of SAMPLEDELAY is used to control the acquisition period. Delays for each of the 16 steps can be configured independently via the respective ADC_DELAY_j register.

12.1.1.3.1.3.1 Open Delay

OPENDELAY defaults to a value of zero which causes the acquisition period to begin as soon as the step starts. The start of the acquisition period can be delayed one SMPL_CLK clock period for each incremental value of OPENDELAY.

12.1.1.3.1.3.2 Sample Delay

SAMPLEDELAY defaults to a value of zero which causes the acquisition period to be equal to two SMPL_CLK clock periods. The acquisition period can be extended one SMPL_CLK clock for each incremental value of SAMPLEDELAY.

The value of SAMPLEDELAY should be configured to provide enough time for the respective external voltage source to completely charge the AFE input capacitance during the acquisition period.

12.1.1.3.1.4 Interrupts

The ADC has 9 internal events that can trigger an interrupt to the processor. These events are logically or'ed together to produce a single interrupt to the processor. The user can individually enable or disable each interrupt source via the ADC_ENABLE_SET and ADC_ENABLE_CLR registers. Once an interrupt is generated, the ADC_STATUS register can be read to determine which interrupt source(s) interrupted the processor. The interrupt source(s) can be cleared by writing a '1' to the corresponding bit of the ADC_STATUS register.

The following interrupts are supported by the device ADC:

- An ENDOSEQUENCE interrupt is generated after the FSM sequencer completes the last enabled step.
- FIFO0UNFL/FIFO1UNFL or FIFO0OVFL/FIFO1OVFL interrupts. Each FIFO also has the ability to generate overrun and underflow interrupts. The ADC does not recover from overrun or underflow conditions automatically. Therefore, software will need to disable and re-enable the ADC after this occurs. The FSM sequencer must be Idle before turning the ADC module back on. This can be confirmed by reading the ADC_SEQUENCER_STAT register, when FSM_BUSY = 0x0 and STEP_IDLE = 0x10000.
- FIFO0THRS and FIFO1THRS interrupts. Each FIFO has the ability to generate an interrupt when the FIFO word count has reached a programmable threshold value. The FIFO0THRS and FIFO1THRS interrupt is generated when the value of NUMWDS in the respective ADC_FIFO0WC or ADC_FIFO1WC register equals the word count threshold value programmed in THRESHOLD of the respective ADC_FIFO0THRESHOLD or ADC_FIFO1THRESHOLD register.
- OUTOFRANGE interrupt. This interrupt can be enabled or disabled on each step. If enabled, the ADC data value is compared to the low and high thresholds programmed in the global ADC_RANGE register. The OUTOFRANGE interrupt is generated if the ADC data value is greater than the value programmed in HIRANGE or less than the value programmed in LOWRANGE.
- AFE_EOC_MISSING interrupt. This interrupt is generated when the FSM sequencer does not receive an expected EOC from the AFE.

12.1.1.3.1.5 Power Management

The software also has the option to turn off the AFE power by writing to the ADC_CONTROL[4] PD bit. By default, after the initial power on the AFE is powered down and software is responsible for turning it on. Software must wait minimum 4 μ s after a AFE power up and before starting a conversion (must be followed every time the AFE is powered up). It is the software's responsibility to empty the FIFO before requesting the ADC to enter sleep state.

12.1.1.3.1.6 DMA Requests

Each FIFO can be serviced by the processor or DMA. The user can individually enable or disable each FIFO DMA request via the ADC_DMAENABLE_SET and ADC_DMAENABLE_CLR registers.

12.1.1.3.2 ADC AFE Functional Description

The AFE contains a single 12-bit successive approximation ADC which can be connected to one of eight user selectable analog inputs for each step executed by the FSM sequencer. There is also an option to configure the ADC to operate in differential mode where it samples the differential voltage applied to two of eight user selectable analog inputs.

The ADC sits idle until the FSM sequencer sends a Start of Conversion (SOC) pulse. Once the FSM sequencer sends a SOC pulse to the ADC, it begins sampling the analog input signal on the rising edge of SOC and continues sampling the analog input signal one cycle of SMPL_CLK after the falling edge of SOC. The SOC pulse width will be the value of SAMPLEDELAY plus one SMPL_CLK periods, so the total ADC acquisition time will be the value of SAMPLEDELAY plus two SMPL_CLK periods. The ADC captures the analog input signal at the end of the acquisition period and starts conversion, which requires thirteen SMPL_CLK periods to digitize the sampled input. An EOC signal is returned to the FSM sequencer to indicate the digital data is ready.

The ADC output is positive binary weighted data ranging from 0 to $(2^{12} - 1)$. When configured for single-ended mode, ADC output data values 0 to $(2^{12} - 1)$ represents a corresponding input voltage that ranges from the ADC negative reference (REFN) voltage to the ADC positive reference (REFP) voltage. When configured for differential mode, ADC output data values 0 to $((2^{12}/2) - 1)$ represents a corresponding negative differential input voltage that ranges from the REFP voltage to the REFN voltage and output data values $(2^{12}/2)$ to $(2^{12} - 1)$ represents a corresponding positive differential input voltage that ranges from the REFN voltage to the REFP voltage.

Using the minimum values of OPENDELAY and SAMPLEDELAY, the ADC can sample an analog input every 15 SMPL_CLK periods.

[Figure 12-3](#) illustrates the operation of the FSM sequencer and ADC AFE, with indicators showing when the hardware configuration defined by ADC_CONFIG_j and ADC_DELAY_j registers are applied.

Note

[Figure 12-3](#) assumes both steps shown are software enabled with averaging turned off, an OPENDELAY value of 1, and SAMPLEDELAY value of 0. The analog input is sampled for the duration of the SOC pulse plus one cycle of the SMPL_CLK. If the value of OPENDELAY were 0, it would appear as if the time associated with the Open portion of the FSM waveform would be removed from all the waveforms.

Figure 12-3. Example Timing Diagram for Sequencer

12.1.1.3.2.1 AFE Functional Block Diagram

The AFE has 8 analog inputs which can be configured as either singled-ended or differential inputs to the ADC. The user may configure a step to use any 1 of the 8 inputs when operating in single-ended mode or any 2 of the 8 inputs when operating in differential mode. For more information, refer to [Figure 12-4](#) and the ADC_CONFIG_j register field descriptions.

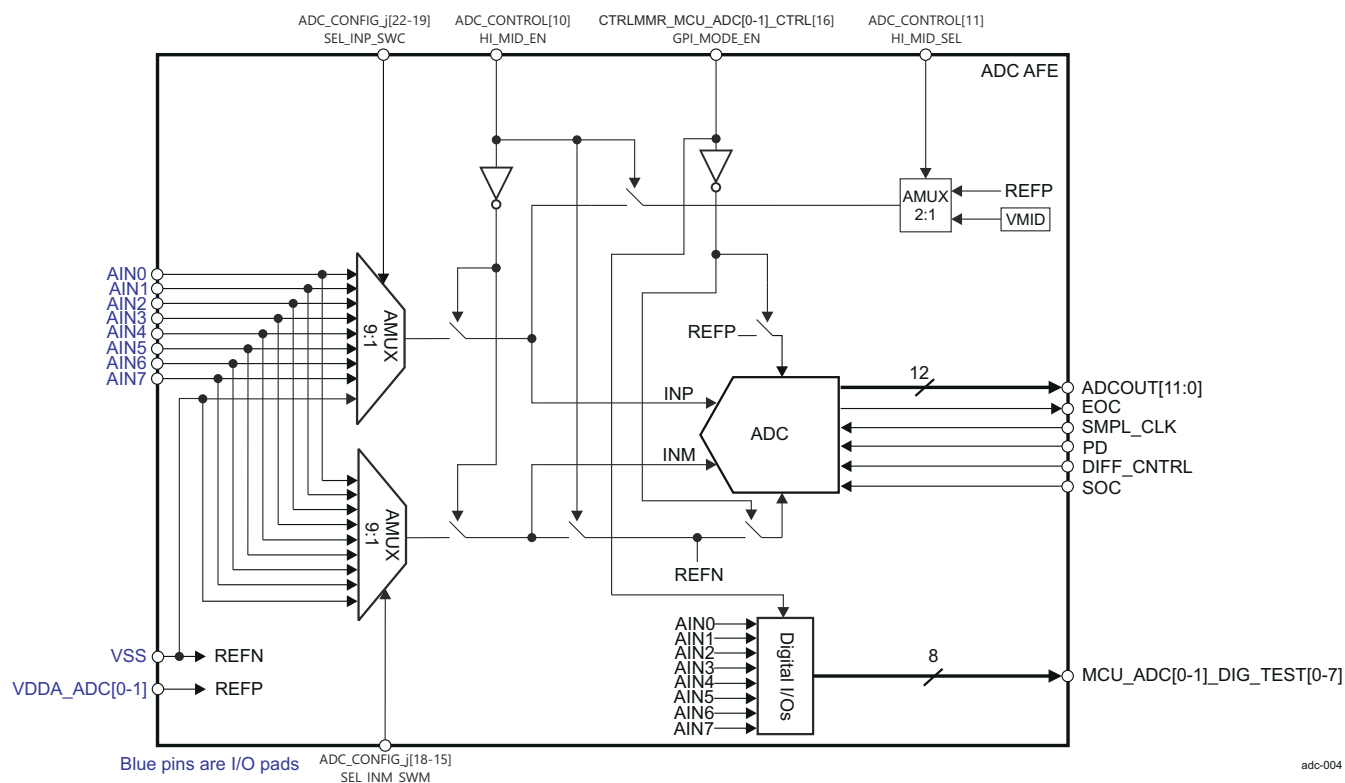

Figure 12-4. Functional Block Diagram

12.1.1.3.3 ADC FIFOs and DMA

12.1.1.3.3.1 FIFOs

There are two sample FIFOs (ADC_FIFO0 and ADC_FIFO1), which store sample data from the AFE. Can be configured, via the respective ADC_CONFIG_j register.

The processor can read ADC data directly from the FIFO by using the respective ADC_FIFO0DATA or ADC_FIFO1DATA register. The internal logic will pop the next data from the FIFO and increment the FIFO read pointers.

The FIFO data will no longer be accessible after the ADC is disabled because the FIFO pointers are reset. Therefore, it is important to read all FIFO data before disabling the ADC.

12.1.1.3.3.2 DMA

The ADC has a dedicated slave port for the DMA which allows it to perform continuous burst reads when accessing the FIFOs.

Each FIFO has its own DMA request which can be enabled via the ADC_DMAENABLE_SET register and disabled via the ADC_DMAENABLE_CLR register.

The first DMA request is generated after the FIFO leaves the EMPTY state and fills to the level programmed in DMAREQLEVEL of the respective ADC_FIFO0DMAREQ or ADC_FIFO1DMAREQ register.

Subsequently, a new DMA request is automatically generated on the next clock cycle after the current DMA access completes if the previous DMA access did not empty the FIFO.

12.1.1.3.4 ADC Error Correcting Code (ECC)

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC Aggregator provides a single EOI-handshake based interrupt to the host (for both single and double error detections).

The ECC Aggregator will write 0's to all of memory after reset is released. The ADC_SEQUENCER_STAT[6] MEM_INIT_DONE bit will be 0 during this period and will be set to 1 upon completion.

For more information about the ECC Aggregator, see *ECC Aggregator* and *ADC ECC Registers*.

See also *Testing ECC Error Injection* and *ADC ECC Registers*.

12.1.1.3.4.1 Testing ECC Error Injection

The read enable (REN) input to the RAMs instantiated in this module are constantly tied to 1'b1. As a result, read is continuously in progress.

In order to test ECC single error injection on a particular RAM row, the following conditions have to be maintained before setting the ADC_ECC_CTRL[3] FORCE_SEC bit:

- ADC_ECC_CTRL[5] FORCE_N_ROW bit has to be clear. This is required in order to configure required row in
- ADC_ECC_CTRL[6] ERROR_ONCE bit has to be clear. If this bit is set, the ECC error occurs immediately after setting ADC_ECC_CTRL[3] FORCE_SEC bit since REN is always set
- ADC_ECC_ERR_CTRL1[31-0] ECC_ROW bit field has to be point to the required row address

12.1.1.3.5 ADC Functional Debug Mode

The ADC function can be validated by measuring known reference voltage sources. This feature provides register control that connects the AFE to known reference voltage sources. However, it does not automatically configure the FSM to perform conversions to measure these sources. Software will need to configure the FSM to perform a measurement after selecting this mode of operation.

ADC_CONTROL[10] HI_MID_EN is used to disconnect the AFE from all analog inputs and connect it to one of two known reference voltage sources. ADC_CONTROL[11] HI_MID_SEL is used to select REFP or VMID as the known reference voltage source.

The conversion results is expected to produce a full scale value when the AFE is connected to REFP and approximate half scale value when the AFE is connected to VMID.

The steps are:

- Disable the ADC if previously enabled and wait until the FSM is not busy.
- Put the AFE in a functional debug mode by setting the ADC_CONTROL[10] HI_MID_EN bit to 1.
- Select one of the two reference voltage sources by setting the ADC_CONTROL[11] HI_MID_SEL bit.
 - 0 selects VMID
 - 1 selects REFP
- Configure the FSM to measure the selected reference voltage source.
- Enable the ADC and evaluate the results.
- When debug is complete, disable the ADC and wait until the FSM is not busy, re-program the FSM for functional operation, then re-enable the ADC.

12.1.2 General-Purpose Interface (GPIO)

This chapter describes the General-Purpose Input/Output (GPIO) for the device.

12.1.2.1 GPIO Overview

The General-Purpose Input/Output (GPIO) peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs. When configured as an output, the user can write to an internal register to control the state driven on the output pin. When configured as an input, user can obtain the state of the input by reading the state of an internal register.

In addition, the GPIO peripheral can produce host CPU interrupts and DMA synchronization events in different interrupt/event generation modes.

12.1.2.1.1 GPIO Features

Each channel in the GPIO modules has the following features:

- Supports 9 banks of 16 GPIO signals
- Supports up to 9 banks of interrupt capable GPIOs
- Interrupts:
 - Can enable interrupts for each bank of 16 GPIO signals
 - Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO signal
- Set/clear functionality:
 - Firmware writes 1 to corresponding bit position(s) to set or to clear GPIO signal(s). This allows multiple firmware processes to toggle GPIO output signals without critical section protection (disable interrupts, program GPIO, re-enable interrupts, to prevent context switching to another process during GPIO programming).
- Separate Input/Output registers:
 - If preferred by firmware, some GPIO output signals can be toggled by direct write to the output register(s) in addition to set/clear.
 - Output register, when read in, reflects output drive status. This, in addition to the input register reflecting pin status this allows wired logic to be implemented.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.1.2.2 GPIO Environment

This section describes the GPIO external connections (environment).

Table 12-8 describes the GPIO I/O signals.

Table 12-8. GPIO I/O Signals

Module Pin	I/O ⁽¹⁾	Description
GPIO_BANK[0-8]_[0-15]	I/O	General-purpose input/output. ⁽²⁾

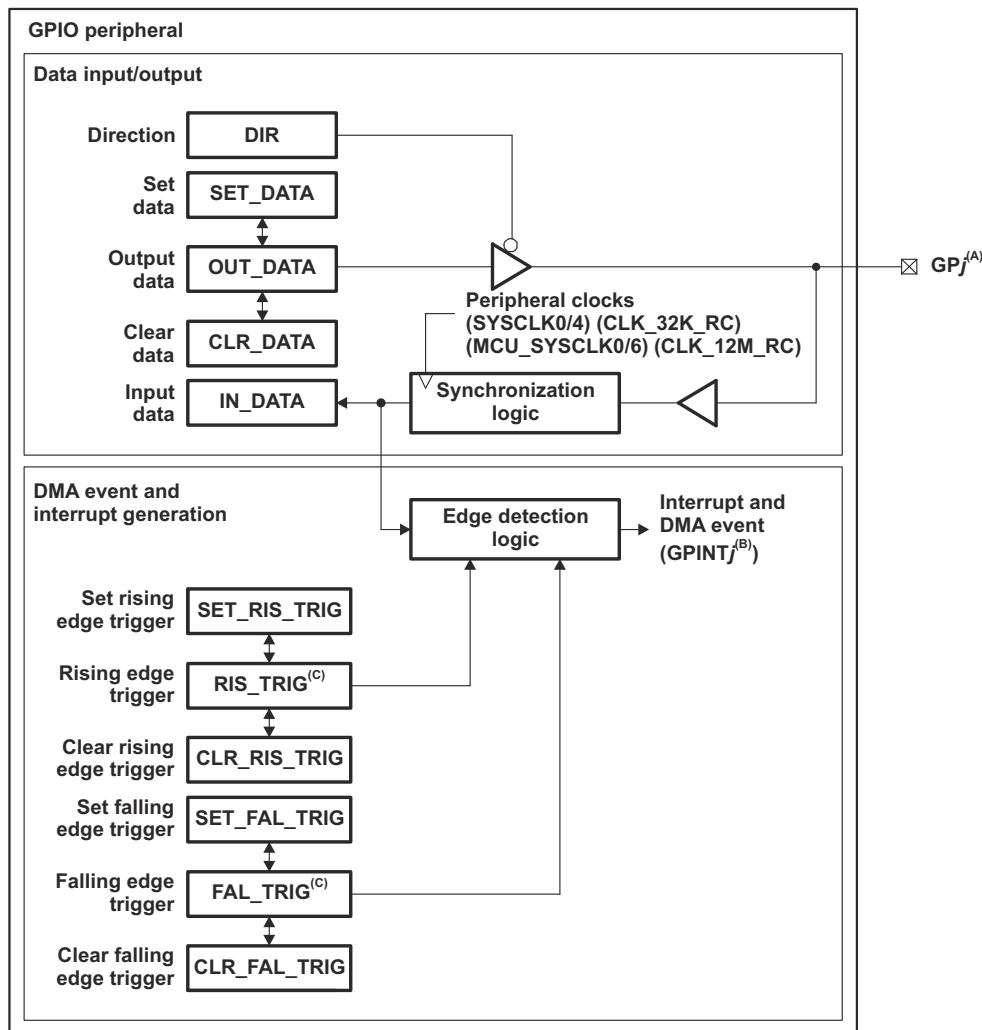

(1) I = Input; O = Output; I/O = Bidirectional

(2) Only GPIOs enabled through from the CTRLMMR_WKUP_PADCONFIG0 to CTRLMMR_WKUP_PADCONFIG93 or from the CTRLMMR_PADCONFIG0 to CTRLMMR_PADCONFIG172 registers for a particular instance can operate on I/O pins. For more information see *Pad Configuration Registers*.

12.1.2.3 GPIO Functional Description

12.1.2.3.1 GPIO Block Diagram

Figure 12-5 shows the general-purpose interface block diagram.

gpio_005

- A. Some of the GPj pins are muxed with other device signals. For details, see the device-specific Datasheet.
- B. All GPINTj can be used as host CPU interrupts and synchronization events to the DMA.
- C. The RIS_TRIG and FAL_TRIG registers are internal to the GPIO module and are not visible to the host CPU.

Figure 12-5. GPIO Block Diagram

12.1.2.3.2 GPIO Function

Each GPIO pin (GPj) can be independently configured as either an input or an output using the GPIO direction registers. The GPIO direction register (DIR) specifies the direction of each GPIO signal. Logic 0 indicates the GPIO pin is configured as output, and logic 1 indicates input.

When configured as output, writing a 0x1 to a bit in the set data register drives the corresponding GPj to a logic-high state. Writing a 0x1 to a bit in the clear data register drives the corresponding GPj to a logic-low state. The output state of each GPj can also be directly controlled by writing to the output data register.

For example, to set GP8 to a logic-high state, the software can perform one of the following:

- Write 100h to the GPIO_SET_DATA01 register.
- Write 0h to the GPIO_DIR01 register to configure as output pin.

- Read in GPIO_OUT_DATA01 register, change bit 8 to 0x1, and write the new value back to GPIO_OUT_DATA01.

To set GP8 to a logic-low state, the software can perform one of the following:

- Write 100h to the GPIO_CLR_DATA01 register.
- Write 0h to the GPIO_DIR01 register to configure as output pin.
- Read in GPIO_OUT_DATA01 register, change bit 8 to 0x0, and write the new value back to GPIO_OUT_DATA01.

Note that writing a 0x0 to bits in the set data and clear data registers does not affect the GPIO pin state.

Also, for GPIO pins configured as input, writing to the set data, clear data, or output data registers does not affect the pin state.

For a GPIO pin configured as input, reading the input data register (IN_DATA) will return the pin state. Reading the SET_DATA register or the CLR_DATA data register will return the value in OUT_DATA, not the actual pin state. The pin state is available by reading the input data register. Note that when the direction is configured as input, the output state is determined by software's programming set/clear/output registers, and may not agree with the pin state, which is driven by an external device.

12.1.2.3.3 GPIO Interrupt and Event Generation

Each GPIO pin (GPj) can be configured to generate a host CPU interrupt (GPINTj) or a synchronization event to the DMA (GPINTj). Configuration is on per-bank basis. Each bit of the BINTEN parameter dictates YES/NO option for each bank. Bit 0 controls bank 0, bit 1 controls bank 1, and so on.

The interrupt can be generated on the rising-edge, falling-edge, or on both edges of the GPIO signal. The edge detection logic is synchronized to the GPIO peripheral clock.

The direction of the GPIO pin does not need to be input when using the pin to generate the interrupt or DMA event. When the GPIO pin is configured as input, transitions on the pin trigger interrupts or DMA events. When the GPIO pin is configured as output, software can toggle the GPIO output register to change the pin state and in turn trigger the interrupt or DMA event.

Note that the direction of the pin need not be input for interrupt generation to work. When the GPIO pin is configured as input, transitions on the pin trigger interrupts. When the GPIO pin is configured as output, firmware can toggle the GPIO output register to change the pin state, and in turn trigger interrupts.

Each interrupt output of GPIO signal are available at the module boundary. Each group of 16 GPIO_INTR_INTj signals also has their masked interrupt outputs ORed together to generate a per bank interrupt, available at the module boundary. The idea is to either connect individual interrupts or per bank interrupts to the system interrupt controller.

12.1.2.3.3.1 Interrupt Enable (per Bank)

The GPIO_BINTEN register provides interrupt enable/disable feature for each bank of 16 GPINT signals.

12.1.2.3.3.2 Trigger Configuration (per Bit)

Two internal registers, RIS_TRIG and FAL_TRIG, specify which edge of the GPj signal generates an interrupt or DMA event. Each bit in these two registers corresponds to a GPj pin. [Table 12-9](#) describes the host CPU interrupt and DMA event generation of GPj pin based on the bit settings of the RIS_TRIG and FAL_TRIG registers.

Table 12-9. GPIO Interrupt and DMA Event Configuration Options

RIS_TRIG Bit n	FAL_TRIG Bit n	Host CPU Interrupt and DMA Event Generation
0	0	GPINTj interrupt and DMA event is disabled
0	1	GPINTj interrupt and DMA event is triggered on falling edge of GPj signal
1	0	GPINTj interrupt and DMA event is triggered on rising edge of GPj signal
1	1	GPINTj interrupt and DMA event is triggered on both rising and falling edge of GPj signal

The RIS_TRIG and FAL_TRIG registers are not directly accessible or visible to the host CPU. These registers are accessed indirectly through four registers: SET_RIS_TRIG, CLR_RIS_TRIG, SET_FAL_TRIG, and CLR_FAL_TRIG. Writing 1 to a bit on the SET_RIS_TRIG register sets the corresponding bit on the RIS_TRIG register. Writing 1 to a bit of the CLR_RIS_TRIG register clears the corresponding bit on the RIS_TRIG register. Writing to the SET_FAL_TRIG and CLR_FAL_TRIG registers works the same way on the FAL_TRIG register.

Reading the SET_RIS_TRIG or CLR_RIS_TRIG register returns the value of the RIS_TRIG register. Reading from the SET_FAL_TRIG and CLR_FAL_TRIG register returns the value of the FAL_TRIG register.

To use the GPIO pins as sources for host CPU interrupts and DMA events, the associated bank interrupt enable register bit in GPIO_BINTEN must also be set to 1. For example, to enable GPIO0_19 (which is in bank 1), GPIO_BINTEN[1] = 1 should be set to enable interrupts for bank 1.

12.1.2.3.3 Interrupt Status and Clear (per Bit)

The INTSTAT registers provide interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding bit position(s). Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

Note

The GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

12.1.2.3.4 GPIO Emulation Halt Operation

The GPIO peripheral is not affected by emulation halts.

12.1.3 Inter-Integrated Circuit (I2C) Interface

This section describes the Inter-Integrated Circuit (I2C) module in the device.

12.1.3.1 I2C Overview

The device contains Inter-Integrated Circuit (I2C) controllers each of which provides an interface between a local host (LH), such as an Arm or a Digital Signal Processor (DSP), and any I2C-bus-compatible device that connects via the I2C serial bus. External components attached to the I2C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I2C interface.

Each multimaster I2C module can be configured to act like a slave or master I2C-compatible device.

Some controllers have dedicated I2C compliant open drain buffers and support high speed mode (up to 3.4 Mbps in 1.8 V mode and up to 400 Kbps in 3.3 V mode). Other controllers are multiplexed with standard LVCMOS I/O, connected to emulate open drain, and support fast mode (up to 400 Kbps in 1.8 V/3.3 V mode). The I2C emulation is achieved by configuring the LVCMOS buffers to output Hi-Z instead of driving high when transmitting logic 1.

For the specific I/O buffer and timing characteristics of the different I2C instances, see the device-specific data sheet.

12.1.3.1.1 I2C Features

Each multicontroller I2C module has the following features:

- Compliant with Philips I2C-bus specification version 2.1
- Supports a standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Supports HS mode (up to 3.4 Mbps) on some instances. See the the device-specific Data Manual for details.
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multicontroller transmitter/target receiver mode
- Multicontroller receiver/target transmitter mode
- Combined controller transmit/receive and receive/transmit mode
- Built-in FIFO for buffered read
- Module enable/disable capability
- Programmable multitarget channel (responds to four separate addresses)
- Programmable clock generation
- 8-bit-wide data access
- Low power consumption
- Support Auto Idle mechanism
- Support Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Wide interrupt capability

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.1.3.1.2 I2C Ports

This section describes I2C ports related to clocks, resets, and hardware requests.

Table 12-13. I2C[0-6] Clocks and Resets

SDA	I/O	I ² C serial data line. Open-drain output buffer.

(1) I = Input; O = Output; I/O = Bidirectional

12.1.3.3 I2C Functional Description

12.1.3.3.1 I2C Block Diagram

Note

DMA mode and SCCB Protocol are not supported on this family of devices.

Figure 12-6 presents the multimaster I2C controller block diagram.

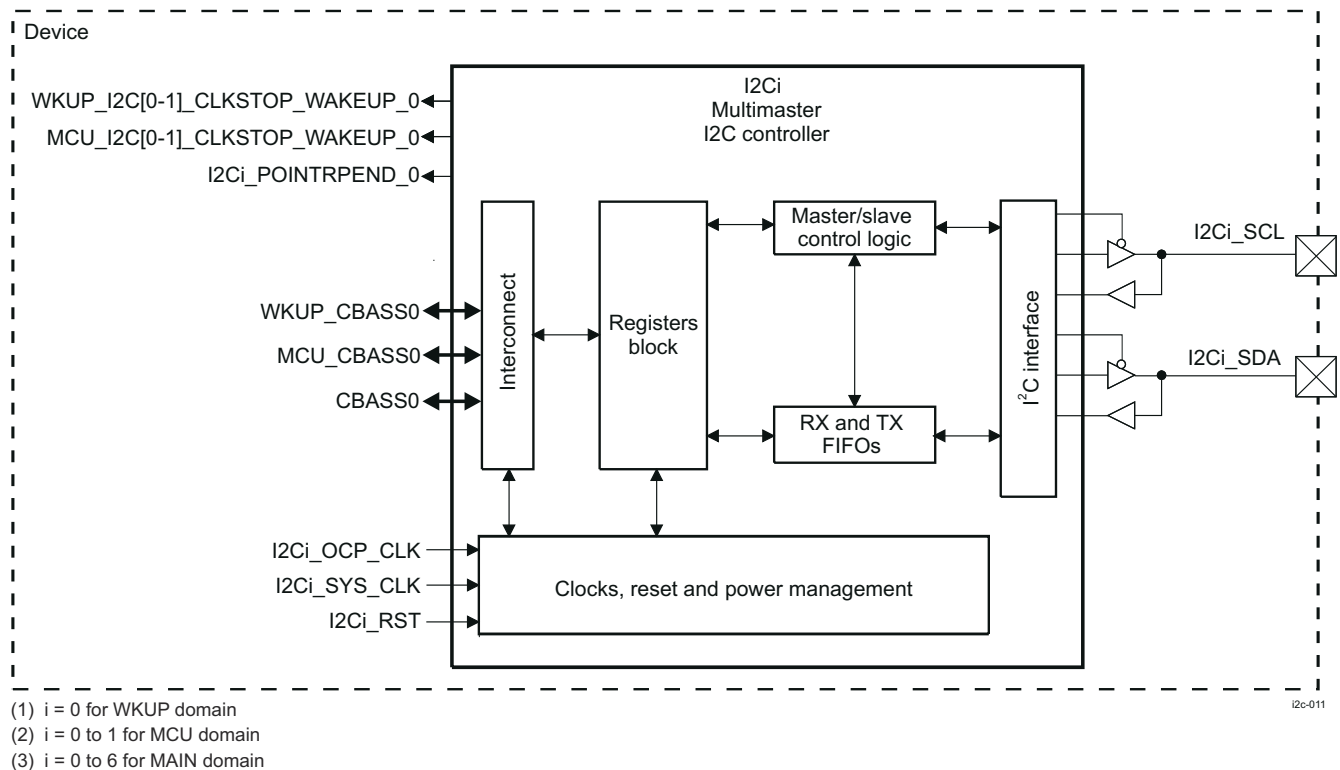

Figure 12-6. I2C Block Diagram

The ten multimaster I2C controllers can be configured in F/S I2C mode or HS I2C mode. The operation mode is selected by configuring the I2C_CON[13-12] OPMODE bit field.

Table 12-16 lists the available operation modes.

Table 12-16. I²C Operation Mode Selection

Operation Mode	Value of I2C_CON[13-12] OPMODE
F/S I ² C	0x0
HS I ² C	0x1
SCCB	0x2
Reserved (not used)	0x3

12.1.3.3.2 I2C Clocks

12.1.3.3.2.1 I2C Clocking

Figure 12-7 shows the I²C clock generation of the I2C controllers.

Figure 12-7. I2C Clock Generation

Each multimaster I2C controller uses the SYS_CLK functional clock in the Device Configuration section. The internal sampling clock INTERNAL_CLK is generated by dividing the functional clock by the I2C_PSC[7-0] PSC bit field value + 1 in F/S mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the SCLL signal is determined by the I2C_SCLL[7-0] SCLL bit field in F/S mode and in the first phase of HS mode; or by the I2C_SCLL[15-8] HSSCLL bit field in the second phase of HS mode.

The high time of the SCLH signal is determined by the I2C_SCLH[7-0] SCLH bit field in F/S mode and in the first phase of HS mode; or by the I2C_SCLH[15-8] HSSCLH bit field in the second phase of HS mode.

Table 12-17 lists the t_{LOW} and t_{high} values in master mode only (in slave mode, the I2C controller does not generate the I2C clock).

Table 12-17. I2C t_{LOW} and t_{high} Values of the I2C Clock

Mode	Clock	t_{Low}	t_{high}
F/S or HS first phase	$INTERNAL_CLK = SYS_CLK / (I2C_PSC[7-0] \text{ PSC bit field} + 1)$	$(I2C_SCLL[7-0] \text{ SCLL bit field value} + 7) \times INTERNAL_CLK \text{ period}$	$(I2C_SCLH[7-0] \text{ SCLH bit field value} + 5) \times I2Ci_INTERNAL_CLK \text{ period}$
HS second phase	SYS_CLK	$(I2C_SCLL[15-8] \text{ HSSCLL bit field value} + 7) \times SYS_CLK \text{ period}$	$(I2C_SCLH[15-8] \text{ HSSCLH bit field value} + 5) \times I2Ci_SYS_CLK \text{ period}$

Note

For HS mode, the I2C_SCLL[15-8] HSSCLL and I2C_SCLL[7-0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2C_SCLH[15-8] HSSCLH and I2C_SCLH[7-0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

Note

The equations in Table 12-17 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at I2C controller outputs. Actual t_{low} and t_{high} periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

CAUTION

During active mode (the I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2C_SCLL and I2C_SCLH registers. Changes may result in unpredictable behavior.

Table 12-18 lists the register values for obtaining the maximum I2C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

Table 12-18. I2C Register Values for Maximum I2C Bit Rates in I2C F/S, I2C HS Modes

	I ² C Mode for			Description
	Standard Mode	Fast Mode	High-Speed Mode	
SYS_CLK frequency (MHz)	96			
OCP_CLK frequency (MHz)	133			
I2C_PSC[7-0] PSC	23	9	1	Prescaler value for F/S and HS modes
INTERNAL_CLK frequency (MHz)	4	9.6	96	
I2C_SCLL[7-0] SCLL	13	7	115	Value for F/S mode and first phase of HS mode
I2C_SCLH[7-0] SCLH	15	5	113	Value for F/S mode and first phase of HS mode
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate
Maximum filter period (ns)	250	104.2	10	
I2C_SCLL[15-8] HSSCLL			12	Values for second phase of HS mode
I2C_SCLH[15-8] HSSCLH			5	Values for second phase of HS mode
HS mode maximum bit rate (Mbps)			3.31	HS mode maximum bit rate
Maximum filter period (ns)			10	

Note

This table presents informative values only for the configuration parameters and the I²C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

Note

For WKUP_I2C0

For MCU_I2C[0-1]

For I2C[0-6]

$I2Ci_INTERNAL_CLK \text{ freq} = I2Ci_SYS_CLK / (PSC + 1)$

$F/S \text{ filter period} = 1 / I2Ci_INTERNAL_CLK$

$HS \text{ filter period} = 1 / I2Ci_SYS_CLK \text{ freq}$

$HS \text{ bit rate} = I2Ci_SYS_CLK \text{ freq} / (HSSCLL + 7 + HSSCLH + 5)$

$FS \text{ bit rate} = I2Ci_INTERNAL_CLK / (SCLL + 7 + SCLH + 5)$

12.1.3.3.2.2 I2C Automatic Blocking of the I2C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I²C clock after the target addressing phase, when the I2C controller is addressed by an external controller device using a certain Own Address.

The release of the I²C clock can be performed independently for each Own Address (I2C_OA, and I2C_OAx registers, where x = 1, 2, 3) by deasserting the corresponding bit in the I2C_SBLOCK register.

12.1.3.3.3 I2C Software Reset

Each multicontroller I2C supports the software reset by accessing the I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2C_CON[15] I2C_EN bit to 0).
2. Set the I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2C_CON[15] I2C_EN bit to 1.
4. Check the I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

Note

The I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multicontroller I2C in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I2C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I2C controller.

The I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2C_CON[15] I2C_EN bit to 1.

12.1.3.3.4 I2C Power Management

[Table 12-19](#) describes power-management features available for the multimaster I2C controllers.

Note

For information about source clock gating, see *Power*, in the *Device Configuration*.

Note

Some of the I2C features described in this section may not be supported on this family of devices. For more information, see *I2C Not Supported Features*.

Table 12-19. I2C Local Power-Management Features

Feature	Registers	Description
Clock auto gating	I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2C_SYSC[4-3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2C_SYSC[9-8] CLOCKACTIVITY	For configuration details, see Table 12-20 .
Global wake-up enable	I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

Table 12-20. I2C Clock Activity Settings

I2C_SYSC[9-8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	OCP_CLK	SYS_CLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; Functional clock is enabled
01	ON	OFF	Functional clock is disabled; Interface clock is enabled
11	ON	ON	Both clocks are enabled.

12.1.3.3.5 I2C Interrupt Requests

The I2C controller must allocate a minimum of five registers for interrupts.

- Interrupt Raw Status (I2C_IRQSTATUS_RAW)
- Interrupt Enabled Status (I2C_IRQSTATUS)
- Interrupt Enable Set (I2C_IRQENABLE_SET)
- Interrupt enable Clear (I2C_IRQENABLE_CLR)
- End of interrupt (I2C_EOI)

End of Interrupt (I2C_EOI) is used by software to trigger an interrupt service completion.

Table 12-21 lists the event flags, and their mask, that can cause module interrupts.

Table 12-21. I2C Events

Event Flag	Event Unmask	Event Mask	Description
I2C_IRQSTATUS[0] AL	I2C_IRQENABLE_SET[0] AL_IE	I2C_IRQENABLE_CLR[0] AL_IE	Arbitration lost. This bit is automatically set by the hardware when it loses the arbitration in controller transmit mode, an interrupt is signaled to the host.
I2C_IRQSTATUS[1] NACK	I2C_IRQENABLE_SET[1] NACK_IE	I2C_IRQENABLE_CLR[1] NACK_IE	No acknowledgement. Bit is set when No Acknowledge is received, an interrupt is signaled to the host.
I2C_IRQSTATUS[2] ARDY	I2C_IRQENABLE_SET[2] ARDY_IE	I2C_IRQENABLE_CLR[2] ARDY_IE	Register access ready. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the host.
I2C_IRQSTATUS[3] RRDY	I2C_IRQENABLE_SET[3] RRDY_IE	I2C_IRQENABLE_CLR[3] RRDY_IE	Receive data ready. Set to 1 by core when in receiver mode, a new data can be read. An interrupt is signaled to the host.
I2C_IRQSTATUS[4] XRDY	I2C_IRQENABLE_SET[4] XRDY_IE	I2C_IRQENABLE_CLR[4] XRDY_IE	Transmit data ready. Set to 1 by core when transmitter is ready for new data. An interrupt is signaled to the host.
I2C_IRQSTATUS[5] GC	I2C_IRQENABLE_SET[5] GC_IE	I2C_IRQENABLE_CLR[5] GC_IE	General call. Set to 1 by core when General Call address was detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[6] STC	I2C_IRQENABLE_SET[6] STC_IE	I2C_IRQENABLE_CLR[6] STC_IE	Start condition detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[7] AERR	I2C_IRQENABLE_SET[7] AERR_IE	I2C_IRQENABLE_CLR[7] AERR_IE	Bus Access Error. An interrupt is signaled to the host.
I2C_IRQSTATUS[8] BF	I2C_IRQENABLE_SET[8] BF_IE	I2C_IRQENABLE_CLR[8] BF_IE	Bus free. An interrupt is signaled to the host.
I2C_IRQSTATUS[9] AAS	I2C_IRQENABLE_SET[9] AAS_IE	I2C_IRQENABLE_CLR[9] AAS_IE	Address recognized as target. An interrupt is signaled to the host.
I2C_IRQSTATUS[10] XUDF	I2C_IRQENABLE_SET [10] XUDF_IE	I2C_IRQENABLE_CLR[10] XUDF_IE	Transmit underflow. An interrupt is signaled to the host.
I2C_IRQSTATUS[11] ROVR	I2C_IRQENABLE_SET [11] ROVR_IE	I2C_IRQENABLE_CLR[11] ROVR_IE	Receive overrun. An interrupt is signaled to the host.
I2C_IRQSTATUS[12] BB	N/A	N/A	Bus busy indicator
I2C_IRQSTATUS[13] RDR	I2C_IRQENABLE_SET [13] RDR_IE	I2C_IRQENABLE_CLR[13] RDR_IE	Receive draining. An interrupt is signaled to the host.
I2C_IRQSTATUS[14] XDR	I2C_IRQENABLE_SET [14] XDR_IE	I2C_IRQENABLE_CLR[14] XDR_IE	Transmit draining. An interrupt is signaled to the host.

12.1.3.3.6 I2C Programmable Multitarget Channel Feature

This feature allows each multicontroller I2C to be addressed using four separate Own Addresses configured in the I2C_OA and I2C_OAx registers (where x = 1, 2, 3). An additional register (I2C_ACTOA) is used to indicate to the LH which address is used by the external controller to communicate with the I2C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2C_CON[7] XOA0, I2C_CON[6] XOA1, I2C_CON[5] XOA2, or I2C_CON[4] XOA3).

12.1.3.3.7 I2C FIFO Management

Each multicontroller I2C implements two internal 8-bit FIFOs, the RX and TX FIFOs.

The depth of the RX and TX FIFOs can be checked by reading the I2C_BUFSTAT[15-14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

12.1.3.3.7.1 I2C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2C_IRQENABLE_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2C_BUF[13-8] RXTRSH bit field value + 1 for the RX FIFO or the I2C_BUF[5-0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I2C controller in receive mode and/or from any source to the I2C controller FIFO in transmit mode).

Figure 12-8 and Figure 12-9 show receive and transmit operations, respectively, from a FIFO management point of view.

i2c-013

Figure 12-8. I2C Receive FIFO Interrupt Request Generation

In Figure 12-8, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2C_BUF[13-8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

i2c-014

Figure 12-9. I2C Transmit FIFO Interrupt Request Generation

In [Figure 12-9](#), the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2C_IRQENABLE_CLR [4] XRDY_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF[5-0] TXTRSH + 1 or I2C_BUF[5-0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see [Section 12.1.3.3.7.3, Draining Feature \[I2C Mode Only\]](#)).

Note

In target transmit mode (the I2C_CON[10] MST bit is cleared and the I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external controller can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in target transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2C_BUF[6] TXFIFO_CLR bit.

12.1.3.3.7.2 I2C FIFO Polling Mode

In FIFO polling mode (the I2C_IRQENABLE_SET[4] XRDY_IE and I2C_IRQENABLE_SET[3] RRDY_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2C_IRQSTATUS_RAW[4] XRDY and the I2C_IRQSTATUS_RAW[3] RRDY bits (the I2C_IRQSTATUS_RAW[13] RDR and I2C_IRQSTATUS_RAW[14] XDR bits can also be polled if the draining feature is enabled). The I2C_IRQSTATUS_RAW[4] XRDY and I2C_IRQSTATUS_RAW[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

12.1.3.3.7.3 I2C Draining Feature

Note

DMA mode and SCCB Protocol are not supported on this family of devices.

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2C_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold and the I2C_BUF[5-0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2C_IRQSTATUS_RAW[7] AERR bit.

The draining mechanism generates an interrupt using the I2C_IRQSTATUS_RAW[13] RDR or I2C_IRQSTATUS_RAW[14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2C_BUFSTAT[13-8] RXSTAT or I2C_BUFSTAT[5-0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (controller or target), if the RX FIFO threshold (the I2C_BUF[13-8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I²C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2C_IRQSTATUS_RAW[13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2C_BUFSTAT[13-8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2C_BUFSTAT[13-8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In controller transmit mode, if the TX FIFO threshold (the I2C_BUF[5-0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2C_IRQSTATUS_RAW[14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2C_BUFSTAT[5-0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2C_BUFSTAT[5-0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In controller mode, the LH can alternately not check the values of the I2C_BUFSTAT[5-0] TXSTAT and I2C_BUFSTAT[13-8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2C_CNT[15-0] DATACOUNT bit field value modulo I2C_BUF[13-8] RXTRSH or I2C_BUF[5-0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2C_IRQENABLE_SET[14] XDR_IE or I2C_IRQENABLE_SET[13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2C_BUF[5-0] TXTRSH bit field value + 1 for the TX threshold or the I2C_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold).

12.1.3.3.8 I2C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For standard mode (for example, the I2C_PSC[7-0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2C_I2C_PSC[7-0] PSC bit field.

12.1.3.3.9 I2C System Test Mode

A system test mode is available for multicontroller I2C module testing. This mode is enabled by setting the I2C_SYSTEST[15] ST_EN bit to 1. When this bit is cleared to 0, the I2C controller is configured in normal operation mode.

In system test mode, the I2C_SYSTEST[13-12] TMODE bit field selects the type of test. [Table 12-22](#) lists the tests available for the multicontroller HS I2C controllers.

Table 12-22. I2C List of Tests

I2C_SYSTEST[13-12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of SCL serial clock line	The SCL line is driven with a permanent clock as if controlled with the parameters set in the I2C_PSC, I2C_SCLL, and I2C_SCLH registers.
11	Loop-back mode + SCL/SDA I/O	In controller transmit mode only, data transmitted out of the I2C_DATA register (write action) is received in the same I2C_DATA register through an internal path through the FIFO buffers. The interrupt request is normally generated if it is enabled. Moreover, the SCL and SDA are controlled with the I2C_SYSTEST[3-0] bits.

Note

When the I2C_SYSTEST[13-12] TMODE bit field is set to 11, the I2C controller must be configured in I²C F/S (I2C_CON[13-12] OPMODE set to 00) or I²C HS mode (I2C_CON[13-12] OPMODE set to 01).

Note

In normal operation mode (the I2C_SYSTEST[15] ST_EN bit cleared to 0), the I2C_SYSTEST[3-0] bits that control the SCL, SDA lines in system test mode are read-only bits.

In system test mode (the I2C_SYSTEST[15] ST_EN bit set to 1), the I2C_IRQSTATUS_RAW[4] XRDY, I2C_IRQSTATUS_RAW[3] RRDY, I2C_IRQSTATUS_RAW[10] XUDF, I2C_IRQSTATUS_RAW[11] ROVR, I2C_IRQSTATUS_RAW[2] ARDY and I2C_IRQSTATUS_RAW[1] NACK status bits can be set to 1 when the I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2C_SYSTEST[11] SSB bit to 0 does not clear the I2C_IRQSTATUS_RAW bits to 0. The I2C_IRQSTATUS_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

12.1.3.4 I2C Programming Guide

12.1.3.4.1 I2C Low-Level Programming Models

12.1.3.4.1.1 I2C Programming Model

This section describes the programming model of the multimaster I2C controllers configured in I²C mode.

12.1.3.4.1.1.1 Main Program

12.1.3.4.1.1.1.1 Configure the Module Before Enabling the I2C Controller

Before enabling the I2C controller, perform the following steps:

1. Enable the functional and interface clocks (see *WKUP I2C Clocks and Resets*, *MCU_I2C Clocks and Resets*, and *I2C Clocks and Resets*).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2C_PSC[7-0] PSC bit field. This value depends on the frequency of the functional clock (SYS_CLK).
3. Program the I2C_SCLL[7-0] SCLL and I2C_SCLH[7-0] SCLH bit fields to obtain a bit rate of 100 Kbps or 400 Kbps. These values depend on the internal sampling clock frequency (see [Table 12-17](#)).
4. (Optional) Program the I2C_SCLL[15-8] HSSCLL and I2C_SCLH[15-8] HSSCLH bit fields to obtain a bit rate of 400 Kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 12-17](#)).
5. Configure the Own Address of the I2C controller by storing it in the I2C_OA register. Up to four Own Addresses can be programmed in the I2C_OA and I2C_OAx registers (where x = 1, 2, 3) for each I2C controller.

Note

For a 10-bit address, set the corresponding expand Own Address bit in the I2C_CON register.

6. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2C_BUF[5-0] TXTRSH bit field to (TX threshold – 1) and the I2C_BUF[13-8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
7. Take the I2C controller out of reset by setting the I2C_CON[15] I2C_EN bit to 1.

12.1.3.4.1.1.1.2 Initialize the I2C Controller

To initialize the I2C controller, perform the following steps:

1. Configure the I2C_CON register:
 - For controller or target mode, set the I2C_CON[10] MST bit (0: target; 1: controller).
 - For transmitter or receiver mode, set the I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2C_IRQENABLE_SET register to 1 (the I2C_IRQENABLE_SET [4] XRDY_IE bit for the transmit interrupt, the I2C_IRQENABLE_SET [3] RRDY bit for the receive interrupt).

12.1.3.4.1.1.1.3 Configure Target Address and the Data Control Register

In controller mode, configure the target address register by programming the I2C_SA[9-0] SA bit field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2C_CNT[15-0] DCOUNT bit field.

Note

For a 10-bit address, set the I2C_CON[8] XSA bit to 1.

12.1.3.4.1.1.1.4 Initiate a Transfer

Poll the I2C_IRQSTATUS_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2C_CON[0] STT and I2C_CON[1] STP bits. To initiate a transfer, the I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2C_CON[1] STP bit to 1.

12.1.3.4.1.1.5 Receive Data

Poll the I2C_IRQSTATUS_RAW [3] RRDY bit, or use the RRDY interrupt (the I2C_IRQENABLE_SET [3] RRDY_IE bit must be set to 1) to read the receive data in the I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2C_BUF[13-8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2C_IRQENABLE_SET [13] RDR_IE bit to 1).

Note

In receive mode only, the I2C_IRQSTATUS_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I2C controller simply holds SCL to low to prevent other bytes from being received.

The I2C_IRQSTATUS_RAW[7] AERR bit is set to 1 when a read access is performed in the I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

12.1.3.4.1.1.6 Transmit Data

Poll the I2C_IRQSTATUS_RAW [4] XRDY bit, or use the XRDY interrupt (the I2C_IRQENABLE_SET [4] XRDY_IE bit must be set to 1) to write data to the I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2C_BUF[5-0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2C_IRQENABLE_SET [14] XDR_IE bit to 1).

Note

In transmit mode only, the I2C_IRQSTATUS_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In controller transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2C_CNT[15-0] DCOUNT bit field is not 0).

In target transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I2C controller device still requests data bytes to be read.

The I2C_IRQSTATUS_RAW [7] AERR bit is set to 1 when a write access is performed in the I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

12.1.3.4.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2C_IRQSTATUS_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2C_IRQSTATUS_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2C_IRQSTATUS_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2C_IRQSTATUS_RAW [3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2C_IRQSTATUS_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2C_IRQSTATUS_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2C_IRQSTATUS_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2C_IRQSTATUS_RAW [7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2C_IRQSTATUS_RAW [8] BF bit) and resolve accordingly.

12.1.3.4.1.1.3 Programming Flow-Diagrams

Figure 12-10 through Figure 12-16 are procedure flow charts for programming the F/S and HS I2C modes.

i2c-018

Figure 12-10. I2C Setup Procedure

- The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C_IRQSTATUS register.
- Reprogram the registers means: I2C_CON[11] STB and/or I2C_CON[10] MST bit and/or I2C_SA[9-0] SA register and/or I2C_CNT[15-0] DCOUNT register and/or I2C_CON[0] STT bit and/or I2C_CON[1] STP bit.

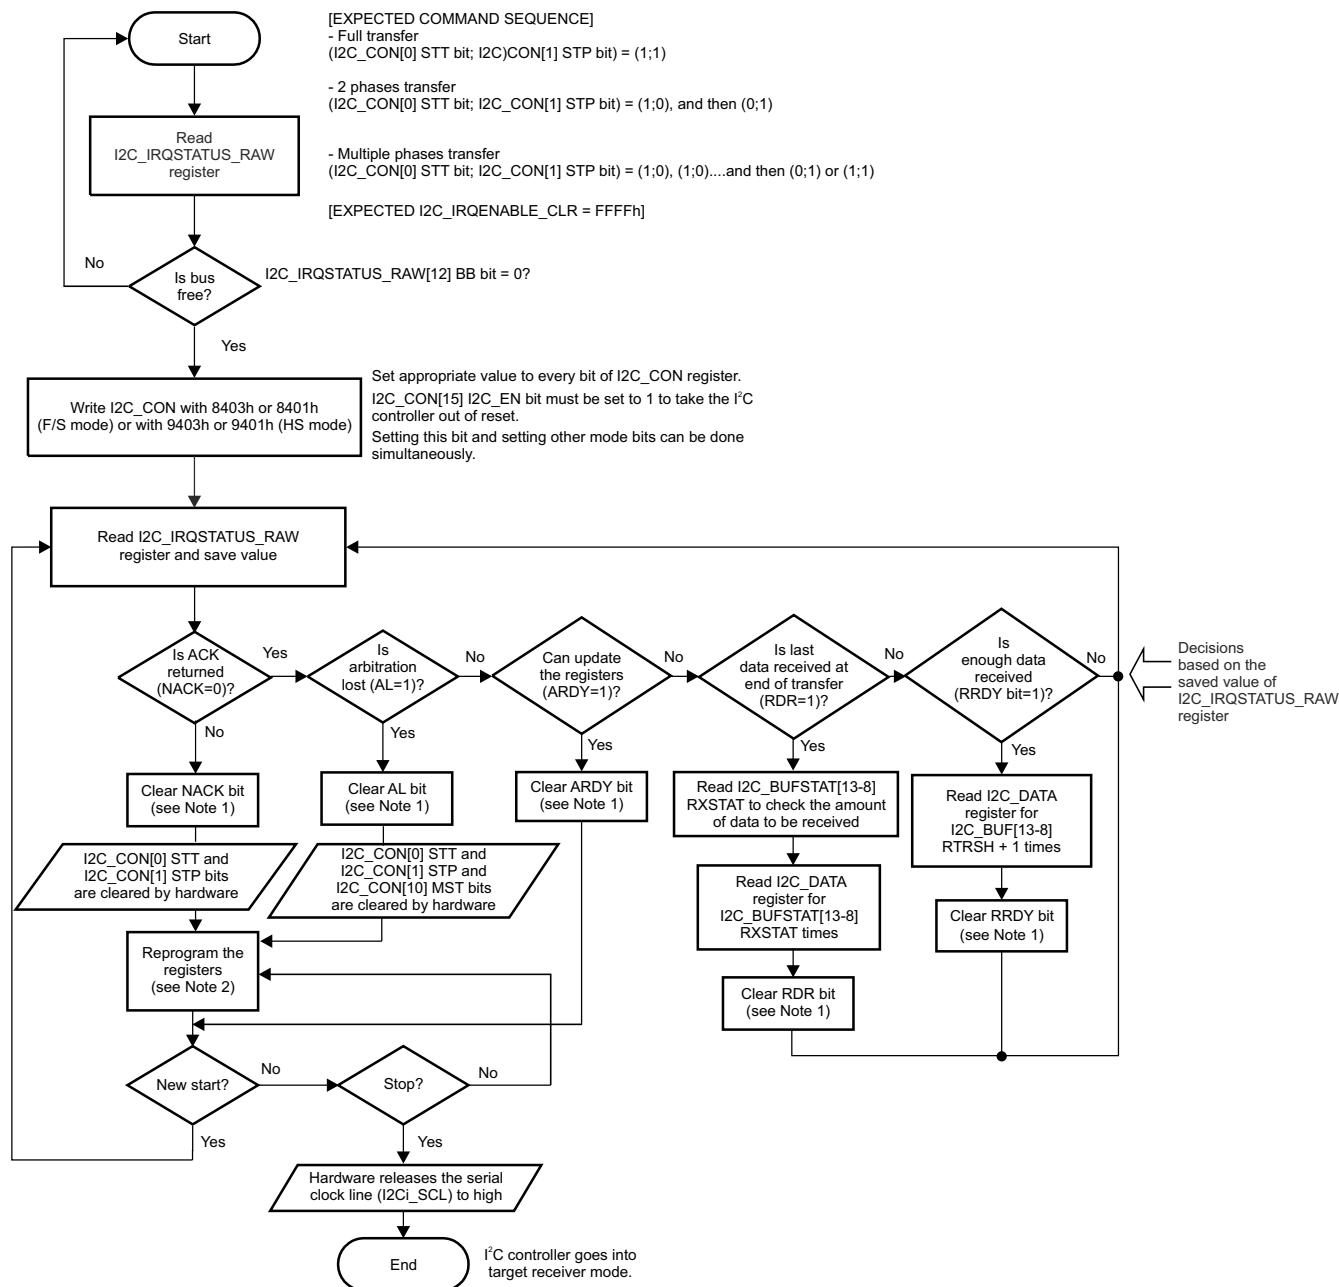

Figure 12-11. I2C Controller Transmitter Mode, Polling Method, in F/S and HS Modes

Note

The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

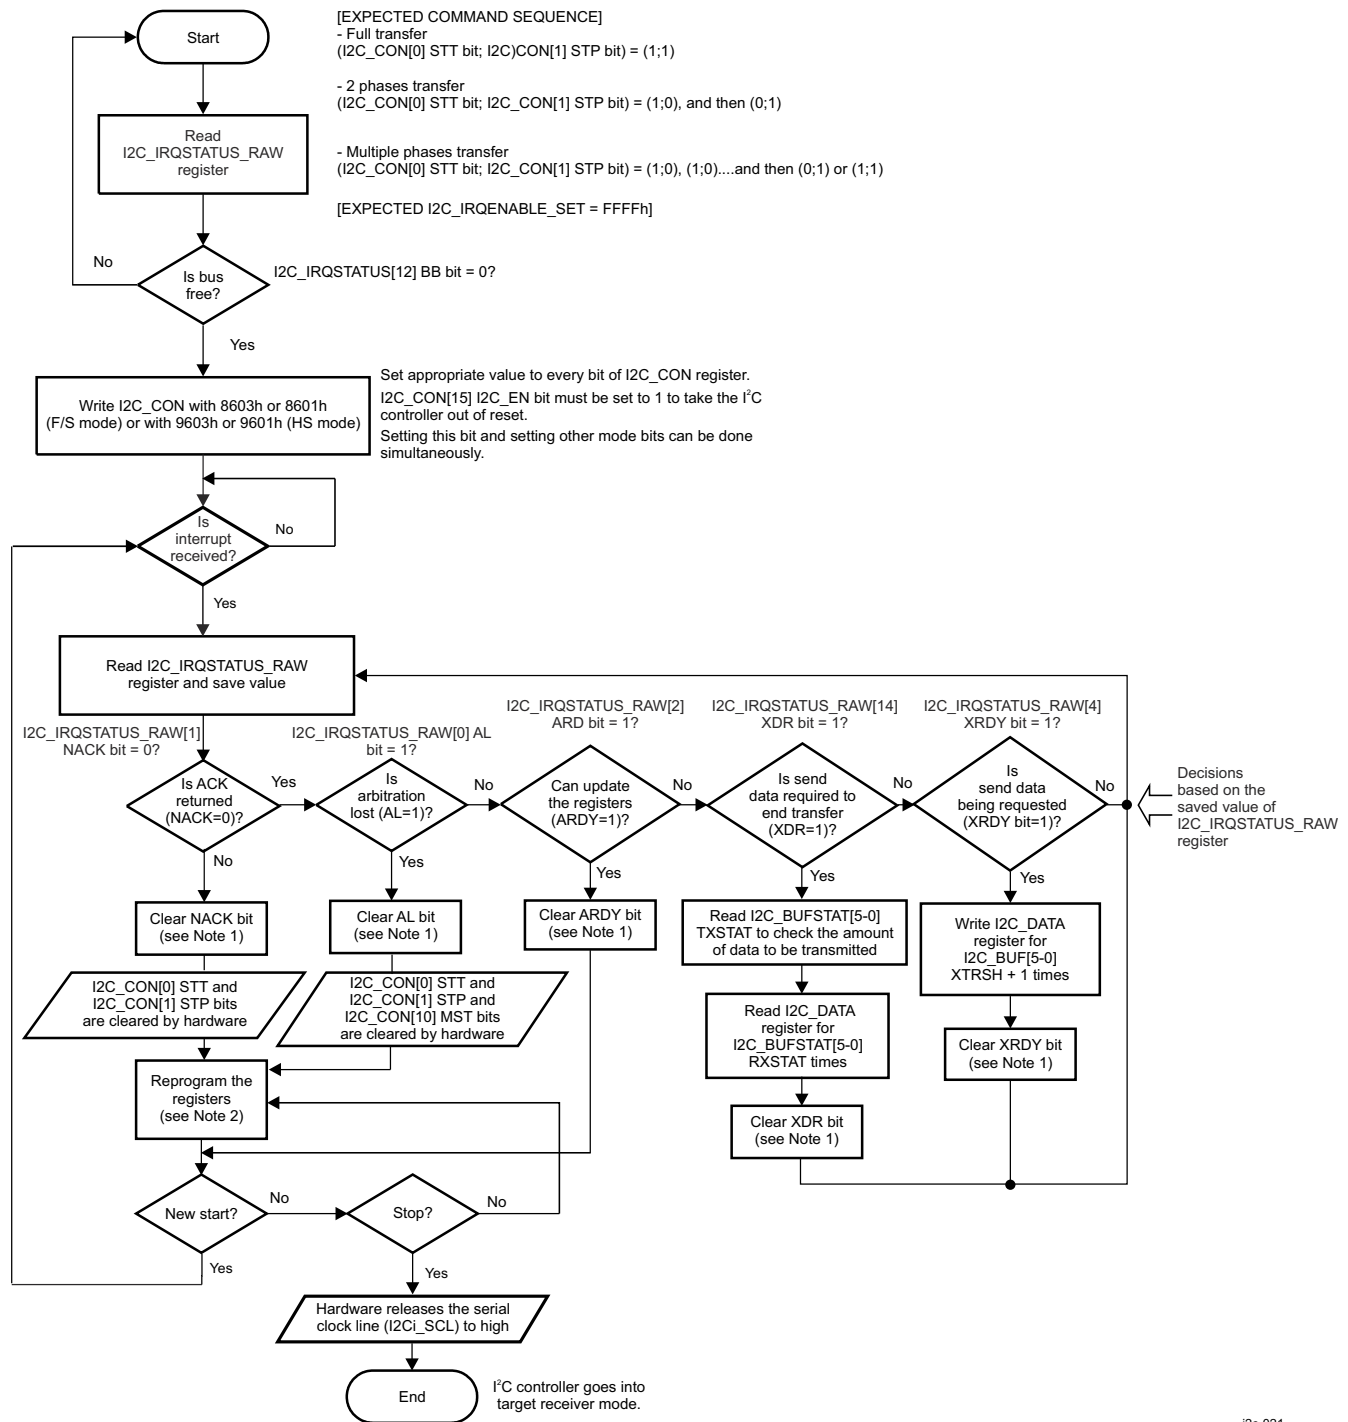

Note

In HS mode, the Sr condition and clock frequency switching are automatically generated by the multicontroller I2C.

- A. The NACK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2C_IRQSTATUS register.
- B. Reprogram registers means: I2C_CON[11] STB and/or I2C_CON[10] MST bit and/or I2C_SA[9-0] SA register and/or I2C_CNT[15-0] DCOUNT register and/or I2C_CON[0] STT bit and/or I2C_CON[1] STP bit.

12.1.4 Improved Inter-Integrated Circuit (I3C) Interface

This section describes the Improved Inter-Integrated Circuit (I3C) module in the device.

12.1.4.1 I3C Overview

The device contains Improved Inter-Integrated Circuit (I3C) an interface between a local host (LH), such as an Arm, and any I3C-bus-compatible device that connects via the I3C serial bus.

For the specific I/O timing characteristics of the I3C , see the device-specific data sheet.

12.1.4.1.1 I3C Features

I3C module has the following features:

- Communication Modes:
 - Single Data Rate (SDR) mode
 - High Data Rate – Dual Data Rate (HD-DDR) mode
- Bus Modes:
 - Pure Bus Mode (supports only I3C devices). Maximum supported frequency is 10.375 MHz
- Master and Multi-Master modes
- Common Command Codes (CCC)
- Bus Enumeration and Discovery:
 - Slaves implement standardized characteristics registers that can be queried by the master after power up to enumerate the devices attached to the bus.
- Hot-Join capability:
 - A slave device can be powered on and join the bus after initial enumeration.
- In Band Interrupts (IBI):
 - Slave devices request interrupts through the I3C bus rather than with separate side-band signals. This reduces the total IO count of the SoC as well as PCB routing.
- Dynamic Address Assignment (DAA):
 - The master can assign each slave device an address during configuration. This supports IBI because interrupt priority among slaves is arbitrated with the same address arbitration scheme that is used for all communication.
- Static Addressing (SA)
- FIFO Buffers:
 - CMD Queueing out going commands:
 - CMD0_FIFO stores the least significant half-word of the command
 - CMD1_FIFO stores the most significant half-word of the command
 - TXFIFO stores data transmitted with each command
 - RXFIFO stores data received as command response
 - IBI_DATA_FIFO stores data received as part of the in-band-interrupt transfer (IBI can transfer 0, 1, or N bytes of data payload depending on the slave)
- Immediate high priority command queue
- Registers to store the parameters for the response to an IBI interrupt from a number of slaves:
 - Each register holds the slave address and appropriate response type and payload length information for two different slaves, so that the controller can process in band interrupts without CPU intervention.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.1.4.1.2 I3C Ports

Table 12-23. I3C0 Clocks and Resets

Interrupt Requests		
Module Interrupt Signal	Description	Type
I3C_I3C_INT_0	I3C interrupt request	Level
I3C_PCLK_ECC_UNCORR_LVL_0	I3C PCLK ECC interrupt request	Level
I3C_SCLK_ECC_UNCORR_LVL_0	I3C SCLK ECC interrupt request	Level
I3C_I3C_NONFATAL_INT_0	I3C non fatal interrupt request	Level
I3C_I3C_FATAL_INT_0	I3C fatal interrupt request	Level

12.1.4.2 I3C Environment

This section describes the I3C external connections (environment).

[Table 12-25](#) describes the I3C I/O signals.

Table 12-25. I3C I/O Signals

Module Pin	I/O ⁽¹⁾	Description
SCL	I/O	I ³ C serial clock line. Emulated open-drain output buffer.
SDA	I/O	I ³ C serial data line. Emulated open-drain output buffer.
SDAPULLEN	O	I ³ C data pull enable. ⁽²⁾

(1) I = Input; O = Output; I/O = Bidirectional

(2) Enable buffer/switch for open drain class pull-up, enabled during open drain mode.

12.1.4.3 I3C Functional Description

12.1.4.3.1 I3C Block Diagram

Figure 12-17 presents the I3C controller block diagram.

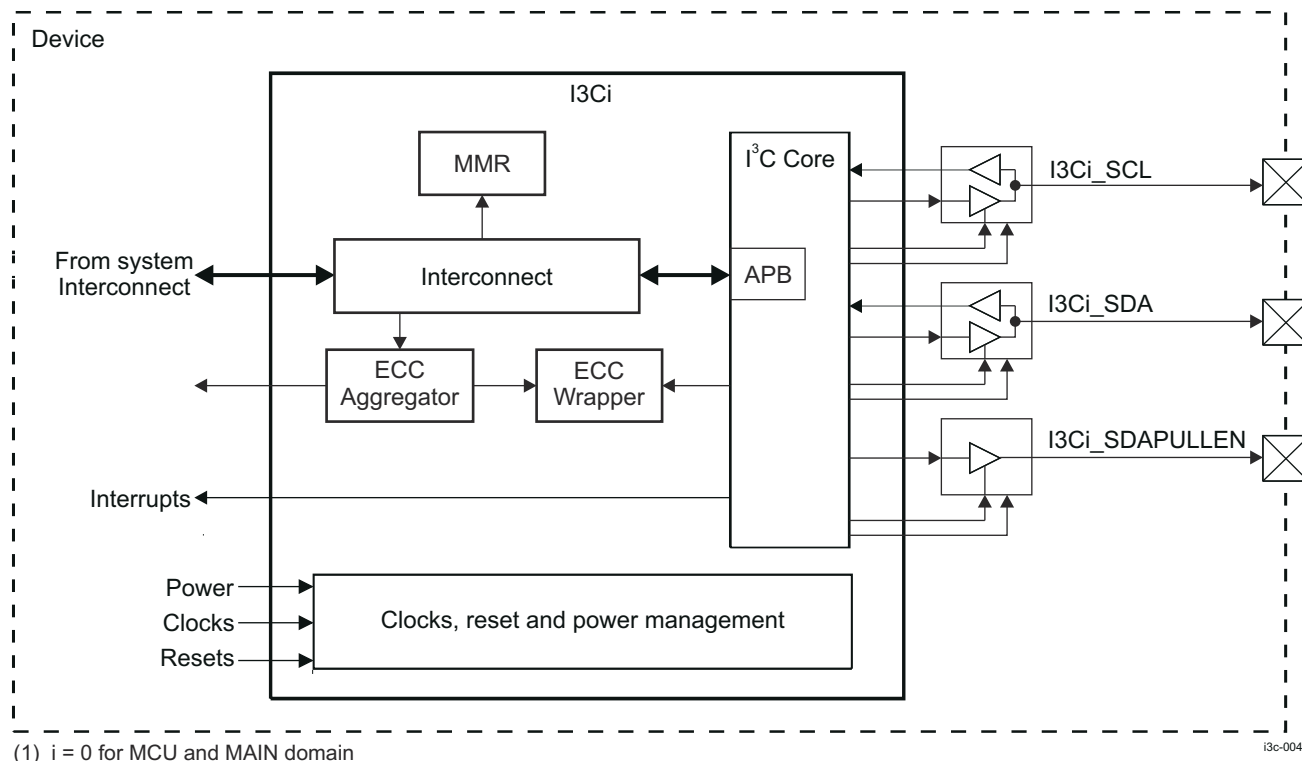

Figure 12-17. I3C Block Diagram

The two I3C controllers can be configured in SDR I3C mode or HD-DDR I3C mode. Default operation mode is SDR mode.

Table 12-26 lists the available operation modes.

Table 12-26. I3C Operation Mode Selection

Operation Mode	Value of I3C_CMD0_FIFO[31] IS_DDR
SDR I3C	0x0
HD-DDR I3C	0x1

12.1.4.3.2 I3C Clock Configuration

The I3C controller allows to program time base for SCL clock generation. Programmable frequency dividers are provided for I3C messaging modes independently. Based on type of messaging that is processed, one of the fields placed in I3C_PRESCAL_CTRL0 register is used to establish constant ratio between the clocks and SCL clock for all messaging modes. I3C messaging uses the value of I3C field in I3C_PRESCAL_CTRL0 register, and is combined with the frequency of inputs. In order to handle timing requirements specified for I3C slaves I3C_PRESCAL_CTRL1 register is provided.

Programming the prescalers should be performed prior to enabling I3C controller with I3C_CTRL[31] DEV_EN bit.

12.1.4.3.2.1 Setting Base Frequencies

To obtain desired base frequency of SCL signal for SDR/HDR I3C messaging (I3C_FREQ) the I3C_PRESCAL_CTRL0[9-0] I3C bit-field should be programmed with value defined by the following equation:

Figure 12-18. I3C Base Frequency

Programming the prescalers must be performed prior to enabling I³C Master controller with I3C_CTRL[31] DEV_EN bit in the control register.

In all timing schemes, the base frequency resulting from prescalers corresponds directly to the duration of the high level of the SCL line which takes always 50% of the base period. Depending on various conditions, the duration of low level is extended beyond the base period as necessary.

There is a specific relationship between SCL frequency and system clock frequency, which requires system clock to have a multiple of four cycles per each SCL period. Thus the selection of system clock frequency must be done with caution, since only specific frequencies will allow configuring SCL to fit into desired bandwidth.

Table 12-27 presents achievable SCL frequencies for exemplary set of system clock frequency values.

Table 12-27. Achievable SCL Frequencies

frequency	I3C_PRESCAL_CTRL0[9-0] I3C	Actual frequencies
100 MHz	0x2	8.33 MHz
133 MHz	0x3	8.313 MHz
166 MHz	0x3	10.375 MHz
200 MHz	0x4	10 MHz

12.1.4.3.2.2 Asymmetric Push-Pull SCL Timing

In case of I³C messaging, asymmetric generation pattern for driving SCL can be enabled. The main purpose for this feature is supporting I3C slaves that are not capable to use maximal SCL frequency during private read/write data transfers. Host can recognize limited speed device by examining value of I3C_DEV_IDn_RR2[15-8] bit-field for n = 0 to 11. Maximum frequency supported by slave can be retrieved by GETMSCL command. The low period of SCL is extended by the value programmed in I3C_PRESCAL_CTRL1[15-8] PP_LOW bit-field, which can be calculated using the following equation:

Figure 12-19. SCL Asymmetric Push-Pull

The I3C_PRESCAL_CTRL1[15-8] PP_LOW resolution is set to ¼ of SCL period. The high period of the SCL remains unchanged and is equal to half period of I³C frequency.

The low period used in push-pull mode for slaves with limited SCL capability results from following equation:

$$SCL_LOW = I3C_PRESCAL_CTRL1[15-8] PP_LOW \times \frac{T}{4}$$

i3c_014

Where:

SCL_LOW: SCL low period.
T: base SCL period.

Figure 12-20. SCL Asymmetric Push-Pull Actual Low Period

12.1.4.3.2.3 Open-Drain SCL Timing

In open-drain mode, due to protocol requirement, low period cannot be shorter than 160ns to support slowly rising SDA line. To fulfill this constrain in I³C SDR mode, the low period must be always extended beyond the value resulting from the base I³C frequency. The low period of SCL is extended by the value programmed in I3C_PRESCAL_CTRL1[7-0] OD_LOW bit-field, which can be calculated using the following equation:

Figure 12-21. SCL Open-Drain Low Period

The I3C_PRESCAL_CTRL1[7-0] OD_LOW bit-field resolution is set to ¼ of SCL period. The high period remains unchanged and is equal to half-period of I³C frequency.

The actual SCL low period used in open drain mode results from the following equation:

$$\text{SCL_LOW} = \text{I3C_PRESCL_CTRL1}[7-0] \text{ OD_LOW} \times \frac{T}{4}$$

i3c_015

Where:

SCL_LOW: SCL low period.

T: base SCL period.

Figure 12-22. SCL Open-Drain Actual Low Period

12.1.4.3.2.4 Changing Programmed Frequencies

Since SCL clock is derived, in order to change the SCL timing for any mode or to keep current I³C bus timing, the following procedure should be used:

1. Disable the I3C controller by setting the I3C_CTRL[31] DEV_EN bit to 0.
2. Adjust to the new frequency if necessary, avoiding any glitches during change.
3. Reprogram the prescaler registers to achieve desired I³C timing.
4. Enable the core by setting the I3C_CTRL[31] DEV_EN bit to 1.

12.1.4.3.3 I3C Interrupt Requests

The I3C controller has two sets of five interrupt registers:

- Interrupt Enable Register (I3C_MST_IER)
- Interrupt Disable Register (I3C_MST_IDR)
- Interrupt Mask Register (I3C_MST_IMR)
- Interrupt Clear Register (I3C_MST_ICR)
- Interrupt Status Register (I3C_MST_ISR)

After reset, status (I3C_MST_ISR) and mask (I3C_MST_IMR) registers both read zeroes, so all interrupts are disabled. CPU handles interrupts by several typical operations:

- To activate an interrupt, interrupt enable register (I3C_MST_IER) should be programmed with 0x1 on bit positions corresponding to interrupts sources which should be signaled to CPU. This interrupt mask is written to I3C_MST_IMR and defines which sources will be propagated.
- After receiving interrupt, I3C_MST_ISR should be read to identify the interrupt source. Since I3C_MST_ISR is always updated by all interrupt sources regardless of I3C_MST_IMR, the I3C_MST_ISR value should be compared to the programmed mask (stored in software or read from I3C_MST_IMR) as it can contain other flags which were not propagated. Interrupt handler should clear flag which triggered interrupt in I3C_MST_ISR by writing 0x1 to corresponding bits of I3C_MST_ICR. It is crucial for correct interrupt source identification to read status, apply mask and clear current interrupt flag before another (from the same or different source) interrupt can occur, so these actions should be executed at the beginning of the interrupt handler routine.
- If during operation additional interrupt sources need to be enabled, clearing their flags prior to enabling is necessary to avoid false signaling of events which occurred earlier.
- To disable interrupt source anytime during operation, corresponding bit in interrupt disable register (I3C_MST_IDR) should be programmed with 0x1, which in turn clears corresponding bit in I3C_MST_IMR, disabling interrupt source.

12.1.4.3.4 I3C Power Configuration

Before I3C controller is put into operation, several settings need to be adjusted after cycling the power on. The general settings collected in I3C_CTRL register. For most common usage scheme, two fields are the most important:

1. I3C_CTRL[31] DEV_EN bit allows enabling and disabling the I³C bus controller. It must be enabled before any I³C bus message is initiated, however following settings need to be programmed prior to enabling controller:
 - a. Bus Mode (Only Pure Bus Mode is supported)
 - b. SCL Divider prescalers (See *I3C Clock Configuration*)
 - c. Devices Retaining Registers (See *I3C Retaining Registers Space*)

During normal operation the controller should stay enabled. Before disabling, the I3C_MST_STATUS0[18] IDLE should be examined to confirm that no bus operation is pending.

2. I3C_CTRL[1-0] BUS_MODE bit-field is set to Pure Bus Mode by default. The I3C controller supports only I3C compatible devices on I3C bus and if changed bit-field has no effect. For more information see *I3C Not Supported Features*.

12.1.4.3.5 I3C Dynamic Address Management

Enumeration of I3C devices involves Dynamic Address Assignment procedure. At power up of the I3C bus, the I3C Master should provide dynamic address for all I3C devices under the following conditions:

- If I3C Slave devices with Static Address are available (not supported for this device), firmware may choose to assign Dynamic Address using SETDASA CCC to shorten bus initialization time; such devices are called Static I3C Devices.
- For the devices that are enumerated using SETDASA CCC command the Provisional ID, BCR and DCR information should be manually acquired, using GETPID / GETBCR / GETDCR CCC commands. This step is not mandatory if the values are known prior to bus initialization and programmed into I3C Master by host application.
- Devices with no Static Address and these with Static Address not enumerated receive Dynamic Address using the DAA procedure initiated by issuing the ENTDAAC CCC command.
- For the devices that are enumerated using ENTDAAC CCC command the Provisional ID, BCR and DCR information are automatically received during DAA procedure.

During I3C bus operation, current master can disable one or all I3C devices by sending Direct or Broadcast RSTDAA CCC command. In such case, corresponding *_CLR bits in I3C_DEVS_CTRL should be set by firmware to clean retaining registers. In order to re-enable these devices, DAA procedure must be performed (initiated by master or by Hot-Join requests sent by slave devices).

Depending on I3C slave implementation, the slave that received RSTDAA CCC command may restore its static address. In order to perform private transfers to such slave or assign dynamic address using SETDASA CCC command rather than DAA procedure, the corresponding I3C_DEV_IDn_RR0[7-0] DEV_ADDR bit field (n = 0 to 11) should be updated with static address. Clearing Retaining Registers by setting corresponding I3C_DEVS_CTRL register is not mandatory in this scenario.

Current master can also assign new Dynamic Address to device which already has one by sending SETNEWDA command. After sending this command with new Dynamic Address in the data field, the I3C_DEV_IDn_RR0[7-0] DEV_ADDR bit field (n = 0 to 11) must be also updated with this address in order to perform subsequent transaction to this device.

12.1.4.3.6 I3C Retaining Registers Space

The information on configuration, Provisional ID, BCR and DCR of each device connected to the I3C bus is stored by the I3C master in a set of retaining registers divided into Device ID sections associated with each device. Application host take any action to guarantee maintaining this information anytime the bus topology changes.

The retaining register space is divided to up to 12 sections (depending on selected configuration), from I3C_DEV_ID0 to I3C_DEV_ID11. Each containing three 32-bit registers to hold whole necessary information on I3C devices connected to the bus (e.g. hot-join device is attached, some of DA are reset to new value, etc.).

The AMBA APB interface address space for retaining registers starts at 0x080 and is divided into 12 quadruplets.

The map organization is presented in [Table 12-28](#) below.

Table 12-28. Retaining Registers Map Organization

Register	Address	Contents
I3C_DEV_ID0_RR0	0x080	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID0_RR1	0x084	Register stores MSB of Provisional ID ⁽¹⁾
I3C_DEV_ID0_RR2	0x088	Register stores LSB of Provisional ID, DCR, BCR ⁽¹⁾

Table 12-28. Retaining Registers Map Organization (continued)

Register	Address	Contents
I3C_DEV_ID1_RR0	0x090	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID1_RR1	0x094	Register stores MSB of Provisional ID ⁽¹⁾
I3C_DEV_ID1_RR2	0x098	Register stores LSB of Provisional ID, DCR, BCR ⁽¹⁾
I3C_DEV_ID2_RR0	0x0A0	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID2_RR1	0x0A4	Register stores MSB of Provisional ID ⁽¹⁾
I3C_DEV_ID2_RR2	0x0A8	Register stores LSB of Provisional ID, DCR, BCR ⁽¹⁾
...
I3C_DEV_ID11_RR0	0x130	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID11_RR1	0x134	Register stores MSB of Provisional ID ⁽¹⁾
I3C_DEV_ID11_RR2	0x138	Register stores LSB of Provisional ID, DCR, BCR ⁽¹⁾

(1) The information is relevant only for I³C devices and is automatically filled by hardware during DAA procedure. Application host needs to fill the information for all devices with Dynamic Addresses Assignment with SETDASA CCC command.

A special device control register (I3C_DEVS_CTRL) is provided to store information on devices currently connected to the bus. Each DeviceID section contains configuration register and two registers holding Provisional ID, BCR and DCR of the corresponding device. The active state bit is set automatically by hardware after Dynamic Address is assigned to given device. Firmware shall set it for devices enumerated with SETDASA CCC command after their Retaining Registers are configured and before any transaction to these devices is initiated.

The clearing bits need to be set by firmware every time RSTDAA CCC is send to corresponding devices (firmware should clear all of them for broadcast RSTDAA) or controller constantly receives NACK response and application recognizes device as no longer connected to the bus.

12.1.4.3.7 I3C Dynamic Address Assignment Procedure

The I3C bus initialization procedure can be decomposed into three main stages, described below:

- **Stage 1:** On startup, the I3C master does not have any information about I³C slave devices and all Retaining Registers are set to the default reset vector table;
- **Stage 2:** Is fully maintained by application host. The first register section (Device ID0) is reserved for I3C master self-description. The following registers starting from Device ID1 will be filled by DAA procedure in Stage 3. This implies rules firmware should follow:
 - I³C devices with Static Address which firmware assume to enumerate with SETDASA CCC command shall be localized in Retaining Registers table (see [Figure 12-23](#)) after address space that reserved for I³C devices intended to be enumerated with ENTDA A;
 - Corresponding I3C_DEVS_CTRL bits for active should be set;
- **Stage 3:** Before attempting DAA procedure, firmware should take following actions:
 - For Static I3C Devices intended to be enumerated with SETDASA CCC command:
 - Configuration registers should be programmed with Static Addresses and other settings relevant for I3C device;
 - Corresponding I3C_DEVS_CTRL bits for active should be set;
 - Dynamic Addresses should be assigned using SETDASA CCC command;
 - Configuration registers should be programmed with just assigned Dynamic Addresses;
 - Provisional ID / BCR / DCR Registers (I3C_DEV_IDn_RR1 and I3C_DEV_IDn_RR1, n = 0 to 11) should be programmed with data either predefined by application or obtained by reading PID / BCR / DCR with related CCC;
 - For I³C Devices intended to be enumerated with ENTDA A CCC command:
 - Configuration registers should be programmed with Dynamic Addresses and other settings relevant for I3C Device;

Once all above conditions are satisfied the firmware can issue the ENTDAACCC command, which is considered as start condition for Stage 3.

Figure 12-23 presents the I³C bus initialization for DAA procedure.

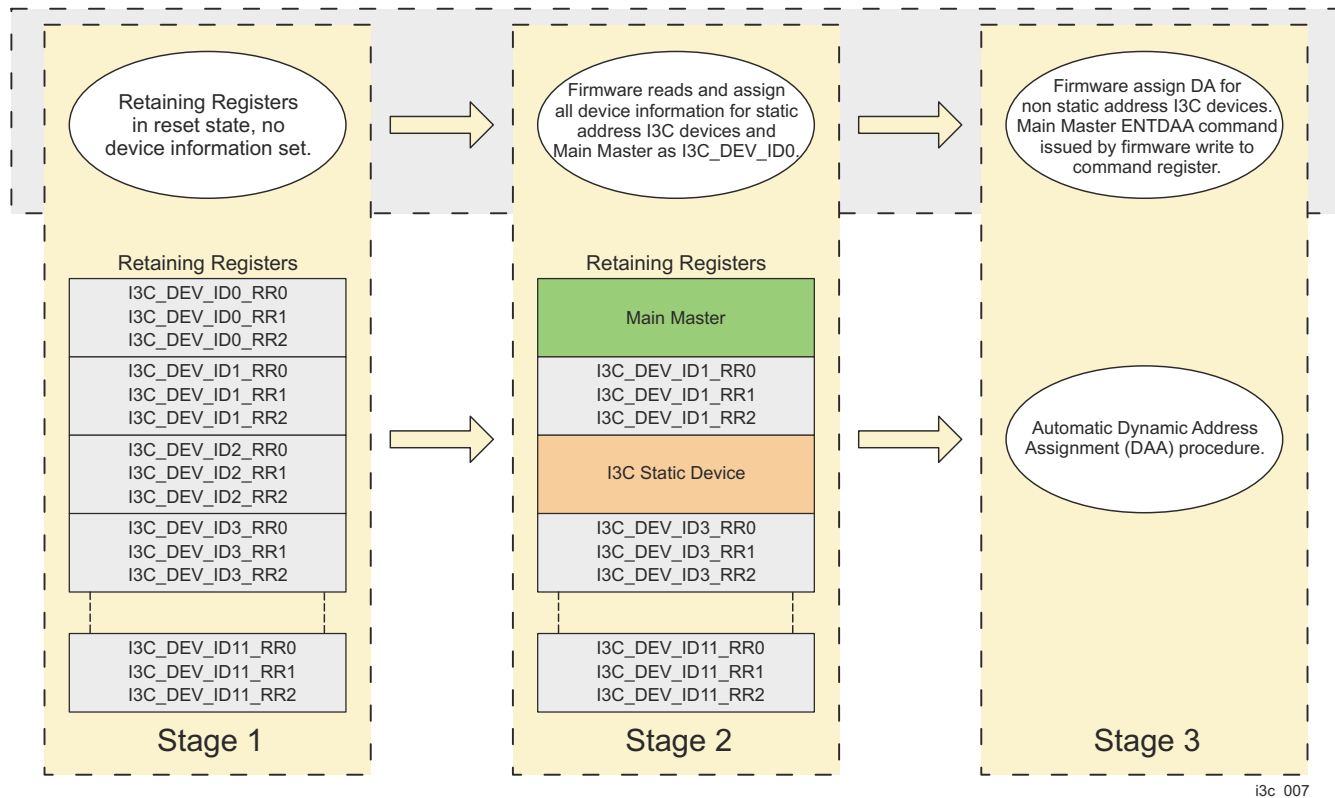

Figure 12-23. Power-up I³C Bus Initialization

During automatic Dynamic Address Assignment procedure, the I³C devices send their Provisional ID, BCR and DCR using open-drain class driver. The Device ID sections are assigned to the I3C Devices based on the Provisional ID arbitration. As a result, the lower value of the Provisional ID the device has, the lower position in retaining registers map it gets. Once device gets Dynamic Address and its Retaining Registers are filled, corresponding I3C_DEVS_CTRL bit for active is set automatically.

Figure 12-24 presents the I³C flow diagram for DAA procedure.

Note

Note

12.1.4.3.8 I3C Sending CCC Messages

Following are the only relevant Command Word fields for CCC message:

- When sending a sequence of two identical directed CCC messages to different slaves, the I3C_CMD0_FIFO[29] BCH and I3C_CMD0_FIFO[25] RSBC Command Word fields can be used to send the second message as short CCC. I3C_CMD0_FIFO[29] BCH should be set to 0 for the second CCC message. Instead of sending the broadcast address, waiting for it to be acknowledged and then sending the message code, this will issue restart pattern and immediately transfer the address and payload afterwards. If I3C_CMD0_FIFO[29] BCH is set

to 1 the second CCC message is sent with broadcast address and command code in the beginning. In all other CCC message cases the I3C_CMD0_FIFO[29] BCH field is disregarded. Because the short CCC is preceded by restart pattern in order for this to work the I3C_CMD0_FIFO[25] RSBC field for the first command should also be set to 1.

Table 12-29 below summarizes available CCC set along with their payload layout in data FIFOs and Command Word settings.

Table 12-29. CCC Commands

CCC ⁽¹⁾	Description	Payload Layout ⁽²⁾	PL	RNW
ENEC_BC (0x00) ENEC_DC (0x80)	Enables slave event driven interrupts	TX FIFO: {28'b0, 1'bHJ, 1'b0, 1'bMR, 1'bINT} (HJ – Hot-Join, MR – Mastership Request IBI, INT – regular IBI)	1	0
DISEC_BC (0x01) DISEC_DC (0x81)	Disables slave event driven interrupts	TX FIFO: {28'b0, 1'bHJ, 1'b0, 1'bMR, 1'bINT} (HJ – Hot-Join, MR – Mastership Request IBI, INT – regular IBI)	1	0
ENTAS0_BC (0x02) ENTAS0_DC (0x82)	Set activity to State 0 (normal operation)	No payload	0	0
RSTDAA_BC (0x06) RSTDAA_DC (0x86)	Forget current Dynamic Address and wait for new one	No payload	0	0
ENTDAA_BC (0x07)	Enter DAA procedure to assign Dynamic Addresses to unassigned devices	See Section 12.1.4.4.3, Initiate DAA Procedure	0	0
SETMWL_BC (0x09) SETMWL_DC (0x89)	Set maximum write length of a single private transfer	TX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Write Length value)	2	0
SETMRL_BC (0x0A) SETMRL_DC (0x8A)	Set maximum read length of a single private transfer	TX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Write Length value)	2	0
DEFSLVS_BC (0x08)	Broadcast triples of DA, DCR and SA (or 0) for each slave	No payload	0	0
ENTHDR_BC (0x20)	Switch to HD-DDR mode	No payload	0	0
SETDASA_DC (0x87)	Set Dynamic Address to slave with Static Address	TX FIFO: {24'b0, 7'bDA, 1'bP} (DA – new Dynamic Address, P – XNOR of DA bits)	1	0
SETNEWDA_DC (0x88)	Assign new Dynamic Address	TX FIFO: {24'b0, 7'bDA, 1'bP} (DA – new Dynamic Address, P – XNOR of DA bits)	1	0
GETMWL_DC (0x8B)	Get maximum write length of a single private transfer	RX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Write Length value)	2	1
GETMRL_DC (0x8C)	Get maximum read length of a single private transfer	RX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Read Length value)	2	1
GETPID_DC (0x8D)	Get Slave's Provisional ID value	RX FIFO[n+1]: {16'b0, PID0, PID1} RX FIFO[n]: {PID2, PID3, PID4, PID5}	6	1
GETBCR_DC (0x8E)	Get Device's Bus Characteristic Register value	RX FIFO: {24'b0, BCR}	1	1
GETDCR_DC (0x8F)	Get Device's Characteristic Register value	RX FIFO: {24'b0, DCR}	1	1
GETSTATUS_DC (0x90)	Read Device's operating status	RX FIFO: {16'b0, 2'bAM, 1'bPE, 1'b0, 4'bINT, 8'b0} (AM – Activity Mode, PE – Protocol Error, INT – Pending Interrupt number)		
GETACCMST_DC (0x91)	Get accept mastership	RX FIFO: {24'b0, SlaveAddr}	1	1

Table 12-29. CCC Commands (continued)

CCC ⁽¹⁾	Description	Payload Layout ⁽²⁾	PL	RNW
GETMXDS_DC (0x94)	Read Maximum SCL Frequency of the slave	RX FIFO: {16'b0, MaxRd , MaxWr } (MaxRd – Clock to Data Turnaround Time and Maximum Sustained Read Data Rate, MaxWr – Maximum Sustained Write Data Rate)	1	1
GETHDCAP (0x96)	Ask slave for HDR modes it supports (can be sent only if BCR identifies HDR support)	RX FIFO: {24'b0, HDCAP } (HDCAP – HDR capability modes)	1	1

(1) CCC column displays:

- The name of the Common Command Code, suffixed with _BC for Broadcast CCC and _DC for Direct CCC;
- In parentheses is value of CCC field to be used in Command Word 1;

(2) Payload Layout column displays:

- {<...>, <field1>, <field0>} - concatenation of 8-bit CCC data fields within 32-bit FIFO cell;
- <width>'b<field_name> - field <field_name> takes <width> bits (8 bits if not specified);
- The payload fields are denoted in bold;

12.1.4.3.9 I3C In-Band Interrupt

In order to handle an incoming In-Band Interrupt from particular slave device, the address and configuration of IBI handling for this device needs to be stored in the I3C_SIR_MAP0 through I3C_SIR_MAP5 registers. This register map holds information on device address, length of payload, device role and response. The map organization is presented in the [Table 12-30](#) below.

Table 12-30. SIR Map Organization

Register	[31-16] bit fields	[15-0] bit fields
I3C_SIR_MAP0	Device 1	Device 0
I3C_SIR_MAP1	Device 3	Device 2
I3C_SIR_MAP2	Device 5	Device 4
I3C_SIR_MAP3	Device 7	Device 6
I3C_SIR_MAP4	Device 9	Device 8
I3C_SIR_MAP5	Reserved	Device 10

All devices requesting IBI, but not added to the SIR Map, will receive the NACK response from I3C master device.

Example for IBI Map configuration looks as follows:

- Write 0x80470445 which is translated to the following configurations for first two devices:
 - Regular slave with DA = 0x22 to be ACKed and receive 4 bytes of payload (Device 0)
 - Secondary master with DA = 0x23 to be ACKed and receive no payload (Device 1)
- Write 0x004A0749 which is translated to the following configurations for the third and fourth device:
 - Regular slave with DA = 0x24 to be ACKed and receive 7 bytes of payload (Device 2)
 - Regular slave with DA = 0x25 to be NACKed (Device 3)
- Write 0x0000034D which configures the last fifth device as follows:
 - Regular slave with DA = 0x26 to be ACKed and receive 3 bytes of payload (Device 4)

After receiving regular or mastership request IBI interrupt, firmware needs to read the I3C_IBIR register to determine which device requested IBI. The ordering of bits in the I3C_IBIR register corresponds to ordering of devices stored in I3C_SIR_MAP0 through I3C_SIR_MAP5 registers. Note that the IBI capable devices are enumerated and ordered independently from device ordering in the retaining registers used during DAA procedure.

12.1.4.3.9.1 Regular I3C Slave In-Band Interrupt

When regular IBI request appears on the I³C bus, I³C master hardware automatically handles whole IBI procedure based on settings in I3C_SIR_MAP0 through I3C_SIR_MAP5 registers. As the IBI procedure

acknowledged by I3C master finishes (including payload reception), host is informed by the IBI interrupt that such event occurred and was successfully processed. At this point, firmware should:

1. Read I3C_IBIR register to determine requesting device
2. Read related payload from IBI RX FIFO
3. Execute related action (application/system dependent), if any designed for particular IBI/device.

12.1.4.3.9.2 Current Master Takeover In-Band Interrupt

When mastership takeover IBI request appears on the I³C bus, I³C master hardware automatically sends the response based on settings in I3C_SIR_MAP0 through I3C_SIR_MAP5 registers. After this host is informed by the I3C_MST_ISR interrupt that handoff procedure should be executed. At this point, firmware should:

1. Read I3C_IBIR register to determine requesting device (optionally, if such information is useful for application host)
2. Send the GETACCMST CCC to confirm mastership handover
3. Wait for the completion of pending I3C master command signaled by I3C_MST_ISR interrupt – at this moment I3C master switches to the slave mode
4. Write 0x001FXXXX to FLUSH_CTRL register to flush the FIFOs as the slave mode reuses TX and RX FIFOs (bits marked X hold RX_FIFO threshold so should be set/maintained as needed)
5. Depending on application/system, prepare for slave operation

Note that it is firmware and/or system responsibility to provide bus information to Secondary Masters before mastership handover is granted. It can be achieved in several ways:

- Secondary Masters listen to the bus during DAA and store necessary data
- Main Master sends DEFSLVS CCC after each ENTDA / RSTDA / SETNEWD / SETDASA sequence that modifies bus

12.1.4.3.10 I3C Hot-Join Request

In order to accept any Hot-Join (HJ) request from slave device, application needs to set the I3C_CTRL[6] HJ_ACK and I3C_CTRL[8] HJ_DISEC control bits that define its response for Hot-Join request. Based on I3C_CTRL[6] HJ_ACK value the I3C master accepts or refuses the Hot-Join request by providing respectively ACK or NACK bit right after I3C_CMD0_FIFO[0] RNW bit. I3C_CTRL[8] HJ_DISEC bit controls whether master starts DAA procedure or sends broadcast DISEC command to disable HJ requests.

If Hot-Join request occurs, the application processor is notified by the I3C_MST_ISR interrupt. The application processor is aware how this particular Hot-Join request should be handled by checking current setting (can read the control bits or the stored previously used setting). In case of acknowledged request with subsequent DAA, the application processor is notified of automatically completed enumeration of hot-joined device by subsequent I3C_MST_ISR interrupt and simultaneously set I3C_MST_STATUS0 flag. In case of DISEC command, only I3C_MST_ISR interrupt will be set.

It is recommended to keep the I3C_CTRL[6] HJ_ACK bit disabled until the bus initialization procedure is completed in order to prevent slaves from indirect DAA enforcement.

12.1.4.3.11 I3C Immediate Commands

Immediate Command Register is implemented in order to allow the application processor to issue immediate command which has a higher priority over the ordinary command. The immediate commands are supposed to be used in exceptional cases and only CCC commands are applicable. The I3C supports only one immediate command at a time and it is accessed by the host through two APB registers: I3C_IMD_CMD0 and I3C_IMD_CMD1. If a normal command is currently being executed and new immediate command is loaded, then controller waits to finish the current command and after that starts executing the higher priority command regardless of the content of the ordinary command FIFO. Immediate command can be used only for CCC commands and the corresponding payload must not exceed 4 bytes. As a result the GETPID and DEVSLVS CCC commands cannot be executed using immediate commands. The format for the immediate command words is the same as for the ordinary commands, although some fields are reserved since not used or fixed for CCC commands (writing to these fields has no effect).

12.1.4.3.12 I3C Host Commands

The normal operation of the controller allows the firmware to build a message and then issue the transaction to the I3C controller. The command queue is provided in order to allow the host to load a request for multiple messages. Single message consists of two 32-bit words (Command Word0 and Command Word1). In order to issue the transaction the following procedure should be followed:

- Write the payload to the TX FIFO (applicable for write transfers only);
- Write Command Word1;
- Write Command Word0;

If controller is enabled (I3C_CTRL[31] DEV_EN bit is set to 0x01), writing Command Word0 triggers the execution of the command, resulting in start condition on the I3C bus.

12.1.4.3.13 I3C Sending Private Data in SDR Messages

The I3C controller supports private data transfers in Single Data Rate with SCL frequencies up to 10.375 MHz. It supports all types of SDR transfers and provides hardware built-in features for transfers to I3C slave devices with limited maximum SCL frequency. Before any private transfer to the slave devices occurs, bus mode and SCL prescalers shall be programmed properly. Controller also provides vendor extension to the basic transfers which simplifies addressing internal registers of slave devices. To take advantage of this extension, the I3C controller must communicate with the slave devices supporting such transmission scheme.

The extension, called XMIT modes, combines standard private write and read frames to pass the slave register sub-address in addition to the actual payload. Four transmit modes are designed for specific usage:

- XMIT00 – burst (byte-by-byte) transfer with static register sub-address. Sends static sub-address followed by data bytes only. Expecting slave will make self-increment of the address for each data byte or will have payload buffer implemented.
- XMIT01 – single transfer with incremented register sub-address. Each data byte followed by repeated start condition and the slave's internal register address are incremented explicitly.
- XMIT10 – single transfer with static register sub-address. Each data byte followed by repeated start condition, register sub-address remains intact.
- XMIT11 – burst (byte-by-byte) transfer without register sub-address (first data byte after the slave address is a payload byte).

In addition to the multiple transmit modes, I3C controller has an option to provide 16-bit address of the internal register in slave device to support slaves with more than 256 internal addresses.

For arbitration priorities management, private SDR commands may use Broadcast Command Header or not. This is controlled by BCH field of command descriptor.

12.1.4.3.13.1 SDR Private Write Message

The Private Write message transmitted over I3C bus in all supported transmit modes is presented in [Figure 12-25, Master Write Transaction for Single and Multi Address Sequences](#). The provided transmit modes use additional I3C write frame that utilizes the data field to pass slave register address ahead of payload byte(s). As writing command word triggers start condition immediately, it shall be guaranteed by firmware that the data payload is written to the Tx FIFO in advance before it is going to be transmitted.

The completion of the message frame on the I3C bus is signaled by the I3C_MST_ISR[16] IMM_COMP interrupt.

In case of transfers with data payload greater than the TX FIFO size, firmware can use I3C_MST_ISR[15] TX_THR interrupt to fill the FIFO on time. The system design should prevent the TX FIFO from underflow. During the time elapsed between reading the last four bytes from almost empty TX FIFO and reading the subsequent one, firmware is required to refill the TX FIFO.

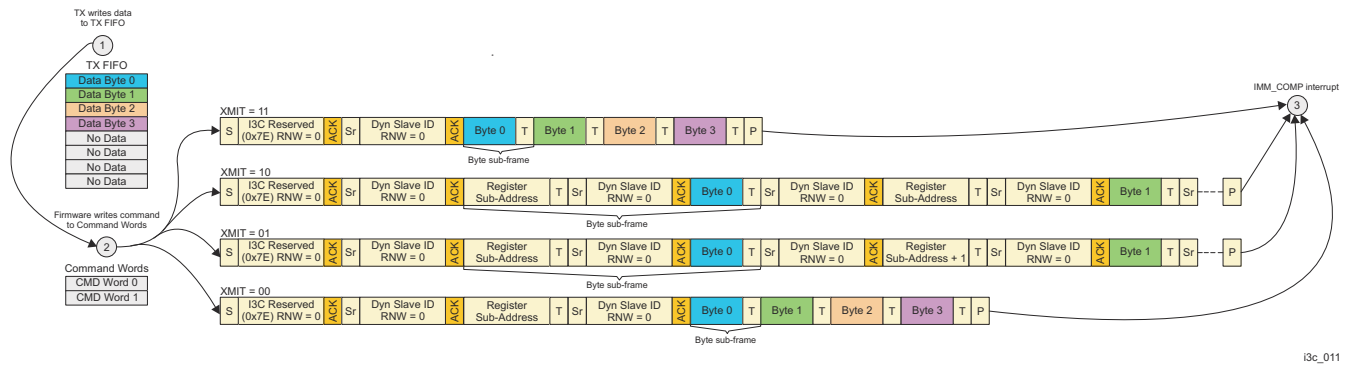

Figure 12-25. Master Write Transaction for Single and Multi Address Sequences

12.1.4.3.13.2 SDR Private Read Message

The Private Read message transmitted over I3C bus in all supported transmit modes is presented in [Figure 12-26, Master Read Transaction for Single and Multi Address Sequences](#)

Similarly to Private Write message, each I3C read frame is preceded by I3C write frame which sends slave register address to be read. After sending the command, firmware should wait for I3C_MST_ISR[16] IMM_COMP interrupt which signals the end of message and RX FIFO content ready to read.

In case of payload lengths exceeding RX FIFO size, firmware should utilize I3C_MST_ISR[7] TX_THR interrupt to read RX FIFO before it gets filled and prevent from data corruption. For easier management of long FIFO and/or long host read intervals, the amount of data available in FIFO that triggers the interrupt can be programmed according to actual conditions in given system.

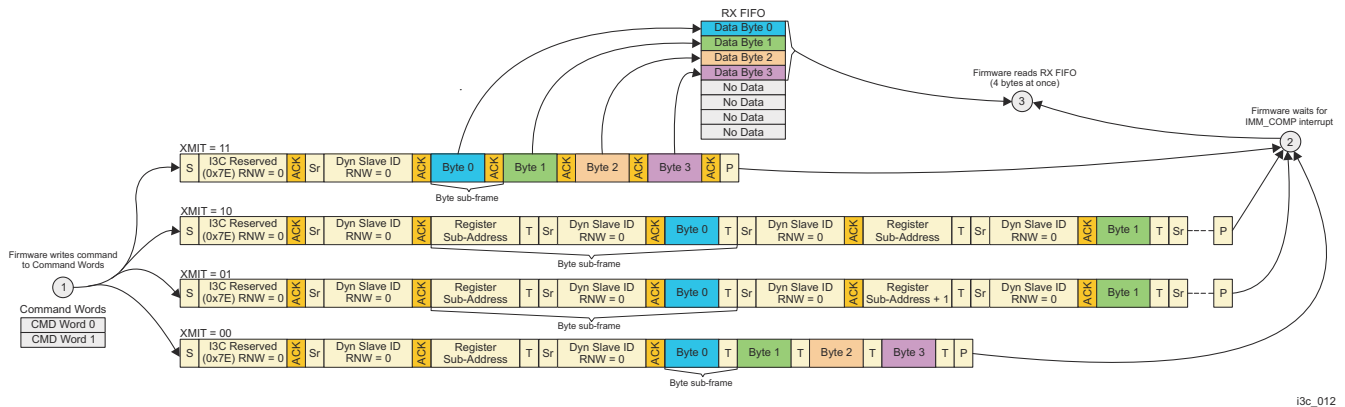

Figure 12-26. Master Read Transaction for Single and Multi Address Sequences

12.1.4.3.13.3 SDR Payload Length Adjustment

In case of Private Write SDR commands, the payload length that needs to be specified is always equal to the number of data bytes sent to slave in Private Write transmission. If the payload specified is greater than slave's capability, the data are simply ignored by slave.

In case of Private Read SDR commands slave is the device which normally decides how many bytes it is able to send and when the read transfer is terminated. This can also result from hardware architecture or from SETMRL CCC command sent earlier to the slave.

For simplified handling I3C design triggers the read abort procedure after receiving specified number of payload bytes. This matters in these transfer modes which send data bytes after one another. If one of these modes is used, the I3C_CMD0_FIFO[23-12] PL_LEN bit-field is interpreted as payload size that should not be reached during transfer rather than the actual number of bytes to be received. This applies only to read transfer from I3C devices.

Table 12-31. Payload Setting in SDR Mode

Transmission	I3C_CMD0_FIFO[28-27] XMIT_MODE	I3C_DEV_IDn_RR0[9] IS_I3C (n = 0 to 11)	I3C_CMD0_FIFO[23-12] PL_LEN
I3C, NCA	11	1	Abort limit ⁽¹⁾
I3C, Single	00	1	Abort limit ⁽¹⁾
I3C, Multi-Static	10	1	Number of bytes to receive
I3C, Multi-Incremental	01	1	Number of bytes to receive

- (1) If payload size is known, it can be set to one more than the known size; otherwise it should be set to MRL+1 where MRL is value programmed with SETMRL CCC in particular slave or its hardware payload size limit, if known.

12.1.4.4 I3C Programming Guide

12.1.4.4.1 I3C Power-On Programming Model

Typical power-on programming sequence is as follows:

1. Program bus description into Retaining Registers according [Section 12.1.4.3.6](#) and I3C_DEVS_CTRL.
2. If default values of SCL prescalers do not fit applied clock frequencies, program PRESCL_CTRL0 and PRESCL_CTRL1 according [Section 12.1.4.3.2](#).
3. If any of following applies:
 - a. Address Header Optimization is to be enabled.
 - b. Halt mechanism should be enabled.

then alter values of I3C_CTRL[1-0] BUS_MODE, I3C_CTRL[3] AHDR_OPT and I3C_CTRL[30] HALT_EN fields, respectively:

- a. Program I3C_CTRL register with value 0x80000000 to enable the controller.

12.1.4.4.2 I3C Static Devices Programming

I3C devices shipped with Static Address can be enumerated prior to DAA procedure using SETDASA CCC command. In order to enumerate I3C device firmware needs to follow procedure:

1. Prepare device's retaining register:
 - a. Write corresponding I3C_DEV_IDn_RR0 (offset 0x080 + (n × 0x010)) for n = 0 to 11:
 - i. I3C_DEV_IDn_RR0[9] IS_I3C (n = 0 to 11): 0x01
 - ii. I3C_DEV_IDn_RR0[7-0] DEV_ADDR bit-field (n = 0 to 11): set to device's Static Address for [7-1] bits and set to Static Address parity for bit 0
2. Issue SETDASA CCC:
 - a. Make sure that controller is enabled.
 - b. Write new Dynamic Address to TX FIFO.
 - c. Write Command Word1 with SETDASA CCC value:
 - i. I3C_CMD1[7-0] CCC bit-field: 0x87
 - d. Write Command Word0 with following field values:
 - i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
 - ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x01
 - iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: Static Address
 - iv. I3C_CMD0_FIFO[0] RNW bit: 0x00
3. Enable at least COMP, NACK and INVALID_DA interrupts by writing 0h to IER register.
4. Wait for COMP interrupt (read I3C_MST_ISR).
5. If COMP and no other interrupt occurs, continue. Otherwise, handle the error situation.
6. Fill Dynamic Address into device configuration register:
 - a. Modify I3C_DEV_IDn_RR0 (offset 0x080 + (n × 0x010)) for n = 0 to 11 register by writing Dynamic Address to DEV_ADDR field and its parity to ADDR_PAR field (keep values of other fields)
7. If not already known to application host, retrieve BCR with GETBCR CCC:
 - a. Write Command Word1 with GETBCR CCC value:
 - i. I3C_CMD1[7-0] CCC bit-field: 0x8E
 - b. Write Command Word0 with following field values:
 - i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
 - ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x01
 - iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: Dynamic Address
 - iv. I3C_CMD0_FIFO[0] RNW bit: 0x01
 - c. Wait for COMP interrupt
 - d. Read RX FIFO register - BCR is stored in bits [7:0]
8. Optionally retrieve Provisional ID and DCR with corresponding CCCs:
 - a. Write Command Word1 with GETDCR CCC value:
 - i. I3C_CMD1[7-0] CCC bit-field: 0x8F
 - b. Write Command Word0 with following field values:

- i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
 - ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x01
 - iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: Dynamic Address
 - iv. I3C_CMD0_FIFO[0] RNW bit: 0x01
- c. Wait for COMP interrupt
- d. Read RX FIFO register - DCR is stored in bits [7:0]
- e. Write Command Word1 with GETPID CCC value:
 - i. I3C_CMD1[7-0] CCC bit-field: 0x8D
- f. Write Command Word0 with following field values:
 - i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
 - ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x06
 - iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: Dynamic Address
 - iv. I3C_CMD0_FIFO[0] RNW bit: 0x01
- g. Wait for COMP interrupt
- h. Read RX FIFO register twice – PID bytes are stored in two FIFO locations. See [Table 12-29](#)
9. Write retrieved device configuration data to retaining registers:
 - a. Write four MSB of obtained PID value into I3C_DEV_IDn_RR1 (offset 0x084 + (n × 0x010)) for n = 0 to 11:
 - b. Write two LSB of obtained PID value as well as BCR and DCR values into I3C_DEV_IDn_RR2 (offset 0x088 + (n × 0x010)) for n = 0 to 11:

Note

SETDASA CCC command has advantage over DAA in shorter time spent on device configuration as retrieving PID and DCR (6 + 1 bytes transmitted over I3C bus) is optional and can be skipped if not used.

12.1.4.4.3 I3C DAA Procedure Initiation

To initiate the DAA procedure I3C needs to issue ENTDAACCC command following the below procedure:

1. Enable at least COMP and NACK interrupts.
2. Issue ENTDAACCC command:
 - a. Make sure controller is enabled.
 - b. Write Command Word1 with ENTDAACCC command value:
 - i. I3C_CMD1[7-0] CCC bit-field: 0x07
 - c. Write Command Word0 with following field values:
 - i. I3C_CMD0_FIFO[30] IS_CCC bit: 0x01
 - ii. I3C_CMD0_FIFO[23-12] PL_LEN bit-field: 0x00
 - iii. I3C_CMD0_FIFO[7-1] DEV_ADDR bit-field: 0x00
 - iv. I3C_CMD0_FIFO[0] RNW bit: 0x00
3. Wait for COMP interrupt (read I3C_MST_ISR)
4. If COMP and no other interrupt occurs, continue. Otherwise, handle the error situation. NACK interrupt indicates no slave devices available on bus.
5. Read I3C_MST_STATUS0[25] DAA_COMP bit. It is asserted simultaneously with I3C_MST_ISR interrupt flag.

Note

DAA procedure takes significant amount of time since there are always 9 bytes of data transmitted for each device (PID, BCR, DCR from device and DA to device), so for maximum bus size it will take 99 bytes.

12.1.4.4.4 I3C SDR Write Message Programming Model

To accomplish the SDR write transfer, the host must perform the following steps:

1. Write all payload data bytes into TX FIFO buffer:

- a. Write first four or less bytes to be sent, with first byte stored at LSB position.
- b. Repeat writes until whole payload is written.
2. Write Private Write command to command queue:
 - a. Write the Command Word 1 (I3C_CMD1_FIFO) with slave CSR address:
 - i. CSR (bits [15:0] or [7:0]): Slave register address
 - b. Write the Command Word0 (I3C_CMD0_FIFO) with following data fields:
 - i. I3C_CMD0_FIFO[31] IS_DDR: 0x0
 - ii. I3C_CMD0_FIFO[30] IS_CCC: 0x0
 - iii. I3C_CMD0_FIFO[28-27] XMIT_MODE: Transmit Mode
 - iv. I3C_CMD0_FIFO[26] SB_CA: 0x1 for 16-bit CSR address, 0x0 otherwise
 - v. I3C_CMD0_FIFO[23-12] PL_LEN: Number of bytes to send
 - vi. I3C_CMD0_FIFO[7-1] DEV_ADDR: Slave Address
 - vii. I3C_CMD0_FIFO[0] RNW: 0x0
3. Wait for transfer completion notified by I3C_MST_ISR[16] IMM_COMP bit, which indicates that all data of particular command are successfully transmitted to the slave.

12.1.4.4.5 I3C SDR Read Message Programming Model

To accomplish the SDR read transfer, the host must perform the following steps:

1. Write Private Write command to command queue:
 - a. Write the Command Word1 (I3C_CMD1_FIFO) with slave CSR address:
 - i. CSR (bits [15:0] or [7:0]): Slave register address
 - b. Write the Command Word0 (I3C_CMD0_FIFO) with following data fields:
 - i. I3C_CMD0_FIFO[31] IS_DDR: 0x0
 - ii. I3C_CMD0_FIFO[30] IS_CCC: 0x0
 - iii. I3C_CMD0_FIFO[28-27] XMIT_MODE: Transmit Mode
 - iv. I3C_CMD0_FIFO[23-12] PL_LEN: See [Section 12.1.4.3.13.3](#)
 - v. I3C_CMD0_FIFO[7-1] DEV_ADDR: Slave Address
 - vi. I3C_CMD0_FIFO[0] RNW: 0x1
2. Wait for transfer completion notified by I3C_MST_ISR[16] IMM_COMP bit, which indicates that all data of particular command are successfully sent by the slave device and received data are ready to be read by the host.
3. Read all payload data bytes from RX FIFO buffer:
 - a. Read first four or less received bytes, with first received byte stored at LSB position.
 - b. Repeat reads until whole payload is read.

12.1.4.4.6 I3C DDR Write Message Programming Model

To accomplish the DDR write transfer, the host must perform the following steps:

1. Prepare HDR-DDR message words (each 20-bit word is LSB aligned in TX FIFO cell; set bits unspecified below to 0):
 - a. Write command word for write HDR-DDR command to TX FIFO using following field values:
 - i. Preamble (bits [19:18]): 0x01
 - ii. CMD (bits[17:10]): Write Command Code (from 0x00 to 0x7F)
 - iii. DA (bits[9:3]): Slave Dynamic Address
 - iv. Parity (bits[1:0]): Parity (XOR of odd and even bits of 16-bit payload)
 - b. Write first data word to TX FIFO using following field values:
 - i. Preamble (bits [19:18]): 0x10
 - ii. Data (bits[17:2]): 16-bit data
 - iii. Parity (bits[1:0]): Parity
 - c. Write zero or more subsequent data words to TX FIFO using following field values:
 - i. Preamble (bits [19:18]): 0x11
 - ii. Data (bits[17:2]): 16-bit data
 - iii. Parity (bits[1:0]): Parity
 - d. Write CRC word to TX FIFO:

- i. Preamble (bits [19:18]): 0x01
 - ii. Token (bits[17:14]): Ch
 - iii. CRC (bits[13:9]): CRC5
- e. Repeat steps 1(a) to 1(d) as many write commands are to be sent.
2. Write ENTHDR CCC command to command queue:
 - a. Write the Command Word1 (I3C_CMD1_FIFO) of ENTHDR CCC.
 - b. Write the Command Word0 (I3C_CMD0_FIFO) of ENTHDR CCC with following data fields:
 - i. I3C_CMD0_FIFO[31] IS_DDR: 0x0
 - ii. I3C_CMD0_FIFO[30] IS_CCC: 0x1
 - iii. I3C_CMD0_FIFO[0] RNW: 0x0
3. Write HDR-DDR command(s) to command queue:
 - a. Write the Command Word1 (I3C_CMD1_FIFO).
 - b. Write the Command Word0 (I3C_CMD0_FIFO) with following data fields:
 - i. I3C_CMD0_FIFO[31] IS_DDR: 0x1
 - ii. I3C_CMD0_FIFO[23-12] PL_LEN: Number of TX FIFO words
 - c. Repeat steps 2(a) and 2(b) as many write commands are prepared in TX FIFO in step 1.
4. Wait for transfer completion notified by I3C_MST_ISR[16] IMM_COMP bit, which indicates that all data of particular command are successfully transmitted to the slave.

If I3C_MST_ISR[16] IMM_COMP interrupt is utilized, the controller allows the application processor to perform other tasks or sleep while message is being sent.

In case of multiple command issued to command queue, I3C_MST_ISR[5] CMDD_EMP interrupt may be utilized instead. It indicates completion of all commands in command queue and allows yet more efficient application processor resources management. It is issued simultaneously with the I3C_MST_ISR[5] CMDD_EMP interrupt corresponding to the last command in the queue.

12.1.4.4.7 I3C DDR Read Message Programming Model

To accomplish the DDR read transfer, the host must perform the following steps:

1. Prepare HDR-DDR message words (each 20-bit word is LSB-aligned in TX FIFO cell, set bits unspecified below to 0):
 - a. Write Command Word for Read HDR-DDR command to TX FIFO using following field values:
 - i. Preamble (bits [19:18]): 2'b01
 - ii. CMD (bits[17:10]): Read Command Code (0x80..0xBF)
 - iii. DA (bits[9:3]): Slave Dynamic Address
 - iv. Parity (bits[1:0]): Parity (XOR of odd and even bits of 16-bit payload)
 - b. Repeat step 1(a) as many read commands are to be sent.
2. Write ENTHDR CCC command to command queue:
 - a. Write the Command Word1 (I3C_CMD1_FIFO) of ENTHDR CCC.
 - b. Write the Command Word0 (I3C_CMD0_FIFO) of ENTHDR CCC with following data fields:
 - i. I3C_CMD0_FIFO[31] IS_DDR: 0x0
 - ii. I3C_CMD0_FIFO[30] IS_CCC: 0x1
 - iii. I3C_CMD0_FIFO[0] RNW: 0x0
3. Write HDR-DDR command(s) to command queue:
 - a. Write the Command Word1 (I3C_CMD1_FIFO)
 - b. Write the Command Word0 (I3C_CMD0_FIFO) with following data fields:
 - i. I3C_CMD0_FIFO[31] IS_DDR: 0x1
 - ii. I3C_CMD0_FIFO[23-12] PL_LEN: 0x1
 - c. Repeat steps 2(a) and 2(b) as many read commands are prepared in TX FIFO in step 1.
4. Wait for transfer completion notified by I3C_MST_ISR[16] IMM_COMP bit in interrupt status register, which indicates that all data of particular command are successfully sent by the slave device and received data are ready to be read by the host.
5. Read received payload:
 - a. Read first data word from RX FIFO extracting field values:

- i. Preamble (bits [19:18]): 0x10
- ii. Data (bits[17:2]): 16-bit data
- iii. Parity (bits[1:0]): Parity
- b. Read zero or more subsequent data words from RX FIFO extracting field values as long as the read preamble matches following value:
 - i. Preamble (bits [19:18]): 0x11
 - ii. Data (bits[17:2]): 16-bit data
 - iii. Parity (bits[1:0]): Parity
- c. As read preamble changes, read CRC Word:
 - i. Preamble (bits [19:18]): 0x01
 - ii. Token (bits[17:14]): Ch
 - iii. CRC (bits[13:9]): CRC5
- d. Confirm (by firmware) that CRC5 value matches data payload received.

If I3C_MST_ISR[16] IMM_COMP interrupt is utilized, the controller allows the application processor to perform other tasks or sleep while message is being sent.

In case of multiple command issued to command queue, I3C_MST_ISR[5] CMDD_EMP interrupt may be utilized instead of I3C_MST_ISR[16] IMM_COMP. It indicates completion of all commands in command queue and allows yet more efficient application processor resources management. It is issued simultaneously with the I3C_MST_ISR[16] IMM_COMP interrupt corresponding to the last command in the queue.

12.1.5 Multichannel Serial Peripheral Interface (MCSPI)

This section describes the Multichannel Serial Peripheral Interface (MCSPI) modules for the device.

12.1.5.1 MCSPI Overview

The MCSPI module is a multichannel transmit/receive, master/slave synchronous serial bus.

There are MCSPI modules in the device.

12.1.5.1.1 SPI Features

The SPI module includes the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to channels in controller mode, or single channel in receive mode
- Controller multichannel mode:
 - Full duplex/half duplex
 - Transmit-only/receive-only/transmit-and-receive modes
 - Flexible input/output (I/O) port controls per channel
 - Programmable clock granularity
 - Per channel configuration for clock definition, polarity enabling, and word width
- Single interrupt line for multiple interrupt source events
- Enable the addition of a programmable start-bit for MCSPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- Programmable shift operations (1-32 bits)
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.1.5.1.2 MCSPI Ports

This section describes module ports related to clocks, resets, and hardware requests.

Table 12-32. MCSPI Clocks and Resets

Clocks	
Module Clock Input	Description
MCSPi_ICLK	MCSPi Interface Clock
MCSPi_FCLK	MCSPi Functional Clock
Resets	
Module Reset Input	Description
MCSPi_RST	MCSPi Asynchronous Reset
MCSPi_POR_RST	MCSPi Power-On Reset

Table 12-33. MCSPI Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCSPI_INTR_SPI_0	MCSPI Interrupt Request	Level
DMA Events		
Module DMA Event	Description	Type
MCSPI_DMA_WRITE_EVENT0	MCSPI Channel 0 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT0	MCSPI Channel 0 Receive (Read) Request Line	Pulse
MCSPI_DMA_WRITE_EVENT1	MCSPI Channel 1 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT1	MCSPI Channel 1 Receive (Read) Request Line	Pulse
MCSPI_DMA_WRITE_EVENT2	MCSPI Channel 2 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT2	MCSPI Channel 2 Receive (Read) Request Line	Pulse
MCSPI_DMA_WRITE_EVENT3	MCSPI Channel 3 Transmit (Write) Request Line	Pulse
MCSPI_DMA_READ_EVENT3	MCSPI Channel 3 Receive (Read) Request Line	Pulse

12.1.5.2 MCSPI Environment

This section describes the MCSPI external connections (environment).

[Table 12-34](#) describes the MCSPI I/O signals in master mode.

Table 12-34. MCSPI I/O Signals (Master Mode)

Module Pin	I/O ⁽¹⁾	Description
SPICLK	O	MCSPI Serial clock output for master mode.
SPIDAT[0]	O ⁽²⁾	MCSPI Data I/O for master mode.
SPIDAT[1]	I ⁽³⁾	MCSPI Data I/O for master mode.
SPIEN[i]	O	MCSPI Chip-select i output for master mode

(1) I = Input; O = Output

(2) Example configuration only. Can be configured either as input or as output depending on MCSPI_CHCONF_0/1/2/3[18] IS and MCSPI_CHCONF_0/1/2/3[16] DPE0.

(3) Example configuration only. Can be configured either as input or as output depending on MCSPI_CHCONF_0/1/2/3[18] IS and MCSPI_CHCONF_0/1/2/3[17] DPE1.

[Table 12-35](#) describes the MCSPI I/O signals in slave mode.

Table 12-35. MCSPI I/O Signals (Slave Mode)

Module Pin	I/O ⁽¹⁾	Description
SPICLK	I	MCSPI serial clock input for slave mode.
SPIDAT[0]	I ⁽²⁾	MCSPI Data I/O for slave mode.
SPIDAT[1]	O ⁽³⁾	MCSPI Data I/O for slave mode.
SPIEN[i]	I ⁽⁴⁾	MCSPI chip-select i input for slave mode.

(1) I = Input; O = Output

(2) Example configuration only. Can be configured either as input or as output depending on MCSPI_CHCONF_0/1/2/3[18] IS and MCSPI_CHCONF_0/1/2/3[16] DPE0.

(3) Example configuration only. Can be configured either as input or as output depending on MCSPI_CHCONF_0/1/2/3[18] IS and MCSPI_CHCONF_0/1/2/3[17] DPE1.

(4) The chip-select input in slave mode can be selected through the MCSPI_CHCONF_0/1/2/3[22-21] SPIENSLV bit field.

12.1.5.3 MCSPI Functional Description

12.1.5.3.1 SPI Block Diagram

Figure 12-27 shows the SPI module.

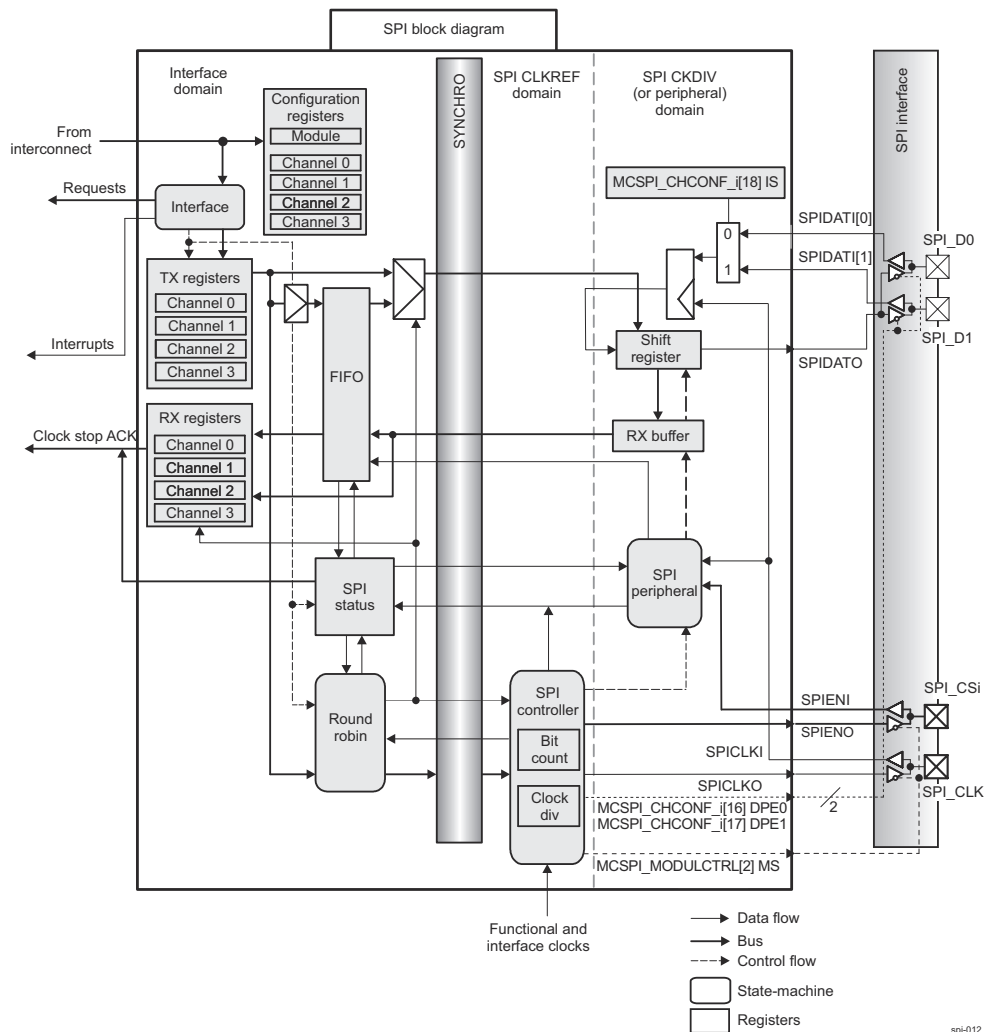

Figure 12-27. SPI Block Diagram

12.1.5.3.2 MCSPI Reset

The MCSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPI_RST). MCSPI can be reset by software through the MCSPI_SYSCONFIG[1] SOFTRESET bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the MCSPI_SYSCONFIG register is not affected by that software reset.

12.1.5.3.3 MCSPI Controller Mode

12.1.5.3.3.1 Controller Mode Features

The MCSPI controller mode supports multichannel communication with up to four independent MCSPI communication channel contexts. The MCSPI initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN[i]) signals.

Connected to multiple external devices, the MCSPI exchanges data with one MCSPI device at a time through two main modes (available in peripheral mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Note

There is a fixed chip select line allocation in multichannel controller mode. Channel *i* is mapped to SPIEN[*i*].

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of MCSPI.

Three interrupt events can be used for data transmission and reception in controller mode (for more information about interrupts, see [Section 13.1.3.4.7.1, Interrupt Events in Controller Mode](#)).

12.1.5.3.3.2 Controller Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The controller transmit-and-receive mode is programmable per channel (the MCSPI_CHCONF_0/1/2/3[13-12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPI_TX_0/1/2/3 transmitter register state, the MCSPI_RX_0/1/2/3 receiver register state, and round-robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- Rule 1: Only enabled channels (the MCSPI_CHCTRL_0/1/2/3[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPI_TX_0/1/2/3 transmitter register is not empty (the MCSPI_CHSTAT_0/1/2/3[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI_TX_0/1/2/3 register is empty when the shift register is assigned, the TXx_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the MCSPI_CHSTAT_0/1/2/3[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPI_RX_0/1/2/3 register cannot be overwritten. The MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set to this mode.

When MCSPI word transfer completes (the MCSPI_CHSTAT_0/1/2/3[2] EOT bit is set), the updated MCSPI_TX_0/1/2/3 register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral.

[Figure 12-28](#) shows an example of a full-duplex system with a controller device on the left and a peripheral device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral. At the same time, WordB transfers from the peripheral to the controller.

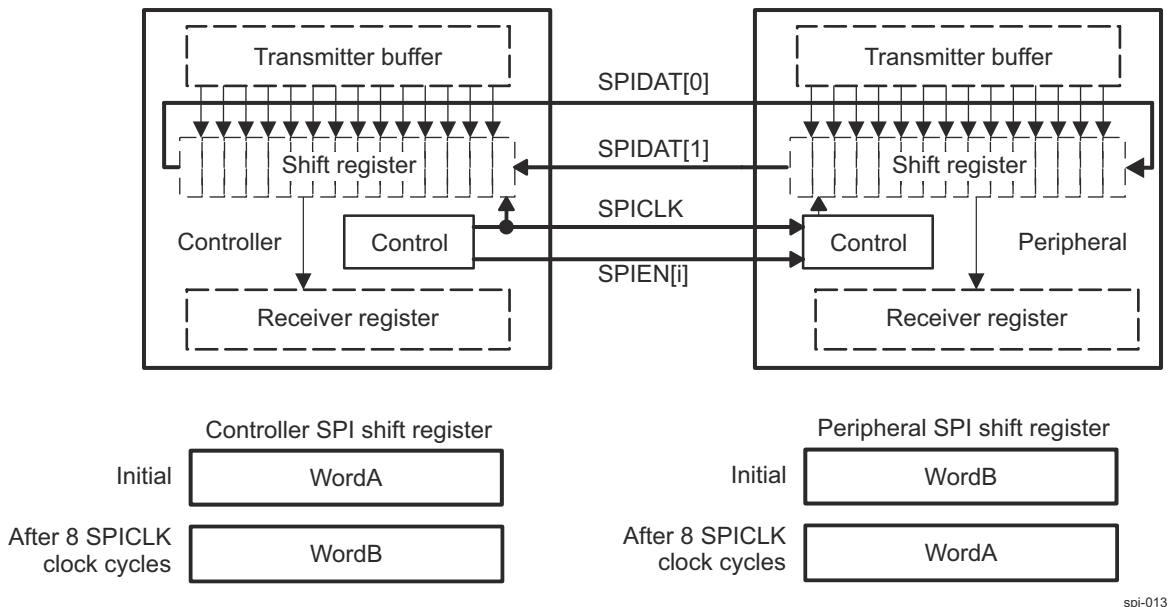

Figure 12-28. MCSPI Full-Duplex Transmission (Example)

12.1.5.3.3.3 Controller Transmit-Only Mode (Half Duplex)

The controller transmit-only mode prevents the processor from reading the MCSPI_RX_0/1/2/3 register (minimizing data movement) when only transmission is meaningful.

The controller transmit-only mode is programmable per channel (the MCSPI_CHCONF_0/1/2/3[13-12] TRM bit field). Transmission starts only after data is loaded into the MCSPI_TX_0/1/2/3 register.

Rule 1 and Rule 2, defined in [Section 12.1.5.3.3.2](#), apply in this mode.

Rule 3, defined in [Section 12.1.5.3.3.2](#), does not apply.

In controller transmit-only mode, the MCSPI_RX_0/1/2/3 register state FULL does not prevent transmission and the MCSPI_RX_0/1/2/3 register is always overwritten with the new MCSPI word. This event is not significant when only transmission is meaningful. Thus, the RX0_OVERFLOW bit in the MCSPI_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX_FULL interrupt and the DMA read requests.

The transfer status is given by the MCSPI_CHSTAT_0/1/2/3[2] EOT bit.

12.1.5.3.3.4 Controller Receive-Only Mode (Half Duplex)

The controller receive mode prevents the processor from refilling the MCSPI_TX_0/1/2/3 register (minimizing data movement) when only reception is meaningful.

The controller receive mode is programmable per channel (the MCSPI_CHCONF_0/1/2/3[13-12] TRM bit field).

The controller receive-only mode enables channel scheduling only on the empty state of the MCSPI_RX_0/1/2/3 register.

Rule 1 and Rule 3, defined in [Section 12.1.5.3.3.2](#), apply in this mode.

Rule 2, defined in [Section 12.1.5.3.3.2](#), does not apply.

In the controller receive-only mode, software must write dummy data to the MCSPI_TX_0/1/2/3 register. Only one dummy write is enough to receive any number of words from the peripheral. Software must ensure that the MCSPI_TX_0/1/2/3 register is always full (the TXx_EMPTY bits of MCSPI_IRQSTATUS) when receiving. The content of the MCSPI_TX_0/1/2/3 register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the MCSPI_TX_0/1/2/3 register, the TXx_EMPTY and TXx_UNDERFLOW bits in the MCSPI_IRQSTATUS register are never set in receive-only mode.

The MCSPI_CHSTAT_0/1/2/3[2] EOT bit gives the status of serialization. The RXx_FULL bits of the MCSPI_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI_RX_0/1/2/3 register. The MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

12.1.5.3.3.5 Single-Channel Controller Mode

When the MCSPI is configured as a controller device with a single enabled channel (MCSPI_MODULCTRL[2] MS = 0 and MCSPI_MODULCTRL[0] SINGLE = 1), the assertion of the SPIEN[i] signal is optional depending on device connected to the controller. In 3-pin mode (MCSPI_MODULCTRL[1] PIN34 = 1) the controller starts transmitting data when a write to the MCSPI_TX_0/1/2/3 register or the FIFO is performed. In 4-pin mode (MCSPI_MODULCTRL[1] PIN34 = 0) the assertion and de-assertion of SPIEN[i] is controlled by software using the MCSPI_CHCONF_0/1/2/3[20] FORCE bit.

12.1.5.3.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the MCSPI word transfer to complete (wait until the MCSPI_CHSTAT_0/1/2/3[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

12.1.5.3.3.5.2 Force SPIEN[i] Mode

Continuous transfers are allowed manually by keeping the SPIEN[i] signal active for successive MCSPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIEN[i] line. This mode is supported by all channels and any controller sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIEN[i] active mode is supported when:

- A single channel is used (with the MCSPI_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (MCSPI_CHCONF_0/1/2/3).

The state of the SPIEN[i] signal is programmable:

- Writing 1 to the MCSPI_CHCONF_0/1/2/3[20] FORCE bit drives the SPIEN[i] line high when the MCSPI_CHCONF_0/1/2/3[6] EPOL bit is set to 0. SPIEN[i] is driven low when the MCSPI_CHCONF_0/1/2/3[6] EPOL bit is set to 1.
- Writing 0 to the MCSPI_CHCONF_0/1/2/3[20] FORCE bit drives the SPIEN[i] line low when the MCSPI_CHCONF_0/1/2/3[6] EPOL bit is set to 0. SPIEN[i] is driven high when the MCSPI_CHCONF_0/1/2/3[6] EPOL bit is set to 1.
- A single channel is enabled (the MCSPI_CHCTRL_0/1/2/3[0] EN bit is set to 1). The first enabled channel activates the SPIEN[i] line.

When the channel is enabled, the SPIEN[i] signal activates with the programmed polarity. As in the multichannel controller mode, the transfer start depends on the status of the MCSPI_TX_0/1/2/3 register (the MCSPI_CHSTAT_0/1/2/3[1] TXS bit), the status of the MCSPI_RX_0/1/2/3 register (the MCSPI_CHSTAT_0/1/2/3[1] RXS bit), and the defined mode (the MCSPI_CHCONF_0/1/2/3[13-12] TRM bit field) of the channel enabled.

The MCSPI_CHSTAT_0/1/2/3[2] EOT bit gives the transfer status of each MCSPI word. The RXx_FULL bit in the MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RX_0/1/2/3 register.

A change in the configuration parameters is propagated directly on the MCSPI interface. If the SPIEN[i] signal is activated, ensure that the configuration is changed only between MCSPI words to avoid corrupting the current transfer.

Note

To avoid data corruption, SPIEN[i] polarity and SPICLK phase and SPICLK polarity must not be modified when the SPIEN[i] signal is activated.

A delay between MCSPI words that requires the connected MCSPI peripheral device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last MCSPI word, the channel must be deactivated (the MCSPI_CHCTRL_0/1/2/3[0] EN bit set to 0) and SPIEN[i] can be forced to its INACTIVE state using the MCSPI_CHCONF_0/1/2/3[20] FORCE bit.

Figure 12-29 and Figure 12-30 show successive transfers with SPIEN[i] maintained active low with a different configuration for each MCSPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 12-29. Continuous Transfers With SPIEN[i] Maintained Active (Single-Data-Pin Interface Mode)

Figure 12-30. Continuous Transfers With SPIEN[i] Maintained Active (Dual-Data-Pin Interface Mode)

Note

The SPIEN[i] signal can be maintained active via software using the MCSPI_CHCONF_0/1/2/3[20] FORCE bit only when the MCSPI_MODULCTRL[0] SINGLE bit is set to 0x1.

12.1.5.3.3.5.3 Turbo Mode

Turbo mode improves the throughput of the MCSPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI_RX_0/1/2/3 register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the MCSPI_CHCONF_0/1/2/3[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 12.1.5.3.3.2, *Controller Transmit-and-Receive Mode (Full Duplex)*). An enabled channel can be scheduled if its receive register is full (the MCSPI_CHSTAT_0/1/2/3[0] RXS bit) when the shift-register is assigned until the shift register is full.

The MCSPI_RX_0/1/2/3 register cannot be overwritten in turbo mode. Consequently, the MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

12.1.5.3.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the MCSPI word to indicate whether the next MCSPI word must be handled as a command or as data. This feature is available only in controller mode. Start-bit mode

cannot be used at the same time as turbo mode and/or force SPIEN[i] mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the MCSPI_CHCONF_0/1/2/3[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the MCSPI_CHCONF_0/1/2/3[24] SBPOL bit is set to 0, the MCSPI word must be handled as a command. When the MCSPI_CHCONF_0/1/2/3[24] SBPOL bit is set to 1, the MCSPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the MCSPI_CHCONF_0/1/2/3[24] SBPOL bit before writing the MCSPI word to be transmitted to the TX register.

12.1.5.3.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in controller mode with automatic CS generation (the MCSPI_MODULCTRL[0] SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when MCSPI_MODULCTRL[1] PIN34 set to 0.

This mode is programmable per channel through the MCSPI_CHCONF_0/1/2/3[26-25] TCS0 bit field.

Figure 12-31 shows the CS SPIEN timing controls.

Figure 12-31. CS SPIEN Timing Controls

Note

Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

12.1.5.3.3.8 Programmable MCSPI Clock (SPICLK)

In controller mode, the baud rate of the MCSPI serial clock is programmable.

An internal reference clock, SPICLKREF, is used as input of a programmable divider (the MCSPI_CHCONF_0/1/2/3[5-2] CLKD bit field) to generate the bit rate of the serial output clock SPICLK. Table 12-36 summarizes the supported divisor values.

Table 12-36. MCSPI Controller Clock Rates

Divider	Clock Rate
1	50 MHz ⁽¹⁾
2	25 MHz ⁽¹⁾
4	12.5 MHz
8	6.25 MHz

Table 12-36. MCSPI Controller Clock Rates (continued)

Divider	Clock Rate
16	3.125 MHz
32	1.5625 MHz
64	781.25 kHz
128	390 kHz ⁽²⁾
256	195 kHz ⁽²⁾
512	97.7 kHz ⁽²⁾
1024	48.8 kHz ⁽²⁾
2048	24.4 kHz ⁽²⁾
4096	12.2 kHz ⁽²⁾
8192 and higher: Division not supported	—

- (1) These frequencies are not necessarily supported by all MCSPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device-specific Data sheet.
- (2) Approximate Frequency

12.1.5.3.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the MCSPI_CHCONF_0/1/2/3[5-2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the MCSPI_CHCONF_0/1/2/3[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the MCSPI_CHCTRL_0/1/2/3[15-8] EXTCLK bit field is concatenated with the MCSPI_CHCONF_0/1/2/3[5-2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the MCSPI_CHCONF_0/1/2/3[1] POL and MCSPI_CHCONF_0/1/2/3[0] PHA bits (see [Table 12-37](#)).

Table 12-37. CLKSPIO High/Low Time Computation

Clock Ratio F_{RATIO}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{HIGH_REF}	T_{LOW_REF}
Even ≥ 2	$T_{ref} * (F_{RATIO}/2)$	$T_{ref} * (F_{RATIO}/2)$
Odd $\geq (POL = PHA)$	$T_{ref} * (F_{RATIO} - 1)/2$	$T_{ref} * (F_{RATIO} + 1)/2$
Odd $\geq (POL \neq PHA)$	$T_{ref} * (F_{RATIO} + 1)/2$	$T_{ref} * (F_{RATIO} - 1)/2$

Note

F_{RATIO} = SPICLK frequency (F_{OUT}) division ratio
 T_{HIGH} = SPICLK high time period
 T_{LOW} = SPICLK low time period
 T_{ref} = MCSPI_FCLK period
 T_{HIGH_REF} = MCSPI_FCLK high time period
 T_{LOW_REF} = MCSPI_FCLK low time period

If the CLKG bit is set to 1; F_{RATIO} = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

$$\text{Duty_cycle} = (1 - 1/F_{\text{RATIO}})/2$$

Table 12-38 shows examples of clock granularity with a clock source frequency of 50 MHz.

Table 12-38. Clock Granularity Examples

EXTCLK	CLKD	CLKG	F _{RATIO}	PHA	POL	T _{HIGH} (ns)	T _{LOW} (ns)	T _{PERIOD} (ns)	Duty Cycle	F _{OUT} (MHz)
X	0	0	1	X	X	10.0	10.0	20.0	50–50	50
X	1	0	2	X	X	20.0	20.0	40.0	50–50	25
X	2	0	4	X	X	40.0	40.0	80.0	50–50	12.5
X	3	0	8	X	X	80.0	80.0	160.0	50–50	6.2
0	0	1	1	X	X	10.0	10.0	20.0	50–50	50
0	1	1	2	X	X	20.0	20.0	40.0	50–50	25

0	2	1	3	1	1	20.0	40.0	60.0	33–66	16.6
0	3	1	4	X	X	40.0	40.0	80.0	50–50	12.5
5	0	1	81	1	0	820.0	800.0	1620.0	50.6–49.4	0.617
5	7	1	88	X	X	880.0	880.0	1760.0	50–50	0.568

12.1.5.3.4 MCSPI Peripheral Mode

To select the MCSPI peripheral mode, set the MCSPI_MODULCTRL[2] MS bit.

A MCSPI peripheral device can be connected to up to four external MCSPI controller devices but handles transactions with one MCSPI controller device at a time.

In peripheral mode, the MCSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN[i]) and receives an MCSPI clock (SPICLK) from the external MCSPI controller device. Only channel 0 can be configured as a peripheral but through the MCSPI_CHCONF_0[22-21] SPIENSLV bit field any of the SPIEN[i] signals can be used to select the MCSPI module. In peripheral mode and when the MCSPI_MODULCTRL[1] PIN34 is set to 0x0 (default behaviour), the MCSPI uses the edge of SPIEN[i] to detect word length. For this reason, SPIEN[i] must become inactive between each word.

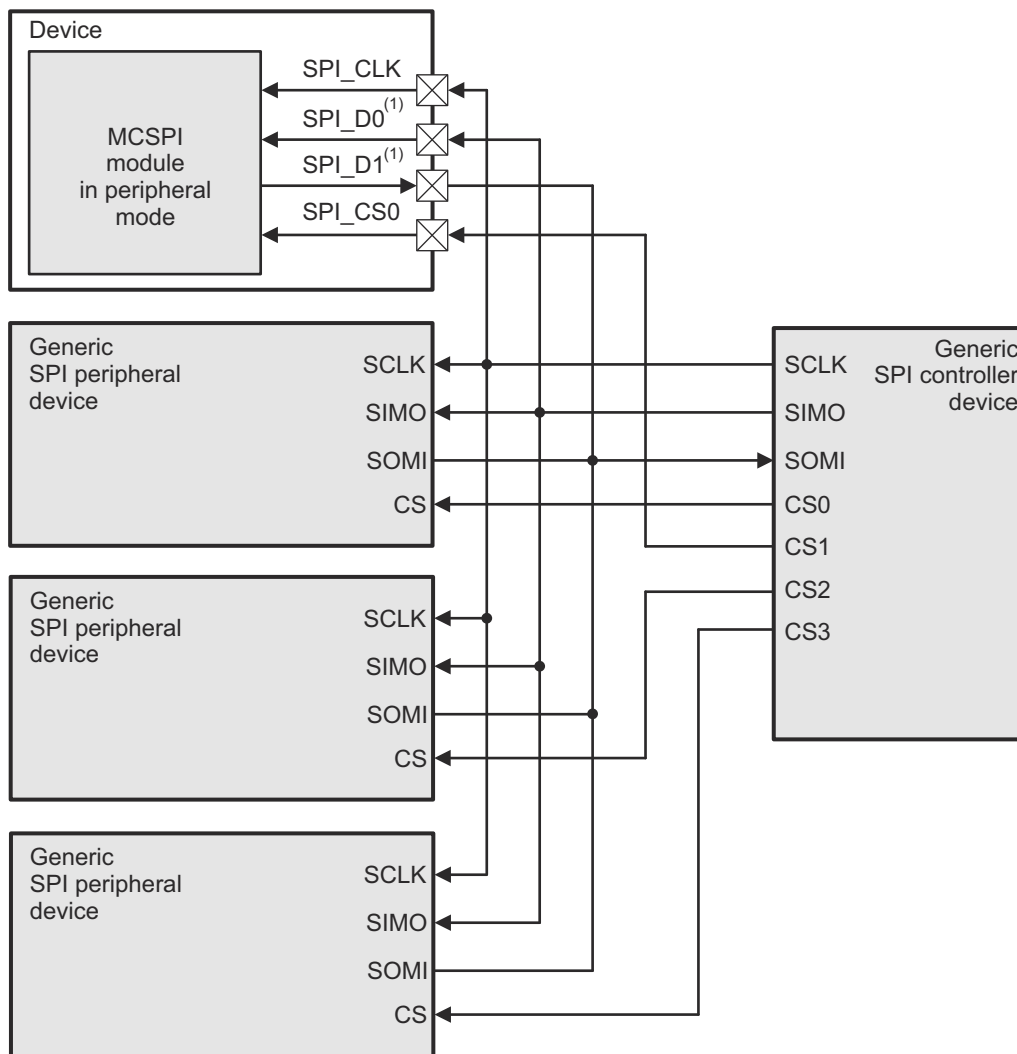

When the MCSPI_MODULCTRL[1] PIN34 is set to 0x0, the MCSPI does not support SPIEN[i] active between MCSPI words. In this case, the MCSPI uses the edge to detect word length.

When the MCSPI_MODULCTRL[1] PIN34 is set to 0x1, a multiword transfer can be performed without needing the external MCSPI controller to deactivate SPIEN[i] between each word as in this case the MCSPI module works in 3-pin peripheral mode and SPIEN[i] is not needed.

12.1.5.3.4.1 Dedicated Resources

Only channel 0 can be enabled in peripheral mode.

Figure 12-32 shows an example of four peripherals wired on a single controller device.

spi-017

- A. Direction depends on MCSPI_CHCONF_0/1/2/3[16] DPE0, MCSPI_CHCONF_0/1/2/3[17] DPE1 and MCSPI_CHCONF_0/1/2/3[18] IS bits

Figure 12-32. Example of MCSPI Peripheral With One Controller and Multiple Peripheral Devices on Channel 0

Channel 0 in peripheral mode has the following resources:

- Its own channel enable, programmable with the MCSPI_CHCTRL_0[0] EN bit. This channel must be enabled before transmission and reception.
- For this mode, the peripheral-select signal can be detected on any of the SPIEN[i] ports. This is programmable with the MCSPI_CHCONF_0[22-21] SPIENSLV bit field.
- Its own transmitter register, MCSPI_TX_0, on top of the common transmit shift register. If the MCSPI_TX_0 register is empty, the MCSPI_CHSTAT_0[1] TXS bit is set. If MCSPI is selected by an external controller (the active signal on the SPIEN[i] port assigned to channel 0), the MCSPI_TX_0 register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI_TX_0 register must be loaded before MCSPI is selected by a controller.
- Its own receiver register, MCSPI_RX_0, on top of the common receive shift register. If the MCSPI_RX_0 register is full, the MCSPI_CHSTAT_0[0] RXS bit is set.

Note

The MCSPI_TX_1/2/3 and MCSPI_RX_1/2/3 registers are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the MCSPI_CHCONF_0:
 - Transmit and receive modes, programmable with the TRM field
 - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The MCSPI modules are in peripheral mode after reset and must be properly configured for the modules to act in controller mode.)
 - MCSPI word length, programmable with the WL bit
 - SPIEN[i] polarity, programmable with the EPOL bit
 - SPICLK polarity, programmable with the POL bit
 - SPICLK phase, programmable with the PHA bit

The SPICLK frequency of a transfer is controlled by the external MCSPI controller connected to the MCSPI peripheral device. The MCSPI_CHCONF_0[5-2] CLKD bit field is not used in peripheral mode.

Note

The configuration of the channel can be loaded in the MCSPI_CHCONF_0 only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of MCSPI. DMA requests are asserted using the MCSPI_CHCONF_0[15] DMAR bit for reading and the MCSPI_CHCONF_0[14] DMAW bit for writing.
- Four interrupt events (see [Section 12.1.5.3.7.2, Interrupt Events in Peripheral Mode](#)).

12.1.5.3.4.2 Peripheral Transmit-and-Receive Mode

The peripheral receive mode is programmable (set the MCSPI_CHCONF_0[13-12] TRM bit field to 0x0).

In peripheral transmit-and-receive mode, the MCSPI_TX_0 register must be loaded before MCSPI is selected by an external MCSPI controller device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TX_0 register content is always loaded in the shift register whether it is updated or not. The event TX0_UNDERFLOW is activated accordingly and does not prevent transmission.

When the MCSPI word transfer completes (the MCSPI_CHSTAT_0[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use MCSPI as a peripheral transmit-only device, the RX0_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RX_0 register (see [Section 12.1.5.3.7.2, Interrupt Events in Peripheral Mode](#)).

12.1.5.3.4.3 Peripheral Transmit-Only Mode

The peripheral transmit-only mode is programmable (set the MCSPI_CHCONF_0[13-12] TRM bit field to 0x2) and avoids the requirement for the processor to read the MCSPI_RX_0 register (minimizing data movement) only when transmission is meaningful.

To use the MCSPI as a peripheral transmit-only device, the RX0_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RX_0 register.

When the MCSPI word transfer completes, the MCSPI_CHSTAT_0[2] EOT bit is set.

[Figure 12-33](#) shows a half-duplex system with a controller device on the left and a transmit-only peripheral device on the right. Each time a bit transfers out from the peripheral, 1 bit transfers in the controller. After eight cycles of the serial clock SPICLK, WordB transfers from the peripheral to the controller.

spi-018

k = 0 or 1 depending on MCSPI_CHCONF_0/1/2/3[16] DPE0, MCSPI_CHCONF_0/1/2/3[17] DPE1 and MCSPI_CHCONF_0/1/2/3[18] IS bits

Figure 12-33. MCSPI Half-Duplex Transmission (Transmit-Only peripheral)

12.1.5.3.4.4 Peripheral Receive-Only Mode

The peripheral receive mode is programmable (set the MCSPI_CHCONF_0[13-12] TRM bit field to 0x1).

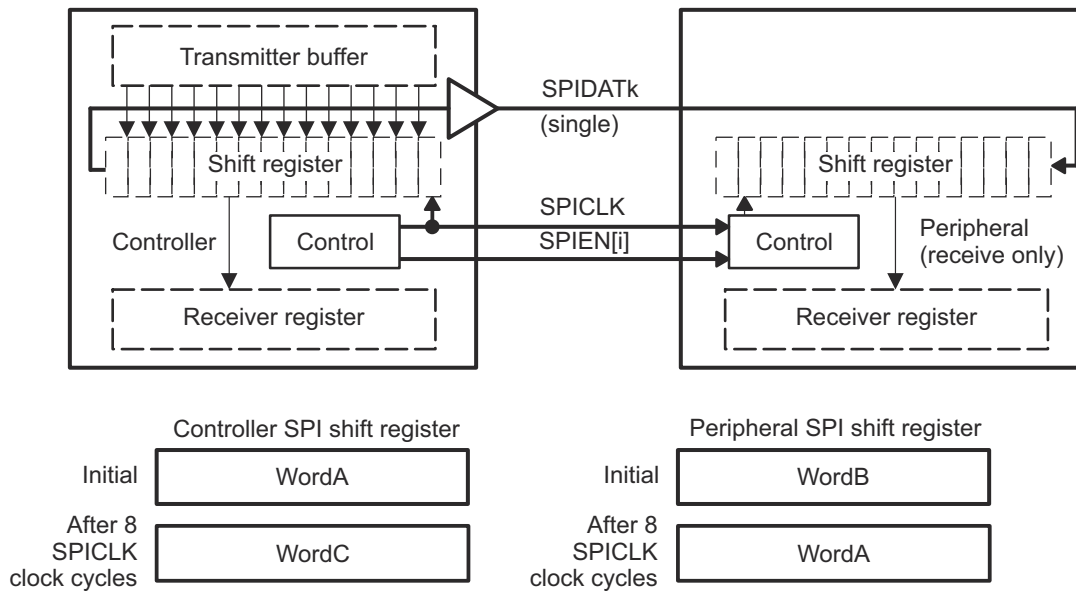

In receive-only mode, the MCSPI_TX_0 register must be loaded before the MCSPI is selected by an external MCSPI controller device. The MCSPI_TX_0 register content is always loaded into the shift register whether it is updated or not. The TX0_UNDERFLOW event is activated accordingly and does not prevent transmission.

When the MCSPI word transfer completes (the MCSPI_CHSTAT_0[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use the MCSPI as a peripheral receive-only device, the TX0_EMPTY and TX0_UNDERFLOW interrupts and the DMA write requests must be disabled due to the state of the MCSPI_TX_0 register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 12-34 shows a half-duplex system with a controller device on the left and a receive-only peripheral device on the right. Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral.

spi-019

k = 0 or 1 depending on MCSPI_CHCONF_0/1/2/3[16] DPE0, MCSPI_CHCONF_0/1/2/3[17] DPE1 and MCSPI_CHCONF_0/1/2/3[18] IS bits

Figure 12-34. MCSPI Half-Duplex Transmission (Receive-Only Peripheral)

12.1.5.3.5 MCSPI 3-Pin or 4-Pin Mode

Depending on targeted application the MCSPI interface can be configured to use 3 or 4 pins through the MCSPI_MODULCTRL[1] PIN34 bit. If this bit is set to 0, MCSPI is in 4-pin mode using the SPICLK, SPIDAT[0], SPIDAT[1] and SPIEN[i] signals. If PIN34 is set to 1 the controller is in 3-pin mode and SPIEN[i] is not used. In this mode all options related to chip select management are useless (EPOL, FORCE and TCS0 bits of MCSPI_CHCONF_0/1/2/3). 3-pin and 4-pin operation applies to both controller and peripheral modes.

12.1.5.3.6 MCSPI FIFO Buffer Management

The MCSPI controller has a built-in 64-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the MCSPI_CHCONF_0/1/2/3[28] FFER or MCSPI_CHCONF_0/1/2/3[27] FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Controller or peripheral mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (MCSPI_CHCONF_0/1/2/3[11-7] WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see [Figure 12-35](#)) or receive (see [Figure 12-36](#)) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see [Figure 12-37](#)).

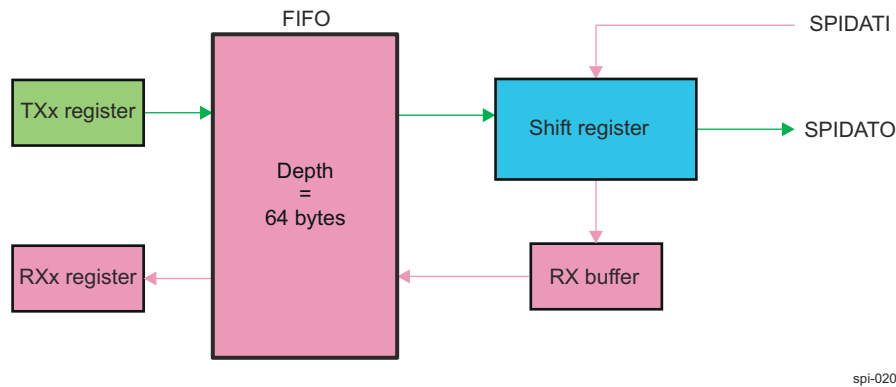

Figure 12-35. Buffer Used in Transmit Direction Only

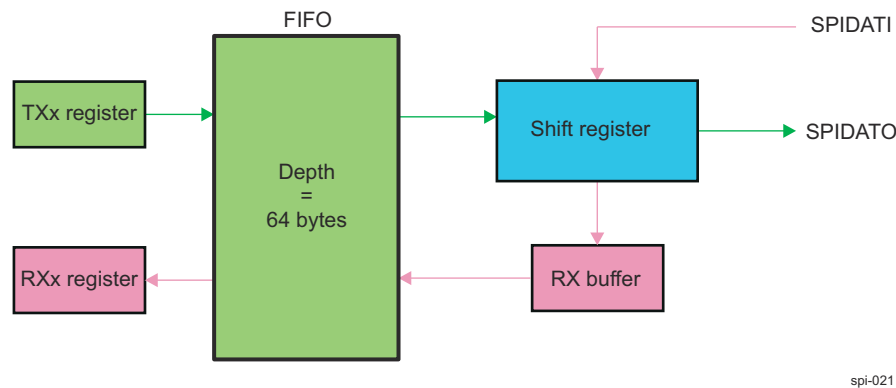

Figure 12-36. Buffer Used in Receive Direction Only

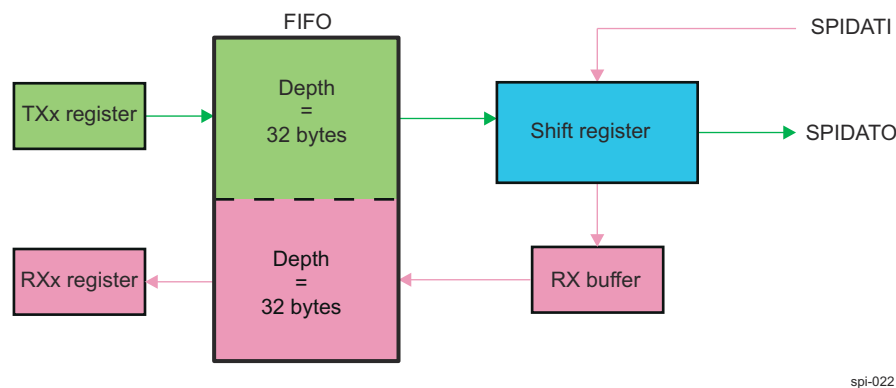

Figure 12-37. Buffer Used for Transmit and Receive Directions

Two levels (MCSPI_XFERLEVEL[5-0] AEL and MCSPI_XFERLEVEL[13-8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the MCSPI word length. The driver must set these values as a multiple of the MCSPI word length defined in WL. [Table 12-39](#) lists the number of bytes written in the FIFO, depending on the word length.

Table 12-39. FIFO Writes, Word Length Relationship

	MCSPI Word Length (WL)		
	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

12.1.5.3.6.1 Buffer Almost Full

The MCSPI_XFERLEVEL[15-8] AFL bit field is needed when the buffer is used to receive an MCSPI word from a peripheral (the MCSPI_CHCONF_0/1/2/3[28] FFER bit must be set to 1). It defines the almost-full buffer status. See [Figure 12-38](#).

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the processor to enable the system to read AFL + 1 bytes from the receive register.

Note

AFL + 1 must correspond to a multiple value of the MCSPI_CHCONF_0/1/2/3[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

Figure 12-38. Buffer Almost Full Level (AFL)

Note

The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the request is asserted on the same conditions as the MCSPI_IRQSTATUS RXx_FULL flag.

12.1.5.3.6.2 Buffer Almost Empty

The MCSPI_XFERLEVEL[7-0] AEL bit field is needed when the buffer is used to transmit an MCSPI word to a peripheral (the MCSPI_CHCONF_0/1/2/3[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See [Figure 12-39](#).

When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the processor to enable the system to write AEL + 1 bytes to the transmit register.

Note

AEL + 1 must correspond to a multiple value of the MCSPI_CHCONF_0/1/2/3[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

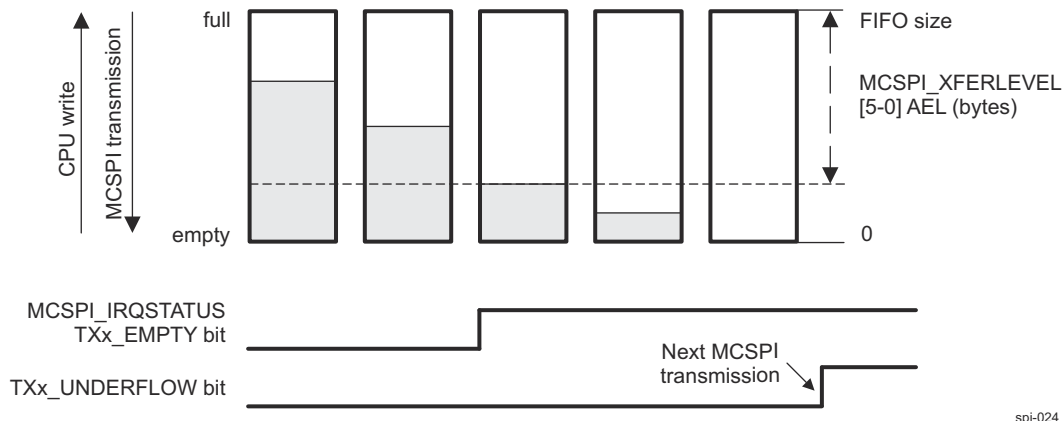

Figure 12-39. Buffer Almost Empty Level (AEL)

Note

The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the request is asserted on the same conditions as the MCSPI_IRQSTATUS TXx_EMPTY flag.

12.1.5.3.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the MCSPI_XFERLEVEL[31-16] WCNT bit field to define the number of MCSPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of MCSPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many MCSPI transfers have been done. For received words, software must poll the MCSPI_CHSTAT_i[5] RXFFE bit and read the MCSPI_RX_0/1/2/3 receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the MCSPI_IRQSTATUS[17] EOW bit is set), the user can disable the channel and poll the MCSPI_CHSTAT_0/1/2/3[5] RXFFE bit to know the last MCSPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

12.1.5.3.6.4 Multiple MCSPI Word Access

The processor has the ability to perform multiple MCSPI word access to the receive or transmit registers within a single 32-bit interface access by setting the MCSPI_MODULCTRL[7] MOA to 1 under specific conditions:

- The channel selected has the FIFO enable.
- Only FIFO sense enabled support the kind of access.
- MCSPI_MODULCTRL[7] MOA is set to 1.
- Only 32-bit interface access and data width can be performed to receive or transmit registers, for other kind of access the processor must de-assert MCSPI_MODULCTRL[7] MOA bit.
- The level MCSPI_XFERLEVEL[7-0] AEL and MCSPI_XFERLEVEL[15-8] AFL must be 32-bit aligned, it means that AEL[0] = AEL[1] = 1 or AFL[0] = AFL[1] = 1.
- If MCSPI_XFERLEVEL[31-16] WCNT is used it must be configured according to MCSPI word length.
- The word length of MCSPI words allows to perform multiple MCSPI access, that means that MCSPI_CHCONF_0/1/2/3[11-7] WL is <16.

The number of MCSPI word access depends on MCSPI word length:

- $3 \leq WL \leq 7$, MCSPI word length smaller or equal to byte length, 4 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI_XFERLEVEL[31-16] WCNT), set the bit field to WCNT[0] = WCNT[1] = 0.

- $8 \leq WL \leq 15$, MCSPI word length greater than byte or equal to 16-bit length, 2 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI_XFERLEVEL[31-16] WCNT)), set the bit field to WCNT[0] = 0.
- $16 \leq WL$ Multiple MCSPI word access is not applicable.

12.1.5.3.6.5 First MCSPI Word Delay

Figure 12-40 shows the MCSPI controller ability to delay the first MCSPI word transfer to give time for system to complete some parallel processes or fill the FIFO in order to improve transfer bandwidth. This delay is applied only on first MCSPI word after MCSPI channel enabled and first write in transmit register. It is based on output clock frequency.

This option is meaningful in controller mode and single channel mode asserted through MCSPI_MODULCTRL[0] SINGLE.

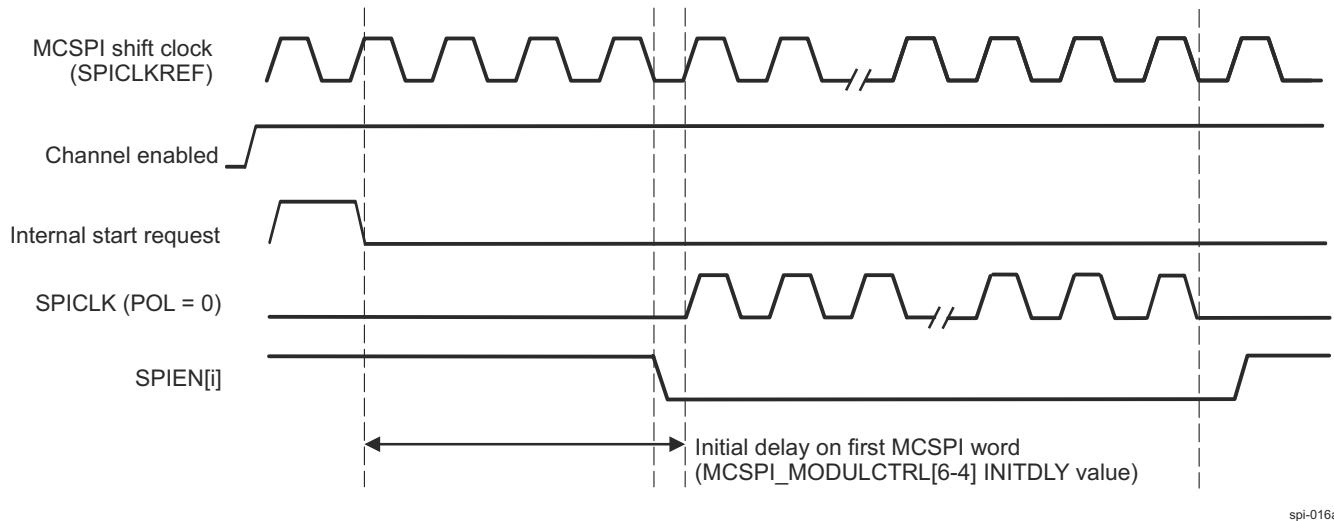

Figure 12-40. Controller Single Channel Initial Delay

Few delay values are available: No delay, 4/8/16/32 MCSPI cycles.

Its accuracy is half cycle in clock bypass mode and depends on clock polarity and phase.

12.1.5.3.7 MCSPI Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the MCSPI_IRQSTATUS register (RXx_FULL, TXx_UNDERFLOW, TXx_EMPTY, etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the MCSPI_IRQENABLE register (RXx_FULL_ENABLE, TXx_UNDERFLOW_ENABLE, TXx_EMPTY_ENABLE, etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The MCSPI supports interrupt-driven and polling operations.

12.1.5.3.7.1 Interrupt Events in Controller Mode

In controller mode, the interrupt events related to the state of the MCSPI_TX_0/1/2/3 register are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the state of the MCSPI_RX_0/1/2/3 register is RXx_FULL.

12.1.5.3.7.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TX_0/1/2/3 register is empty (transient event). Enabling a channel automatically triggers this event, except in controller receive-only mode (see Section 12.1.5.3.3.4, *Controller Receive-Only Mode*). When the FIFO buffer is enabled (the

MCSPi_CHCONF_0/1/2/3[27] FFEW bit is set to 1), the MCSPi_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPi_XFERLEVEL[5-0] AEL bit field.

The MCSPi_TX_0/1/2/3 register must be loaded with data to remove the source of the interrupt; the MCSPi_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPi_TX_0/1/2/3 register defined by the MCSPi_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

12.1.5.3.7.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPi_TX_0/1/2/3 register or the FIFO is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPi (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in controller mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPi_TX_0/1/2/3 register, because the channel is enabled. To avoid having a TXx_UNDERFLOW event, the MCSPi_TX_0/1/2/3 register must seldom be loaded.

The MCSPi_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

12.1.5.3.7.1.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPi_RX_0/1/2/3 register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPi_CHCONF_0/1/2/3[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPi_XFERLEVEL[13-8] AFL threshold.

The MCSPi_RX_0/1/2/3 register must be read to remove the source of the interrupt; the MCSPi_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPi_RX_0/1/2/3. The processor must perform the correct number of reads.

12.1.5.3.7.1.4 End Of Word Count

The MCSPi_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPi_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPi transfer is halted on the channel using the FIFO buffer as soon as MCSPi_XFERLEVEL[31-16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPi_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

12.1.5.3.7.2 Interrupt Events in Peripheral Mode

In peripheral mode, the interrupt events related to the state of the MCSPi_TX_0/1/2/3 register are TX0_EMPTY and TX0_UNDERFLOW. The interrupt events related to the state of the MCSPi_RX_0/1/2/3 are RX0_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPi_IRQSTATUS register.

12.1.5.3.7.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPi_TX_0/1/2/3 register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the

MCSPi_CHCONF_0/1/2/3[27] FFEW bit is set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPi_XFERLEVEL[5-0] AEL bit field.

The MCSPi_TX_0/1/2/3 register must be loaded with data to remove the source of the interrupt; the MCSPi_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPi_TX_0/1/2/3 register defined by MCSPi_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

12.1.5.3.7.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the MCSPi_TX_0/1/2/3 register is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPi (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in peripheral mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPi_TX_0/1/2/3 register because the channel is enabled.

The MCSPi_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

12.1.5.3.7.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPi_RX_0/1/2/3 register is being filled (transient event). When the FIFO buffer is enabled (the MCSPi_CHCONF_0/1/2/3[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the MCSPi_XFERLEVEL[13-8] AFL bit field.

The MCSPi_RX_0/1/2/3 register must be read to remove the source of the interrupt; the MCSPi_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPi_RX_0/1/2/3. The processor must perform the correct number of reads.

12.1.5.3.7.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in peripheral mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the MCSPi_RX_0/1/2/3 register or FIFO is full when a new MCSPi word is received. The MCSPi_RX_0/1/2/3 register is always overwritten with the new MCSPi word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0_OVERFLOW event should not appear in peripheral mode using the FIFO.

The RX0_OVERFLOW event indicates an error (data loss) in peripheral mode.

The MCSPi_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

12.1.5.3.7.2.5 End Of Word Count

The MCSPi_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPi_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPi transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

12.1.5.3.7.3 Interrupt-Driven Operation

An interrupt enable bit in the MCSPI_IRQENABLE register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the processor must:

1. Read the MCSPI_IRQSTATUS register to identify which event occurred.
2. Read the MCSPI_RX_0/1/2/3 register that corresponds to the event to remove the source of an RXx_FULL event or write into the MCSPI_TX_0/1/2/3 register that corresponds to the event to remove the source of a TXx_EMPTY event. No action is required to remove the source of the TXx_UNDERFLOW and RX0_OVERFLOW events.
3. Set the corresponding bit of the MCSPI_IRQSTATUS register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

12.1.5.3.7.4 Polling

When the interrupt capability of an event is disabled in the MCSPI_IRQENABLE register, the interrupt line is not asserted, but the status bits in the MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx_FULL: To remove the source of the event, the processor must read the corresponding MCSPI_RX_0/1/2/3 register.
- TXx_EMPTY: To remove the source of the event, the processor must write into the corresponding MCSPI_TX_0/1/2/3 register.
- TXx_UNDERFLOW and RX0_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the MCSPI_IRQSTATUS register to 1. This does not affect the interrupt line state.

12.1.5.3.8 MCSPI DMA Requests

Each MCSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per MCSPI channel (one for read and one for write).

The DMA read request line is asserted when the MCSPI channel is enabled and new data is available in the receive register of the MCSPI channel. A DMA read request can be individually masked with the MCSPI_CHCONF_0/1/2/3[15] DMAR bit. The DMA read request line is de-asserted when reading of the MCSPI_RX_0/1/2/3 register of the MCSPI channel completes.

The DMA write request line is asserted when the MCSPI channel is enabled and the MCSPI_TX_0/1/2/3 register of the MCSPI channel is empty. A DMA write request can be individually masked with the MCSPI_CHCONF_0/1/2/3[14] DMAW bit. The DMA write request line is de-asserted when loading of the MCSPI_TX_0/1/2/3 register of the channel completes.

12.1.5.3.9 MCSPI Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity.

12.1.5.3.9.1 Normal Mode

In normal mode, internal MCSPI module clocks are automatically switched off (autogated) when there is no activity in peripheral or controller mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The MCSPI_SYSCONFIG[0] AUTOIDLE bit is set.

- In controller mode, there is no data to transmit or receive in all channels.
- In peripheral mode, the MCSPI is not selected by the external controller and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In controller mode, an internal access occurs.
- In peripheral mode, an internal access occurs or the MCSPI is selected by the external controller.

12.1.5.3.9.2 Idle Mode

Note

Some of the MCSPI features described in this section may not be supported on this family of devices. For more information, see *MCSPI Not Supported Features*.

At the power management level, when all conditions to shut off the MCSPI_FCLK or MCSPI_ICLK clocks are met, the corresponding LPSC asserts a clock stop request to the MCSPI. Although this procedure is completely hardware-oriented and out of software control, the method in which the MCSPI module acknowledges the clock stop request can be configured through the MCSPI_SYSCONFIG[4-3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgement modes are:

- Force-idle mode (the MCSPI_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0): The MCSPI module acknowledges unconditionally the clock stop request, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The MCSPI never acknowledges the clock stop request and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow shut off of MCSPI_FCLK and MCSPI_ICLK.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The MCSPI acknowledges the clock stop request, depending on its internal activity. MCSPI acknowledges the shut off of MCSPI_FCLK and MCSPI_ICLK only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the MCSPI also offers an additional feature to control gating of MCSPI_FCLK or MCSPI_ICLK. The MCSPI_SYSCONFIG[9-8] CLOCKACTIVITY bit field determines which clock shuts down (MCSPI_FCLK, MCSPI_ICLK, neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the MCSPI to determine on which part of the module the conditions to acknowledge the clock stop request are tested. For example, if MCSPI_FCLK is not shut off on clock stop request, the MCSPI considers only MCSPI_ICLK and the associated pending activities before acknowledging the request.

Some MCSPI features are associated with MCSPI_ICLK and others with MCSPI_FCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if MCSPI acknowledges the clock stop request.

12.1.5.3.9.2.1 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the MCSPI_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0.
 - In force-idle mode, the MCSPI responds unconditionally to the clock stop request by de-asserting unconditionally the interrupt and DMA request lines, if asserted.
 - The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI_IRQSTATUS register.
 - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely de-asserted. The interface clock and MCSPI clock provided to the MCSPI can be switched off.
 - A clock stop request during an MCSPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.

12.1.5.4 MCSPI Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the MCSPI module.

12.1.5.4.1 MCSPI Operational Mode Configuration

12.1.5.4.1.1 MCSPI Operational Modes

The selection of the working mode is done with the MCSPI_CHCONF_0/1/2/3 register.

Table 12-40. MCSPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set receive mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x1
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 12-41. MCSPI Transmit Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x2
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 12-42. MCSPI Transmit-and-Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x0
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

12.1.5.4.1.1.1 Common Transfer Sequence

MCSPI module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT-RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN[i] lines assertion/deassertion: automatic, manual

For all these sequences, the host process contains the main process and the interrupt routines.

The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

Table 12-43 represents the main sequence which is common to all transfers.

In multi-channel controller mode, the sequences of different channels can be run simultaneously.

Table 12-43. Common Transfer Sequence (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel i bits]	0b1111
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	0x-
Write MCSPI_CHCONF_0/1/2/3 to configure the channel	MCSPI_CHCONF_0/1/2/3	0x-
Start the channel	MCSPI_CHCTRL_0/1/2/3[0] EN	1
Wait for the first write request (TX empty or DMA write)		
Write the transmitter register with data	MCSPI_TX_0/1/2/3	0x-
Wait for the host event for end of transfer		

Table 12-43. Common Transfer Sequence (Main Process) (continued)

Step	Register/Bit Field/Programming Model	Value
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

12.1.5.4.1.1.2 End of Transfer Sequences

The end of transfer depends on the transfer mode. [Table 12-44](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 12-44. End of Transfer Sequences

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
CONTROL LER Normal	End of transfer sequence	See Section 12.1.5.4.1.1.3		See Section 12.1.5.4.1.1.4.1	See Section 12.1.5.4.1.1.4.2	See Section 12.1.5.4.1.1.5.1	See Section 12.1.5.4.1.1.5.2
	Minimum number of word	1	1	1	1	1	2
	DMA transfer size		N		N		N-1
CONTROL LER Turbo	End of transfer sequence	See Section 12.1.5.4.1.1.3		See Section 12.1.5.4.1.1.4.1	See Section 12.1.5.4.1.1.4.2	See Section 12.1.5.4.1.1.6.1	See Section 12.1.5.4.1.1.6.2
	Minimum number of word	1	1	1	1	2	3
	DMA transfer size		N		N		N-2
PERIPHER AL	End of transfer sequence	See Section 12.1.5.4.1.1.3		See Section 12.1.5.4.1.1.4.1	See Section 12.1.5.4.1.1.4.2	See Section 12.1.5.4.1.1.7	
	Minimum number of word	1	1	1	1	1	1
	DMA transfer size		N		N	N	N

The transfer to execute has a size of N words.

The different sequences can be merged in one process to manage transfers of several types. The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write_count = 0
- read_count = 0
- channel_enable = FALSE
- last_transfer = FALSE
- last_request = FALSE

They are initialized before starting the channel.

12.1.5.4.1.1.3 Transmit-and-Receive (Controller and Peripheral)

If the requests are configured in DMA, write_count and read_count are assigned with 'N' when the DMA handlers have completed their 'N' CBASS0 accesses.

Table 12-45. Transmit-and-Receive (Controller and Peripheral) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait for write_count = N AND read_count = N		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

Table 12-46. Transmit-and-Receive (Controller and Peripheral) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111

Table 12-46. Transmit-and-Receive (Controller and Peripheral) (Interrupt Routine) (continued)

Step	Register/Bit Field/Programming Model	Value
IF: TXx_EMPTY		
Write the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
Increment write_count +1		
IF: RXx_FULL		
Read the receiver register	MCSPi_RX_0/1/2/3	
Increment read_count +1		
ENDIF		

12.1.5.4.1.1.4 Transmit-Only (Controller and Peripheral)

12.1.5.4.1.1.4.1 Based on Interrupt Requests

Table 12-47. Transmit-Only With Interrupts (Controller and Peripheral) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

Table 12-48. Transmit-Only With Interrupts (Controller and Peripheral) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
IF: TXx_EMPTY AND write_count < N		
Write the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
Increment write_count +1		
ELSEIF: write_count ≥ N		
last_transfer = TRUE		
ENDIF		

12.1.5.4.1.1.4.2 Based on DMA Write Requests

When the DMA handler has completed its 'N' CBASS0 accesses, write_count is assigned with 'N'.

Table 12-49. Transmit-Only With DMA (Controller and Peripheral) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until write_count = N		
Disable DMA write request	MCSPi_CHCONF_0/1/2/3[14] DMAW	0
Wait until last_transfer = TRUE

Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
IF: RXx_FULL		
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		
ENDIF		

12.1.5.4.1.1.8 Transfer Procedures With FIFO

These flows describe the transfer with FIFO.

The MCSPi module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT-RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see [Section 12.1.5.3.6, MCSPi FIFO Buffer Management](#).

Table 12-61. FIFO Mode Common Sequence (Controller) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS	1
Write MCSPi_IRQENABLE to enable interrupts	MCSPi_IRQENABLE	1
Write MCSPi_CHCONF_0/1/2/3 to configure the channel	MCSPi_CHCONF_0/1/2/3	0x-
Write MCSPi_XFERLEVEL	MCSPi_XFERLEVEL	0x-
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
IF: Receive only		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
ENDIF		
Wait for the host event for end of transfer		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

12.1.5.4.1.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in [Section 12.1.5.4.1.1.8, Transfer Procedures With FIFO](#).

In multi-channel, only one channel can use the FIFO.

Before enabling the FIFO for a channel (MCSPI_CHCONF_0/1/2/3[28] FFER and MCSPI_CHCONF_0/1/2/3[27] FFEW bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Peripheral mode, the channel 0 only can be activated. The correct SPIEN line is chosen in MCSPI_CHCONF_0[22-21] SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request has been released by writing the MCSPI_TX_0/1/2/3 register, even in receive-only mode (only one write request occurs in this case).

12.1.5.4.1.1.8.2 End of Transfer Sequences in FIFO Mode

Table 12-62 summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 12-62. End of Transfer Sequences in FIFO Mode

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See Figure 12-41	See Figure 12-43	See Figure 12-44
No	See Figure 12-42	See Figure 12-43	See Figure 12-45

The end of transfer sequences are described from the start of the channel.

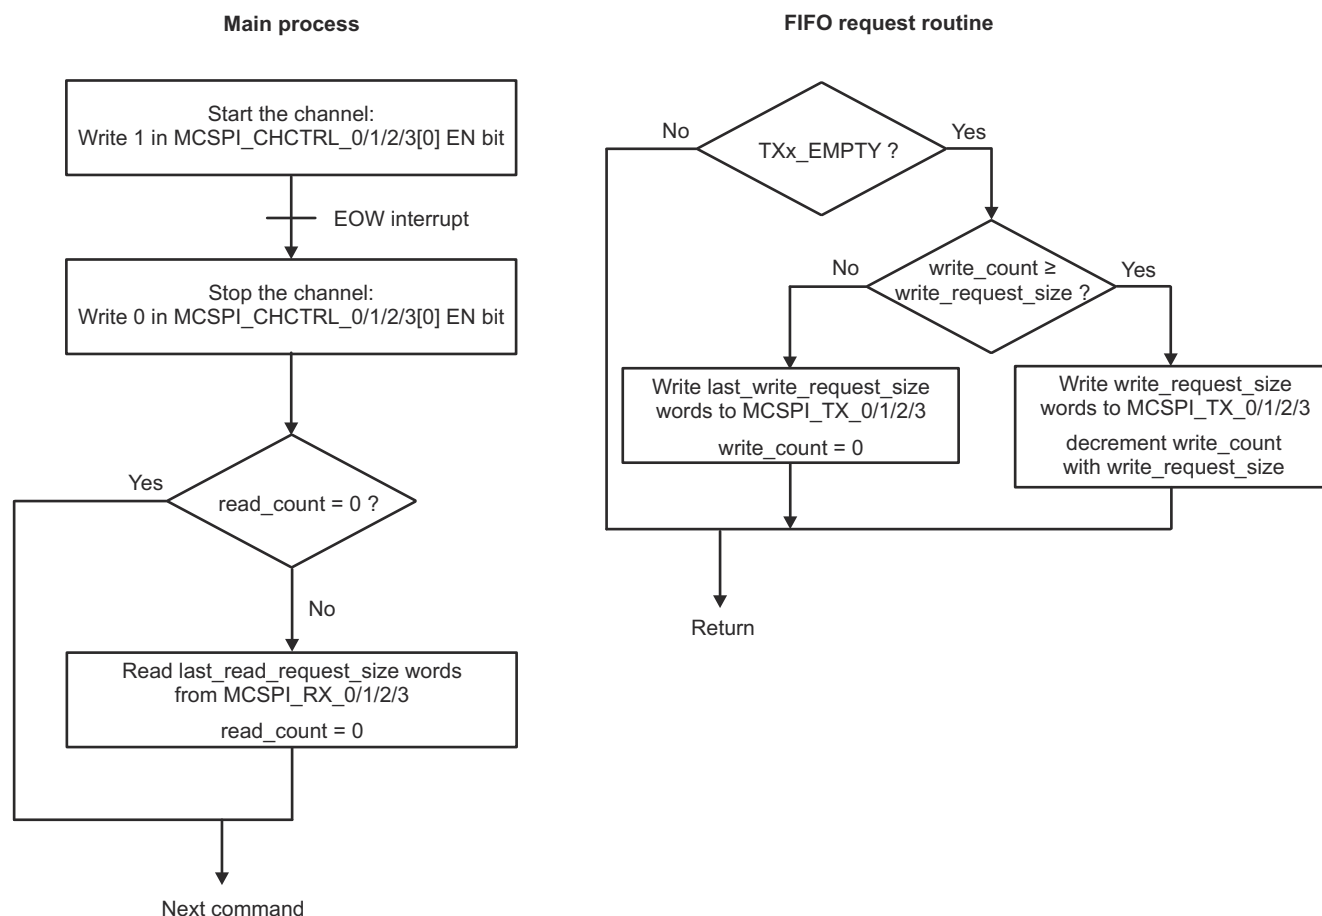

In these sequences, some soft variables are used:

- write_count = N
- read_count = N
- last_request = FALSE

They are initialized before starting the channel.

12.1.5.4.1.1.8.3 Transmit-and-Receive With Word Count

[Figure 12-41](#) shows the flow of a transfer in transmit-and-receive mode, with word count.

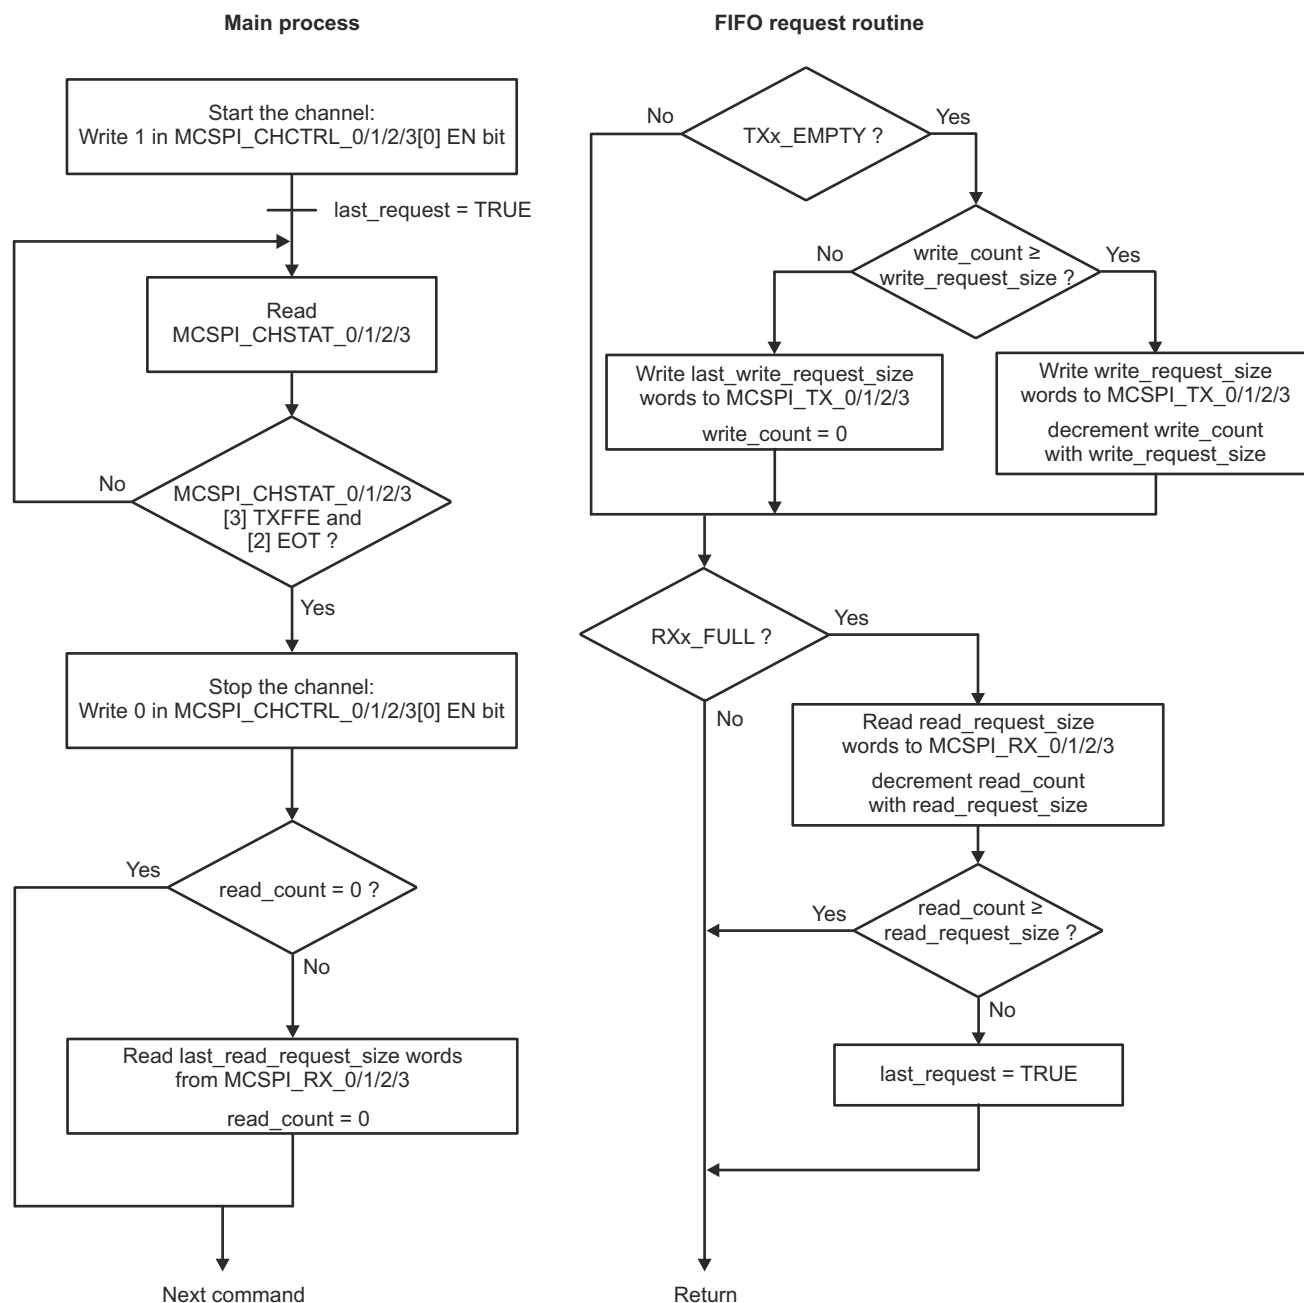

mcspi_025

Figure 12-41. FIFO Mode Transmit-and-Receive With Word Count (Controller)

12.1.5.4.1.1.8.4 Transmit-and-Receive Without Word Count

Figure 12-42 shows the flow of a transfer in transmit-and-receive mode, without word count.

mcspi_026

Figure 12-42. FIFO Mode Transmit-and-Receive Without Word Count (Controller)

12.1.5.4.1.1.8.5 Transmit-Only

Figure 12-43 shows the flow of a transfer in transmit-only mode, with or without word count. The difference between word count enabled or not is just on the condition after starting the channel:

- word count enable: wait for EOW interrupt
- word count disable: wait for write_count = 0

mcspi_027

Table 12-66. Transmit-and-Receive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-42.	
Start the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Write the transmitter register with data.	MCSPi_TX_0/1/2/3	0x-
Wait until transmit/receive word?	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Read the receiver register.	MCSPi_RX_0/1/2/3	0x-

12.1.6 Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the function, operation, and configuration of the Universal Asynchronous Receiver/Transmitter (UART)/RS-485/Infrared Data Association (IrDA)/Consumer Infrared (CIR)/ISO 7816 module in the device.

Note

UART and USART acronyms are used interchangeably in this section.

12.1.6.1 UART Overview

The UART is a slave peripheral that utilizes the DMA for data transfer or interrupt polling via host CPU. There are UART modules in the device. All UART modules support IrDA and CIR modes when 48 MHz function clock is used. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

12.1.6.1.1 UART Features

The UART includes the following features:

- 16C750-compatible
- RS-485 external transceiver auto flow control support
- 64-byte FIFO buffer for receiver and 64-byte FIFO buffer for transmitter
- Programmable interrupt trigger levels for FIFOs
- Programmable sleep mode
- The 48 MHz functional clock is default option and allows baud rates up to 3.6 Mbps
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Optional multi-drop transmission
- Configurable time-guard feature
- Configurable data format:
 - Parity bit: Even, Odd, None
 - Stop-bit: 1, 1.5, 2 bit
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- False start bit detection
- Line break generation and detection
- Fully prioritized interrupt system controls
- Internal test and loopback capabilities
- Modem control functions (CTS, RTS)
- Only module instance in MAIN domain has extended modem control signals (DCD, RI, DTR, DSR)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.1.6.1.2 IrDA Features

The IrDA includes the following features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
 - Slow infrared (SIR 115.2 KBAUD), medium infrared (MIR 0.576 MBAUD) and fast infrared (FIR 4.0 MBAUD) operations (very fast infrared (VFIR) is not supported)
 - Frame formatting: addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
 - Asynchronous transparency (automatic insertion of break character)
 - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
 - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection
- IrDA mode when 48 MHz function clock is used

12.1.6.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR includes the following features to provide CIR support for remote-control applications:

- Transmit and receive mode
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle
- CIR mode when 48 MHz function clock is used

12.1.6.1.4 UART Ports

Table 12-67. UART Clocks and Resets

Clocks	
Module Clock Input	Description
UART_ICLK	UART interface clock
UART_FCLK	UART functional clock
Resets	
Module Reset Input	Description
UART_RST	UART reset

Table 12-68. UART Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
USART_0_INT	UART interrupt request	Level
DMA Events		
Module DMA Event	Description	Type
USART_x_EVT0	UART transmit request line	Level
USART_x_EVT1	UART receive request line	Level

12.1.6.2 UART Environment

This section describes the UART/RS-485/IrDA/CIR external connections (environment).

[Table 12-69](#) lists the UART interface input/output (I/O) signals.

Table 12-69. UART I/O Signals

Module Pin Name	I/O ⁽¹⁾	Description
RX	I	Serial data input
TX	O	Serial data output ⁽²⁾
CTS	I	Clear to send ⁽³⁾
RTS	O	Request to send ⁽⁴⁾
DCD	I	Data Carrier Detect ⁽⁵⁾
DSR	I	Data Set Ready ⁽⁶⁾
DTR	O	Data Terminal Ready ⁽⁷⁾
RIN	I	Ring Indicator ⁽⁸⁾

(1) I = Input; O = Output

(2) Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UART_MDR1[2-0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).

(3) Active-low modem status signal. Reading the UART_MSR[4] NCTS_STS bit checks the condition of CTS. Reading the UART_MSR[0] CTS_STS bit checks a change of state of CTS since the last read of the modem status register. The auto-CTS mode uses CTS to control the transmitter.

- (4) When active (low), the module is ready to receive data. Setting the UART_MCR[1] RTS bit activates RTS signal, which becomes inactive as the result of a module reset, loopback mode, or clearing the UART_MCR[1] RTS bit. In auto-RTS mode, RTS signal becomes inactive as a result of the receiver threshold logic.
- (5) Active-low modem status signal. The condition of DCD can be checked by reading the UART_MSR[7] NCD_STS bit. Any change in its state can be detected by reading the UART_MSR[3] DCD_STS bit.
- (6) Active-low modem status signal. Reading the UART_MSR[5] NDSR_STS bit checks the condition of DSR. Reading the UART_MSR[1] DSR_STS bit checks a change of state of DSR since the last read of the UART_MSR register.
- (7) When active (low), this signal informs the modem that the module is ready to communicate. It is activated by setting the UART_MCR[0] DTR bit.
- (8) Active-low modem status signal. The condition of RIN can be checked by reading the UART_MSR[6] NRI_STS bit. Any change in its state can be detected by reading the UART_MSR[2] RI_STS bit.

Table 12-70 lists the RS-485 interface input/output (I/O) signals.

Table 12-70. UART I/O Signals (RS-485 Mode)

Module Pin	I/O ⁽¹⁾	Description
RX	I	Serial data input
TX	O	Serial data output
DIR	O	RS-485 Direction

- (1) I = Input; O = Output

Table 12-71 lists the IrDA interface I/O signals.

Table 12-71. UART I/O Signals (IrDA Mode)

Module Pin	I/O ⁽¹⁾	Description
RX	I	Serial data input
TX	O	Serial data output in CIR and IrDA modes (SIR, MIR, and FIR). ⁽²⁾
SD	O	SD mode is used to configure the transceivers. ⁽³⁾

- (1) I = Input; O = Output
- (2) In other modes, this pin is set to the reset value (inactive state).
- (3) The SD pinout (see UART_ACREG[6] SD_MOD bit).

12.1.6.3 UART Functional Description

12.1.6.3.1 UART Block Diagram

The UART module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, RS-485, IrDA, or CIR) and enables the mechanism corresponding to the chosen function.
- Register mode: Enables conditional access to registers.

For more information about mode configuration, see *Mode Selection*.

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses a dedicated state-machine that is responsible for the transition between FIFO data and the associated frame data.
- Interrupt management: Different interrupt types are generated depending on the chosen function. In each mode, when an interrupt is generated, the UART_IIR_UART register indicates the interrupt type.
 - UART mode interrupts: Seven interrupts prioritized in six different levels
 - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
 - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

In parallel with these functional blocks, a power-saving strategy exists for each function.

The UART block diagram is shown below.

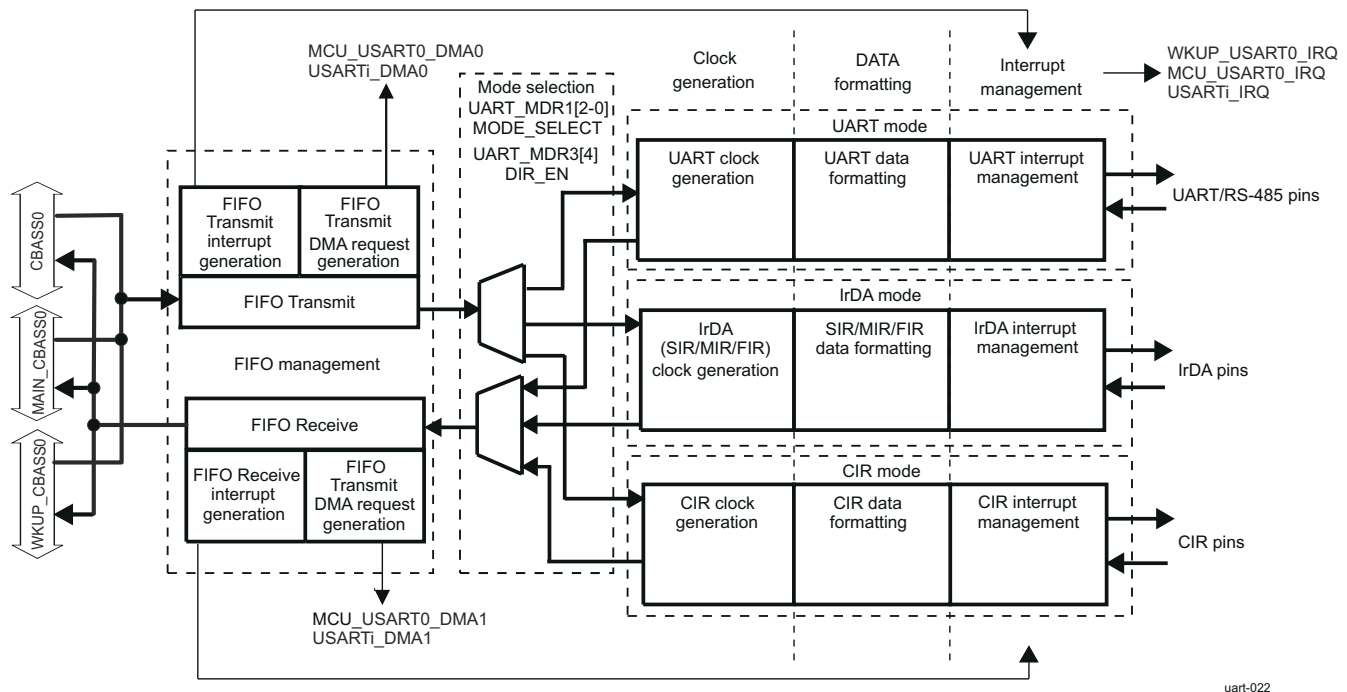

Figure 12-46. UART Functional Block Diagram

12.1.6.3.2 UART Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses.

12.1.6.3.3 UART Software Reset

The UART_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

12.1.6.3.3.1 Independent TX/RX

The receiver and transmitter are enabled by default after reset. Software can choose to disable, re-enable or to reset either the RX or the TX side independently of the other through the UART_ECR register.

12.1.6.3.4 UART Power Management

12.1.6.3.4.1 UART Mode Power Management

12.1.6.3.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UART_IER_UART[4] SLEEP_MODE bit to 1 (when the UART_EFR[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RX, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the RX line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see [Section 12.1.6.3.5.1.2, Wake-Up Interrupt](#).

Note

There must be no writing to the divisor latches, UART_DLL and UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UART_IER_UART[4] SLEEP_MODE bit before writing to the UART_DLL or UART_DLH register.

12.1.6.3.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

For more information, see *Power*, in the *Device Configuration*.

12.1.6.3.4.2 IrDA Mode Power Management

12.1.6.3.4.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART_MDR1[3] IR_SLEEP bit to 1.

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RXD, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the RXD line or when data is written to the TX FIFO.

12.1.6.3.4.2.2 System Power Saving

System power saving for the IrDA mode has the same function as for the UART mode (see [Section 12.1.6.3.4.1.2, System Power Saving](#)).

12.1.6.3.4.3 CIR Mode Power Management

12.1.6.3.4.3.1 Module Power Saving

Module power saving for the CIR mode has the same function as for the IrDA mode (see [Section 12.1.6.3.4.2.1, Module Power Saving](#)).

12.1.6.3.4.3.2 System Power Saving

System power saving for the CIR mode has the same function as for the UART mode (see [Section 12.1.6.3.4.1.2, System Power Saving](#)).

12.1.6.3.4.4 Local Power Management

[Table 12-72](#) describes power-management features available for the UART.

Note

For information about source clock gating and the sleep/wake-up transitions description, see *Power*, in the *Device Configuration*.

Table 12-72. UART Local Power-Management Features

Feature	Registers	Description
Clock autogating		
Peripheral idle modes		
Clock activity	N/A	Feature not available
Controller standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

12.1.6.3.5 UART Interrupt Requests

12.1.6.3.5.1 UART Mode Interrupt Management

12.1.6.3.5.1.1 UART Interrupts

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UART_IIR_UART) sets the UART_IIR_UART[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UART_IIR_UART[5-1] bit field. [Table 12-73](#) summarizes the interrupt control functions.

Table 12-73. UART Mode Interrupts

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	N/A	No Interrupt	N/A	N/A
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR_UART register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register if using the default timeout behavior: EFR2[6]=0 Cleared by reading its value (IIR) if using the periodic timeout behavior: EFR2[6]=1

Table 12-73. UART Mode Interrupts (continued)

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000100	2	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears
000010	3	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears
000000	4	Modem status	See the UART_MSR register.	Read the MSR register
010000	5	XOFF interrupt/ special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR_UART register, if special character interrupt
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high)	Read the UART_IIR_UART register

For the receiver-line status interrupt, the UART_LSR_UART[7] RX_FIFO_STS bit generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UART_IIR_UART register.

12.1.6.3.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the RX_CTS_DSR_WAKE_UP_ENABLE bit of the Supplementary Control Register (SCR[4]) is set to 1. The IIR register is not modified when it occurs, SSR[1] must be checked to detect a wake-up event. When a wake-up event occurs, the only way to clear it is to reset SCR[4] to 0. Wake-up can also occur if the WER[7] TX_WAKEUP_EN is set to 1 and one of the following events occurs:

1. THR interrupt is enabled and occurs (omitted if TX DMA request is enabled)
2. TX DMA request is enabled and occurs
3. TX_STATUS_IT is enabled and occurs (only IrDA and CIR modes). Cannot be used with THR Interrupt.

12.1.6.3.5.2 IrDA Mode Interrupt Management

12.1.6.3.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART_IER_IRDA). The interrupt status of the device can be checked by reading the interrupt identification register (UART_IIR_IRDA).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART_IER_IRDA and UART_IIR_IRDA mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see [Table 12-74](#)). The interrupt line is activated when any interrupt is generated (there is no priority).

Table 12-74. IrDA Mode Interrupts

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the UART_RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.

Table 12-74. IrDA Mode Interrupts (continued)

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
5	TX status	UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error OR Transmission of the last bit of the IrDA frame completed successfully.	Read the UART_RESUME register OR Read the UART_IIR_IRDA register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR_IRDA register.

12.1.6.3.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see [Section 12.1.6.3.5.1.2, Wake-Up Interrupt](#)).

12.1.6.3.5.3 CIR Mode Interrupt Management

12.1.6.3.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART_IER_CIR). The interrupt status of the device can be checked by reading the interrupt identification register (UART_IIR_CIR).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART_IER_CIR and UART_IIR_CIR mappings, depending on the selected mode.

[Table 12-75](#) lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART_IIR_CIR[5] TX_STATUS_IT bit is to indicate that the last bit of infrared data was passed to the TX pin.

Table 12-75. CIR Mode Interrupts

IIR_CIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0			
1	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR register until the interrupt condition disappears
2			
3			
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is complete successfully	Read the UART_IIR_CIR register
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

12.1.6.3.5.3.2 Wake-Up Interrupts

The wake-up interrupt for CIR mode has the same function as that for UART mode (see [Section 12.1.6.3.5.1.2, Wake-Up Interrupt](#)).

12.1.6.3.6 UART FIFO Management

The FIFO is accessed by reading and writing the UART_RHR and UART_THR registers. Parameters are controlled using the FIFO control register (UART_FCR) and supplementary control register (UART_SCR). Reading the UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. [Figure 12-47](#) shows the FIFO management registers.

Note

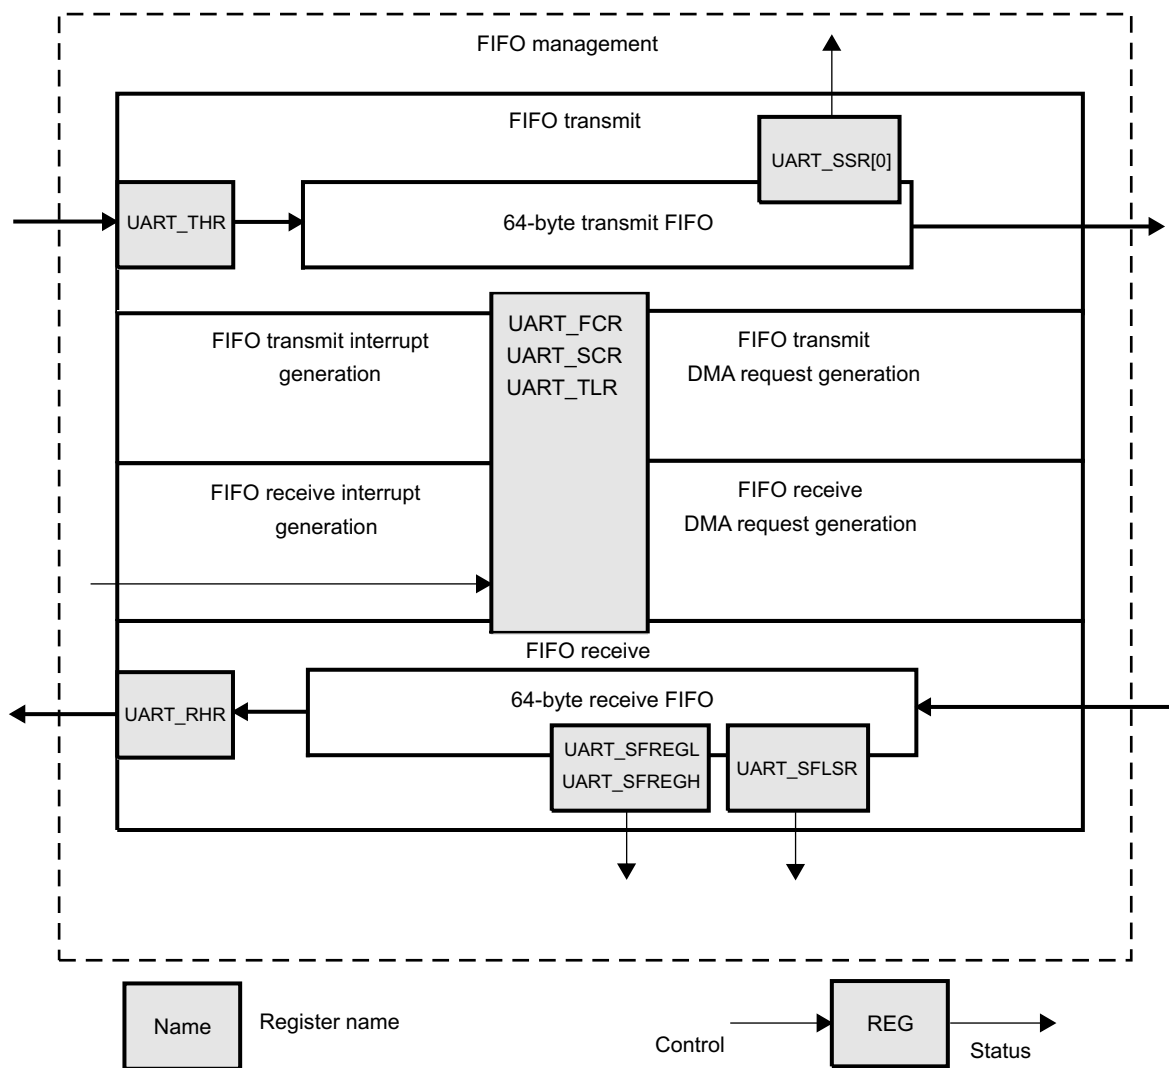

Data in the UART_RHR register is not overwritten when an overflow occurs.

Note

The UART_SFLSR, UART_SFREGL, and UART_SFREGH status registers are used in IrDA mode only. For information about their use, see [Section 12.1.6.3.8.3.3, IrDA Data Formatting](#).

Note

Bits UART_FCR[2] TX_FIFO_CLEAR and UART_FCR[1] RX_FIFO_CLEAR are automatically cleared by hardware after $4 \times + 5 \times \text{UARTi_FCLK}$ clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

uart-023

Figure 12-47. UART FIFO Management Registers**12.1.6.3.6.1 FIFO Trigger****12.1.6.3.6.1.1 Transmit FIFO Trigger**

[Table 12-76](#) lists the TX FIFO trigger level settings.

Table 12-76. UART TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[5-4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)

Table 12-76. UART TX FIFO Trigger Level Setting Summary (continued)

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	!= 0x0	Defined by the UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TLR[3:0] (higher bits) and FCR[5:4] (lower bits) from 1 to 63 spaces with a granularity of 1 space. Note: The combination of TLR[3:0]=0000 and FCR[5:4]=00 (all zeros) is not supported (min 1 space required). All zeros will result in unsupported behavior.

12.1.6.3.6.1.2 Receive FIFO Trigger

Table 12-77 lists the RX FIFO trigger-level settings.

Table 12-77. UART RX FIFO Trigger-Level Setting Summary

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[7-6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UART_TLR[7-4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of TLR[7:4] and FCR[7:6] from 1 to 63 characters with a granularity of one character. Note: The combination of TLR[7:4]=0000 and FCR[7:6]=00 (all zeros) is not supported (min 1 character required). All zeros will result in unsupported behavior.

The receive threshold is programmed using the UART_TCR[7-4] RX_FIFO_TRIG_START and UART_TCR[3-0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR_LENGTH} + \text{Parity} + \text{Stop} - 0.5)] \times \text{Baud_rate} + 4 \times \text{FCLK}$$

Note

The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UART_TCR[7-4] RX_FIFO_TRIG_START bit field or the UART_FCR[7-6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

12.1.6.3.6.2 FIFO Interrupt Mode

In FIFO interrupt mode (the FIFO control register UART_FCR[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UART_IER_UART register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UART_TLR[7-4] RX_FIFO_TRIG_DMA and UART_TLR[3-0] TX_FIFO_TRIG_DMA bit fields or the UART_FCR[7-6] RX_FIFO_TRIG and UART_FCR[5-4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the Host CPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UART_TCR[3-0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 12-48 shows the generation of the RX FIFO interrupt request.

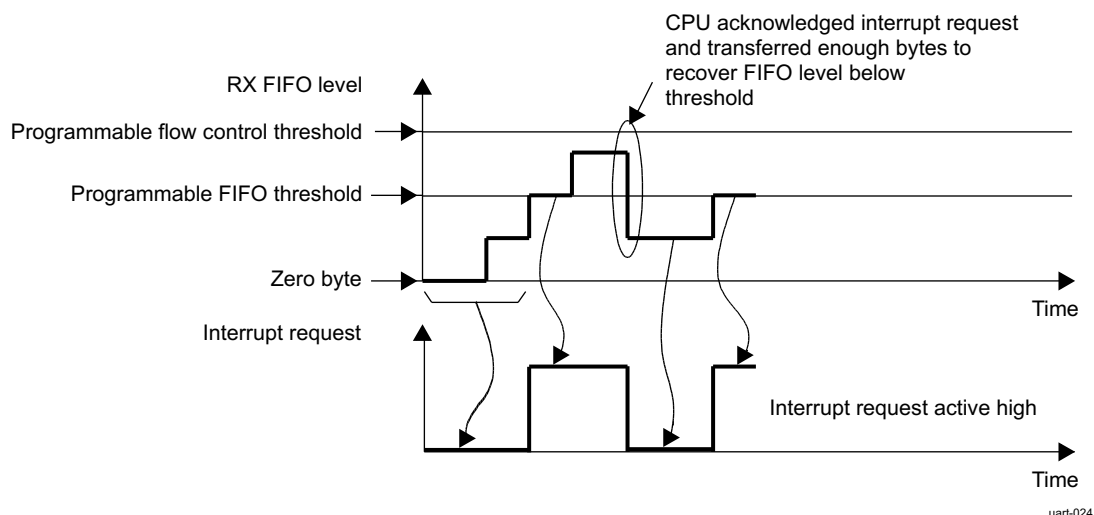

Figure 12-48. UART RX FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the Host CPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 12-49 shows the generation of the TX FIFO interrupt request.

Figure 12-49. UART TX FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

12.1.6.3.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UART_FCR[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UART_IER_UART register), the status of the receiver and transmitter can be checked by polling the line status register (UART_LSR_UART).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the Host CPU.

12.1.6.3.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in *UART Hardware Requests*, assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the signals (where $i = 0$ to .

signals are not used by the module in mode 2 and mode 3:

The DMA mode and signals usage can be selected as follows:

- When `SCR[0]=0`:
 - Setting `FCR[3]` to 0 enables DMA mode 0
 - Setting `FCR[3]` to 1 enables DMA mode 1
- When `SCR[0]=1`:
 - `SCR[2:1]` determines DMA mode 0 to 3 according to the Supplementary Control Register (SCR) description.

For example:

- If no DMA operation is desired: set `SCR[0]` to 1 and `SCR[2:1]` to 00 (`FCR[3]` is discarded)
- If DMA mode 1 is desired: either set `SCR[0]` to 0 and `FCR[3]` to 1 or set `SCR[0]` to 1 and `SCR[2:1]` to 01 (`FCR[3]` is discarded)

If the FIFOs are disabled (`FCR[0]=0`), DMA operations occur in single character transfers.

Note that when DMA Mode 0 has been programmed, the signals associated with DMA operation are not active.

Depending on `UART_MDR3[2] SET_DMA_TX_THRESHOLD`, the threshold can be programmed different ways:

- `SET_TX_DMA_THRESHOLD = 1`:
The threshold value will be the value of the `UART_TX_DMA_THRESHOLD` register. If `SET_TX_DMA_THRESHOLD + TX trigger spaces 64`, then the default method of threshold is used: threshold value = TX FIFO size.
- `SET_TX_DMA_THRESHOLD = 0`:
The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

12.1.6.3.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers `UART_SCR[0] DMA_MODE_CTL = 0` and `UART_FCR[3] DMA_MODE = 1`:
 - a. Set the `UART_SCR[2:1] DMA_MODE_2` bit fields to 01 (DMA mode 1)
 - b. Set the `UART_SCR[0] DMA_MODE_CTL` bit to 1 (this setting of `UART_SCR[0] DMA_MODE_CTL` will ignores `UART_FCR[3] DMA_MODE_CTL` bit)

Note

It is strongly suggested to do steps 'a' and 'b' in two separate write in order to avoid malfunction of the device.

- c. Set the `UART_FCR[3] DMA_MODE` bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of `UART_SCR[0] DMA_MODE_CTL` bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting `UART_ACREG[5] DIS_IR_RX` bit

Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- d. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- e. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
- f. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- g. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
2. DMA mode 1 is set (both TX/RX DMA) by registers UART_FCR[3] DMA_MODE = 0 and UART_SCR[0] DMA_MODE_CTL = 1, UART_SCR[2-1] DMA_MODE_2 = 01. It is almost the same as above, but steps 'a', and 'b' can be skipped:
 - a. Set the UART_FCR[3] DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART_SCR[0] DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART_ACREG[5] DIS_IR_RX bit

Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- b. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- c. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
- d. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- e. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
3. DMA mode 3 is set (TX DMA only) by registers UART_FCR[3] DMA_MODE = 0 and UART_SCR[0] DMA_MODE_CTL = 1, UART_SCR[2-1] DMA_MODE_2 = 11. It is the same as above:
 - a. Set the UART_FCR[3] DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART_SCR[0] DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART_ACREG[5] DIS_IR_RX bit

Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- b. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- c. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
- d. Set the UART_FCR[2-1] DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- e. Set the UART_SCR[2-1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

12.1.6.3.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 12-50 through Figure 12-53 show the supported DMA operations.

Figure 12-50. UART Receive FIFO DMA Request Generation (32 Characters)

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UART_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

Figure 12-51. UART Transmit FIFO DMA Request Generation (56 Spaces)

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UART_TLR register.

The threshold can be programmed in a number of ways. [Figure 12-51](#) shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UART_FCR[5-4] TX_FIFO_TRIG bit field or the UART_TLR[3-0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART module).

[Figure 12-52](#) shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART module.

Figure 12-52. UART Transmit FIFO DMA Request Generation (8 Spaces)

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see [Figure 12-53](#)). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UART_DLL and UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Figure 12-53. UART Transmit FIFO DMA Request Generation (1 Space)

The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting UART_MDR3[1] NONDEFAULT_FREQ bit and UART_TX_DMA_THRESHOLD register (see [Figure 12-54](#)). In the example, the UART_TX_DMA_THRESHOLD[5-0] TX_DMA_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the UART_DLL and UART_DLH registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the UART_MDR3[1] NONDEFAULT_FREQ value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

uart-036

Figure 12-54. UART Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)

12.1.6.3.6.4.3 DMA Transmission

Figure 12-55 shows DMA transmission.

uart-030

Figure 12-55. DMA Transmission

1. Data to be transmitted are put in the device memory reserved for UART transmission by the DMA:
 - a. Until the TX FIFO trigger level is not reached, a DMA request is generated
 - b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UART_THR empty (TX FIFO empty).

Note

In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UART_THR register empties.

12.1.6.3.6.4.4 DMA Reception

Figure 12-56 shows DMA reception.

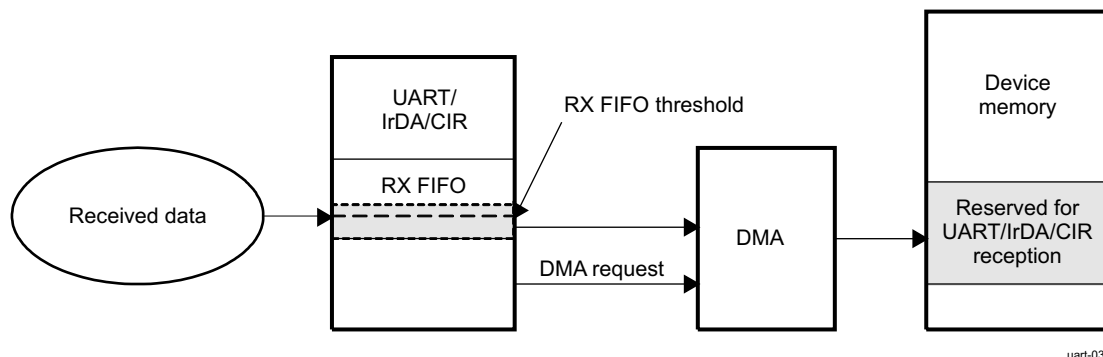

Figure 12-56. DMA Reception

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
 - a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
 - b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

12.1.6.3.7 UART Mode Selection

12.1.6.3.7.1 Register Access Modes

12.1.6.3.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UART_LCR register determines the register access mode (see [Table 12-78](#)).

Table 12-78. UART Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7-0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7-0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

12.1.6.3.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in [Table 12-100](#), *UART Load FIFO Triggers Defined by the Concatenated Value*.

[Table 12-79](#) through [Table 12-81](#) summarize the register access submodes.

Table 12-79. UART Subconfiguration Mode A Summary

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 12-79. UART Subconfiguration Mode A Summary (continued)

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

Table 12-80. UART Subconfiguration Mode B Summary

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 12-81. UART Suboperational Mode Summary

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

12.1.6.3.7.1.3 Registers Available for the Register Access Modes

Table 12-82 lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

Table 12-82. UART Register Access Mode Overview

12.1.6.3.7.2 UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UART_MDR1[2:0] MODE_SELECT bit field (see [Table 12-83](#)).

Table 12-83. UART Mode Selection

Value	Mode
0x0:	UART 16× mode
0x1:	SIR mode
0x2:	UART 16× auto-baud
0x3:	UART 13× mode
0x4:	MIR mode
0x5:	FIR mode
0x6:	CIR mode
0x7:	Disable (default state)

MODE_SELECT is effective when the module is in operational mode (see [Section 12.1.6.3.7.1, Register Access Modes](#)).

To select a RS-485 mode, set the UART_MDR3[4] DIR_EN bit field to 0x1.

12.1.6.3.7.2.1 Registers Available for the UART Function

Only the registers listed in [Table 12-84](#) are used for the UART function.

Table 12-84. UART Mode Register Overview

- (2) REGISTER_NAME[m:n] notation indicates that only register bits numbered m to n apply to the CIR function.

12.1.6.3.8 UART Protocol Formatting

12.1.6.3.8.1 UART Mode

12.1.6.3.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-57 shows the baud rate generator and associated controls.

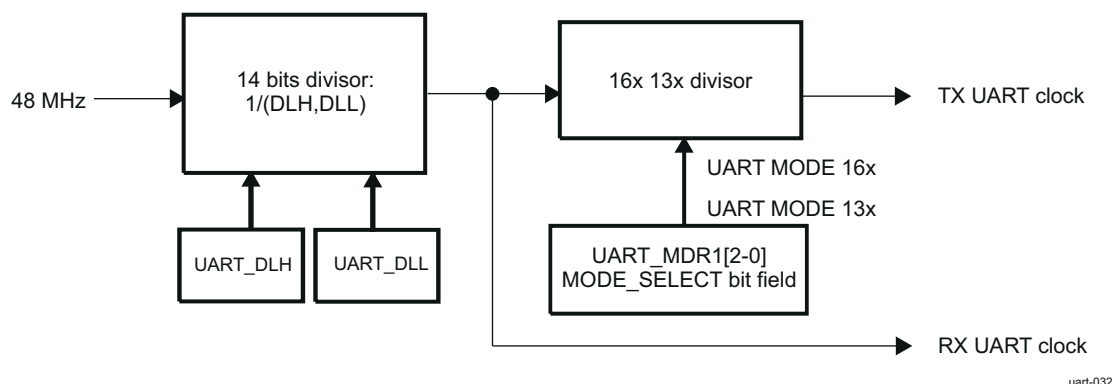

Figure 12-57. UART Baud Rate Generation

CAUTION

Before initializing or modifying clock parameter controls (UART_DLH, UART_DLL), UART_MDR1[2-0] MODE_SELECT = DISABLE must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

12.1.6.3.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16× mode: Divisor value = Operating frequency / (16× baud rate)
- UART 13× mode: Divisor value = Operating frequency / (13× baud rate)

Table 12-87. UART Baud Rate Settings (48-MHz Clock)

12.1.6.3.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

12.1.6.3.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UART_LCR register.

Character length is specified using the UART_LCR[1-0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UART_LCR[5-3] PARITY_EN, UART_LCR[5-3] PARITY_TYPE_1, and UART_LCR[5-3] PARITY_TYPE_2 bit fields (see [Table 12-88](#)).

Table 12-88. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

12.1.6.3.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UART_EFR[7] AUTO_CTS_EN and UART_EFR[6] AUTO_RTS_EN bit fields, respectively.

With auto-CTS, CTS signal must be active before the module can transmit data.

Auto-RTS activates the RTS output only when there is enough room in the RX FIFO to receive data. It deactivates the RTS output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UART_TCR register determine the levels at which RTS is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UART_TCR register. RTS is active if the RX FIFO level is below the HALT trigger level in the UART_TCR[3-0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, RTS is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

RTS is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UART_TCR[7-4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

In this case, RTS is an active-low signal.

- Auto-CTS:

The transmitter circuitry checks CTS before sending the next data byte. When CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, CTS must be deasserted before the middle of the last stop-bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the CTS state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, CTS is an active-low signal.

12.1.6.3.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UART_EFR) and the modem control register (UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UART_EFR[3-0] bit field (see [Table 12-89](#)).

Two other enhanced features relate to software flow control:

- XON-any function (UART_MCR[5] XON_EN): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

Note

The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UART_EFR[5] SPECIAL_CHAR_DETECT): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UART_IIR_UART) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UART_IIR_UART. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 12-89. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 ⁽¹⁾
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 ⁽¹⁾

- (1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UART_XON1_ADDR1[7-0] XON_WORD1 bit field. XON2 is defined in the UART_XON2_ADDR2[7-0] XON_WORD2 bit field.
XOFF1 is defined in the UART_XOFF1[7-0] XOFF_WORD1 bit field. XOFF2 is defined in the UART_XOFF2[7-0] XOFF_WORD2 bit field.

12.1.6.3.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UART_IIR_UART[4] bit (if enabled by UART_IER_UART[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UART_IIR_UART[4] bit is cleared and the XOFF interrupt disappears.

Note

When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UART_EFR[1-0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UART_EFR[1-0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

12.1.6.3.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UART_TCR[3-0] RX_FIFO_TRIG_HALT. As soon as the RX FIFO reaches the trigger level programmed by UART_TCR[7-4] RX_FIFO_TRIG_START, two XON1 characters are sent, so the data transfer recovers.

Note

If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

12.1.6.3.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
 - 115.2K baud
 - 57.6K baud
 - 38.4K baud
 - 28.8K baud
 - 19.2K baud
 - 14.4K baud
 - 9.6K baud
 - 4.8K baud
 - 2.4K baud

- 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

Note

The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UART_MDR1[2-0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UART_DLL, UART_DLH, and UART_LCR[5-0] bit field settings are not used; instead, the UART_UASR register is updated with the configuration detected by the autobauding logic.

UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UART_LCR, UART_DLL, and UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UART_MDR1[2-0] MODE_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115.2 bps (10 possibilities)

12.1.6.3.8.1.3.5 Error Detection

When the UART_LSR_UART register is read, the UART_LSR_UART[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UART_LSR_UART register and then reading the UART_RHR register identifies errors in a character.

Reading the UART_RHR register updates the BI, FE, and PE bits (see [Table 12-73](#) for the UART mode interrupts).

The UART_LSR_UART[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

Note

Reading the UART_LSR_UART register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UART_RHR register.

Reading the UART_LSR_UART register clears the OE bit if it is set (see [Table 12-73](#) for the UART mode interrupts).

12.1.6.3.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the Host CPU with the UART_IIR_UART[5-1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the Host CPU must:

- Reset the RX FIFO.
- Read the UART_RESUME register, which clears the internal flag.

12.1.6.3.8.1.3.7 Time-Out and Break Conditions

12.1.6.3.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (RX) is high for a time that equals 4x the programmed word length + 12 bits or manually configured amount of baud clocks, if a value other zero is set in the timeout register. RX is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on RX.

There are two modes of operation:

- In default operation on the UART_EFR2[6] TIMEOUT_BEHAVE is set to 0. For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on RX or when the UART_RHR register is read.
- Optionally, for choose to enable the timeout counter even if no character has been received by setting UART_EFR2[6] TIMEOUT_BEHAVE bit. This will generate periodic interrupts if the RX line remains idle. In this mode the counter will auto-reset when a timeout has been reached. Reading the UART_IIR_UART will clear the interrupt, but not the counter.

12.1.6.3.8.1.3.7.2 Break Condition

When a break condition occurs, TX is pulled low. A break condition is activated by setting the UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UART_LSR_UART[6] TX_SR_E bit is set to 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

12.1.6.3.8.2 RS-485 Mode

12.1.6.3.8.2.1 RS-485 External Transceiver Direction Control

The UART_MDR3[4] DIR_EN bit enables hardware control over an external transceiver to support RS-485. The direction signal comes across the DIR port. The direction polarity is controlled by the UART_MDR3[3] DIR_POL bit. The direction is determined by the hardware monitoring the TX FIFO and the TX shift register. When both are empty the transceiver is set to RX. There is a guard band delay counter of 3 bit clock cycles after the TX shift register is going empty to allow time for the stop bit to transition through the transceiver before a direction change to receive might be applied.

Figure 12-58 shows the direction control.

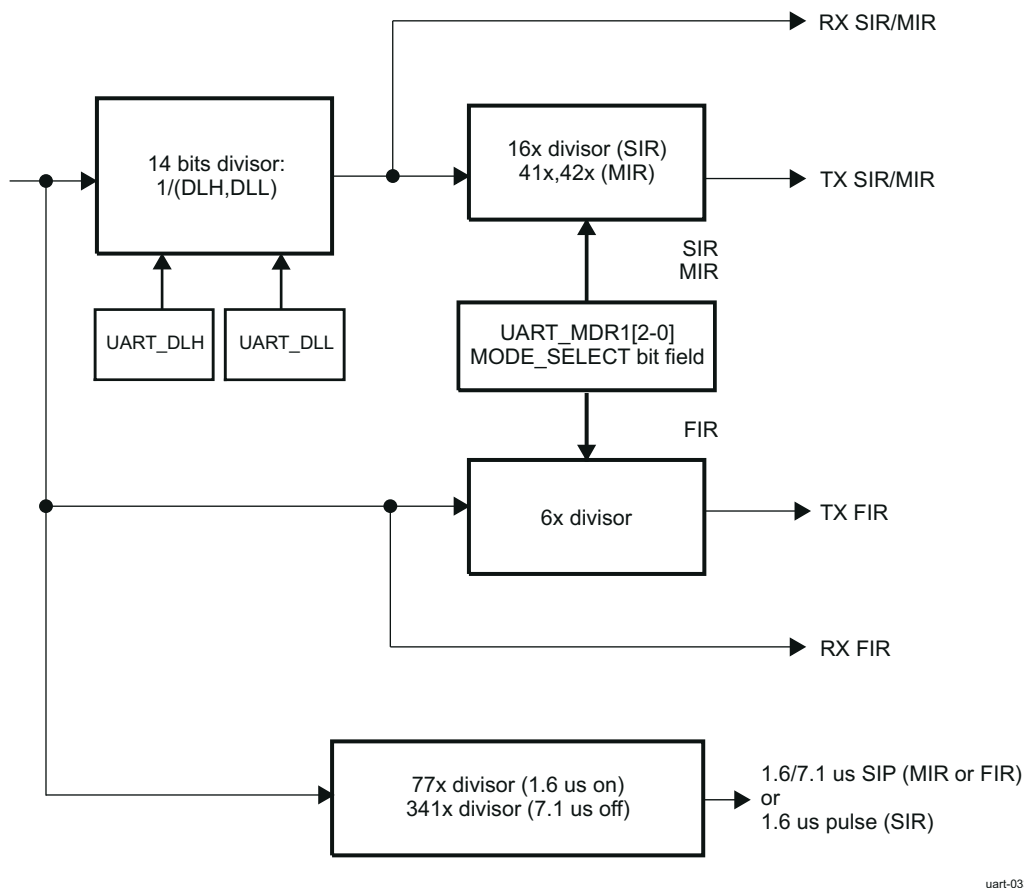

(1) Assumes DIR_POL = 1

uart-038

Figure 12-58. RS-485 External Transceiver Direction Control**12.1.6.3.8.3 IrDA Mode****12.1.6.3.8.3.1 IrDA Clock Generation: Baud Generator**

The IrDA function contains a programmable baud generator and a set of fixed divisors that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-59 shows the baud rate generator and associated controls.

uart-033

Figure 12-59. IrDA Baud Rate Generator

CAUTION

Before initializing or modifying clock parameter controls (UART_DLH, UART_DLL), MODE_SELECT=DISABLE (UART_MDR1[2-0] MODE_SELECT) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

12.1.6.3.8.3.2 Choosing the Appropriate Divisor Value

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16× baud rate)
- MIR mode: Divisor value = Operating frequency/(41×/42× baud rate)
- FIR mode: Divisor value = None

Table 12-90 lists the IrDA baud rate settings.

Table 12-90. IrDA Baud Rate Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 μs

(1) Average value

Note

Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

12.1.6.3.8.3.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

12.1.6.3.8.3.3.1 IR RX Polarity Control

The UART_MDR2[6] IRRXINVERT bit provides the flexibility to invert the RX pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.

12.1.6.3.8.3.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the RX input can be disabled by the UART_ACREG[5] DIS_IR_RX bit.

12.1.6.3.8.3.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART_XON1_ADDR1[7-0] XON_WORD1 and UART_XON2_ADDR2[7-0] XON_WORD2 bit fields.

Setting the UART_EFR[0] bit to 1 selects address1 checking. Setting the UART_EFR[1] bit to 1 selects address2 checking. Setting the UART_EFR[1-0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

12.1.6.3.8.3.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART_MDR1[7] FRAME_END_MODE bit to 0. The Host CPU writes the value of the frame length to the UART_TXFLH and UART_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the UART_MDR1[7] FRAME_END_MODE bit to 1. The Host CPU writes 1 to the UART_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the Host CPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

12.1.6.3.8.3.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the Host CPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the Host CPU writes 1 to the UART_ACREG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

12.1.6.3.8.3.3.6 Error Detection

When the UART_LSR_UART register is read, the UART_LSR_UART[4-2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see [Table 12-74](#)). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

12.1.6.3.8.3.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the Host CPU must:

- Reset the TX FIFO.
- Read the UART_RESUME register, which clears the internal flag.

This function can be disabled by the UART_ACREG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

12.1.6.3.8.3.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see [Section 12.1.6.3.8.1.3.6, Overrun During Receive](#)).

12.1.6.3.8.3.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART_SFREGH[3-0] MSB and UART_SFREGL[3-0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART_SFLSR register. Reading the UART_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The Host CPU uses the frame-length information to locate the frame boundary in the received frame data. The Host CPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the Host CPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

12.1.6.3.8.3.3.10 Multi-drop Parity Mode with Address Match

Multi-drop mode is enabled in the UART_EFR2 register.

Address matching mode is only available with 8 bit character length setting. UART_LCR[1-0] CHAR_LENGTH bit fields should always be set to 0x11 (8 bits) prior to enabling the feature.

This mode allows the transmitter to send data on a line where multiple receivers are connected, when supported. In this mode, a set parity bit is used to mark an address, and a parity of 0 denotes data.

This setting affects how the parity is generated. Writing a 0x1 into the UART_ECR[0] A_MULTIDROP bit will set the parity bit for the next byte to be sent, which will then be considered an address, for sending a data frame, the UART_ECR[0] A_MULTIDROP bit has to be cleared.

On reception if the feature is enabled by setting the UART_EFR2[2] MULTIDROP bit to 0x1 incoming frames with parity set to 0x1 are treated as address frames and with parity set to 0x0 as data frames. The receiver will drop all data frames until a matching address frame was found.

The matching address is determined by the values set in UART_MAR, UART_MMR and UART_MBR registers and the value set in UART_EFR2[7] BROADCAST bit.

Table 12-91 summarizes the operation of address matching based on the mentioned values.

Table 12-91. Details of address matching

Received frame	Received parity	Frame type	UART_MAR	UART_MMR	UART_MBR	UART_EFR2[7] BROADCAST	Operation of receiver	Address matching
0xXX ⁽²⁾	0	DATA	X ⁽¹⁾	X ⁽¹⁾	0xXX ⁽²⁾	X ⁽¹⁾	Drops data until matching address found	N/A
0xXX ⁽²⁾	1	ADDRESS	0xXX ⁽²⁾	0x00	0xXX ⁽²⁾	0	Matches any address	Yes
0xEF	1	ADDRESS	0xXX ⁽²⁾	0xXX ⁽²⁾	0xEF	1	Matches broadcast address	Yes
0x1A	1	ADDRESS	0x1A	0xFF	0xXX ⁽²⁾	0	Single address match	Yes
0xF5	1	ADDRESS	0xF3	0xF9	0xXX ⁽²⁾	0	Group address match	Yes

(1) X indicates a do not care bit value

(2) 0xXX indicates a do not care 8 bit hexadecimal value

The possible values for matching address can be calculated in the following way:

- Single and Group addresses can be formed by masking the UART_MAR registers value with the value set in the UART_MMR register, bits set to 0x0 in the UART_MMR register result in do not care values.
- Broadcast addresses can be set in the UART_MBR register if broadcast address is enabled in the UART_EFR2[7] BROADCAST bit, the module will match on received address frames containing the broadcast address.
- For more details, see example below:
 - UART_MAR: 0xF3, UART_MMR: 0xF9, UART_MBR: 0xFF
 - Single and Group addresses: 0xF1, 0xF3, 0xF5, 0xF7
 - Broadcast addresses: 0xFF

If an address match occurred the matching address value can be obtained from the UART_RHR register in the following way:

- If the FIFO is disabled or the threshold is set to 0x1, the matching address can be directly read from UART_RHR as the FIFO will not be overwritten.
- If the FIFO is enabled or the threshold is greater than 0x1, the matching address will be the latest frame in the FIFO with a parity error bit set.

For received data, the parity error bit in the UART_LSR_UART register is set when a bit with a parity of 0x1 is received indicating an address frame and the received address matches based on the values of UART_MAR, UART_MMR, UART_MBR and UART_EFR2[2] MULTIDROP bit.

In Multi-drop mode no parity is used, as the parity bit is used to differentiate address and data frames. The parity error bit is used for indicating an address match.

For enabling the interrupt generation for address matching UART_IER_UART[2] LINE_STS_IT bit has to be set to 0x1.

An interrupt for the matching address can be identified by reading the UART_IIR_UART[5-1] IT_TYPE bit fields, a value of 0x00011 indicates a receiver line status error. After the UART_LSR_UART[2] RX_PE bit has to be read, a value of 0x1 indicates that an address match occurred. The reception of a frame is indicated with a value of 0x1 in the UART_LSR_UART[0] RX_FIFO_E bit as the matching value is written into the FIFO regardless of the frame type (data or address). UART_LSR_UART[7] RX_FIFO_STS bit will also be set to 0x1 as the parity error bit is used to indicate a matching address.

Note that the operation of the UART_LSR_UART[2] RX_PE bit depends on the value set in UART_EFR2[2] MULTIDROP bit. If UART_EFR2[2] MULTIDROP bit is set to 0x0, UART_LSR_UART[2] RX_PE bit is used to indicate a received parity error. If UART_EFR2[2] MULTIDROP bit is set to 0x1, the receiver is in Multi-drop Address Match mode, thus the value in UART_LSR_UART[2] RX_PE bit is used to indicate an address match.

The interrupt is cleared the same way in both operation modes: reading the UART_LSR_UART register updates the values.

This feature is available in UART and synchronous modes. The ISO7816 has not defined Multidrop Parity Mode, so the feature should be left off.

12.1.6.3.8.3.3.11 Time-guard

The time-guard feature enables the UART interface to operate with slow remote devices.

When set, it will insert a number of idle states between transmitting two characters, the length of which can be set in the UART_TIMEGUARD register. The value in the register defines the number of baud clocks of idle period to insert.

This idle state essentially acts like a long stop bit. In UART and synchronous modes, a Timeguard is added in addition to the stop bit. In ISO7816 there is a waiting period rather than an actual stop bit. Software should set 1-2 or more Timeguard cycles according to the protocol used and the card requirements.

12.1.6.3.8.3.4 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

12.1.6.3.8.3.4.1 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART_ACREG[1] ABORT_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

CAUTION

When the TX FIFO is not empty and the UART_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

12.1.6.3.8.3.4.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6- μ s pulse duration methods. The UART_ACREG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

12.1.6.3.8.3.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART_MDR1[2-0] MODE_SELECT = 0x0) and the UART_MDR2[3] PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART_LCR[1-0] CHAR_LENGTH bit field = 0x3 (8 data bits)
- UART_LCR[2] NB_STOP bit = 0x0 (1 stop-bit)
- UART_LCR[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

12.1.6.3.8.3.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the CPU reads the line status register (UART_LSR_UART) to detect errors in the received frame.

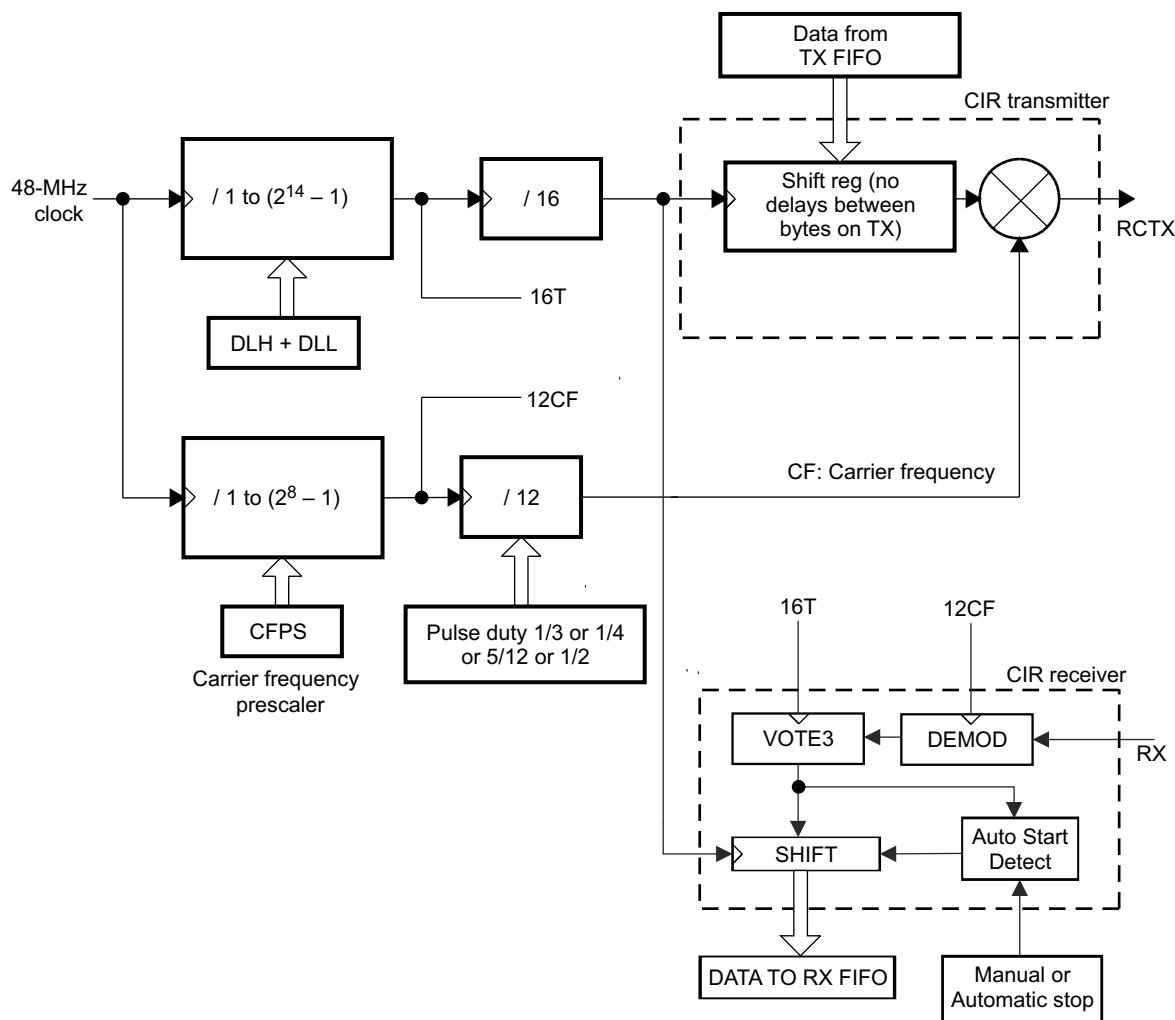

When the UART_MDR1[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART_ACREG[3] SEND_SIP bit.

The CPU can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

12.1.6.3.8.4 CIR Mode

12.1.6.3.8.4.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the Host CPU must develop a data structure that combines 1 and 0 with a t period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in [Figure 12-60](#).

uart-034

Figure 12-60. CIR Mode Block Components

Based on the requested modulation frequency, the UART_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK} / 12) / \text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

Note

The UART_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART_MDR2 register. [Table 12-92](#) shows the duty cycle.

Table 12-92. CIR Duty Cycle

UART_MDR2[5-4] CIR_PULSE_MODE	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

12.1.6.3.8.4.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

12.1.6.3.8.4.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see [Section 12.1.6.3.8.3.3.1, IR RX Polarity Control](#)).

12.1.6.3.8.4.2.2 CIR Transmission

In transmission, the Host CPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a t period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
 - Controlling the start of the frame using the UART_MDR1[5] SCT bit and the UART_ACREG[2] SCTX_EN bit, depending on the timer status
 - Using the UART_IIR_UART[5] TX_STATUS_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

12.1.6.3.8.4.2.3 CIR Reception

There are 2 ways to stop a CIR reception:

- The Host CPU can disable the reception by setting the UART_ACREG[5] DIS_IR_RX bit to 1. When it considers that the reception is finished because a large number of 0 has been received. To receive a new frame, the UART_ACREG[5] DIS_IR_RX bit must be set to 0.
- An automatic stop mechanism can be configured by setting a value in the BOF length register (UART_EBLR). If the value set in the UART_EBLR register is different than 0, this features is enabled and the number of bits received will begin counting from 0. When the counter reaches the value defined in the UART_EBLR register, reception is automatically disabled and UART_IIR_CIR[2] RX_STOP_IT bit is set. When a 1 is detected on the RX pin, reception is automatically re-enabled.

There is a limitation when receiving data in UART CIR mode. Certain IrDA transceivers on the market have a characteristic that causes shrinking of the received modulation pulse hold-time. The UART receive filtering schema is based on the same encoding mechanism used for transmission.

For the following scenario:

- Shift register period: 0.9μs
- Modulation frequency: 36kHz
- Duty cycle: 1/4 of a modulation frequency period

Data sent with these conditions would contains 7μs pulses within a 28μs period. The UART expects to receive similar incoming data on receive, but various transceiver timing characteristics typically only send 2μs modulated pulses. These 2μs pulses will be filtered out and RX FIFO will not receive data. This does not affect UART CIR mode in transmission.

CIR RX demodulation can be bypassed by setting the UART_MDR3[0] DISABLE_CIR_RX_DEMOD bit.

12.1.6.4 UART Programming Guide

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

Note

Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 12.1.6.3.7.1, Register Access Modes](#).

12.1.6.4.1 UART Mode selection

[Table 12-93](#) describes how to set different register access mode.

Table 12-93. UART Configure Register Access Mode

Step	Register/Bit Field/Programming Model	Value
Set the register access mode A	UART_LCR[7] DIV_EN	1
	UART_LCR[7-0]	≠0xBF
Set the register access mode B	UART_LCR[7-0]	0xBF
Set the operational mode	UART_LCR[7] DIV_EN	0

12.1.6.4.2 UART Submode selection

This section describes how to set different register access submode.

Table 12-94. UART Configure Register Access Submode TCR_TLR

Step	Register/Bit Field/Programming Model	Value
Configure the submode TCR_TLR		
Configure mode B	see Table 12-93	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1
Configure mode A	see Table 12-93	0x1
Set the submode TCR_TLR	UART_MCR[6] TCR_TLR	1

Table 12-95. UART Configure Register Access Submode MSR_SPR

Step	Register/Bit Field/Programming Model	Value
First option: configure the submode MSR_SPR		
Configure mode B	see Table 12-93	
Set the submode MSR_SPR	UART_EFR[4] ENHANCED_EN	0
Second option: configure the submode MSR_SPR		
Configure mode B	see Table 12-93	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1
Set the submode MSR_SPR	UART_MCR[6] TCR_TLR	0

Table 12-96. UART Configure Register Access Submode XOFF

Step	Register/Bit Field/Programming Model	Value
Configure of the XOFF		
Configure B	see Table 12-93	

Table 12-96. UART Configure Register Access Submode XOFF (continued)

Step	Register/Bit Field/Programming Model	Value
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0

12.1.6.4.3 UART Load FIFO trigger and DMA mode settings

12.1.6.4.3.1 DMA mode Settings

To enable and configure program the DMA mode, perform the following steps:

Table 12-97. DMA Mode Settings

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration	UART_SCR[0] DMA_MODE_CTL	-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	=0
Select the DMA mode, for more information see Section 12.1.6.3.6.4	UART_FCR[3] DMA_MODE	-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	=1
Select the DMA mode, for more information see Section 12.1.6.3.6.4	UART_SCR[2-1] DMA_MODE_2	-

12.1.6.4.3.2 FIFO Trigger Settings

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

Table 12-98. Load FIFO Triggers Defined by the FCR

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 12-94	0x-
Set the desire RX FIFO trigger level	UART_FCR[5-4] TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7-6] RX_FIFO_TRIG	0x-

Table 12-99. Load FIFO Triggers Defined by the TLR

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 12-94	0x-
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA	0x-

Table 12-100. Load FIFO Triggers Defined by the Concatenated Value

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 12-94	0x-
Set the register bit	UART_SCR[7] RX_TRIG_GRANU1	1
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA UART_FCR[7-6] RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6] TX_TRIG_GRANU1	1
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA UART_FCR[5-4] TX_FIFO_TRIG	0x-

12.1.6.4.4 UART Protocol, Baud rate and interrupt settings

12.1.6.4.4.1 Baud rate settings

Table 12-101. UART Baud Rate Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Switch to register configuration mode B	see Table 12-93	
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see Table 12-93	

Table 12-101. UART Baud Rate Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Disable sleep mode	UART_IER_UART[4] SLEEP_MODE	0
Switch to register configuration mode A or B	see Table 12-93	
Set the appropriate divisor value	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x-

12.1.6.4.4.2 Interrupt settings

Table 12-102. UART Interrupt Settings

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see Table 12-93	0x7
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see Table 12-93	
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER_UART[7] CTS_IT UART_IER_UART[6] RTS_IT UART_IER_UART[5] XOFF_IT UART_IER_UART[4] SLEEP_MODE UART_IER_UART[3] MODEM_STS_IT UART_IER_UART[2] LINE_STS_IT UART_IER_UART[1] THR_IT UART_IER_UART[0] RHR_IT	0x-

12.1.6.4.4.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

Table 12-103. UART Protocol Settings

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see Section 12.1.6.3.8.1.3.1 , <i>Frame Formatting</i>	UART_LCR[5] PARITY_TYPE_2 UART_LCR[4] PARITY_TYPE_1 UART_LCR[3] PARITY_EN UART_LCR[2] NB_STOP UART_LCR[1-0] PARITY_LENGTH	0x-
Switch to register operational mode	UART_LCR[7] DIV_EN UART_LCR[6] BREAK_EN	0

12.1.6.4.4.4 UART/RS-485/IrDA(SIR/MIR/FIR)/CIR

Table 12-104. UART Mode Selection

Step	Register/Bit Field/Programming Model	Value
Load the desired UART/IrDA (SIR, MIR, FIR)/CIR modes, see Section 12.1.6.3.7.2 , <i>UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection</i>	UART_MDR1[2-0] MODE_SELECT	0x-
Load the desired RS-485 mode, see Section 12.1.6.3.7.2 , <i>UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection</i>	UART_MDR3[4] DIR_EN	0x1

12.1.6.4.4.5 UART Multi-drop Parity Address Match Mode Configuration

Table 12-105. UART Multi-drop Parity Address Match Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Disable receive mode	UART_ECR[3] RX_EN	0
Enable Multi-drop parity Address match mode	UART_EFR2[2] MULTIDROP	1
Set the matching device address	UART_MAR[7-0] ADDRESS	0x-
Set the address match masking	UART_MMR[7-0] MASK	0x-

Table 12-105. UART Multi-drop Parity Address Match Mode Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Set the broadcast address match	UART_MBR[7-0] BROADCAST_ADDRESS	0x-
Enable broadcast address matching if needed	UART_EFR2[7] BROADCAST	1
Enable receive mode	UART_ECR[3] RX_EN	1

12.1.6.4.5 UART Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

12.1.6.4.5.1 Hardware Flow Control Configuration

Table 12-106. UART Hardware Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 12-94	0x7
Load the start and halt trigger value.	UART_TCR[7-4] AUTO_RTS_START UART_TCR[3-0] AUTO_RTS_HALT	0x-
Enable or disable receive and transmit hardware flow control mode.	UART_EFR[7] AUTO_CTS_EN UART_EFR[6] AUTO_RTS_EN	0x-

12.1.6.4.5.2 Software Flow Control Configuration

Table 12-107. UART Software Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see Table 12-96	
Load the software control characters	UART_XON1_ADDR1[7-0] XON_WORD1 UART_XON2_ADDR2[7-0] XON_WORD2 UART_XOFF1[7-0] XOFF_WORD1 UART_XOFF2[7-0] XOFF_WORD2	0x-
Set the register access submode TCR_TLR	see Table 12-94	
Enable or disable XON any function (0: Disable; 1: Enable).	UART_MCR[5] XON_EN	--
Load start and halt trigger value for software flow control	UART_TCR[7-4] AUTO_RTS_START UART_TCR[3-0] AUTO_RTS_HALT	0x-
Enable or disable special character function (0: Disable; 1: Enable)	UART_EFR[5] SPEC_CHAR	0x-
Set the software flow control mode	UART_EFR[3-0] SW_FLOW_CONTROL	0x-

12.1.6.4.6 IrDA Programming Model

12.1.6.4.6.1 SIR mode

12.1.6.4.6.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 115.2 kbps, FIFOs disabled, 2 stop-bits, and 8-bit word length:

Table 12-108. SIR Mode Receive Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate(115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x1A 0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00

Table 12-108. SIR Mode Receive Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

12.1.6.4.6.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 115.2 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

Table 12-109. SIR Mode Transmit Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB	0x1A
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 6 bytes	UART_TXFLL[7-0] TXFLL	0x06
Set the seven starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
Set SIR pulse width to be 1.6 μ s	UART_ACREG[7] PULSE_TYPE	1

12.1.6.4.6.2 MIR mode

12.1.6.4.6.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

Table 12-110. MIR Mode Receive Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (1.152 bps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set MIR mode	UART_MDR1[2-0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force outputs DTR and RTS to active	UART_MCR[1-0]	0x3
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

12.1.6.4.6.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

Table 12-111. MIR Mode Transmit Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 kbps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x4

Table 12-111. MIR Mode Transmit Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 60 bytes	UART_TXFLL[7-0] TXFLL	0x3C
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

12.1.6.4.6.3 FIR mode**12.1.6.4.6.3.1 Receive**

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

Table 12-112. FIR Mode Receive Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB UART_DLH[7-0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see Section 12.1.6.4.3 , <i>Load FIFO trigger and DMA mode settings</i>	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x5
Set frame length	UART_RXFLL[7-0] RXFLL	0xA
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

12.1.6.4.6.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

Table 12-113. FIR Mode Transmit Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see Section 12.1.6.4.3 , <i>Load FIFO trigger and DMA mode settings</i>	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Set FIR mode and enable auto-SIP mode	UART_MDR1[7-0]	0x45
Set frame length	UART_TXFLL[7-0] TXFLL UART_TXFLH[7-0] TXFLH	0x4 0x0
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	1
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08

Table 12-113. FIR Mode Transmit Settings (continued)

Step	Register/Bit Field/Programming Model	Value
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

12.2 High-speed Serial Interfaces

This section describes the high-speed serial interfaces in the device.

12.2.1 Gigabit Ethernet MAC (CPSW)

This chapter describes the Gigabit Ethernet MAC (Media Access Controller). For conceptual purposes the below documentation refers to this MAC as being a two port CPSW with port 0 being the CPPI DMA host port and port 1 being the Ethernet port.

12.2.1.1 MCU_CPSW0 Overview

The two-port Gigabit Ethernet MAC (MCU_CPSW0) subsystem provides Ethernet packet communication for the device and is configured in a similar manner as an Ethernet switch.

MCU_CPSW0 features the Reduced Gigabit Media Independent Interface (RGMII), Reduced Media Independent Interface (RMII), and the Management Data Input/Output (MDIO) interface for physical layer device (PHY) management.

Figure 12-61 shows the MCU_CPSW0 module overview.

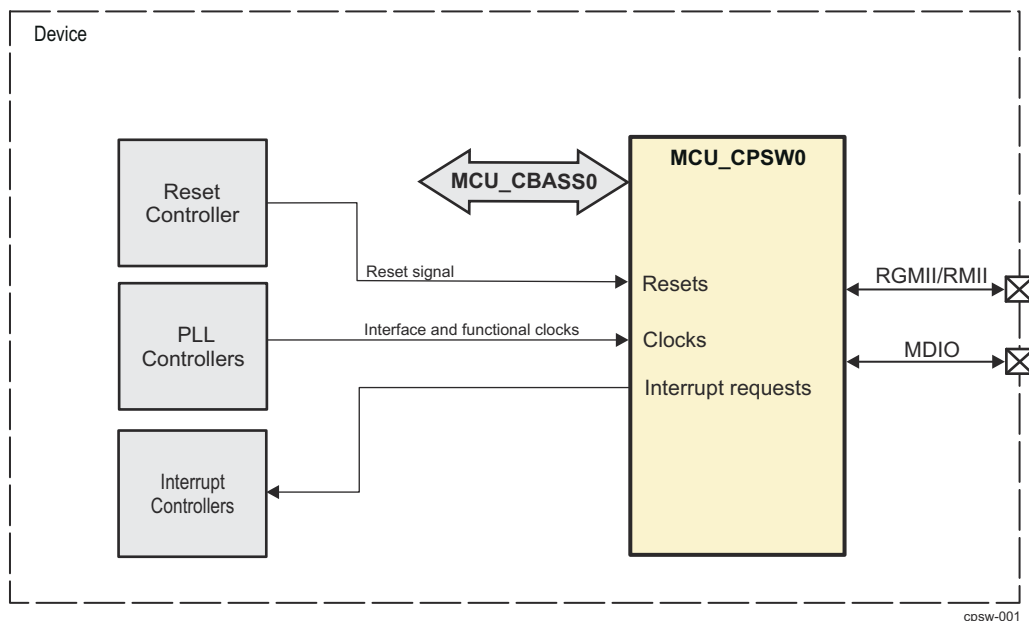

Figure 12-61. MCU_CPSW0 Overview

12.2.1.1.1 CPSW Features

The 2-port CPSW subsystem provides the following features:

- One Ethernet port (port 1) with selectable RGMII and RMII interfaces and an internal Communications Port Programming Interface (CPPI) port (port 0)
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
 - Timestamp module capable of time stamping external timesync events like Pulse-Per-Second and also generating Pulse-Per-Second outputs
 - CPTS module that supports time stamping for IEEE1588 with support for 4 hardware push events and generation of compare output pulses
- DSCP Priority Mapping (IPv4 and IPv6)
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control Support (802.3x)
- Wire rate switching (802.1d)
- Non-Blocking switch fabric
- Time Sensitive Network Support

- IEEE P802.3br/D2.0 Interspersing Express Traffic
- IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE)
 - 64 ALE table entries
 - Configurable number of addresses plus VLANs
 - Wire rate lookup
 - Host controlled time-based aging and/or auto-aging
 - Spanning tree support
 - L2 address lock and L2 filtering support
 - MAC authentication (802.1x)
 - Receive-based or destination-based Multicast and Broadcast rate limits
 - MAC address blocking
 - Source port locking
 - OUI (Vendor ID) host accept/deny feature
 - Configurable number of classifier/policers (8)
 - VLAN support
 - 802.1Q compliant
 - Auto add port VLAN for untagged frames on ingress
 - Auto VLAN removal on egress and auto pad to minimum frame size
- EtherStats and 802.3Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Ethernet Mac transmit to Ethernet Mac receive Loopback mode (digital loopback) supported
- CPSGMII Loopback Modes (transmit to receive)
- Maximum frame size of 2024 bytes
- Management Data Input/Output (MDIO) module for PHY Management with Clause 45 support
- Programmable interrupt control with selected interrupt pacing
- Host port CPPI Streaming Packet Interface (CPPI_GCLK)
- Digital loopback and FIFO loopback modes supported
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECCDED)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.2.1.1.2 Terminology

Terminology:

AVB	Audio Video Bridging
AVBTP	Audio Video Bridging Transport Protocol
BMCA	Best Master Clock Algorithm
CFI	Canonical Format Indicator
CPPI	Communications Port Programming Interface
CPSW	Common Platform Switch
DLR	Device Level Ring
DSCP	Differentiated Services Code Point
EEE	Energy Efficient Ethernet
EMAC	Ethernet Media Access Control
EOP	End of Packet
EOQ	End of Queue
IPG	Inter-Packet Gap
LPI	Low Power Indicator
MDIO	Management Data Input/Output
MOF	Middle of Frame
OUI	Organizationally Unique Identifier
PFC	Priority based Flow Control
PTP	Precision Time Protocol
RMON	Remote Monitoring
RTCP	RTP Control Protocol
RTP	Real-time Transport Protocol
SCR	Switched Central Resource
SRP	Stream Reservation Protocol
TOS	Type of Service
VLAN	Virtual Local Area Network

12.2.1.1.3 MCU_CPSW0 Ports

Table 12-114. MCU_CPSW0 Clocks and Resets

Clocks	
Module Clock Input	Description
CPPI_ICLK	CPPI packet streaming interface clock (333-MHz). Main clock for MCU_CPSW0.
GMII_RFT_CLK	125-MHz GMII Gigabit mode clock.
RGMII_MHZ_5_CLK	5-MHz RGMII reference clock.
RGMII_MHZ_50_CLK	50-MHz RGMII reference clock.
RGMII_MHZ_250_CLK	250-MHz RGMII reference clock.
RMII_MHZ_50_CLK	50-MHz RMII reference clock.
CPTS_RFT_CLK	CPTS IEEE 1588 clock.
GMII1_MT_CLK	
GMII1_MR_CLK	
RGMII1_RXC_I	RGMII reference clock that provides the timing reference for receive operations.
RGMII1_TXC_O	RGMII transmit reference clock.
MDIO_MCLK	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
Resets	
Module Reset Input	Description
MCU_CPSW0_RST	Module Reset

Table 12-115. MCU_CPSW0 Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCU_CPSW0_STAT_PEND_0	MCU_CPSW0 statistic pending interrupt 0	Level
MCU_CPSW0_MDIO_PEND_0	MCU_CPSW0 MDIO interrupt	Level
MCU_CPSW0_EVNT_PEND_0	MCU_CPSW0 event pending interrupt	Level
MCU_CPSW0_ECC_SEC_PEND_0	MCU_CPSW0 SEC ECC error interrupt	Level
MCU_CPSW0_ECC_DED_PEND_0	MCU_CPSW0 DED ECC error interrupt	Level
Time Sync and Compare Events		
Module Event	Description	Type
MCU_CPSW0_CPTS_COMP_0	MCU_CPSW0 compare event interrupt	Edge
MCU_CPSW0_CPTS_GENF0_0	MCU_CPSW0 CPTS generator function event interrupt 0	Edge
MCU_CPSW0_CPTS_GENF1_0	MCU_CPSW0 CPTS generator function event interrupt 1	Edge
MCU_CPSW0_CPTS_SYNC_0	MCU_CPSW0 CPTS sync event interrupt	Edge

12.2.1.2 CPSW Functional Description

The two-port switch Ethernet subsystem module (CPSW) is compliant to the IEEE Std 802.3 Specification. CPSW top level functional block diagram is shown in [Figure 12-62](#).

12.2.1.2.1 Functional Block Diagram

The two-port Ethernet subsystem consists of:

- CPSW_2G
- One RGMII interface module
- One RMII interface module
- One Host Port 0 CPPI Packet Streaming Interface
- CPSW subsystem control registers (REG)
- One MDIO interface module
- One Interrupt Controller module

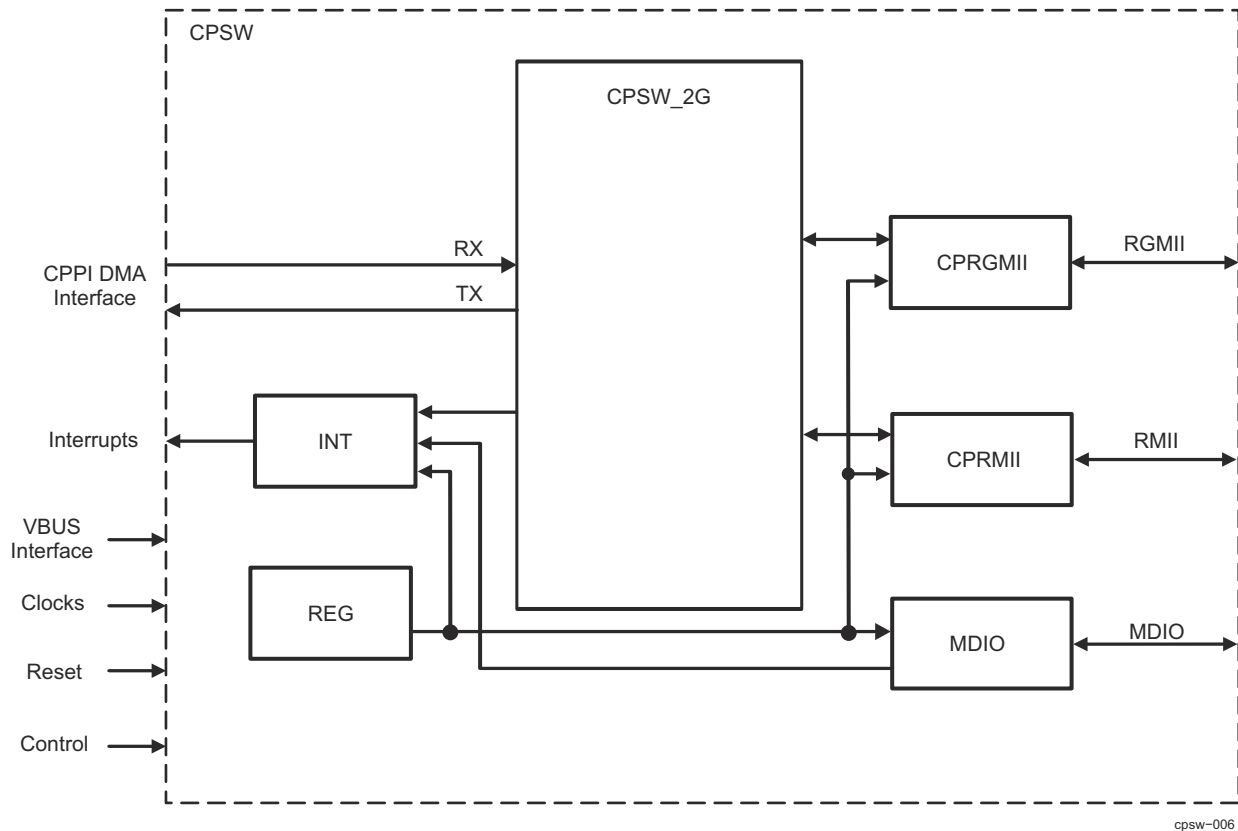

Figure 12-62. CPSW Top Level Block Diagram

12.2.1.2.2 CPSW Ports

The Ethernet Subsystem has two ports. Port 0 is the Host port (internal to the Subsystem). Port 1 is the external port connected to RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the CPPI Host Port
- Port1 is referred to the interfaces RGMII/RMII

12.2.1.2.2.1 Interface Mode Selection

The two-port switch (CPSW) Ethernet Subsystem has one 10/100/1000 Ethernet port with selectable RMII, and RGMII interfaces.

The interface mode is selected by configuring the Ethernet interface mode selection bitfield (MODE_SEL) in the CTRLMMR_MCU_ENET_CTRL register.

See the device-specific Datasheet for configuring the pin mux mode as per the interface selected.

12.2.1.2.3 Clocking

12.2.1.2.3.1 Subsystem Clocking

CPSW clocking summary is shown in *CPSW Integration*.

12.2.1.2.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

12.2.1.2.3.2.1 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

12.2.1.2.3.2.2 RMII Interface Clocking

RMII interface clock RMII_50MHZ_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

MCU_RMII1_REF_CLK device pin or internal RGMII_MHZ_50_CLK clock (default clock) can be selected through CTRLMMR_MCU_ENET_CLKSEL[0] RMII_CLK_SEL and one of these clocks can be used as the clock source for RMII interface. For more details on RMII clocking, please see *CPSW Integration*

CTRLMMR_MCU_CLKOUT0_CTRL[4] CLK_EN and CTRLMMR_MCU_CLKOUT0_CTRL[0] CLK_SEL bits are used to enable and select the clock source for MCU_CLKOUT0 device pin.

12.2.1.2.3.2.3 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (CPPI_ICLK) clock. The application software or driver must control the divide-down value.

See the CPSW_MDIO_CONTROL_REG register for configuring the Clock Divider ([15-0]CLKDIV) value.

12.2.1.2.4 Software IDLE

The submodule software idle register bits enable CPSW operation to be completely or partially suspended by software control. There are two CPSW submodules that contain software idle register bits. Each of the two submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW module enters the idle state when all two submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the two submodule idle bits. The CPSW_2G is in the idle state when all two submodules are in the idle state. The CPSW_SOFT_IDLE_REG[0] SOFT_IDLE bit may be set if desired after the submodules are in the idle state. The SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

12.2.1.2.5 Interrupt Functionality

CPSW Ethernet Subsystem has six interrupt outputs:

- EVNT_PEND - CPTS Event Pending Interrupt
- STAT_PEND0 – Statistics Pending Interrupts
- ECC_DED_INT - ECC DED Level Interrupt
- ECC_SEC_INT - ECC SEC Level Interrupt
- MDIO_INTR - MDIO Pending Interrupt (combined MDIO_LINKINT and MDIO_USERINT events)

12.2.1.2.5.1 EVNT_PEND Interrupt

See *Common Platform Time Sync (CPTS)* for more details on this interrupt.

12.2.1.2.5.2 Statistics Interrupt (STAT_PEND0)

The statistics level interrupt (STAT_PEND0) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement any statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The statistics are mapped into internal memory space and are 32-bits wide. The raw and masked statistics interrupt status may be read by reading the CPSW_CPTS_INTSTAT_RAW_REG and CPSW_CPTS_INTSTAT_MASKED_REG registers, respectively.

The statistics interrupt is enabled by setting to 1h the TS_PEND_EN bit in the CPSW_CPTS_INT_ENABLE_REG register.

12.2.1.2.5.3 ECC DED Level Interrupt (ECC_DED_INT)

Level interrupt (ECC_DED_INT) indicating an ECC double error has been detected.

12.2.1.2.5.4 ECC SEC Level Interrupt (ECC_SEC_INT)

Level interrupt (ECC_SEC_INT) indicating an ECC single error has been detected and corrected.

12.2.1.2.5.5 MDIO Interrupts

Normal Mode: (CPSW_MDIO_POLL_REG[30] STATECHANGEMODE = 0h)

MDIO_LINKINT event is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR_MON field of the CPSW_MDIO_USER_PHY_SEL_REG_k register and the corresponding LINKINT_ENABLE bit is set. The MDIO_LINKINT event is also captured in the MDIO CPSW_MDIO_LINK_INT_MASKED_REG register. When the GO bit in the CPSW_MDIO_USER_ACCESS_REG_k register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the CPSW_MDIO_USER_INT_MASK_SET_REG register is set, the MDIO_USERINT signal is asserted. The MDIO_USERINT event is also captured in the CPSW_MDIO_USER_INT_MASKED_REG register.

State Change Mode: (CPSW_MDIO_POLL_REG[30] STATECHANGEMODE = 1h)

In State Change Mode, the MDIO will assert MDIO_LINKINT[0] when any bit in the MDIO CPSW_MDIO_ALIVE_REG or CPSW_MDIO_LINK_REG registers changes due to MDIO operations. The MDIO_LINKINT event is also captured in the CPSW_MDIO_LINK_INT_MASKED_REG register. MDIO_LINKINT[1] output is unused in State Change Mode. The CPSW_MDIO_USER_PHY_SEL_REG_k registers are unused in state change mode.

Manual Mode: (CPSW_MDIO_POLL_REG[31] MANUALMODE = 1h)

Manual Mode allows software to directly control the MDIO serial clock output (CPSW_MDIO_MANUAL_IF_REG[2] MDIO_MDCLK_O) and the MDIO serial data output enable (CPSW_MDIO_MANUAL_IF_REG[1] MDIO_OE). Manual Interface Mode is enabled when the MANUALMODE bit is set in the CPSW_MDIO_POLL_REG register. Manual Mode is intended to be used by software for slow speed general purpose IO operations and not for MDIO PHY operations.

12.2.1.2.6 CPSW_2G

The CPSW_2G RMII/ RGMII interface is compliant to the IEEE Std 802.3 Specification.

The CPSW_2G contains one Ethernet port interface (Ethernet port 1), one CPPI packet streaming interface host port (port 0), Common Platform Time Sync (CPTS), ALE Engine and Statistics (STATS). A top-level block diagram of the CPSW_2G is shown in [Figure 12-63](#).

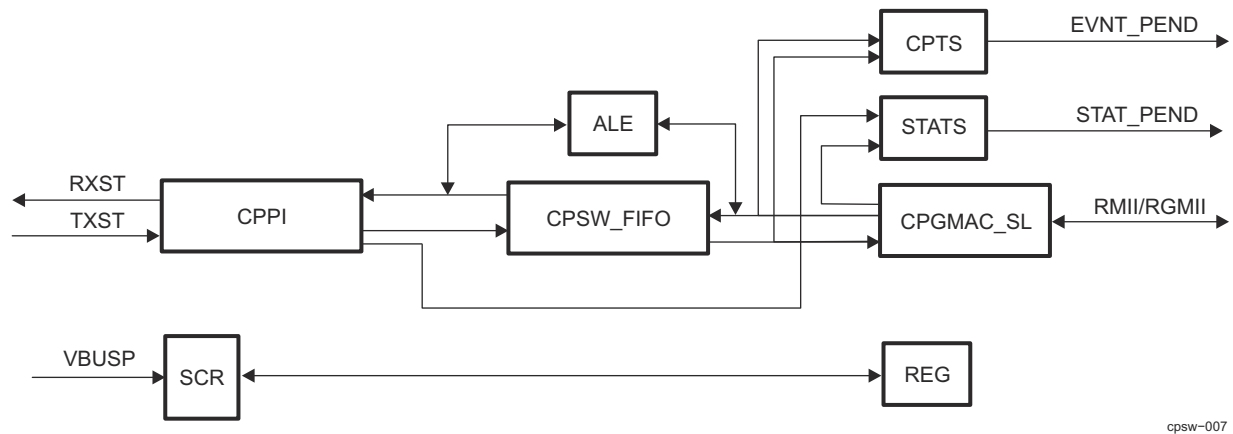

Figure 12-63. CPSW_2G Block Diagram

12.2.1.2.6.1 Address Lookup Engine (ALE)

The Address Lookup Engine (ALE) is a sub-block of the CPSW Switch and it processes all received packets and determines to which port(s) the packet should be forwarded. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE_ALE bit in the CPSW_ALE_CONTROL register is set. All packets are dropped when the ENABLE bit is cleared to 0.

12.2.1.2.6.1.1 Error Handling

In normal operation, the Ethernet port modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a MAC control packet. However, when the CPSW_PN_MAC_CONTROL_REG configuration bit(s) RX_CEF_EN, RX_CSF_EN, or RX_CMF_EN are set, error frames, short frames or MAC control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a MAC control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). Packets with errors that are forwarded to the host have no VLAN untagging or drop due to rate limiting. No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address. Directed packets from the host are not learned, updated, or touched.

12.2.1.2.6.1.2 Bypass Operations

The ALE may be configured to operate in bypass mode by setting the ENABLE_BYPASS bit in the CPSW_ALE_CONTROL register. When in bypass mode, all Ethernet port received packets are forwarded only to the host port (port 0). In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

12.2.1.2.6.1.3 OUI Deny or Accept

The ALE may be configured to operate in OUI deny mode by setting the ENABLE_OUI_DENY bit in the CPSW_ALE_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the SUPER bit set. When ENABLE_OUI_DENY bit is cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory address table entry. Broadcast packets will be dropped unless the broadcast address is entered into the table with the SUPER bit set. Unicast packets will be dropped unless the unicast address is in the table with BLOCK and SECURE both set (supervisory unicast packet).

12.2.1.2.6.1.4 Statistics Counting

ALE sends many statistics along with the frame routing so the CPSW can count them on a per port basis. There are many reasons to drop frames the below drop events are individually counted in CPSW per port statistics counters. For more information on ALE statistics please refer to the *CPSW Network Statistics* section.

12.2.1.2.6.1.5 Automotive Security Features

The ALE has many automotive security features that most enterprise switches do not require.

- VLANs can be configured to not allow fragmented IPv4 frames. That is a VLAN can be configured to not allow fragmented IPv4 traffic.
- VLANs can be configured to only allow up to four different IPv4 Protocols or IPv6. Next Header values, for example a VLAN can be configured to only allow TCP traffic in both IPv4 and IPv6 packets.
- Drop invalid Source Addresses, that is drop Source Addresses with bit 40 set (Multicast/Broadcast indicator on Destination Addresses)
- IEEE802.3 Length Check, drop frames that the IEEE802.3 Length is not contained within the frame. (Ether Types 0-1500)
- Any Source Address can be secured to a port dropping any attempts from other ports to masquerade as a service.
- Any source or destination address can be blocked.
- Per Port or Per VLAN ingress checking, dropping traffic from non-member ports.
- Classification, Policing on L2 and L3 information.

12.2.1.2.6.1.6 CPSW Switching Solutions

The host port can operate in many different modes as well depending on the functionality of the host. It is important to understand the modes and configure them properly.

The ALE Table is designed to maximize the modes without compromise of the system functionality as well.

12.2.1.2.6.1.6.1 Basics of 2-port Switch Type

The 2-port switch has a host port, and that port can operate in two fundamental modes. Bridge mode allows the host to extend the switched domain to another network like Wi-Fi or another multi-port switch. In this case the host must be able to see unknown unicast addresses so they can be broadcast to the other network. In Port mode the host need not see any unknown unicast traffic. The CPSW_ALE_CONTROL[8] EN_HOST_UNI_FLOOD bit determines the host mode for unknown unicast traffic. This bit should only be set if you are bridging two or more networks together.

Essentially the two port switch is a MAC with all the switching features like VLAN insertion, removal, update, etc.

The 2-port switch would normally have a very small ALE table. Its primary use is for the Host filtering features. For example you would not ever need to auto learn or add addresses of external nodes to the ALE table, the table's primary purpose is to host unicast addresses, multicast addresses, VLANs, IP addresses etc.

12.2.1.2.6.1.7 VLAN Routing and OAM Operations

12.2.1.2.6.1.7.1 InterVLAN Routing

The CPSW module supports wire rate InterVLAN routing for a small number of routes, that is the host will setup an ALE classifier with an associated egress operation that will cause the CPSW to perform particular egress operations. The ALE can optionally check time to live validity as well.

The ALE uses the classifier along with an egress opcode, destination port mask and TTL check field to tell the CPSW to manipulate the packet on the egress. The CPSW will use the opcode along with a per port operation table to process the packet. By setting up the CPSW egress operation table you can replace the DA, SA and VLAN along with optionally updating the time to live IP header field. This allows the CPSW to perform the routing function for a small set of routes without getting the local host/CPU involved.

The Egress opcode will only be used for a classifier match and the packet would normally be sent only to the host. That is the host would have routed the packet but the CPSW has been configured to do the work instead. In the event that the time-to-live check feature is enabled and the time-to-live is either 0 or 1, the packet will not get the egress opcode and instead be sent to the host as if the route is not setup. This allows the host to deal with invalid TTL fields.

12.2.1.2.6.1.7.2 OAM Operations

The ALE supports OAM loopback on ports so that a remote link can be tested. That is a port placed in OAM loopback will echo packets received on a port back to the port with an egress op of 0xFF which will swap the SA and DA on egress in the CPSW.

Any supervisory packet will not be affected, so the spanning tree and other bridging functions are not affected.

Packets will only be echoed if the port is in OAM loopback mode, the received packet is not a supervisor packet. The port is in a forwarding state and the packet received DA!=SA and there are no errors in the packet.

When a port is in OAM loopback the port will not egress traffic from other ports, no address for loop backed traffic will be learned if enabled. Any packet received on the OAM loopback port with an error will be processed as if the port is not in OAM. That is if the host has enabled copy errored frames the errored frames will be sent to the host instead.

12.2.1.2.6.1.8 Supervisory packets

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise blocked to be forwarded for special purposes.

12.2.1.2.6.1.9 Address Table Entry

The ALE table contains multiple table entry types. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 12-116. Learned Address Control Bits

Bit(s)	Value
Ageable	1
Touch	1
BLOCK	0
SECURE	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40**.

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40**.

12.2.1.2.6.1.9.1 Free Table Entry

Table 12-117. Free (Unused) Address Table Entry Bit Values

70:62	61:60	59:0
Reserved	ENTRY_TYPE (00)	Reserved

12.2.1.2.6.1.9.2 Multicast Address Table Entry

Table 12-118. Multicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
-------	-------	----	----	-------	-------	-------	------

Table 12-118. Multicast Address Table Entry Bit Values (continued)

Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (01)	Reserved	MULTICAST_ADDRESS
----------	-----------	-------	----------	-----------------	--------------------	----------	-------------------

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

12.2.1.2.6.1.9.3 VLAN/Multicast Address Table Entry
Table 12-119. VLAN/Multicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (11)	VLAN_ID	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

12.2.1.2.6.1.9.4 Unicast Address Table Entry

Table 12-120. Unicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (01)	Reserved	UNICAST_ADDR ESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

12.2.1.2.6.1.9.5 OUI Unicast Address Table Entry

Table 12-121. OUI Unicast Address Table Entry Bit Values

70:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE (10)	ENTRY_TYPE (01)	Reserved	UNICAST_OUI	Reserved

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

12.2.1.2.6.1.9.6 VLAN/Unicast Address Table Entry

Table 12-122. Unicast Address Table Entry Bit Values

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (11)	VLAN_ID	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

12.2.1.2.6.1.9.7 VLAN Table Entry

Table 12-123. VLAN Table Entry

70:68	67	66	65	64:62	61:60	59:48	47:46	45:44
Reserved	NO_LEARN_MASK	Reserved	VLAN_FORCE_INGRESS_CHECK	Reserved (000)	ENTRY_TYPE (10)	VLAN_ID	Reserved	REG_MCAST_FLOOD_INDEX
43:26	25:24		23:22	21:20		19:2	1:0	
Reserved	FORCE_UNTAGGED_EGRESS		Reserved	UNREG_MCAST_FLOOD_INDEX		Reserved	VLAN_MEMBER_LIST	

No Learn Mask (NO_LEARN_MASK)

When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

VLAN Force Ingress Check (VLAN_FORCE_INGRESS_CHECK)

If the receive port is not a member of this VLAN then the packet is dropped. This is similar to the `ly_REG_Py_VID_INGRESS_CHECK` bit in the `CPSW_ly_ALE_PORTCTL0_y` registers except this check is for this VLAN only (not all VLANs).

Table Entry Type (ENTRY_TYPE)

10: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Registered Multicast Flood Index (REG_MCAST_FLOOD_INDEX)

Index into `CPSW_ALE_MSK_MUX0` to `CPSW_lx_ALE_MSK_MUXx` register array that is used to create the registered multicast flood mask.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

Unregistered Multicast Flood Mask (UNREG_MCAST_FLOOD_INDEX)

Index into `CPSW_ALE_MSK_MUX0` to `CPSW_lx_ALE_MSK_MUXx` register array that is used to create the unregistered multicast flood mask.

VLAN Member List (VLAN_MEMBER_LIST)

This field indicates which port(s) are members of the associated VLAN. One bit per port.

12.2.1.2.6.1.10 ALE Policing and Classification

The ALE has a number of configurable classifier engines (policers) that can be used for classification. Classification is a subset of the policing function and uses a policer without the color marking or rate limiting functions. A policer is a hardware engine that is used for policing. The `POLCNTDIV8` field in the `CPSW_ALE_STATUS` register indicates the number of policers available to be used for classification. Each policer can be enabled to match on one or more of any of the below packet fields for classification. All but Port and Priority are index references to the ALE table entries.

- Port Number
- Priority extracted from VLAN, mapped from DSCP if enabled, or Default Port Priority
- Organization Network Unique identifier - ONU
- Destination Address - DA
- Source Address - SA
- VLANID
- Ether Type
- IP Source Address - IPSA with full CIDR masking
- IP Destination Address - IPSA with full CIDR masking
- Support Host Thread/Flow ID mapping based on any packet classification above

12.2.1.2.6.1.10.1 ALE Classification

When the policers are configured as classifiers, the color marking and policing functions of the policing/classifier engines are not used. One or multiple classifiers can be configured to match on a single packet. For example, a classifier can be enabled to match on priority while another classifier could match IP address.

12.2.1.2.6.1.10.1.1 Classifier to CPPI Transmit Flow ID Mapping

The ALE can generate a 6-bit transmit CPPI Flow ID based on classifier matches that can be used instead of the switch default transmit Flow ID mapping. The switch default flow ID is the remapped received packet

priority (0 to 7). Thread and flow ID are used interchangeably for this since there is a single hardware thread (TXST_THREAD_MREADY) but there are 6-bits of FLOW_ID in the transmit CPPI INFO word 0. When enabled, the highest classifier match can map to a particular 6-bit flow ID value that is associated with the classifier. The ALE also supports an optional ALE default thread/flow ID value in the event that no classifiers match. Each thread/flow ID, including the ALE default thread/flow ID, has an enable such that the ALE default thread/Flow ID is used if enabled and if no matches occur (instead of the remapped received packet priority). If the ALE default is not enabled and no matches occur then the switch default value will be used. If multiple classifier matches occur, the highest match with a thread enable bit set will be used. The resultant flow ID has the CPSW_P0_FLOW_ID_OFFSET_REG register value added to it to determine the actual value in the INFO 0 Flow ID field.

Three registers are used for ALE classification thread/flow ID mapping configuration (CPSW_ALE_THREADMAPDEF, CPSW_ALE_THREADMAPCTL and CPSW_ALE_THREADMAPVAL). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW_ALE_THREADMAPCTL register allows the CPSW_ALE_THREADMAPVAL register contents to be written to the selected classifier. There is a single CPSW_ALE_THREADMAPDEF that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

12.2.1.2.6.1.11 DSCP

The ALE can map DSCP field to priority prior to classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See CPSW_P0_RX_DSCP_MAP_REG_y and CPSW_PN_RX_DSCP_MAP_REG_y registers in the Register Manual section for DSCP mapping.

12.2.1.2.6.1.12 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are *Ingress Filtering*, *VLAN_Aware Lookup*, and *Egress*.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The MCAST_FWD_STATE indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The BLOCK and SECURE bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the Ethernet port to the ALE. Packets with errors may be passed to the host (not aborted) by a Ethernet port port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set in the CPSW_PN_MAC_CONTROL_REG register. Error packets that are passed to the host by the Ethernet port are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with long or short errors received by the host are dropped. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPSW_PN_MAC_CONTROL_REG register:

- [22] RX_CEF_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX_CSF_EN - enables short frames to be forwarded
- [24] RX_CMF_EN - enables MAC control frames to be forwarded.

12.2.1.2.6.1.12.1 Ingress Filtering Process

Condition and action
If ((ALE BYPASS) and (host port is not the receive port)) then use host portmask and go to Egress process
if (directed packet) then use directed port number and go to Egress process
If (Rx ly_REG_Py_PORTSTATE is Disabled) then discard the packet
if ((ALE BYPASS or error packet) and (host port is not the receive port)) then use host portmask and go to Egress process
if (((BLOCK) and (unicast source address found)) or ((BLOCK) and (unicast destination address found))) then discard the packet
if ((ENABLE_RATE_LIMIT) and (rate limit exceeded) and (not BCAST_MCAST_CTL)) then if (((Multicast/Broadcast destination address found) and (not SUPER)) or (Multicast/Broadcast destination address not found)) then discard the packet
if ((not forward state test valid) and (destination address found)) then discard the packet to any port not meeting the requirements <ul style="list-style-type: none"> • Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward state test.
if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding))) then discard the packet to any ports not meeting the above requirements
if (source address found) and (secure) and (not block) and (receive port number != port_number)) then discard the packet
if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode))) then discard the packet
If (VLAN_Unaware) CPSW_ALE_UVLAN_UNTAG = "000000" CPSW_ALE_UVLAN_URCAST = "111111" CPSW_ALE_UVLAN_URCAST = "111111" UVLAN_MEMBER_LIST = "111111" else if (VLAN not found) CPSW_ALE_UVLAN_UNTAG = CPSW_ALE_UVLAN_UNTAG CPSW_ALE_UVLAN_RMCAST = CPSW_ALE_UVLAN_RMCAST CPSW_ALE_UVLAN_RMCAST = CPSW_ALE_UVLAN_RMCAST CPSW_ALE_UVLAN_MEMBER = CPSW_ALE_UVLAN_MEMBER else CPSW_ALE_UVLAN_UNTAG = found CPSW_ALE_UVLAN_UNTAG CPSW_ALE_UVLAN_URCAST = found CPSW_ALE_UVLAN_URCAST CPSW_ALE_UVLAN_RMCAST = found CPSW_ALE_UVLAN_RMCAST UVLAN_MEMBER_LIST = found UVLAN_MEMBER_LIST

if ((not SUPER) and (ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member)) then discard the packet
if ((ENABLE_AUTH_MODE) and (source address not found) and not(destination address found and (SUPER))) then discard the packet
if (destination address equals source address) then discard the packet
if (VLAN_AWARE) goto VLAN_Aware_Lookup process else goto VLAN_Unaware_Lookup process

12.2.1.2.6.1.12.2 VLAN_Aware Lookup Process

Condition and action
if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of the PORT_NUMBER and UVLAN_MEMBER_LIST less the host port and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of the PORT_NUMBER and the UVLAN_MEMBER_LIST and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (SUPER)) then portmask is the PORT_NUMBER and goto Egress process
if (Unicast packet) # destination address not found then portmask is VLAN member LIST less host port and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of CPSW_ALE_UVLAN_URCAST and found destination address/VLAN portmask (PORT_MASK) and UVLAN_MEMBER_LIST and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (SUPER)) then portmask is the PORT_MASK and goto Egress process
if (Multicast packet) # destination address not found then portmask is the logical "AND" of CPSW_ALE_UVLAN_URCAST and UVLAN_MEMBER_LIST then goto Egress process
if (Broadcast packet) then use found UVLAN_MEMBER_LIST and goto Egress process

Note

The UVLAN_MEMBER_LIST, UVLAN_UNREG_MCAST_FLOOD_MASK, UVLAN_REG_MCAST_FLOOD_MASK and UVLAN_FORCE_UNTAGGED_EGRESS are set in the [Section 12.2.1.2.6.1.12.1 Ingress Filtering Process](#), based on VLAN_Unaware, Unknown_VLAN rules and VLAN table entries.

12.2.1.2.6.1.12.3 Egress Process

Condition and action
Clear Rx port from portmask (don't send packet to Rx port).
Clear disabled ports from portmask.

if ((ENABLE_OUI_DENY) and (OUI source address not found) and (not ALE BYPASS) and (not error packet) and ((not mcast destination address) and (SUPER))) then Clear host port from portmask
if ((not ENABLE_OUI_DENY) and (OUI source address found) and (not ALE BYPASS) and (not error packet) and not ((mcast destination address) and (SUPER))) then Clear host port from portmask
if ((ENABLE_RATE_LIMIT) and (BCAST_MCAST_CTL)) then if (not SUPER) and (rate limit exceeded on any tx port) then clear rate limited tx port from portmask If address not found then SUPER cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

12.2.1.2.6.1.12.4 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

12.2.1.2.6.1.12.4.1 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

Condition and action
If (directed) then do not learn, update, or set touched else continue
If (not (Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_LEARN)) then do not learn address
if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not learn address
if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not learn address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address found) and (receive port_number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address else continue
if ((source address found) and (receive port number != PORT_NUMBER)) then update address else continue
if ((source address not found) and (VLAN_AWARE) and not (LEARN_NO_VLANID)) then learn address with VLAN
if ((source address not found) and ((not VLAN_AWARE) or (VLAN_AWARE and LEARN_NO_VLANID))) then learn address without VLAN

12.2.1.2.6.1.12.4.2 Updating Process

Condition and action
if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_SA_UPDATE)) then do not update address

if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not update address
if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not update address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER)) then update address

12.2.1.2.6.1.12.4.3 Touching Process

if ((source address found) and (ageable) and (not touched)) then set touched

12.2.1.2.6.1.13 VLAN Aware Mode

The CPSW is in VLAN aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL_REG register.

In VLAN aware mode, transmitted packet data is changed depending on the packet type (PKT_TYPE), packet priority (PKT_PRI), and VLAN information.

The VLAN_LTYPE_SEL value is selected by the S_CN_SWITCH bit in the CPSW_CONTROL_REG register and is either the VLAN_LTYPE_INNER (8100h default) or VLAN_LTYPE_OUTER (88A8h default) value.

12.2.1.2.6.1.14 VLAN Unaware Mode

An egress port is operating in the VLAN unaware mode when the VLAN_AWARE bit in the CPSW_CONTROL_REG register is cleared to 0h. In VLAN unaware mode, transmit (egress) packets are not modified on egress.

12.2.1.2.6.2 Packet Priority Handling

Packets are received on two ports, one Ethernet port and one CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN_LTYPE_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP_IPV4_EN is set in CPSW_P0_CONTROL_REG or CPSW_PN_CONTROL_REG, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP_IPV6_EN is set in CPSW_P0_CONTROL_REG or CPSW_PN_CONTROL_REG, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority.

The received packet priority is mapped through the receive ports associated packet-priority-to-header-packet-priority-mapping register (CPSW_PN_RX_PRI_MAP_REG) to obtain the header packet priority. The header packet priority is the hardware switch priority. The header packet priority is also used as the actual transmit packet priority if the VLAN information is to be sent on egress.

The header packet priority is mapped at each destination FIFO through the CPSW_PN_TX_PRI_MAP_REG register (header priority to switch priority mapping register) to obtain the hardware switch priority (hardware queue 0 through 7).

12.2.1.2.6.2.1 Priority Mapping and Transmit VLAN Priority

There are three priorities that are used inside the Gigabit Ethernet Switch: **packet priority**, **header packet priority**, and **switch priority**. The **header packet priority** is used as the outgoing VLAN priority if the packet is egressing from the switch with a VLAN tag. The **switch priority** determines which of the 8 FIFO priority queues the packet uses during egress.

Figure 12-64 below, as well as the corresponding explanation that follows, explains each of the priorities, how they are determined, and how they are used. A number in parentheses in the figure indicates a process (Ethernet port ingress, host port egress, etc.). Each bullet in the text following the diagram explains one of the 5 processes pointed out in the figure.

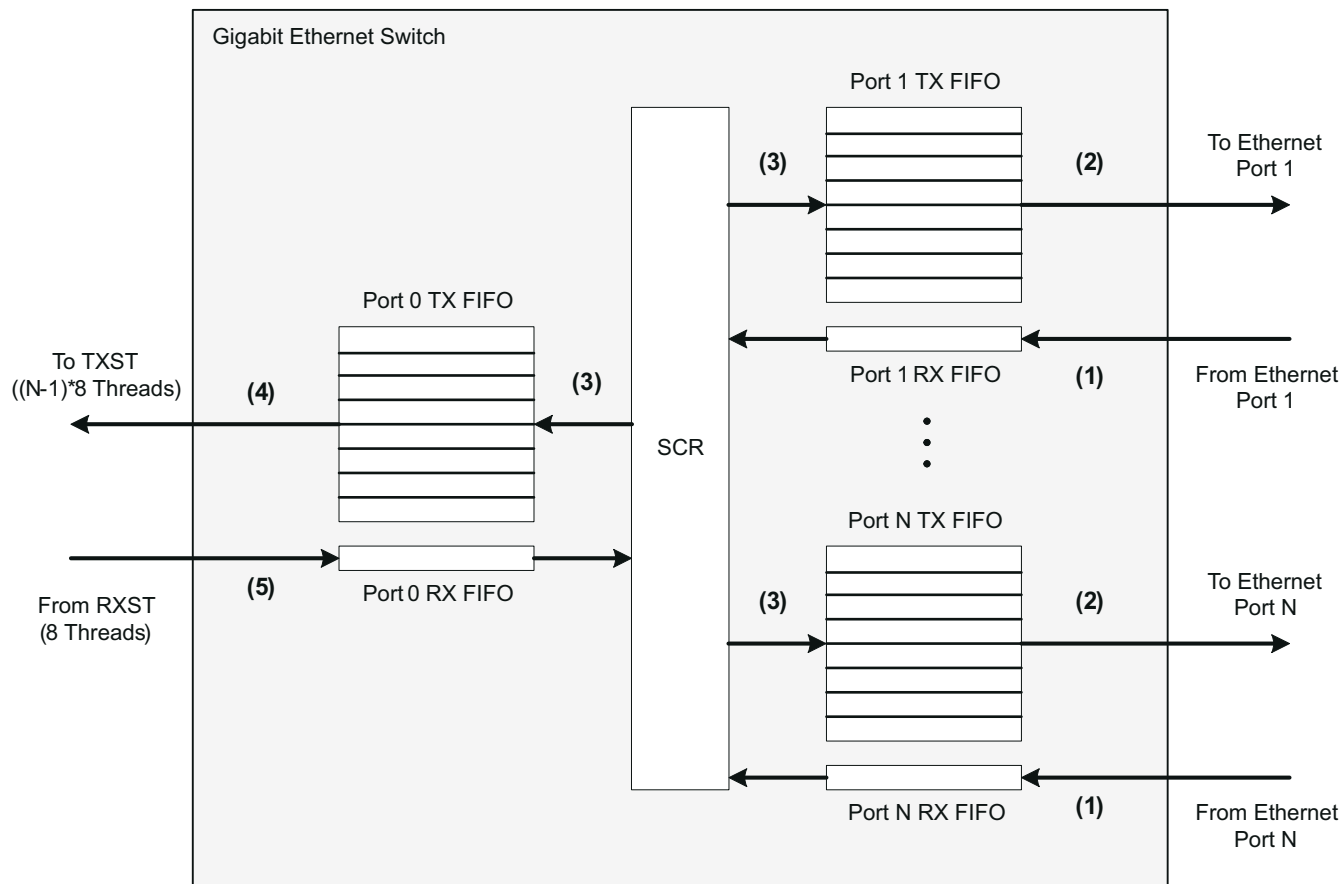

Figure 12-64. Gigabit Ethernet Switch Priority Mapping and Transmit VLAN Processing

From [Figure 12-64](#) above:

- (1) is the ingress process that occurs at the external Ethernet ports
 - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the ingress port's priority. This **packet priority** is then mapped to a **header packet priority** using the CPSW_PN_RX_PRI_MAP_REG register where N is the port where the packet entered the switch. This process is explained in further detail in [Section 12.2.1.2.6.2](#).
- (2) is the egress process that occurs at the external Ethernet ports
 - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1) or (5). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.1.2.6.4.1](#).
- (3) is the process by which it is decided which priority TX queue to place the packet on in the Port N TX FIFO during egress
 - Each Port's TX FIFO has 8 queues that each correspond to a priority that is used when determining which packet will egress from the switch next at that port. The **header packet priority** (Ethernet port ingress, process (1)) or the receive packet thread (host port 0 ingress, process (5)) gets mapped through the CPSW_PN_RX_PRI_MAP_REG register (where N is the egress port number) to determine the **switch priority** of the packet. The **switch priority** determines which TX FIFO queue to place the packet in. The FIFO architecture is described in [Section 12.2.1.2.6.10.11](#). The header packet priority to switch priority mapping is discussed in [Section 12.2.1.2.6.2](#).
- (4) is the egress process that occurs at Host Port 0 toward the transmit streaming interface (TXST)
 - The TXST has 8 egress threads for each external Ethernet port (32 threads in a 5-port switch and 64 threads in a 9-port switch). The TX thread that is selected for a packet is determined by the Ethernet port of ingress and the **switch priority** of the packet that was determined in process (3).
 - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.1.2.6.4.1](#).
- (5) is the ingress process that occurs at Host Port 0
 - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the host port's priority. This packet priority is then mapped to a **header packet priority** using the CPSW_PN_RX_PRI_MAP_REG register.
 - Host port 0 also has a received packet thread. The receive packet thread is based on either the packet's VLAN priority, IPv4 or IPv6 DSCP value, or the streaming interface (RXST) thread that the packet entered host port 0 on.

12.2.1.2.6.3 CPPI Port Ingress

Packets received on the CPPI host port have a received packet priority (0 to 7 with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN_LTYPE_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP_IPV4_EN is set in CPSW_P0_CONTROL_REG or CPSW_PN_CONTROL_REG register, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP_IPV6_EN is set in CPSW_P0_CONTROL_REG or CPSW_PN_CONTROL_REG register, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority

The CPPI Port (port 0) also has a received packet thread. The received packet thread is determined exactly as the received packet priority except for untagged packets. For untagged packets, the received packet thread is the packet streaming interface thread that the packet was received on (instead of the port VLAN priority or DSCP

priority). The received packet thread is the hardware switch priority. The received packet thread only determines which hardware switch priority the packet should be sent to, the egress VLAN rules are identical to packets that were received on Ethernet ports (as determined by the header packet priority).

For CPPI ingress packets, the destination port hardware switch priority is the below selected value remapped through CPSW_PN_RX_PRI_MAP_REG:

1. If the ingress packet is priority tagged or vlan tagged:
 - If RX_REMAP_VLAN in CPSW_P0_CONTROL_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
 - If RX_REMAP_VLAN in CPSW_P0_CONTROL_REG register is set then the destination hardware switch priority is the packet priority value. Port transmit remapping (CPSW_PN_TX_PRI_MAP_REG should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
2. Else if the ingress packet has the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP_IPV4_EN is set in CPSW_P0_CONTROL_REG register:
 - If RX_REMAP_DSCP_V4 bit in CPSW_P0_CONTROL_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
 - If RX_REMAP_DSCP_V4 bit in CPSW_P0_CONTROL_REG register is set then the destination hardware switch priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPv4 packet). Port 1 transmit remapping (CPSW_PN_TX_PRI_MAP_REG should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
3. Else if the ingress packet has the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP_IPV6_EN is set in P0_CONTROL_REG register:
 - If RX_REMAP_DSCP_V6 bit in CPSW_P0_CONTROL_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
 - If RX_REMAP_DSCP_V6 bit in CPSW_P0_CONTROL_REG register is set then the destination hardware switch priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet). Port 1 transmit remapping (CPSW_PN_TX_PRI_MAP_REG should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
4. Else the ingress packet is non-tagged and the destination hardware switch priority is the CPPI receive thread number.

12.2.1.2.6.4 Packet CRC Handling

The P0_TX_CRC_REMOVE bit in the CPSW_CONTROL_REG register determines if host port egress packets have CRC included or not. If P0_TX_CRC_REMOVE is set to 1h then all packets that are transmitted from port 0 do not contain CRC. If P0_TX_CRC_REMOVE bit is cleared to 0h then all packets that are transmitted from port 0 contain CRC. The CRC type, if present, is determined by the CRC_TYPE bit in the CPSW_PN_MAC_CONTROL_REG register. If the CRC_TYPE bit is cleared to 0h then the CRC present in each packet after host port egress is Ethernet CRC. If the CRC_TYPE bit is set to 1h then the CRC present in each packet after host port egress is Castagnoli CRC.

Note

The CRC type present in the packet after host port egress is determined solely by the CRC_TYPE bit in the CPSW_PN_MAC_CONTROL_REG register regardless of the CRC type present in the packet during Ethernet port ingress.

12.2.1.2.6.4.1 Transmit VLAN Processing

Transmit packets are NOT modified during switch egress when the VLAN_AWARE bit in the CPSW_CONTROL_REG register is cleared to 0h. This means that the switch is not in VLAN-aware mode.

The next three sections cover transmit processing when the switch is in VLAN-aware mode for different packet types. The Gigabit Ethernet switch is in VLAN-aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL_REG register. While in VLAN-aware mode, VLAN is added, removed, or replaced according

to the type of packet as well as the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the packet header as explained below.

12.2.1.2.6.4.1.1 Untagged Packets (No VLAN or Priority Tag Header)

Untagged packets are all packets that are not a VLAN packet or a priority tagged packet. According to the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the packet header the packet may exit the switch with a VLAN tag inserted or the packet may leave the switch unchanged. The two cases are discussed below.

- Insert VLAN Case:

Untagged input packets have the header packet VLAN inserted when the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the transmit packet header is de-asserted. For untagged packets, the VLAN EtherType = 0x8100 is inserted after the source address followed by the two byte header packet VLAN. The header packet VLAN is composed of the header packet priority along with the PORT_CFI and PORT_VID values from the CPSW_PN_PORT_VLAN_REG register (where N is the port that the untagged packet entered the switch) through. The packet length/type field is output four bytes later than it is input and is not removed or replaced. If the CRC is present in the packet data (PASS_CRC is asserted), then the packet CRC is replaced with a hardware generated CRC.

- No Change Case:

Untagged input packets are output unchanged when the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS transmit packet header bit is asserted.

12.2.1.2.6.4.1.2 Priority Tagged Packets (VLAN VID == 0 && EN_VID0_MODE == 0h)

Priority tagged packets are packets that contain a VLAN header with VID = 0. According to the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the packet header, priority tagged packets may exit the switch with their VLAN ID and priority replaced or they may have their priority tag completely removed. The two cases are discussed below.

Note

In order for a priority tagged packet to fall into this category the ENABLE_VID0_MODE bit in the CPSW_ALE_CONTROL register must also be set to 0h. If the ENABLE_VID0_MODE bit in the CPSW_ALE_CONTROL register is set to 1h, then packets with a VLAN VID of 0 will fall into the VLAN Tagged Packets category in [Section 12.2.1.2.6.4.1.3](#) below.

- Replace Priority and VLAN ID Case:

Priority tagged input packets have the packet VLAN ID and the packet priority replaced with the header packet VLAN ID and the header packet priority when the transmit packet header CPSW_FORCE_UNTAGGED_EGRESS_REG[1-0] MASK bit is de-asserted. The header packet VLAN ID comes from the PORT_VID bits in the CPSW_PN_PORT_VLAN_REG register (where N is the port where the packet entered the switch). The header packet priority is based on the packet priority to header packet priority mapping in the CPSW_PN_RX_PRI_MAP_REG register (where N is the port where the packet entered the switch).

- Remove VLAN Header Case:

Priority tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority-tagged packets use all four input CRC bytes as pad, input 65-byte priority-tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS_CRC input bit is not asserted - input 64-67 byte (on the wire) priority-tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

12.2.1.2.6.4.1.3 VLAN Tagged Packets (VLAN VID != 0 || (EN_VID0_MODE == 1h && VLAN VID == 0))

VLAN tagged packets are packets that contain a VLAN header specifying the VLAN the packet belongs to (VID), the packet priority (PRI), and the drop eligibility indicator (CFI). According to the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the packet header, VLAN tagged packets may exit the switch with their VLAN priority replaced or they may have their VLAN header completely removed. The two cases are discussed below.

- Replace Priority Case:

VLAN tagged input packets are output with the packet priority replaced with the header packet priority when the transmit packet header CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit is deasserted. The header packet priority is based on the packet priority to header packet priority mapping in the CPSW_PN_RX_PRI_MAP_REG register (where N is the port where the packet entered the switch). If the CRC is present in the packet data (PASS_CRC is asserted), then the packet CRC is replaced with a generated CRC.

- Remove VLAN Header Case:

VLAN tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority tagged packets use all four input CRC bytes as pad, input 65-byte priority tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS_CRC input bit is not asserted - input 64-67 byte (on the wire) priority tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

12.2.1.2.6.4.2 Ethernet Port Ingress Packet CRC

All Ethernet ports check the ingress packet CRC in all modes/speeds. The receive port can check either Ethernet CRC or Castagnoli CRC as determined by the CRC_TYPE bit in the CPSW_PN_MAC_CONTROL_REG register.

12.2.1.2.6.4.3 Ethernet Port Egress Packet CRC

Ethernet ports transmit each egress packet with the CRC selected by the CRC_TYPE bit in the CPSW_PN_MAC_CONTROL_REG register, regardless of the type of CRC that the packet had on ingress to the switch. At the egress port after passing through the switch, the packet CRC is checked for correctness and if the CRC is correct then the packet is output with the generated selected output CRC. If the packet CRC is incorrect, due either to a bit flip in a memory or an error CRC passed in on host ingress, then the generated egress CRC type is used with at least a single byte of the CRC inverted to indicate the error. If the packet length including CRC is divisible by 4 then all 4 CRC bytes will be inverted on error. If there are three bytes remainder after dividing the packet length by 4 then three bytes will be inverted (and so on down to one byte remainder).

12.2.1.2.6.4.4 CPPI Port Ingress Packet CRC

CPPI port ingress packets can be passed in with or without a CRC. The host port is Ethernet CRC only. CPPI ingress packets are not checked for CRC correctness on CPPI ingress, however they are checked for correctness on Ethernet egress and are output with a CRC error if they came in with a CRC error. If a CPPI ingress packet does not have the INFO0 PASSED_CRC bit set then a CRC will be generated for the packet on CPPI ingress. If the PASSED_CRC bit is set then the packet is received and forwarded unchanged. The CRC type is input in the INFO0 word CRC_TYPE bit and must be Ethernet CRC.

12.2.1.2.6.4.5 CPPI Port Egress Packet CRC

The P0_TX_CRC_REMOVE bit in the CPSW_CONTROL_REG register determines if CPPI egress packet have an Ethernet CRC included or not.

12.2.1.2.6.5 FIFO Memory Control

Each of the two CPSW_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each FIFO memory

contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX_MAX_BLKs field in the FIFOs associated CPSW_PN_MAX_BLKs_REG register determines the maximum number of 1k FIFO memory blocks to be allocated to the eight logical transmit queues (transmit total). The RX_MAX_BLKs field in the FIFOs associated CPSW_PN_MAX_BLKs_REG register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX_MAX_BLKs value plus the RX_MAX_BLKs value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports is Port1.

Each transmit FIFO contains a configurable number of blocks (20 max) that are either 1k or 4k byte blocks that can be allocated to any priority.

12.2.1.2.6.6 FIFO Transmit Queue Control

There are eight transmit queues in the Ethernet port transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues).

12.2.1.2.6.6.1 CPPI Port Receive Rate Limiting

Port 0 receive operations can be configured to rate limit the host ingress data for each receive thread (priority). CPPI Receive has 8 threads for QOS. There is a committed information rate (CPSW_P0_PRI_CIR_REG_y, where y = 0 to 7) and an excess information rate for each thread (CPSW_P0_PRI_EIR_REG_y, where y = 0 to 7). Rate limiting is enabled for a thread when the committed information rate for the thread is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited threads does impact the excess information rates. No bulk thread will be enabled to send unless there are CPSW_PN_PRI_CTL_REG[15-12] TX_HOST_BLKs_REM number of unused blocks remaining in each of the Ethernet port transmit FIFOs. The “blocks remaining check” ensures that bulk traffic from the host will not block rate-limited traffic from the host. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then threads 7 and 6 should be configured for committed information (and excess information if desired). When any channels are configured to be rate-limited, the priority type must be fixed for receive. Round-robin priority type is not allowed when rate-limiting is configured for any thread. The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to receive is controlled by the below equation. If the configured excess information rate is zero, then only the committed information rate is transferred:

Priority Transfer rate [Mbit/s] = (((Frequency in MHz) * CPSW_P0_PRI_CIR_REG_y) / 32768) + (((Frequency in MHz) * CPSW_P0_PRI_EIR_REG_y) / 32768))

Where the *frequency* is the CPPI_ICLK frequency (in MHz) and priority 0 to 7.

For example, 10Mbps on priority 7 would give the below:

10Mbps = ~ ((350 * 936) / 32768), at 350Mhz and CPSW_P0_PRI_CIR_REG_y[27-0] PRI_CIR value = 936 (no excess information rate)

12.2.1.2.6.6.2 Ethernet Port Transmit Rate Limiting

Ethernet port transmit operations can be configured to rate limit egress data for each egress priority. There is a committed information rate (CPSW_P0_PRI_CIR_REG_y, where y = 0 to 7) and an excess information rate for each priority (CPSW_P0_PRI_EIR_REG_y, where y = 0 to 7). Rate limiting is enabled for a priority when the committed information rate for the priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk

traffic on other non-rate limited threads does impact the excess information rates. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to send is controlled by the below equation. If the excess information rate is disabled then the committed information rate only is transferred:

Priority Transfer rate [Mbit/s] = (((Frequency in MHZ) * CPSW_P0_PRI_CIR_REG_y) / 32768) + (((Frequency in MHZ) * CPSW_P0_PRI_EIR_REG_y) / 32768))

Where the *frequency* is the CPPI_ICLK frequency (in MHz) and priority 0 to 7.

12.2.1.2.6.7 Interspersed Express Traffic (IET – P802.3br/D2.0)

When IET is enabled through CPSW_CONTROL_REG[17] IET_ENABLE = 1h and configured, IET allows preemptable traffic on selected transmit priorities to be preempted by express traffic on selected express priorities. Received traffic is separated onto express and preempt receive queues. When IET is disabled (IET_ENABLE = 0h), all Ethernet traffic is express traffic and switch operation is as if IET does not exist. Traffic is only intended to be moved to the preempt queue after preemption is verified and enabled.

12.2.1.2.6.7.1 IET Configuration

- Using the preempt receive queue requires more blocks to be allocated to the ports receive FIFO. Write a value of decimal 7 to the CPSW_PN_MAX_BLKs_REG[7-0] RX_MAX_BLKs bit field, and a value of decimal 13 to the CPSW_PN_MAX_BLKs_REG[15-8] TX_MAX_BLKs register for every port to be enabled for IET.
- Write the [23-0]MAC_VERIFY_CNT bit field in the Ethernet port CPSW_PN_IET_VERIFY_REG register to set the verify/response timeout count. The default is 10ms for Gigabit mode. For other time values or link speeds the verify count should be updated. If CPSW_PN_IET_CONTROL_REG[2] MAC_DISABLEVERIFY bit is to be set (this is forced mode) then this step is unneeded.
- The receive FIFO block allocation is insufficient if CPSW_STAT0_RX_BOTTOM_OF_FIFO_DROP/ CPSW_STAT1_RX_BOTTOM_OF_FIFO_DROP[31-0] COUNT is nonzero, indicating that receive packets are being dropped due to FIFO block allocation.
- Write the CPSW_PN_IET_CONTROL_REG register in the Ethernet port as below:
 - Set the CPSW_PN_CONTROL_REG[16] IET_PORT_EN bit. The port will not actually be enabled until bit IET_ENABLE is set in the CPSW_CONTROL_REG.
 - The CPSW_PN_IET_CONTROL_REG[0] MAC_PENABLE bit can be set as desired. No effect will occur until IET_ENABLE is set. This bit enables preemptable packets to be preempted by express traffic but does not preclude packets from being sent to the preempt queue.
 - If verify/response is desired then CPSW_PN_IET_CONTROL_REG[3] MAC_LINKFAIL should be cleared by software to enable verify and response packets. Otherwise, MAC_DISABLEVERIFY bit should be set for forced mode. Verification and response will occur immediately after clearing this bit.
 - Configure the remaining CPSW_PN_IET_CONTROL_REG register bits as desired.
- Set the IET_ENABLE bit in the CPSW_CONTROL_REG register to enable IET operations.
- After preemption has been verified, the CPSW_PN_IET_CONTROL_REG[23-16] MAC_PREMPT field is written to configure the FIFO priorities to be sent to the preempt queue (the other priorities with cleared bits go to the express queue). The hardware switch for each queue from express to preempt happens only when there are no packets queued on the priority.

12.2.1.2.6.8 Enhanced Scheduled Traffic (EST – P802.1Qbv/D2.2)

12.2.1.2.6.8.1 Enhanced Scheduled Traffic Overview

- When enabled and configured, EST allows express queue traffic to be scheduled (placed) on the wire at specific repeatable time intervals.
- EST operates on a repeating time interval generated by the CPTS EST function generator. For example, a 125us repeating time interval can be configured.
- Each Ethernet port has 128 EST fetch commands maximum in the global EST fetch RAM.
- Each 22-bit fetch command consists of a 14-bit fetch count (14 MSB's) and an 8-bit priority fetch allow (8 LSB's) that will be applied for the fetch count time in wireside clocks.

- The configured port fetch commands are executed in sequence, beginning at port address zero each time through the time interval beginning at cycle start.
- EST allows non-scheduled express and preempt queue traffic to be cleared from the wire to ensure that the scheduled traffic is transmitted at the proper time (zero allow).
- EST can be used with or without preemption. The CPSW_PN_IET_CONTROL_REG[23-16] MAC_PREMPT value determines whether the priority is enabled on the express or preempt queue. Whether a priority is on the express or preempt queue only effects the wire clear time from an EST operation perspective.
- Software should not move priorities to the preempt queue unless preemption is configured, enabled, and verified allowing preemption to occur.
- Express packet time stamp events can be enabled to assist software in configuring and timing EST operations.

12.2.1.2.6.8.2 Enhanced Scheduled Traffic Fetch RAM

- The EST fetch RAM is read/writable in the CPSW configuration address space.
- The Ethernet transmit port has 128 locations in the global EST fetch RAM.
 - Ethernet port 1 has EST fetch RAM addresses 0x000-0x07F.
- **One buffer operation:** When CPSW_PN_EST_CONTROL_REG[0] EST_ONEBUF is set to 1h, the 128 port locations operate as one buffer. The EST_BUFACT bit in CPSW_PN_FIFO_STATUS_REG register is the upper address bit of the port's fetch RAM address indicating whether operation is currently in the upper or lower 64 locations of the port's fetch RAM.
- **Two buffer operation:** When CPSW_PN_EST_CONTROL_REG[0] EST_ONEBUF is cleared there are two 64-location buffers with CPSW_PN_EST_CONTROL_REG[1] EST_BUFSEL selecting the buffer to be used. When the buffer is switched by changing the CPSW_PN_EST_CONTROL_REG[1] EST_BUFSEL value, the actual switch occurs on cycle start. The actual buffer being used is indicated by the EST_BUFACT bit in CPSW_PN_FIFO_STATUS_REG. Software should avoid writing the switched out buffer fetch RAM locations until it detects that the actual switch has occurred.
- The first address location in the port's fetch RAM space (location zero) is read at the beginning of each EST time interval (cycle start). Addresses are then read in ascending order for the duration of the interval. The port address zero is then read again at the beginning of the next cycle repeating the time interval packet operations.

12.2.1.2.6.8.3 Enhanced Scheduled Traffic Time Interval

- Each Ethernet port has an Enhanced Scheduled Traffic Function (ESTF) generator in the CPTS submodule.
- The EST function generator generates the EST time interval as a configured number of CPTS reference clocks (CPTS_RFT_CLK).
- The EST function generator rising edge is the cycle start time and the cycle repeats (cycle start occurs) after every time interval.
- The first fetch allowed value is at the port base address zero in the EST fetch RAM and is actually applied 16 wireside clocks after cycle start. The 16 clock cycle delay allows the first fetch value time to be fetched from the EST fetch RAM (prefetch time at cycle start).
- Each successive fetch allow is applied for the associated fetch count thereafter. The minimum non-zero fetch count is 16. The minimum value of 16 guarantees that the next fetch value has time to be fetched before the current fetch count is over. There are 64 maximum fetch values when CPSW_PN_EST_CONTROL_REG[0] EST_ONEBUF = 0h, and 128 maximum fetch values when CPSW_PN_EST_CONTROL_REG[0] EST_ONEBUF = 1h.
- The next cycle start then causes the fetch to once again start at the port address zero.

12.2.1.2.6.8.4 Enhanced Scheduled Traffic Fetch Values

- The 22-bit fetch value is made up of the 14-bit fetch count and the 8-bit fetch allow.
- The fetch time indicates the number of wireside clocks that the fetch allow will be active.
- The fetch count is in Ethernet wireside clocks which is bytes in Gigabit mode (CPSW_PN_MAC_CONTROL_REG[7] GIG = 1h) and nibbles in 10/100Mbps mode.
- When a fetch allow bit is set, the corresponding priority is enabled to begin packet transmission on an allowed priority subject to rate limiting. The actual packet transmission on the wire may carry over into the next fetch count and is the reason for the wire clear time in the fetch zero allow.

- When a fetch allow bit is cleared, the corresponding priority is not enabled to transmit for the fetch count time.
- A non-zero fetch allow value with a non-zero fetch count causes the fetch allow value to be applied for the fetch count number of wireside clocks.
- A zero fetch count causes the associated fetch allow to be held for the duration of the cycle (until the next cycle start).
- A zero fetch allow with a non-zero fetch count is intended to clear the wire for a scheduled (timed) express packet in the next fetch. A zero fetch allow indicates that no packet can be started for transmission for the associated fetch count. The associated fetch count must be sufficient to guarantee that the wire is cleared given that a packet on an allowed priority in the previous fetch could have been started on the previous clock and that there is hardware latency in the clear time. The timed packet should be sent on a priority that is enabled in the next fetch but disabled in the current zero allow fetch. The fetch allow previous to a zero allow should have only preempt priorities enabled or only express priorities enabled but not both.
- The number of clocks required to clear the wire varies depending Ethernet wire speed and on whether express or preempt priorities were allowed in the previous fetch command.

12.2.1.2.6.8.5 Enhanced Scheduled Traffic Packet Fill

Packet fill can be enabled (CPSW_PN_EST_CONTROL_REG[8] EST_FILL_EN = 1h) to occur in the fetch count time associated with a fetched zero allow. The intention with fill is that a smaller packet on a non-timed priority might be able to be inserted on the wire during the wire clear time which would increase wire utilization. Fill is intended to be used with either only express priorities in the previous non-zero fetched allow, or only preempt priorities in the previous non-zero fetched allow but not both. Fill must be configured to ensure that any fill packet does not conflict with the timed express packet allowed in the next fetch.

- **Express fill:**

1. CPSW_PN_EST_CONTROL_REG[8] EST_FILL_EN is set and
2. A fetch contains a non-zero fetch count with a zero fetch allow, and
3. The previous allow contained only express priorities.
4. The fetch count loaded should be at least TBD clocks and the CPSW_PN_EST_CONTROL_REG[25-16] EST_FILL_MARGIN should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
5. The fetch count loaded should be at least TBD clocks and the CPSW_PN_EST_CONTROL_REG[25-16] EST_FILL_MARGIN should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

- **Preempt fill:**

1. CPSW_PN_EST_CONTROL_REG[8] EST_FILL_EN is set and
2. A fetch contains a non-zero fetch count with a zero fetch allow, and
3. The previous allow contained only preempt priorities
4. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
5. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

- **Express non-fill:**

1. CPSW_PN_EST_CONTROL_REG[8] EST_FILL_EN is clear and
2. The previous allow contained only express priorities.
3. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
4. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

- **Preempt non-fill:**

1. CPSW_PN_EST_CONTROL_REG[8] EST_FILL_EN is clear and
2. The previous allow contained only preempt priorities.
3. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
4. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

12.2.1.2.6.8.6 Enhanced Scheduled Traffic Time Stamp

The EST can be configured to generate CPTS timestamp events for selected express traffic. The EST timestamp events use the CPTS host event type (CPSW_CPTS_EVENT_1_REG[23-20] EVENT_TYPE = 7 decimal). The EST timestamps will not override host sent timestamps for packets that were sent from the host with an enabled host timestamp.

- EST Events (host events) contain the below information:
 - Time Stamp of the selected express packet.
 - The event CPSW_CPTS_EVENT_1_REG[28-24] PORT_NUMBER indicates the transmit port number.
 - The event CPSW_CPTS_EVENT_1_REG[23-20] EVENT_TYPE is decimal 7 (host event).
 - The event CPSW_CPTS_EVENT_1_REG[23-20] MESSAGE_TYPE indicates the packet transmit hardware switch priority.
 - The event CPSW_CPTS_EVENT_1_REG[15-0] SEQUENCE_ID upper nibble indicates the packet receive port number.
 - The event CPSW_CPTS_EVENT_1_REG[15-0] SEQUENCE_ID lower byte indicates the sequence number of the express packet in numerical order. The first event is event one, the second is event two and so on. The sequence ID rolls over to zero after 0xFF (8-bits).
 - The event domain is the value from the CPSW_EST_TS_DOMAIN_REG[7-0] EST_TS_DOMAIN register.
- When CPSW_PN_EST_CONTROL_REG[2] EST_TS_EN is set, timestamp events will be generated on selected express traffic.
- When CPSW_PN_EST_CONTROL_REG[3] EST_TS_FIRST is also set, events will be generated only on the first express packet in each time interval. If CPSW_PN_EST_CONTROL_REG[4] EST_TS_ONEPRI is also set then the event will only be on the first CPSW_PN_EST_CONTROL_REG[7-5] EST_TS_PRI express packet in the time interval. If CPSW_PN_EST_CONTROL_REG[4] EST_TS_ONEPRI is clear then the event will be generated on the first express packet in the time interval on any priority.
- When CPSW_PN_EST_CONTROL_REG[3] EST_TS_FIRST is clear, events will be generated on every express packet. If CPSW_PN_EST_CONTROL_REG[4] EST_TS_ONEPRI is set then the event will be generated on every CPSW_PN_EST_CONTROL_REG[7-5] EST_TS_PRI express packet. If CPSW_PN_EST_CONTROL_REG[4] EST_TS_ONEPRI is clear then event will be generated on every express packet on any priority.

12.2.1.2.6.8.7 Enhanced Scheduled Traffic Packets Per Priority

The number of packets allowed in a transmit FIFO priority can be selected by writing a non-zero value to CPSW_P0_RX_PKTS_PRI_REG register (packet priority 0 to 7). Then port 0 receive gap should then be enabled by setting the corresponding priority through CPSW_P0_RX_GAP_REG[7-0] RX_GAP_EN bit field. The receive gap allows a packet to land in the transmit FIFO before another packet is allowed in which guarantees that only the selected number (max) of packets is allowed in on the specified priority. If the receive gap is not enabled, then there might be one or two more packets allowed in on the priority/thread than the packets per priority value has selected (through CPSW_P0_RX_PKTS_PRI_REG register).

12.2.1.2.6.9 Audio Video Bridging

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks*". "a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams*."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)*."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

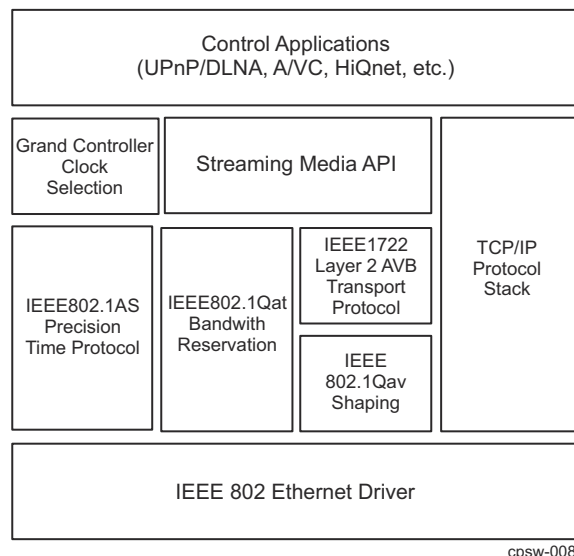

Figure 12-65. The Network Stack with AVB

The following sections describe the media transport protocols that work within the AVB framework.

12.2.1.2.6.9.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))

The protocol defined by 802.1AS automatically selects a device to be the controller clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

Note

The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

Based on IEEE 1588:2002, PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock controller selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2-in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock controller, the Best Controller Clock Algorithm (BCCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandcontroller. Once a Grandcontroller has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Target nodes compare the value of their RTC against the PTP Grandcontroller and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1- μ s accuracy over seven network hops.

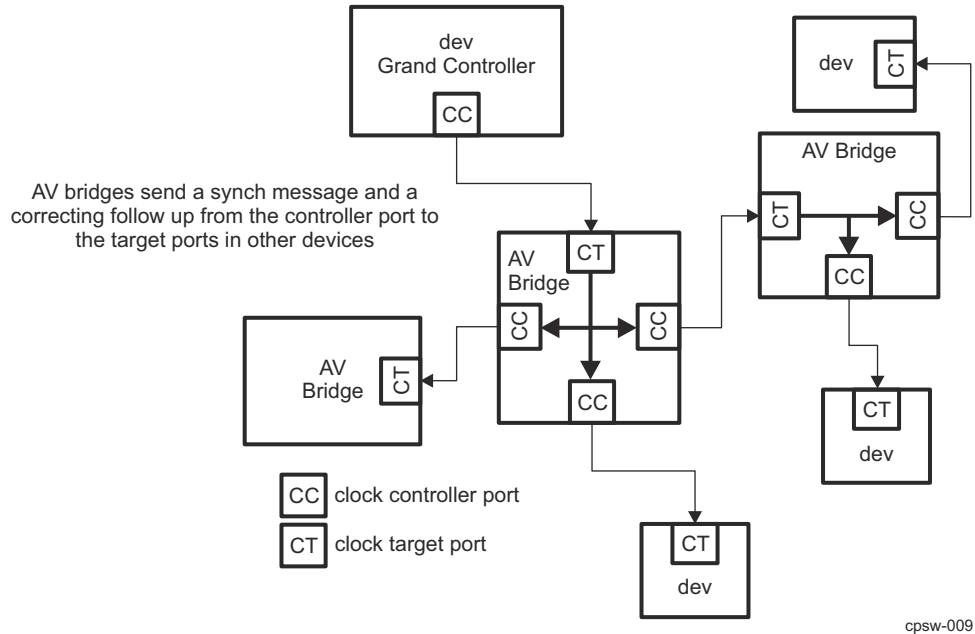

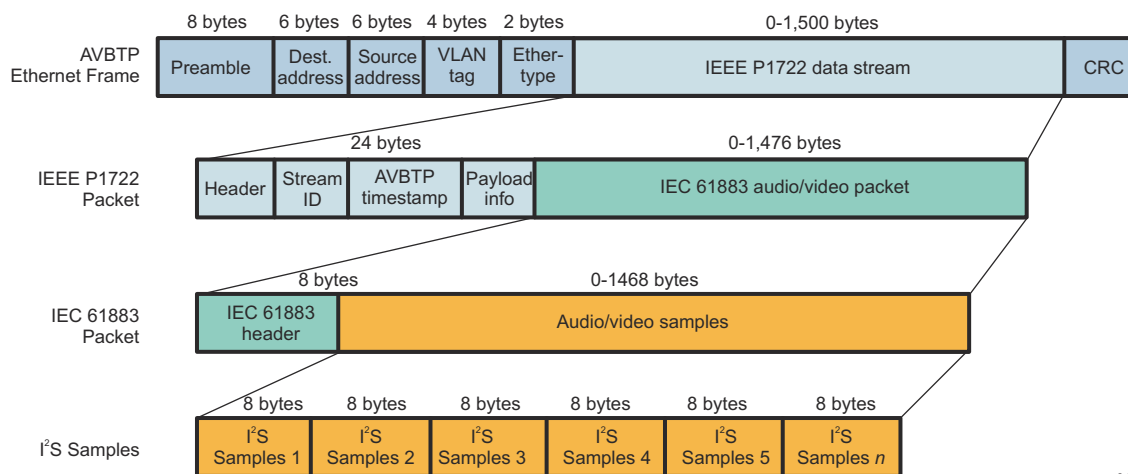

Figure 12-66. AVB Network & PTP Clock Entities

The media transport protocols that work within the AVB framework are:

12.2.1.2.6.9.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in [Figure 12-67](#) and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

IEEE 1722 Packet Construction

cpsw-010

Figure 12-67. IEEE 1722 Packets

1722 or AVBTP Presentation Time and Synchronization:

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

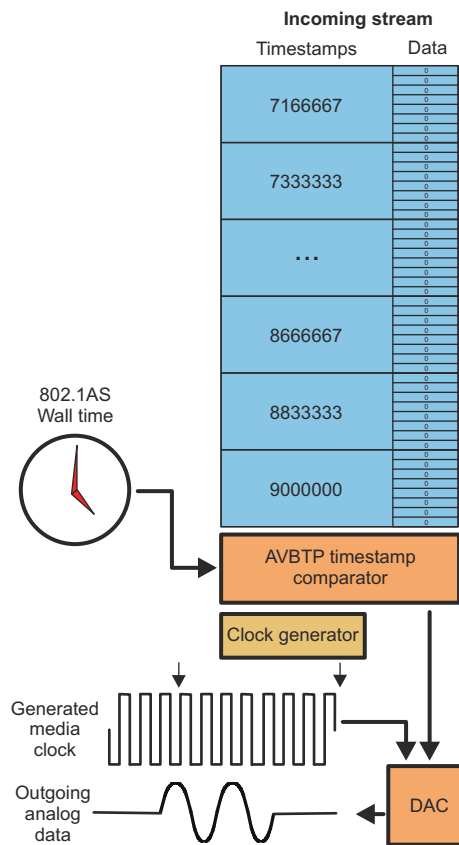

12.2.1.2.6.9.1.1 Cross-timestamping and Presentation Timestamps

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandcontroller. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. [Figure 12-68](#) illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

Presentation timestamps

Cross-time stamped clock recovery

cpsw-011

Figure 12-68. Cross Time Stamping and Presentation Timestamps

12.2.1.2.6.9.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/Video Bridging (AVB) protocols.

12.2.1.2.6.9.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
 - Receive policing
 - Transmit rate control.

End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like [Figure 12-69](#).

Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

cpsw-012

Figure 12-69. AV Stream Queuing/Policing

12.2.1.2.6.9.2.1 Configuring the Device for 802.1Qav Operation

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
 - CPPI TX and RX descriptors
 - VLAN and Priority tags

Table 12-124. Example of TX Configuration

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

Table 12-125. Example of RX Configuration

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
 - ALE in VLAN-ware mode, Non-ALE in bypass mode.

12.2.1.2.6.10 Ethernet MAC Sliver

The Ethernet port peripheral is compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation
- RMII/RGMII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control
- Programmable Inter Packet Gap (IPG).

12.2.1.2.6.10.1 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS_CRC bit is 0h. For the Ethernet port generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS_CRC bit is set.

12.2.1.2.6.10.2 MTXER

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

12.2.1.2.6.10.3 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX_PACE bit in the CPSW_PN_MAC_CONTROL_REG register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

12.2.1.2.6.10.4 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96-bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRC is de-asserted within approximately 48-bit times of MTXEN being de-asserted, then 96-bit times is measured from MTXEN. If the frame suffered a collision, or if MCRC is not de-asserted until more than approximately 48-bit times after MTXEN is de-asserted, then 96-bit times (approximately, but not less) is measured from MCRC.

The Ethernet port transmit inter-packet gap (IPG) may be shortened by eight bit times when short gap is enabled and triggered. Setting the [10] TX_SHORT_GAP_ENABLE bit in the CPSW_PN_MAC_CONTROL_REG register enables the gap to be shortened when triggered. The condition is triggered when the ports associated transmit packet FIFO has a user defined number of FIFO blocks used. The associated transmit FIFO blocks used value determines if the gap is shortened, and so on. The CPSW_GAP_THRESH_REG register value determines the short gap threshold. If the FIFO blocks used is greater than or equal to the GAP_THRESH value then short gap is triggered.

12.2.1.2.6.10.5 Back Off

The Gigabit Ethernet Mac Sliver implements the 802.3 binary exponential back-off algorithm.

12.2.1.2.6.10.6 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the CPSW_PN_MAC_CONTROL_REG register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

12.2.1.2.6.10.7 Speed, Duplex and Pause Frame Support Negotiation

The Ethernet port can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

12.2.1.2.6.10.8 RMII Interface

The CPRMII peripheral is compliant to the RMII specification document.

12.2.1.2.6.10.8.1 Features

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

12.2.1.2.6.10.8.2 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMII_RXER on any di-bit in the received packet will cause an MII_RXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMII_CRS_DV toggle will issue an MII_RXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMII_CRS_DV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

12.2.1.2.6.10.8.3 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the CPGMAC MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The CPGMAC does not source the transmit error (MII_TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMII_TXD[1:0] for each clock that RMII_TXEN is de-asserted.

12.2.1.2.6.10.9 RGMII Interface

The CPRGMII peripheral is compliant to the RGMII specification document.

12.2.1.2.6.10.9.1 Features

- Supports 1000/100/10 Mbps speed
- Full and Half Duplex support (CPGMAC supports only Full duplex in Gigabit mode).
- MII mode support
- Energy Efficient Ethernet Support

12.2.1.2.6.10.9.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

12.2.1.2.6.10.9.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the RGMII_RX_INBAND input is asserted. RGMII_RX_INPUT is asserted by configuring the CTL_EN bit to 1h of the CPSW_PN_MAC_CONTROL_REG register. The link status, duplexity, and speed are determined from the RGMII input data stream RXD[3:0] when RX_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in [Table 12-126](#).

Table 12-126. In-Band Data

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0h: half-duplex	0h: 10-Mbps mode	2.5 MHz	0h: Link is down
1h: full-duplex	1h: 100-Mbps mode	25 MHz	1h: Link is up
	2h: 1000-Mbps mode	125 MHz	
	3h: Reserved	Reserved	

12.2.1.2.6.10.9.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the RGMII_RX_INBAND input is deasserted by setting to 0h bit CTL_EN of the CPSW_PN_MAC_CONTROL_REG register. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the CPSW_PN_MAC_CONTROL_REG[0] FULLDUPLEX and CPSW_PN_MAC_CONTROL_REG[7] GIG bits. If bit [7] GIG = 1h, then CPRGMII is operating in Gigabit mode. If bit [7] GIG is cleared (0h), then CPRGMII is operating in 100 Mbps mode.

12.2.1.2.6.10.9.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRGMII module.

In 10/100 Mbps mode, the TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 Mbps mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII_LINK. Packet transmission will begin on the first TX_CTL rising edge after the 4096 transmit clock count has expired.

12.2.1.2.6.10.10 Frame Classification

Received frames are proper (good) frames if they are between 64 and CPSW_P0_RX_MAXLEN_REG[13:0] RX_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the CPSW_P0_RX_MAXLEN_REG/ CPSW_PN_RX_MAXLEN_REG register. The register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames. If RX_CSF_EN bit in CPSW_PN_MAC_CONTROL_REG is set to 1h, undersized frames from 33 to 63 bytes will be forwarded only to the host on a best effort basis (meaning that the ALE may or may not be able to keep up with the packet rate and the short packet may be dropped due to bandwidth limitations). If RX_CSF_EN and RX_CEF_EN in CPSW_PN_MAC_CONTROL_REG are set, fragment frames from 33 to 63 bytes will also be forwarded only to the host on a best effort basis. Ethernet port received frames shorter than 33 bytes are dropped in all cases.

A received long packet will always contain RX_MAXLEN number of bytes transferred to memory (if CPSW_PN_MAC_CONTROL_REG[22]RX_CEF_EN = 1h). An example with RX_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

12.2.1.2.6.10.11 Receive FIFO Architecture

This section describes the architecture of the Ethernet port's receive FIFOs. Internal to the Gigabit Ethernet switch, all Ethernet ports have an identical associated packet FIFO. Each transmit packet FIFO contains eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each transmit FIFO memory contains 81,920 bytes total organized as 2560 by 256-bit words. Each FIFO also contains a single memory for the receive queue. Each receive FIFO memory contains a total of 32768 bytes total organized as 1024 by 256-bit words.

12.2.1.2.6.11 Embedded Memories

Table 12-127. Embedded Memories

Memory Type Description	Number of Instances	
Single-port 3072-word × 64 RAM	1	(Combined FIFO RAM)
Single-port 128-word × 28-bit RAM	1	1 (EST)

12.2.1.2.6.12 Memory Error Detection and Correction

The CPSW error detection and correction logic uses the ECC Aggregator Module.

The ECC CPSW_ECC_VECTOR register is used to select which ECC RAM's status and control registers are currently being read or written as shown in [Table 12-128](#). The CPSW FIFO RAMs implement ECC only on packet headers. The packet data is protected by Ethernet CRC. The ALE and EST RAMs have complete ECC as normal.

Table 12-128. ECC RAM to CPSW RAM Mapping

ECC RAM Number	CPSW RAM
0	ALE RAM
1	Port 0 FIFO RAM

12.2.1.2.6.12.1 Packet Header ECC

Only packet headers bits are protected by ECC in the FIFO RAMs. The ECC_ERR_CTRL1[31-0] ECC_ROW bit is used to activate a row address where force single-bit error or force double-bit error needs to be applied. ECC_ERR_CTRL2 [15-0] ECC_BIT1 is implemented to determine which bit of the header is flipped for an SEC error when the ECC_CRC_MODE bit is cleared in the CPSW_CONTROL_REG register. The ECC status registers return the RAM row address where the single or double-bit error has occurred (ECC_ERR_STAT2[31-0] ECC_ROW) along with the bit position in the RAM data that is in error (ECC_ERR_STAT1[31-16] ECC_BIT1 value). Forcing double-bit errors in testing can cause indeterminate operation if multiple used packet header bits are flipped given that only single-bit errors are fixed by the ECC logic. Header bits 207 down to 200 are not currently used in the CPSW and may be used to test double bit errors without the possibility of requiring a reset for the switch to recover from the double bit error. No header bits are flipped when ECC_CRC_MODE is set to 1h. Either the RX_ECC_ERR_EN (enable receive ECC error operations) or the TX_ECC_ERR_EN (enable transmit ECC error operations) bits must be set in the CPSW_P0_CONTROL_REG register to test ECC header errors.

The header ECC code is stored in bits 255 down to 208. If any bit is flipped in the ECC code, the flipped bit will be corrected, but the index of the flipped bit will be reported as bit zero. This implies that when the aggregator reports that there is a SEC on bit 0, it can mean two things: either SEC on data bit 0 or SEC somewhere inside the ECC code. Any packet header with ECC error issues a pulse interrupt (ECC_PULSE_INTR) as does an ALE RAM ECC error.

12.2.1.2.6.12.2 Packet Protect CRC

Each packet received without error is passed through the CPSW_3G memories with a generated Ethernet protect CRC. The protect CRC is checked on egress for correctness and removed. If the CRC is correct (no RAM bit errors), then the packet is output with the selected port CRC type. If a protect CRC error is detected on host egress then the TXST_DROP signal will be asserted so that the packet is dropped to the host. If a protect CRC error is detected on Ethernet egress then the egress CRC will be generated on the packet and at least one byte of the CRC will be inverted on output. CRC memory protect errors do not assert the ECC_PULSE_INTR signal. CRC memory protect errors are counted in the associated port statistics registers and issue an interrupt on STAT_PEND_INTR if any CRC memory protect error occurs (and the statistics for that port are enabled). When the ECC_CRC_MODE bit in the CPSW_CONTROL_REG register is set, the ECC_ERR_CTRL2 [15-0] ECC_BIT1 bit field will flip the associated column bit in any FIFO memory read operation, inducing a CRC protect error when the protect CRC is checked. No header bits are flipped when ECC_CRC_MODE is set. Either the RX_ECC_ERR_EN or the TX_ECC_ERR_EN bits must be set in the CPSW_P0_CONTROL_REG register to test packet CRC errors.

12.2.1.2.6.12.3 Aggregator RAM Control

The ECC logic for each FIFO RAM (receive and transmit) is divided into eight separate ECC encoders/decoders that encode/decode 26-bits of data each. Each of the 8 encoders (0 to 7) generates 6-bits of ECC code (48 code bits total), and each of the eight decoders (0 to 7) checks 6-bits of ECC code across the 26-bits of data (208 data bits total). The 48-bits of ECC code are passed through the RAM in the upper 48 unused bits in the header word. The header data bits and ECC code bits are shown in [Table 12-129](#). The [15-0] ECC_BIT1 value returned on

error is a 16-bit value that is the concatenation of 5 bits of zero, 3 bits of the encoder/decoder number (0 to 7), 3 bits of zero, and 5 bits of index into the indicated 26-bit encoder/decoder.

For example, an ECC_BIT1 value of 0x0308 is bit 8 of encoder/decoder 3, which is header bit 86 (that is, $(26 \times 3) + 8$).

Table 12-129. ECC Submodule Header Data Bit to Encoder/Decoder Mapping

Header Data Bits	Encoder/Decoder
25:0	Encoder/Decoder 0 Data
51:26	Encoder/Decoder 1 Data
77:52	Encoder/Decoder 2 Data
103:52	Encoder/Decoder 3 Data
129:104	Encoder/Decoder 4 Data
155:130	Encoder/Decoder 5 Data
181:156	Encoder/Decoder 6 Data
207:182	Encoder/Decoder 7 Data
213:208	Encoder/Decoder 0 ECC
219:214	Encoder/Decoder 1 ECC
225:220	Encoder/Decoder 2 ECC
231:226	Encoder/Decoder 3 ECC
237:232	Encoder/Decoder 4 ECC
243:238	Encoder/Decoder 5 ECC
249:244	Encoder/Decoder 6 ECC
255:250	Encoder/Decoder 7 ECC

12.2.1.2.6.13 Ethernet Port Flow Control

The Ethernet port have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The Ethernet port have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an Ethernet port can be sent to the CPPI port. The destination port can trigger the receive Ethernet port flow control. An Ethernet destination port triggers another Ethernet receive flow control when the destination port is full.

When a packet is received on an Ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the Ethernet port will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX_BLK_CNT = 0h). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX_FLOW_EN bit in CPSW_PN_MAC_CONTROL_REG be set to 1h. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit.

12.2.1.2.6.13.1 Ethernet Receive Flow Control

For every Ethernet port to be configured for full-duplex receive flow control, write a value of decimal 7 to the CPSW_PN_MAX_BLKES_REG[7-0] RX_MAX_BLKES bit field, and a value of decimal 13 to the CPSW_PN_MAX_BLKES_REG[15-8] TX_MAX_BLKES register. This re-allocation allows for flow control runout on the receive FIFO at the expense of FIFO memory on the Ethernet transmit side. 10/100Mbps half-duplex

collision based receive flow control does not need this re-allocation. Receive flow control is enabled by the RX_FLOW_EN bit in the CPSW_PN_MAC_CONTROL_REG register.

12.2.1.2.6.13.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in CPSW_PN_MAC_CONTROL_REG). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

12.2.1.2.6.13.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX bit is set in the CPSW_PN_MAC_CONTROL_REG register). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The Ethernet port will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full at which time the receive FIFO will overrun and CPSW_STAT0_RX_BOTTOM_OF_FIFO_DROP/ CPSW_STAT1_RX_BOTTOM_OF_FIFO_DROP[31-0] COUNT value will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The Ethernet port will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL_SA[47-0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The Ethernet port will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If CPSW_PN_MAC_CONTROL_REG[3] RX_FLOW_EN is cleared to 0h while the pause time is nonzero, then the pause time will be cleared to 0h and a 0 count pause frame will be sent.

12.2.1.2.6.13.2 Flow Control Trigger

Receive flow control is triggered (when enabled), when the number of words in the receive FIFO is greater than or equal to the value written in the CPSW_PN_RX_FLOW_THRESH_REG[8-0] COUNT bit field. The flow control packet runout is then contained in the remainder of the receive FIFO.

12.2.1.2.6.13.3 Ethernet Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the Ethernet port from transmitting any further frames. Incoming pause frames are only acted upon when the [0] FULLDUPLEX and [4] TX_FLOW_EN bits

in the CPSW_PN_MAC_CONTROL_REG register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the [24] RX_CMF_EN (RX Copy MAC Control Frames Enable) bit in the CPSW_PN_MAC_CONTROL_REG register is set. The [4] TX_FLOW_EN and [0] FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- [4] TX_FLOW_EN is set in CPSW_PN_MAC_CONTROL_REG register, and
- the RX maximum frame length is 64 bytes inclusive (CPSW_PN_RX_MAXLEN_REG[13-0] RX_MAXLEN), and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If [4] TX_FLOW_EN in CPSW_PN_MAC_CONTROL_REG register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
 - The reserved multicast destination address 01.80.C2.00.00.01, or the Ethernet port SL_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit CPSW_PN_MAC_TX_PAUSETIMER_REG[15-0] TX_PAUSETIMER. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 Bytes. The standard allows pause frames longer than 64 Bytes to be discarded or interpreted as valid pause frames. The Ethernet port will recognize any pause frame between 64 Bytes and CPSW_PN_RX_MAXLEN_REG[13-0] RX_MAXLEN bytes in length.

12.2.1.2.6.14 Energy Efficient Ethernet Support (802.3az)

Energy Efficient Ethernet (EEE) allows the LPSC to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. The module EEE clock stop interface is used by the external controller to control module EEE operations. EEE operations are configured as shown below:

1. The 12-bit EEE clock pre-scale value is written to the CPSW_EEE_PRESCALE_REG register. The pre-scaler is used to clock all EEE-related counters

2. The port Idle to LPI count values (CPSW_PN_IDLE2LPI_REG[23-0] COUNT) are written with the desired values
3. The port LPI to Wake count values (CPSW_PN_LPI2WAKE_REG[23-0] COUNT) are written with the desired values
4. The [0] EEE_EN bit is set in the switch CPSW_SS_CONTROL_REG register

EEE operation can begin after configuration. The host allows (through LPSC) the CPSW to enter a low power state by asserting the EEE_CLKSTOP_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert EEE_CLKSTOP_REQ to the CPSW.

Each Ethernet port has a transmit and a receive LPI (low power indicate) state. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the CPSW_PN_IDLE2LPI_REG value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPPI (port 0) LPI state includes transmit and receive. The CPPI LPI state is entered when the CPPI transmit and receive have both been idle for the Idle to LPI time (CPSW_P0_IDLE2LPI_REG). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

Note

External PHY signaling has the following conditions:

- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX_CTL at the rising and the falling TXC edges, respectively. RXDV and RXER are the sampled values of RX_CTL at the rising and the falling RXC clock edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the EEE_CLKSTOP_ACK signal is asserted, and the LPSC is allowed to stop the module clock. When EEE_CLKSTOP_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform target read/write operations to the CPSW memory address space, and then turn off the clock again while EEE_CLKSTOP_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting EEE_CLKSTOP_REQ. There must be at least one rising edge of the clock before EEE_CLKSTOP_REQ is de-asserted. The module EEE_CLKSTOP_ACK output signal will be deasserted on the clock after the de-assertion of EEE_CLKSTOP_REQ. The host may queue CPPI receive packets at any time without regard to the CPSW module LPI state. The Host must deassert EEE_CLKSTOP_REQ on wakeup for a minimum of two clock periods. If EEE_CLKSTOP_REQ is deasserted for less than 5 clock periods for a wakeup event from the host to a particular Ethernet port (or visa versa), then the wakeup event will not cause the other Ethernet port to awaken.

The external Ethernet PHY's can also wakeup the LPSC by removing the Ethernet receive LPI indication. If the CPSW module is in Idle state with EEE_CLKSTOP_ACK asserted and the receive LPI indication is removed, the EEE_CLKSTOP_WAKEUP signal will be asynchronously asserted. On wakeup, the LPSC restarts the clock and de-assert the EEE_CLKSTOP_REQ signal. The EEE_CLKSTOP_WAKEUP signal will be synchronously deasserted with EEE_CLKSTOP_ACK. Upon the deassertion of EEE_CLKSTOP_REQ, the Ethernet ports will count the CPSW_PN_LPI2WAKE_REG time for each port at which time the port is available for transmit.

12.2.1.2.6.15 Ethernet Switch Latency

When CPSW is configured as a store and forward switch, the switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

The store and forward latency is shown in [Table 12-130](#):

Table 12-130. Switch Latency

Mode	Latency
Gig (1000)	880 ns
100	1.3 μ s
10	6.5 μ s

12.2.1.2.6.16 MAC Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW operation to be completely or partially suspended. Each Ethernet port has associated emulation control registers (CPSW_EM_CONTROL_REG and CPSW_PN_MAC_EMCONTROL_REG). The submodule emulation control registers must be accessed to facilitate CPSW emulation control. The CPSW module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

Ethernet port Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the CPSW_PN_MAC_EMCONTROL_REG register) allow Ethernet port operation to be suspended. When the emulation suspend state is entered, the Ethernet port will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the Ethernet port after the suspend state is entered are ignored.

Table 12-131 shows the operations of the emulation control input and register bits.

Table 12-131. Emulation Control Input

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

12.2.1.2.6.17 MAC Command IDLE

The CMD_IDLE bit in the CPSW_PN_MAC_CONTROL_REG register allows MAC operation to be suspended. When the idle state is commanded, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the MAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

12.2.1.2.6.18 CPSW Network Statistics

The CPSW has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of MCU_CPSW0_RST. When one or more port enable (Pn_STAT_EN) bits in the CPSW_STAT_PORT_EN_REG register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STAT_PEND0) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

[Section 12.2.1.2.6.18.1](#) and [Section 12.2.1.2.6.18.8](#) summarize network statistics.

12.2.1.2.6.18.1 Rx-only Statistics Descriptions

12.2.1.2.6.18.1.1 Good Rx Frames (Offset = 3A000h - Port 0 or Offset = 3A200h - Port 1)

All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Had a length of 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the *Rx Align/Code Errors* and *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.1.2.6.18.1.2 Broadcast Rx Frames (Offset = 3A004h - Port 0 or Offset = 3A204h - Port 1)

All ports

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for address FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the *Rx Align/Code Errors* and *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.1.2.6.18.1.3 Multicast Rx Frames (Offset = 3A008h - Port 0 or Offset = 3A208h - Port 1)

All ports

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.1.2.6.18.1.6](#), *Rx Align/Code Errors* and [Section 12.2.1.2.6.18.1.5](#), *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.1.2.6.18.1.4 Pause Rx Frames (Offset = 3A20Ch - Port 1)

Ethernet port 1

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (TX_FLOW_EN = 1h).

The port could have been in either half or full-duplex mode.

See the [Section 12.2.1.2.6.18.1.6](#), *Rx Align/Code Errors* and [Section 12.2.1.2.6.18.1.5](#), *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.1.2.6.18.1.5 Rx CRC Errors (Offset = 3A010h - Port 0 or Offset = 3A210h - Port 1)

All ports

The total number of frames received on the port that experienced a CRC error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX_MAXLEN bytes inclusive
- Had no code/align error
- Had a CRC error

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- A frame containing an even number of nibbles, and
- Failing the Frame Check Sequence test.

12.2.1.2.6.18.1.6 Rx Align/Code Errors (Offset = 3A214h - Port 1)

Ethernet port 1

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX_MAXLEN bytes inclusive
- Had either an alignment error, or a code error.

Overruns have no effect upon this statistic.

An alignment error is defined to be:

- A frame containing an odd number of nibbles
- Failing the Frame Check Sequence test if the final nibble is ignored

A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

Note

RFC 1757 etherStatsCRCAAlignErrors Ref. 1.5 can be calculated by summing Rx Align/Code Errors and Rx CRC errors.

12.2.1.2.6.18.1.7 Oversize Rx Frames (Offset = 3A018h - Port 0 or Offset = 3A218h - Port 1)

All ports

The total number of oversized frames received on the port. An oversized frame is defined to be:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX_MAXLEN in bytes
- Had no CRC error, alignment error, or code error.

See the [Section 12.2.1.2.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.2.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.1.2.6.18.1.8 Rx Jabbers (Offset = 3A21Ch - Port 1)

All ports

The total number of jabber frames received on the port. A jabber frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX_MAXLEN in bytes
- Had no CRC error, alignment error or code error

See the [Section 12.2.1.2.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.2.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.1.2.6.18.1.9 Undersize (Short) Rx Frames (Offset = 3A020h - Port 0 or Offset = 3A220h - Port 1)

All ports

The total number of undersized frames received on the port. An undersized frame is defined to be:

- Was any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes
- Had no CRC error, alignment error, or code error

See the [Section 12.2.1.2.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.2.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.1.2.6.18.1.10 Rx Fragments (Offset = 3A024h - Port 0 or Offset = 3A224h - Port 1)

Ethernet port 1

The total number of frame fragments received on the port. A frame fragment is defined to be:

- Any data frame (address matching does not matter)
- Less than 64 bytes long
- Having a CRC error, an alignment error, or a code error
- Not the result of a collision caused by half-duplex, collision-based flow control

See the [Section 12.2.1.2.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.2.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.1.2.6.18.1.11 RX IPG Error (Offset = 3A25Ch - Port 1)

The total number of 10G frames received on a port that had a correct preamble but did not have at least five bytes of IDLE preceding the frame. This does not indicate if the frame with the IPG error was kept or ignored.

12.2.1.2.6.18.1.12 ALE Drop (Offset = 3A028h - Port 0 or Offset = 3A228h - Port 1)

All ports

The total number of frames received on a port such that the destination address was not equal to the source address and the packet was not destined to the port it was received on, but the frame was not forwarded to any port (the PORT_MASK was zero).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was not equal to the source address
- the packet was not destined for the port it was receive on
- had a zero PORT_MASK

12.2.1.2.6.18.1.13 ALE Overrun Drop (Offset = 3A02Ch - Port 0 or Offset = 3A22Ch - Port 1)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to exceeding the maximum ALE lookup rate (Port 0 should not have ALE Overrun Drops because the ingress rate is controlled to prevent it). This statistic should be zero and when non-zero indicates a system clock issue or indicates that short packets were sent with RX_CSF_EN at a rate that exceeded the maximum lookup rate.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- the maximum ALE lookup rate was exceeded so the lookup was aborted and the packet was dropped.

12.2.1.2.6.18.1.14 Rx Octets (Offset = 3A030h - Port 0 or Offset = 3A230h - Port 1)

All ports

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Of length 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.1.2.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.2.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.1.2.6.18.1.15 Rx Bottom of FIFO Drop (Offset = 3A084h - Port 0 or Offset = 3A284h - Port 1)

Ethernet port 1

The total number of frames received on a port that overran the port's receive FIFO and were dropped (bottom of receive FIFO). Port 0 (CPPI receive port) should not drop packets on receive because port 0 receive flow control should be enabled. The Ethernet ports will only drop packets in the receive FIFO when receive flow control is enabled and the sending port ignores sent pause frame and then overruns the receive FIFO. An overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- Was dropped on port 0 due to a lack of memory space in the receive FIFO.

Note

This statistic should be zero if proper flow control is being followed.

Host port 0

This statistic also counts frames dropped on port 0 that were 17 to 63 bytes (only for port 0). For Ethernet ports, the drop count for frames shorter than 33 bytes is included in the undersized or fragment count. Port 0 simply gives an indication that a packet was dropped. No other statistics are counted for frames shorter than 33 bytes.

12.2.1.2.6.18.1.16 Portmask Drop (Offset = 3A088h - Port 0 or Offset = 3A288h - Port 1)

All ports

The total number of frames received on a port that were dropped by the ALE (the ALE did not forward the packet to any port). Port mask drop frame is defined to be:

- Any data or MAC control frame
- Any length greater than 32 bytes
- Was dropped by the ALE due to PORT_MASK=0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

Note

This statistic does not count in the overall total as it includes every packet received greater than 32 bytes that had a zero PORT_MASK.

12.2.1.2.6.18.1.17 Rx Top of FIFO Drop (Offset = 3A08Ch - Port 0 or Offset = 3A28Ch - Port 1)

All ports

The total number of frames received on a port that had a start-of-frame (SOF) overrun on any destination port egress (when attempting to load the packet from the top of the ingress port receive FIFO into any other port's transmit FIFO). If a multicast/broadcast packet is dropped by multiple destination ports then this statistic will increment by the number of ports that dropped the packet. Rx Top Of FIFO Drop is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error or code error
- had a SOF of frame overrun on another port egress.

12.2.1.2.6.18.1.18 ALE Rate Limit Drop (Offset = 3A090h - Port 0 or Offset = 3A290h - Port 1)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to receive rate limiting on this port or due to transmit rate limiting on any destination port (not sent to all expected destination ports if transmit rate limiting).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the receive rate was exceeded and the packet was dropped, or the transmit rate was exceeded to any destination port and the packet was dropped to one or more expected destination ports (indicates that the destinations were reduced due to rate limiting).

12.2.1.2.6.18.1.19 ALE VLAN Ingress Check Drop (Offset = 3A094h - Port 0 or Offset = 3A294h - Port 1)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to VLAN ingress check failure.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the VLAN ID ingress check failed (the receive port was not in the group)
- The address lookup did not return a match with the SUPER bit set.

12.2.1.2.6.18.1.19.1 ALE DA=SA Drop (Offset = 3A098h - Port 0 or Offset = 3A298h - Port 1)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to destination address equal to source address.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was equal to the source address
- the source address was not an entry in the table.

12.2.1.2.6.18.1.19.2 Block Address Drop (Offset = 3A09Ch - Port 0 or Offset = 3A29Ch - Port 1)

The total number of frames received on a port that were dropped (zero PORT_MASK) due to the destination or source address being blocked.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source or destination address matched a table entry with the block bit set.

12.2.1.2.6.18.1.19.3 ALE Secure Drop (Offset = 3A0A0h - Port 0 or Offset = 3A2A0h - Port 1)

The total number of frames received on a port that were dropped (zero port_mask) due to a secure violation (the source address is owned by a different receive port).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source address is an entry in the table with the SECURE bit set and a port number for a different receive port.

12.2.1.2.6.18.1.19.4 ALE Authentication Drop (Offset = 3A0A4h - Port 0 or Offset = 3A2A4h - Port 1)

The total number of frames received on a port that were dropped (zero port_mask) due to authentication failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- CPSW_ALE_CONTROL[1] ENABLE_AUTH_MODE is set to 1h, and
- the source address is not equal to the destination address, and
- the source address is not a table entry, and
- the destination address is not a table entry with the SUPER bit set.

12.2.1.2.6.18.1.19.5 ALE Unknown Unicast (Offset = 3A0A8h - Port 0 or Offset = 3A2A8h - Port 1)

All ports

The total number of frames received on a port that had a unicast destination address with an unknown source address.

- was any data frame with a unicast destination address
- the source address was not a table entry
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

Note: The ALE Unknown Unicast Bytecount statistic is the number of bytes contained in the ALE Unknown Unicast frames.

12.2.1.2.6.18.1.19.6 ALE Unknown Unicast Bytecount (Offset = 3A0ACh - Port 0 or Offset = 3A2ACh - Port 1)

The total number of bytes received on a port that had a unicast destination address with an unknown source address.

12.2.1.2.6.18.1.19.7 ALE Unknown Multicast (Offset = 3A0B0h - Port 0 or Offset = 3A2B0h - Port 1)

The total number of frames received on a port that had a multicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Multicast Bytecount statistic is the number of bytes contained in the ALE Unknown Multicast frames.

12.2.1.2.6.18.1.19.8 ALE Unknown Multicast Bytecount (Offset = 3A0B4h - Port 0 or Offset = 3A2B4h - Port 1)

The total number of bytes received on a port that had a multicast destination address with an unknown source address.

12.2.1.2.6.18.1.19.9 ALE Unknown Broadcast (Offset = 3A0B8h - Port 0 or Offset = 3A2B8h - Port 1)

The total number of frames received on a port that had a broadcast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Broadcast Bytecount statistic is the number of bytes contained in the ALE Unknown Broadcast frames.

12.2.1.2.6.18.1.19.10 ALE Unknown Broadcast Bytecount (Offset = 3A0BCh - Port 0 or Offset = 3A2BCh - Port 1)

The total number of bytes received on a port that had a broadcast destination address with an unknown source address.

12.2.1.2.6.18.1.19.11 ALE Policer/Classifier Match (Offset = 3A0C0h - Port 0 or Offset = 3A2C0h - Port 1)

All ports

The total number of frames received on a port that matched a policer. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

12.2.1.2.6.18.2 ALE Policer Match Red (Offset = 3A0C4h - Port 0 or Offset = 3A2C4h - Port 1)

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

12.2.1.2.6.18.3 ALE Policer Match Yellow (Offset = 3A0C8h - Port 0 or Offset = 3A2C8h - Port 1)

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

12.2.1.2.6.18.4 IET Receive Assembly Error (Offset = 3A140h - Port 0 or Offset = 3A340h - Port 1)

The total number of pretable received frames with IET assembly errors.

- any frame received
- was any size, and
- was a non-initial fragment that mismatched the frame count or fragment count (went to the assembly error state in the IET receive state machine)

12.2.1.2.6.18.5 IET Receive Assembly OK (Offset = 3A144h - Port 0 or Offset = 3A344h - Port 1)

The total number of correctly received and re-assembled preemptable frames.

- any preemptable frame received
- was any size, and
- was correctly received and re-assembled without error

12.2.1.2.6.18.6 IET Receive SMD Error (Offset = 3A148h - Port 0 or Offset = 3A348h - Port 1)

The total number of received frames rejected due to an unknown SMD value or received frames rejected with an SMD-C when no frame is in progress.

- any frame received
- was any size, and
- was rejected because of an unknown SMD value or SMD-C with no frame in progress.

Note: If IET_ENABLE is not set, this statistic counts any received frame with any non express SMD.

12.2.1.2.6.18.7 IET Receive Merge Fragment Count (Offset = 3A14Ch - Port 0 or Offset = 3A34Ch - Port 1)

The total number of received non-initial fragments that did not have an assembly error. The IET stat CPSW_STAT0_RXFRAGMENTS/ CPSW_STAT1_RXFRAGMENTS is derived by adding the Receive Assembly Error count to this value.

- any frame received
- was any size, and
- was a non-initial fragment that did not contain an assembly error

12.2.1.2.6.18.8 Tx-only Statistics Descriptions

The maximum and minimum transmit frame size is software controllable.

12.2.1.2.6.18.8.1 Good Tx Frames (Offset = 3A034h - Port 0 or Offset = 3A234h - Port 1)

All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

12.2.1.2.6.18.8.2 Broadcast Tx Frames (Offset = 3A038h - Port 0 or Offset = 3A238h - Port 1)

All ports

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

12.2.1.2.6.18.8.3 Multicast Tx Frames (Offset = 3A03Ch - Port 0 or Offset = 3A23Ch - Port 1)

All ports

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

12.2.1.2.6.18.8.4 Pause Tx Frames (Offset = 3A240h - Port 1)

Ethernet port 1

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex, carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64-byte multicast frames so will appear in the *Tx Multicast Frames* and *64octet Frames* statistics.

12.2.1.2.6.18.8.5 Deferred Tx Frames (Offset = 3A244h - Port 1)

Ethernet port 1

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic.

12.2.1.2.6.18.8.6 Collisions (Offset = 3A248h - Port 1)

Ethernet port 1

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
 - Was destined for any unicast, broadcast or multicast address
 - Was any size
 - Had no carrier loss and no underrun
 - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions)

CRC errors have no effect upon this statistic.

2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

12.2.1.2.6.18.8.7 Single Collision Tx Frames (Offset = 3A24Ch - Port 1)

Ethernet port 1

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

12.2.1.2.6.18.8.8 Multiple Collision Tx Frames (Offset = 3A250h - Port 1)

Ethernet port 1

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

12.2.1.2.6.18.8.9 Excessive Collisions (Offset = 3A254h - Port 1)

Ethernet port 1

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

12.2.1.2.6.18.8.10 Late Collisions (Offset = 3A258h - Port 1)

Ethernet port 1

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The *Late Collisions* statistic dominates over the single-, multiple-, and excessive- collision statistics. If a late collision occurs, the frame will not be counted in any of these other three statistics.

CRC errors have no effect upon this statistic.

12.2.1.2.6.18.8.11 Carrier Sense Errors (Offset = 3A260h - Port 1)

Ethernet port 1

The total number of frames on the port that experienced carrier loss. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.

CRC errors have no effect upon this statistic.

12.2.1.2.6.18.8.12 Tx Octets (Offset = 3A064h - Port 0 or Offset = 3A264h - Port 1)

All ports

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Was any size
- Had no late or excessive collisions, no carrier loss and no underrun.

12.2.1.2.6.18.8.13 Transmit Priority 0-7 (Offset = 3A380h to 3A3A8h - Port 1)

The total number of frames transmitted on the port from transmit FIFO priority 0-7. Collision retries do not affect this statistic. Pause frames do not affect this statistic.

- Any frame transmitted from priority 0-7, and
- Was less than or equal to CPSW_TX_PRI0_MAXLEN_REG to CPSW_TX_PRI7_MAXLEN_REG
- Collision retries are not counted in this statistic.
- Pause frames are not counted in this statistic.
- Carrier sense errors do not affect this statistic.

Note: The Transmit Priority 0-7 Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 statistic.

12.2.1.2.6.18.8.14 Transmit Priority 0-7 Drop (Offset = 3A3C0h to 3A3E8 - Port 1)

The total number of transmit frames on the port that overran the transmit FIFO priority 0-7 and were dropped. This count includes frames dropped due to CPSW_TX_PRI0_MAXLEN_REG to CPSW_TX_PRI7_MAXLEN_REG.

- Any frame destined to be transmitted from priority 0-7, and
- Was any size, and
- Was dropped due to priority 0-7 FIFO overrun (Start of packet overrun).
- Was dropped due to frame size larger than CPSW_TX_PRI0_MAXLEN_REG to CPSW_TX_PRI7_MAXLEN_REG.

Note: The Transmit Priority 0-7 Drop Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 Drop statistic.

12.2.1.2.6.18.8.15 Tx Memory Protect Errors (Offset = 3A17Ch - Port 0 or Offset = 3A37Ch - Port 1)

All ports

The total number of transmit frames on the port that had a memory protect CRC error on egress:

- Any frame destined to be transmitted,
- Was any size
- Had a memory protect CRC error on egress.

Note

- Frames to the host with memory protect errors are dropped via TXST_DROP. Ethernet frames will have at least one byte of the generated port type CRC inverted on egress.
- This statistic is 8-bits wide only and will not rollover but will limit at 0xFF.
- A non-zero value in this statistic will issue a STAT_PEND0 interrupt for the associated port.

12.2.1.2.6.18.8.16 IET Transmit Merge Hold Count (Offset = 3A350h - Port 1)

The total number of preemptable frames that were preempted and reassembled by the assertion of MAC_HOLD in the CPSW_PN_IET_CONTROL_REG register or were preempted by Enhanced Scheduled Traffic (EST). The IET statistic can be derived and maintained by software.

- Any frame destined to be transmitted on the preemptable port, and
- was any size, and
- was preempted by the assertion of MAC_HOLD.
- was preempted by Enhanced Scheduled Traffic (EST).

12.2.1.2.6.18.8.17 IET Transmit Merge Fragment Count (Offset = 3A154h - Port 0 or Offset = 3A354h - Port 1)

The total number of non-initial preemptable transmit fragments on preemptable transmit.

- Any frame destined to be transmitted on the preemptable port, and
- Was any size, and
- was a non-initial fragment.

12.2.1.2.6.18.9 Rx- and Tx (Shared) Statistics Descriptions

Table 12-132. Rx Statistics Summary

Rx Statistic	Frame/ Oct	Rx/ Rx+ Tx	Frame Type					Frame Size (bytes)								Event					
			MAC control		Data ⁽⁵⁾			<64	64	65-127	128-255	256-511	512-1023	1024-rx_max len	>rx_max len	Flow Coll. ⁽⁸⁾	CRC Error	Align/ Code	Overrun	Addr. Disc.	
			Pause frame	Non-pause ⁽⁴⁾	Multicast	Broadcast	Unicast														
Good Rx Frames	F	Rx	(y ⁽¹⁾	y	y	y	y	y)	n	(y	y	y	y	y	y)	n	- ⁽²⁾	n	n	-	n
Broadcast Rx Frames	F	Rx	(% ⁽⁶⁾	%	n	y)	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n

Table 12-132. Rx Statistics Summary (continued)

Rx Statistic	Frame/ Oct	Rx/ Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data ⁽⁵⁾			<64	64	65-127	128-255	256-511	512-1023	1024-rx_max len	>rx_max len	Flow Coll. (8)	CRC Error	Align/ Code	Overrun	Add. Disc.
			Pause frame	Non-pause ⁽⁴⁾	Multicast	Broadcast	Unicast													
Multicast Rx Frames	F	Rx	(%	%	y)	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Pause Rx Frames	F	Rx	y	n	n	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	-
Rx CRC Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	-	y	-	n
Oversized Rx Frames	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	(y	y)	-	n
Undersized Rx Frames	F	Rx	n	n	(y	y	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	Rx	n	n	(y	y	y)	y ⁽⁷⁾	n	n	n	n	n	n	n	-	(y	y)	-	-
Rx Overruns ⁽⁹⁾	F	Rx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	y)	-	-	-	y	n
64octet Frames	F	Rx+Tx ⁽³⁾	(y	y	y	y	y)	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	y	n	n	n	n	-	-	-	-	n
256-511octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Net Octets	O	Rx+Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y	y	y)	-	-	-	-

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
- (5) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
- (6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (7) "y^" Frame fragments are not counted if less than 8 bytes.
- (8) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
- (9) The rx_overruns stat is for RX_MOF_OVERRUNS and RX_SOF_OVERRUNS added together.

Table 12-133. Tx Statistics Summary

Tx Statistic ⁽⁹⁾	Frame Type							Frame Size (bytes)							Event									
	Fra me/ Oct	Tx/ Rx +Tx	MAC control (4)		Data			64	65- 127	128- 255	256- 511	512- 1023	1024- 535	>1535	CRC Error	Collision Type					No Carrier	Queue d	Def err ed	Und er run
			Pause- MAC	Any- CPU	Multi- cast	Broad- cast	Unicas- t																	
																Flow ⁽⁸⁾	1	2-15	16	Late				
Good Tx Frames	F	Tx	(y ⁽¹⁾)	y	y	y	y	(y	y	y	y	y	y	y	-(⁽²⁾)	-	-	-	n	n	n	-	-	n

Carrier Sense Errors	F	Tx	(y	y	y	y	y	(y	y	y	y	y	y	y	-	-	-	-	-	-	y	-	-	-
64octet Frames	F	Rx+Tx ⁽³⁾	(y	y	y	y	y	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
65-127octet Frames	F	Rx+Tx	(y	y	y	y	y	n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
128-255octet Frames	F	Rx+Tx	(y	y	y	y	y	n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-
256-511octet Frames	F	Rx+Tx	(y	y	y	y	y	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-
512-1023octet Frames	F	Rx+Tx	(y	y	y	y	y	n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-
1024-UPoctet Frames	F	Rx+Tx	(y	y	y	y	y	n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-
Tx Octets	O	Tx	(y	y	y	y	y	(y	y	y	y	y	y	y	-	-	-	-	n	n	n	-	-	n
Net Octets	O	Rx+Tx	(y	y	y	y	y	(y	y	y	y	y	y	y	-	-	\$ ⁽⁷⁾	\$	\$	\$	\$	-	-	-

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
- (5) "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (6) "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.

- (7) "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
- (8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See *Rx Statistics Summary*.)
- (9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

12.2.1.2.6.18.9.1 Rx + Tx 64 Octet Frames (Offset = 3A068h - Port 0 or Offset = 3A268h - Port 1)

All ports

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

12.2.1.2.6.18.9.2 Rx + Tx 65–127 Octet Frames (Offset = 3A06Ch - Port 0 or Offset = 3A26Ch - Port 1)

All ports

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 65 to 127 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.1.2.6.18.9.3 Rx + Tx 128–255 Octet Frames (Offset = 3A070h - Port 0 or Offset = 3A270h - Port 1)

All ports

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 128 to 255 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.1.2.6.18.9.4 Rx + Tx 256–511 Octet Frames (Offset = 3A074h - Port 0 or Offset = 3A274h - Port 1)

All ports

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 256 to 511 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.1.2.6.18.9.5 Rx + Tx 512–1023 Octet Frames (Offset = 3A078h - Port 0 or Offset = 3A278h - Port 1)

All ports

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error

- Was 512 to 1023 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.1.2.6.18.9.6 Rx + Tx 1024_Up Octet Frames (Offset = 3A07Ch - Port 0 or Offset = 3A27Ch - Port 1)

All ports

The total number of frames of size 1024 to RX_MAXLEN bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 1024 to RX_MAXLEN bytes long on receive, or any size on transmit

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.1.2.6.18.9.7 Net Octets (Offset = 3A080h - Port 0 or Offset = 3A280h - Port 1)

All ports

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter)
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced, (that is, multiple retries are counted each time)
- Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting)

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of Ethernet utilization.

12.2.1.2.6.18.10

Table 12-134. Rx Statistics Summary

Rx Statistic	Frame/ Oct	Rx/ Tx	Frame Type					Frame Size (bytes)								Event

512-1023octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	n	n	y	n	-	-	-	-	n			
1024-UPoctet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	n	n	y	n	-	-	-	-	n			
Rx Octets	O	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n		
Net Octets	O	Rx+ Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y	y)	-	-	-	-	-		

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
- (5) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
- (6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (7) "y^" Frame fragments are not counted if less than 8 bytes.
- (8) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
- (9) The rx_overruns stat is for RX_MOF_OVERRUNS and RX_SOF_OVERRUNS added together.

Table 12-135. Tx Statistics Summary

- (7) "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
- (8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See [Table 12-134.](#))
- (9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

12.2.1.2.7 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

Main features of CPTS module are:

- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling
- Supports up to 4 hardware timestamp push inputs
- Supports timestamp counter compare output (CPTS_COMP)
- Supports timestamp counter bit output (CPTS_SYNC)
- Supports a configurable number of timestamp Generator bit outputs (CPTS_GENFn).
- Supports Ethernet Enhanced Scheduled Traffic Operations (CPTS_ESTFn).
- 32-bit and 64-bit timestamp modes with PPM and nudge adjustment.

12.2.1.2.7.1 MCU_CPSW0 CPTS Integration

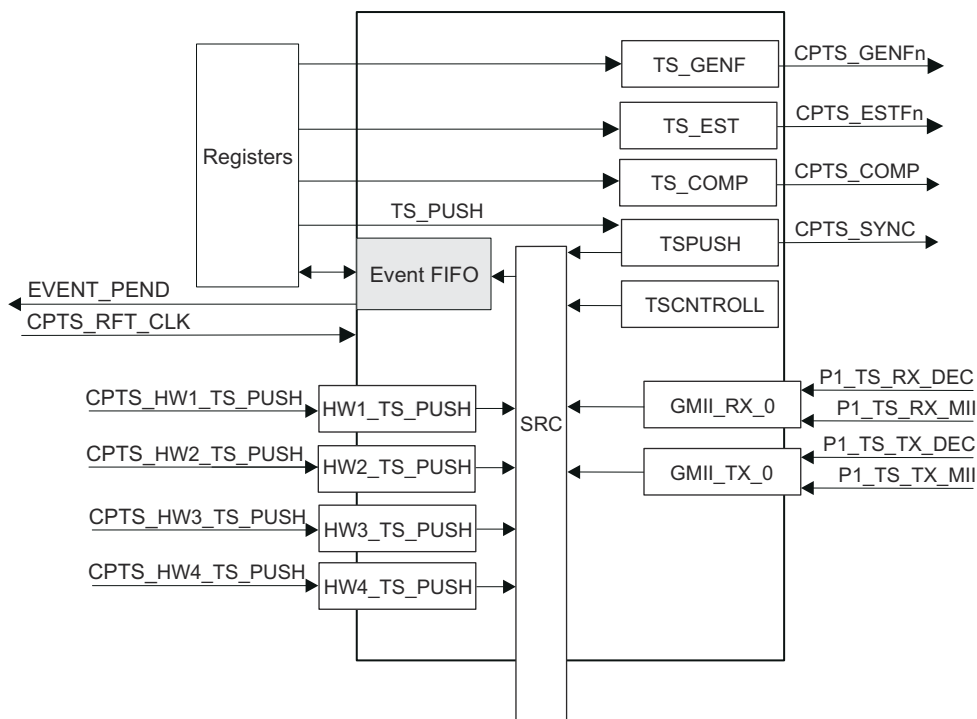

This section describes CPTS module integration in the MCU_CPSW0 module, including information about clocks, resets, and hardware requests.

CPTS IEEE 1588 clock (RCLK) is selected through the CTRLMMR_MCU_ENET_CLKSEL register.

12.2.1.2.7.2 CPTS Architecture

Figure 12-70 shows the architecture of the CPTS module inside the CPSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on external port of the CPSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWN_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value through the Event FIFO. The reference clock used for the time stamp (CPTS_RFT_CLK) can be derived from several sources.

Note: CPTS_HW1_TS_PUSH to CPTS_HW4_TS_PUSH events are used for CPTS implemented in MCU_CPSW0 module.

cpsw-013

Figure 12-70. CPTS Block Diagram

Note

See *MCU_CPSW0 CPTS Integration* for CPTS integration in the device MCU_CPSW0 module.

12.2.1.2.7.3 CPTS Initialization

The CPTS module should be configured as follows:

1. Reset the CPTS module.
2. Write the CPTS_CLKSEL value in the CTRLMMR_MCU_ENET_CLKSEL register with the desired reference clock selection. This value is allowed to be written only when the CPTS_EN bit in the CPSW_CPTS_CONTROL_REG register is cleared to zero.
3. Set the CPTS_EN bit in the CPSW_CPTS_CONTROL_REG register.
4. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPSW_CPTS_INT_ENABLE_REG register.

12.2.1.2.7.4 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS_RFT_CLK rising edge when CPTS_EN bit is set to 1h. When CPTS_EN bit is cleared to 0h, the time stamp value is reset to 0h.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPSW_CPTS_TS_LOAD_VAL_REG / CPSW_CPTS_TS_LOAD_HIGH_VAL_REG and CPSW_CPTS_TS_LOAD_EN_REG registers).

12.2.1.2.7.5 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each CPTS_RFT_CLK rising edge when CPTS_EN bit is set to 1h. When CPTS_EN bit is cleared to 0h, the time stamp value is reset to 0h.

64-bit mode is selected when CPSW_CPTS_CONTROL_REG[5] MODE bit set to 1h.

For test purposes, the time stamp value can be written via the time stamp load function (CPSW_CPTS_TS_LOAD_EN_REG, CPSW_CPTS_TS_LOAD_VAL_REG, and CPSW_CPTS_TS_LOAD_HIGH_VAL_REG registers). The CPSW_CPTS_TS_ADD_VAL_REG feature is included to allow 1ns timestamp operations with an CPTS_RFT_CLK rate less than 1Ghz. [Table 12-136](#) shows the CPTS_RFT_CLK and CPSW_CPTS_TS_ADD_VAL_REG values for 1ns operations.

Table 12-136. ADD_VAL feature

CPTS_RFT_CLK (MHz)	CPSW_CPTS_TS_ADD_VAL_REG[2-0] ADD_VAL
1 GHz	0
500 MHz	1
333.33 MHz	2
250 MHz	3
200 MHz	4
166.66 MHz	5
142.85714 MHz	6
125 MHz	7

12.2.1.2.7.6 64-Bit Timestamp Nudge

The 64-bit TIME_STAMP value can be adjusted by writing the CPSW_CPTS_TS_NUDGE_VAL_REG[7-0] TS_NUDGE_VAL bit field value which is a two's complement value. A value of FFh will subtract 1 clock cycle from the next incremented 64-bit time stamp value (CPSW_CPTS_EVENT_0_REG[31-0] TIME_STAMP and CPSW_CPTS_EVENT_3_REG[31-0] TIME_STAMP value). A nudge value of 1h will add 1 clock cycle to the next incremented TIME_STAMP[63-0] value. For example, if the current TIME_STAMP value is F06h, and

CPSW_CPTS_TS_ADD_VAL_REG[2-0] ADD_VAL = 3h, the next incremented timestamp value would be F0Ah without a nudge and F0Ah +/- [7-0] TS_NUDGE_VAL with a nudge. The [7-0] TS_NUDGE_VAL value is cleared to zero when the nudge has occurred.

12.2.1.2.7.7 64-bit Timestamp PPM

The 64-bit TIME_STAMP can be adjusted by parts per million or by parts per hour. Writing a non-zero value to the CPSW_CPTS_TS_PPM_LOW_VAL_REG[31-0] TS_PPM_LOW_VAL (Time stamp PPM Low value) and CPSW_CPTS_TS_PPM_HIGH_VAL_REG[9-0] TS_PPM_HIGH_VAL (Time stamp PPM High value) enables PPM operations. The adjustment is up or down depending on the [7] TS_PPM_DIR bit in the CPSW_CPTS_CONTROL_REG register. The TIME_STAMP value is increased by the PPM value when [7] TS_PPM_DIR bit is cleared. The TIME_STAMP value is decreased by the PPM value when [7] TS_PPM_DIR bit is set.

Parts Per Million example:

To adjust for 100 parts per million the configured value for TS_PPM[41-0] (through CPSW_CPTS_TS_PPM_LOW_VAL_REG[31-0] TS_PPM_LOW_VAL and CPSW_CPTS_TS_PPM_HIGH_VAL_REG[9-0] TS_PPM_HIGH_VAL) is:
 $1,000,000/100 = 10,000(\text{decimal})$

Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS_RFT_CLK the configured value for TS_PPM[41-0] (through CPSW_CPTS_TS_PPM_LOW_VAL_REG[31-0] TS_PPM_LOW_VAL and CPSW_CPTS_TS_PPM_HIGH_VAL_REG[9-0] TS_PPM_HIGH_VAL) is:
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600 \text{ seconds/hour}) = 34630\text{B8A000} (\text{hex})$

12.2.1.2.7.8 Event FIFO

All time sync events are pushed onto the Event FIFO. There are 32 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

12.2.1.2.7.9 Timestamp Compare Output

CPTS features one Time Stamp Compare (CPTS_COMP) output. The CPTS_COMP function is a software oriented feature that is intended to be replaced going forward by the hardware oriented GENF function. CPTS_COMP is not compatible with timestamp PPM or a non-zero CPSW_CPTS_TS_ADD_VAL_REG[2-0] ADD_VAL value.

12.2.1.2.7.9.1 Non-Toggle Mode: 32-bit

The CPTS_COMP output is asserted for CPSW_CPTS_TS_COMP_LEN_REG[31-0] TS_COMP_LENGTH periods when the CPSW_CPTS_EVENT_0_REG[31-0] TIME_STAMP value (lower 32-bits) compares with the CPSW_CPTS_TS_COMP_VAL_REG[31-0] TS_COMP_VAL and the length value is non-zero. The CPTS_COMP rising edge occurs three CPTS_RFT_CLK clock periods after the values compare. A timestamp compare event is pushed into the event FIFO when CPTS_COMP is asserted. The polarity of the CPTS_COMP output is determined by the CPSW_CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit. The output is asserted low when the polarity bit is 0h.

12.2.1.2.7.9.2 Non-Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIME_STAMP are used (CPSW_CPTS_EVENT_0_REG and CPSW_CPTS_EVENT_3_REG). In 32-bit mode only the lower 32-bits (CPSW_CPTS_EVENT_0_REG) are used.

12.2.1.2.7.9.3 Toggle Mode: 32-bit

The CPTS_COMP output is asserted (CPSW_CPTS_TS_COMP_LEN_REG[31-0] TS_COMP_LENGTH) for CPTS_RFT_CLK clock periods when the TIME_STAMP[31:0] value compares with the CPSW_CPTS_TS_COMP_VAL_REG and the length value is non-zero. The CPTS_COMP toggles thereafter on CPSW_CPTS_TS_COMP_VAL_REG[31-0] TS_COMP_LENGTH for CPTS_RFT_CLK periods. The length high or low can be adjusted by writing the CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE bit field value which is a two's complement value. A value of FFh will subtract one CPTS_RFT_CLK period from the CPSW_CPTS_TS_COMP_VAL_REG[31-0] TS_COMP_LENGTH value. A value of 0x01h will add

one CPTS_RFT_CLK period to the CPSW_CPTS_TS_COMP_LEN_REG[31:0] TS_COMP_LENGTH value. Only a single high or low time is adjusted (nudged) and the CPSW_CPTS_TS_COMP_NUDGE_REG[7:0] NUDGE value is cleared to zero when the nudge has occurred. The CPTS_COMP output is asserted low when the CPSW_CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit is 0h. No compare events and no CPTS_EVT interrupts are generated in toggle mode. The CPSW_CPTS_CONTROL_REG[6] TS_COMP_TOG bit must be set for toggle mode (value 1h). Note this bit must be set before writing a non-zero value to CPSW_CPTS_TS_COMP_VAL_REG register.

12.2.1.2.7.9.4 Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIMESTAMP are used (CPSW_CPTS_EVENT_0_REG and CPSW_CPTS_EVENT_3_REG). In 32-bit mode only the lower 32-bits (CPSW_CPTS_EVENT_0_REG) are used.

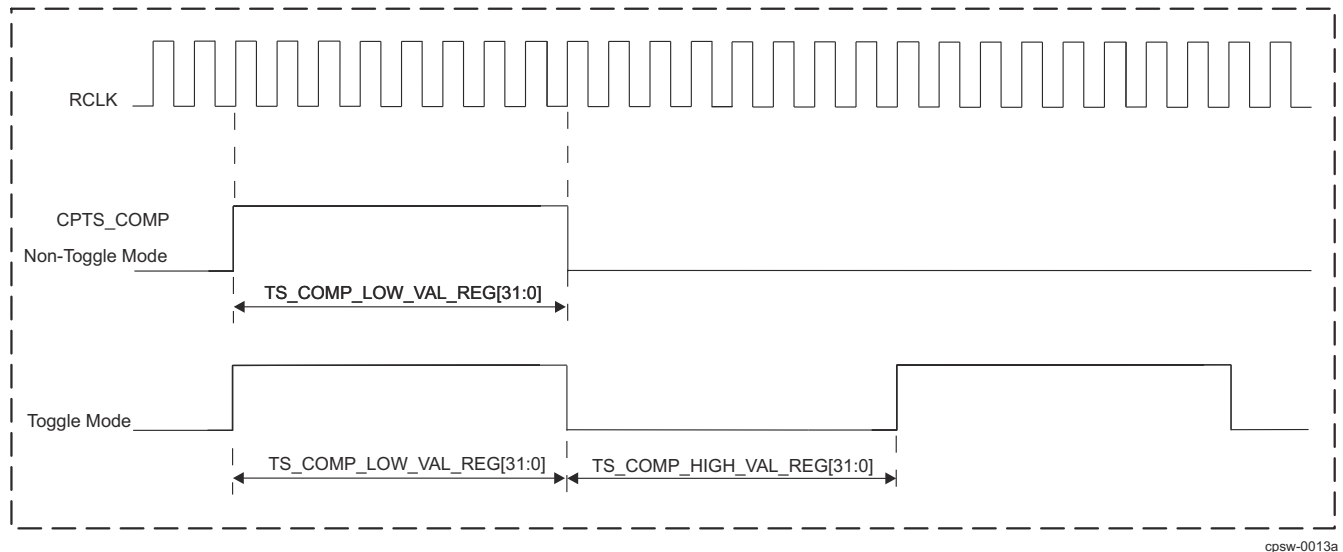

Figure 12-71. CPTS_COMP Output in Toggle and Non-Toggle Mode

12.2.1.2.7.10 Timestamp Sync Output

The CPTS_SYNC output is a selected bit of the [31:0]TIME_STAMP counter value. One of bits 17-31 can be selected in CPSW_CPTS_CONTROL_REG[31:28] TS_SYNC_SEL. The CPTS_SYNC output is disabled when CPSW_CPTS_CONTROL_REG[31:28] TS_SYNC_SEL is zero.

If the selected counter bit is 1 at the time when TS_SYNC_SEL value is written then a rising edge will not occur on the CPTS_SYNC output. A rising edge will occur on the CPTS_SYNC output upon the next transition to 1 of the selected counter bit. The TS_SYNC_SEL value must be written to zero before changing to a different non-zero value. No events are generated due to the CPTS_SYNC operation. The CPTS_SYNC output is two CPTS_RFT_CLK periods after the actual count value.

12.2.1.2.7.11 Timestamp GENFn Output

The CPTS_GENFn outputs have a programmable cycle (frequency) with a PPM feature and software nudge feature. The CPTS_GENFn output cycle is CPSW_GENF0_LENGTH_REG_L[31:0] CPTS_RFT_CLK periods (which is different than CPTS_COMP operation). [Figure 12-72](#) represents the CPTS_GENFn output signal.

The CPTS_GENFn output cycle is CPSW_GENF0_LENGTH_REG_L[31:0] CPTS_RFT_CLK periods beginning when the 64-bit TIME_STAMP value compares with the 64-bit GENFn_COMP value (CPSW_GENF0_COMP_LOW_REG_L and CPSW_GENF0_COMP_HIGH_REG_L registers) and the length value is non-zero. The CPTS_GENFn output cycle repeats thereafter every CPSW_GENF0_LENGTH_REG_L[31:0] CPTS_RFT_CLK periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after

comparison is active high when the CPSW_CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit is low. No compare events and no CPTS_EVT interrupts are generated.

Figure 12-72. CPTS_GENFn Output Signal Diagram

12.2.1.2.7.11.1 GENFn Nudge

The cycle length can be adjusted by writing the CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE register value which is a two's complement value. A value of FFh will subtract 1 CPTS_RFT_CLK from the CPSW_GENF0_LENGTH_REG_L[31-0] value. A value of 1h will add 1 CPTS_RFT_CLK to the CPSW_GENF0_LENGTH_REG_L[31-0] value. The CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred.

12.2.1.2.7.11.2 GENFn PPM

The CPTS_GENFn output cycle can be adjusted by parts per million or by parts per hour. Writing a non-zero value to CPSW_GENF0_PPM_LOW_REG_L/ CPSW_GENF0_PPM_HIGH_REG_L enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single CPTS_RFT_CLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPSW_GENF0_TS_GENF_CONTROL_REG[0] PPM_DIR bit. When PPM_DIR bit is set a single CPTS_RFT_CLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM_DIR bit is cleared a single CPTS_RFT_CLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

Parts Per Million example:

To adjust for 100 parts per million the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG_L and CPSW_GENF0_PPM_HIGH_REG_L) is:
 $1,000,000/100 = 10,000(\text{decimal})$

Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS_RFT_CLK the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG_L and CPSW_GENF0_PPM_HIGH_REG_L) is:
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600 \text{ seconds}/\text{hour}) = 34630\text{B8A000} (\text{hex})$

12.2.1.2.7.12 Timestamp ESTFn

Each Ethernet port has a dedicated ESTFn generator which operates identically to the GENFn function.

12.2.1.2.7.13 Time Sync Events

Time Sync events are 96-bit values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPSW_CPTS_EVENT_0_REG through CPSW_CPTS_EVENT_3_REG hold the data of a time sync event. There are eight types of sync events:

- Time Stamp Push Event
- Time Stamp Counter Rollover Event (32-bit mode only)
- Time Stamp Counter Half-rollover Event (32-bit mode only)
- Hardware Time Stamp Push Event
- Ethernet Receive Event
- Ethernet Transmit Event
- Time Stamp Compare Event
- Host Transmit Event

12.2.1.2.7.13.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the [0]TS_PUSH bit of the CPSW_CPTS_TS_PUSH_REG register. The time stamp value is returned in the event, along with a time stamp push event code. The upper 32-bits (CPSW_CPTS_EVENT_3_REG register) of the timestamp are zero in 32-bit mode.

12.2.1.2.7.13.2 Time Stamp Counter Rollover Event (32-bit mode only)

The CPTS module contains a 32-bit time stamp value (CPSW_CPTS_EVENT_0_REG). The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented. This event occurs only in 32-bit mode.

12.2.1.2.7.13.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value (CPSW_CPTS_EVENT_0_REG[31:0] TIME_STAMP) has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. This event occurs only in 32-bit mode.

The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 12-73](#) shows a misalignment condition. This misaligned event condition arises because an Ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

Host software must detect and correct for misaligned event conditions. For every event time stamp after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

When a rollover occurs, software increments the software time stamp upper value. The misaligned case indicates to software that the misaligned event time stamp has a valid upper value that is pre-increment, so one must be subtracted from the upper value to allow software to calculate the correct time for the misaligned event.

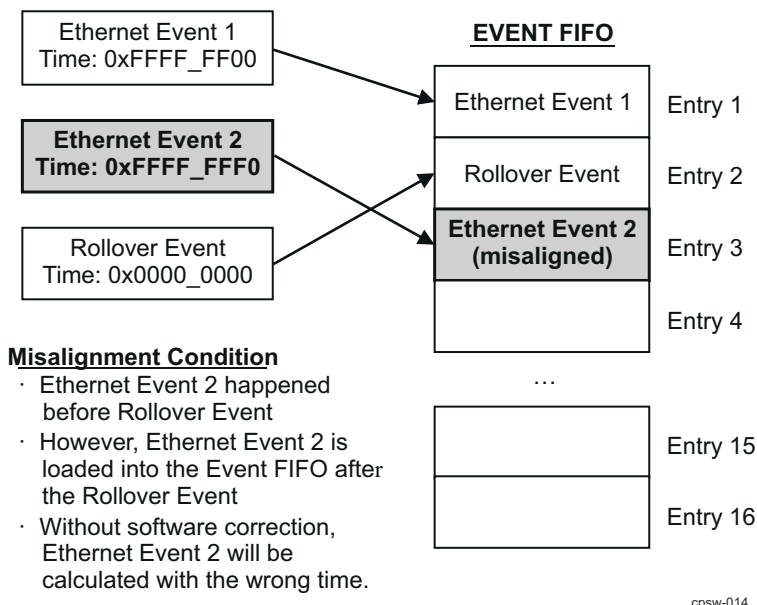

Figure 12-73. Event FIFO Misalignment Condition

12.2.1.2.7.13.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (CPTS_HW[1:4]_TS_PUSH events) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in *CPSW0 CPTS Integration*. The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPSW_CPTS_EVENT_1_REG register indicates the hardware push input that caused the event (encoded).

The hardware time stamp inputs are asynchronous and are low frequency signals. The CPTS logic synchronizes and performs a rising edge detect on the incoming asynchronous input.

Each hardware time stamp input must be asserted for at least 10 periods of the selected CPTS_RFT_CLK clock. Each input can be enabled or disabled by setting the respective bits in the CPSW_CPTS_CONTROL_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

12.2.1.2.7.13.5 Ethernet Port Events

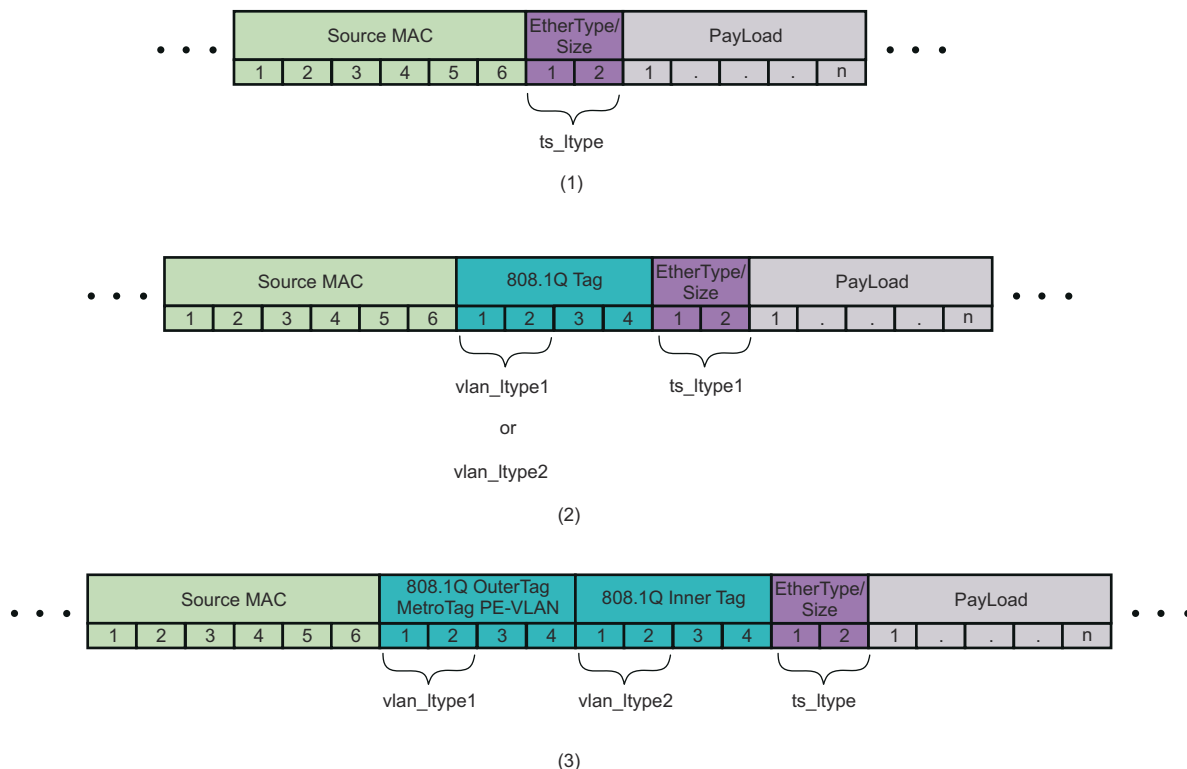

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in [Figure 12-74](#). For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field in the CPSW_PN_TS_SEQ_LTYPE_REG or the TS_LTYPE2 field in CPSW_PN_TS_CTL_LTYPE2_REG register (depending on which enable bit was set) , which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in [Figure 12-74](#). To indicate to the CPTS hardware that a virtual LAN is in use, the TS_TX_VLAN_LTYPE1_EN (or TS_TX_VLAN_LTYPE2_EN) enable bit must be set in the CPSW_PN_TS_CTL_REG register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the TS_VLAN_LTYPE1 (or TS_VLAN_LTYPE2 depending on which enable

bit was set) field in the CPSW_PN_TS_VLAN_LTYPE_REG register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 12-74. In this case, both TS_VLAN_LTYPE1 and TS_VLAN_LTYPE2 must be enabled. The outer tag must match the value of the TS_VLAN_LTYPE1 field, and the inner tag must match the value of the TS_VLAN_LTYPE2 field.

12.2.1.2.7.13.5.1 Ethernet Port Receive Event

This section describes Ethernet port receive events. Ethernet port generates time synchronization events for valid received time sync packets. For every packet received on the Ethernet port, a timestamp will be captured by the receive module inside the CPTS for the corresponding port. The time stamp will be captured by the receive module regardless of whether or not the packet is a time synchronization packet to make sure that the time stamp is captured as soon as possible. The packet is sampled on both the rising and falling edges of the CPTS_RFT_CLK, and the time stamp will be captured once the start of frame delimiter for the receive packet is detected.

After the time stamp has been captured, the receive interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPSW decoder determines if the packet is a valid Ethernet receive time synchronization event. The receive interface for the port will use the following criteria to determine if the packet is a valid Annex D, Annex E, or Annex F time synchronization Ethernet receive event:

Annex D (IPv4)

1. Receive annex D time sync is enabled (TS_RX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x0800

- b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
 5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 22 contains any value if CPSW_PN_TS_CTL_LTYPE2_REG is set to 1h. Byte 22 is the TTL/HOP field.
 6. Byte 23 contains 0x11 (Next Header UDP Fixed).
 7. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h and Bytes 30 through 33 contain:
 - a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set
- OR-
- The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set -OR-
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
 9. The PTP message begins in byte 42.
 10. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
 11. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex E (IPv6)

1. Receive annex E time sync is enabled (TS_RX_ANNEX_E_EN bit is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x86dd.
 - b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second

- packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
 4. Byte 20 contains 0x11 (UDP Fixed Next Header).
 5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 21 contains any value if TS_TTL_NONZERO is set to 1h. Byte 21 is the TTL/HOP field.
 6. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0 and Bytes 38 through 53 contain:
 - a. FF0M:0:0:0:0:0:0:0:0181 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - b. FF0M:0:0:0:0:0:0:0:0182 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - c. FF0M:0:0:0:0:0:0:0:0183 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - d. FF0M:0:0:0:0:0:0:0:0184 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - e. FF0M:0:0:0:0:0:0:0:006B and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set

Note

All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.

-OR-

The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set to 1h and Bytes 38 through 53 contain any value.

7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL2_REG register is set, or
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL2_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the MSG_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.
10. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex F (IEEE 802.3)

1. Receive Annex F time sync is enabled (TS_RX_ANNEX_F_EN is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true:
 - a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG/CPSW_PN_TS_SEQ_LTYPE_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
 - b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
 - c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
 - e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
 - f. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet

- LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
- g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
 - h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register
3. The PTP message begins in the byte after the LTYPE.
 4. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
 5. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

If all of the criteria described above are met for either Annex D, Annex E, or Annex F, and the packet is determined to be a valid time synchronization packet, then the RX interface will push an Ethernet receive event into the event FIFO.

12.2.1.2.7.13.5.2 Ethernet Port Transmit Event

This section describes Ethernet port transmit events. For every packet transmitted on the Ethernet ports, the port transmit interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPTS transmit interface for the port will use the following criteria to determine if the packet is a valid time synchronization Ethernet transmit event. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. To be a valid Ethernet transmit time synchronization event, the conditions listed below must be true for either Annex D, Annex E, or Annex F:

Annex D (IPv4)

1. Transmit time sync is enabled (TS_TX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x0800
 - b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 22 contains any value if TS_TTL_NONZERO is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).

7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
10. The packet was sent by host port 0.

Annex F (IEEE 802.3)

1. Transmit time sync is enabled (TS_TX_ANNEX_F_EN is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true:
 - a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
 - b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
 - c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
 - d. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
 - e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
 - f. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
 - g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
 - h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
3. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
4. The packet was sent by host port 0.

If all of the criteria described above are met, and the packet is determined to be a valid time synchronization packet, then the time stamp for the transmit event will not be generated until the start of frame delimiter of the packet is actually transmitted. The start of frame delimiter will be sampled on every rising and falling edge of the CPTS_RFT_CLK. Once the packet is transmitted, then the TX interface will push an Ethernet transmit event into the event FIFO.

Table 12-137. Values of Message Type Field

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPSW_CPTS_EVENT_1_REG register contains the Message Type and Sequence ID values from the original time sync packet. The CPSW_CPTS_EVENT_0_REG (and CPSW_CPTS_EVENT_3_REG) register contains the time stamp value when the packet arrived at the corresponding port.

Table 12-138. Values of Message Type Field

Message Type	Value (hex)
Sync	0

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPSW_CPTS_EVENT_1_REG register contains the Message Type and Sequence ID values from the original time sync packet. The CPSW_CPTS_EVENT_0_REG (and CPSW_CPTS_EVENT_3_REG) register contains the time stamp value when the packet arrived at the corresponding port.

12.2.1.2.7.14 Timestamp Compare Event

Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode.

12.2.1.2.7.14.1 32-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 32-bit time stamp value (CPSW_CPTS_EVENT_0_REG) compares with the

CPSW_CPTS_TS_COMP_VAL_REG register and the CPSW_CPTS_TS_COMP_LEN_REG value is non-zero. The CPSW_CPTS_TS_COMP_LEN_REG value should be written by software after the CPSW_CPTS_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

12.2.1.2.7.14.2 64-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 64-bit time stamp value (CPSW_CPTS_EVENT_0_REG and CPSW_CPTS_EVENT_3_REG) compares with the CPSW_CPTS_TS_COMP_VAL_REG and CPSW_CPTS_TS_COMP_HIGH_VAL_REG registers and the CPSW_CPTS_TS_COMP_LEN_REG value is non-zero. The CPSW_CPTS_TS_COMP_LEN_REG value should be written by software after the CPSW_CPTS_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

12.2.1.2.7.15 Host Transmit Event

The host can send a packet to be transmitted on an Ethernet port that will generate a time synchronization event. The host sets the TSTAMP_EN bit and sends the DOMAIN, MESSAGE_TYPE, and SEQUENCE_ID in the additional control information that resides in the protocol specific section of the descriptor that is transmitted to the CPSW_3G. An event is then generated and placed on the event FIFO once the packet is transmitted. Host events allow the user to timestamp exactly when a software generated packet exits the device.

12.2.1.2.7.16 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPSW_CPTS_INT_ENABLE_REG register.
2. Upon interrupt, read the CPSW_CPTS_EVENT_0_REG through CPSW_CPTS_EVENT_3_REG registers values.
3. Set the CPSW_CPTS_EVENT_POP_REG[0] EVENT_POP bit to 1h to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPSW_CPTS_INT_ENABLE_REG
2. Upon interrupt, enter the CPTS service routine.
3. Read the CPSW_CPTS_EVENT_0_REG through CPSW_CPTS_EVENT_3_REG registers values.
4. Set the CPSW_CPTS_EVENT_POP_REG[0] EVENT_POP bit to 1h to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than four CPTS_RFT_CLK periods plus four CPPI_ICLK periods.
6. Read the TS_PEND_RAW bit in the CPSW_CPTS_INTSTAT_RAW_REG register to determine if another valid event is in the event FIFO. If bit TS_PEND_RAW is asserted, go to step 3. If bit TS_PEND_RAW is not asserted proceed with step 7.
7. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPSW_CPTS_INTSTAT_RAW_REG register to determine if a valid event is on the event FIFO.

12.2.1.2.8 CPPI Streaming Packet Interface

The receive streaming interface on port 0 of the CPSW is responsible for receiving packet for Ethernet egress data from the packet streaming switch in the . The CPPI receive port is equivalent to an Ethernet port with the difference being that the data is provided to the CPSW in the 128-bit streaming interface data format instead RGMII data format.

In addition to the packet data, the receive streaming interface also can provide additional control information that resides in the information words of the descriptor that was transmitted to the CPSW.

The tables below show the information that may be passed along with which descriptor information word to put it in.

12.2.1.2.8.1 Port 0 CPPI Transmit Packet Streaming Interface (CPSW_2G Egress)

The CPSW2G has a single transmit packet streaming interface. All Ethernet packet data destined for the host (Port 0) is transferred on the transmit packet streaming interface. The transmit packet streaming interface is equivalent to an Ethernet MAC output with the difference being that 128-bit streaming interface data is output. Egress packet data is packed on the 128-bit data bus with all words having 16-bytes except possibly the last packet data word which is the word previous to the EOP word. INFO Word 0–3 is transferred on SOP. The EOP word contains the packet status 0–3 (data type 24) which includes the timestamp and checksum data. Packets are not dropped on the transmit streaming interface due to pushback, but packets may be dropped in the associated priority FIFO.

INFO Word 0–3 and Status Data Word 0–3 (on EOP) are the only non-payload data word types that are transferred. Long packets are truncated at the CPSW_PN_RX_MAXLEN_REG[13:0] RX_MAXLEN byte value of the ingress port (only the CPSW_PN_RX_MAXLEN_REG number of bytes are kept if long packets are transferred due to CPSW_PN_MAC_CONTROL_REG register copy error frames set - RX_CEF_EN). MAC control frames are only transferred if the receiving Ethernet port has the CPSW_PN_MAC_CONTROL_REG[24] RX_CMF_EN bit set.

The error encoding on the TXST_PKT_ERR[3:0] output is shown in [Table 12-139](#).

Table 12-139. Error Encoding on the TXST_PKT_ERR[3:0] Output

TXST_PKT_ERR[3:0]	Description
0000	No Error
0001	CRC Error
0010	Code or alignment error
0011	Short (no code/align/crc error)
0100	FragCRC (short with crc error)
0101	Frag Code/Align (short with code/align error)
0110	Long
0111	Jabber CRC (long with crc error)
1000	Jabber Code/Align (long with code/align error)
1001	Mac ontl packet (CPSW_PN_MAC_CONTROL_REG[24] RX_CMF_EN set on ingress Ethernet port)
1010	Mac control CRC
1011	Mac control Code/Align
1100	Mac control short/frag (short MAC control frame with CRC/Code/Align)
1101	Mac control long/jabber (long MAC control frame with CRC/Code/Align)
1110	Reserved
1111	Reserved

The CPPI Port 0 transmit packet streaming interface has a single output thread. If a packet transmission has begun then the entire packet will be transmitted before the next packet is sent (packet data from multiple packets are not interleaved on the transmit streaming interface). The default egress flow is the port number minus 1, concatenated with the 3-bit Port 0 transmit FIFO hardware switch priority. For example, a packet that was received on port 4 with a Port 0 transmit FIFO hardware switch priority of 5 would be sent on flow 29 (decimal) or flow 0b0011101 (binary). Priority remapping on ingress and Port 0 transmit egress effects the output flow.

INFO Words () are a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

12.2.1.2.8.2 Port 0 CPPI Receive Packet Streaming Interface (CPSW_2G Ingress)

Info Word 0/1/2/3 (INFO1 and INFO3 are ignored) are transferred on SOP. If a timestamp word (Extended Packet Info Word 0/1/2/3) is to be transferred it must be after SOP and before any packet data is transferred. Any following non-data type words will be dropped. The EOP word must be payload data.

Input receive packets cannot be aborted by the host. The INFO Word bit descriptions and Extended Packet INFO Word bit descriptions are shown below. The PASS_CRC bit indicates that the CRC is passed with the packet data. Packets that have a passed CRC that is an error CRC will be output on the Ethernet port with at least one CRC byte inverted to indicate the error if P0_RX_PASS_CRC_ERR bit is set, otherwise they are dropped. The packet is a directed packet when any of the TO_PORT bits are nonzero. A packet may be directed only to a single port. The packet will be sent to the port number indicated. For directed packets the lookup process is skipped to determine the destination. However, in vlan aware mode (when VLAN_AWARE bit in the CPSW_CONTROL_REG register is set to 1h) the lookup is performed to determine untagged egress. Packets longer than the value in CPSW_P0_RX_MAXLEN_REG[13:0] RX_MAXLEN bit field are dropped. Packets shorter than 60-Bytes are padded to 64-Bytes (after adding pad and CRC) if P0_RX_PAD bit in the CPSW_CONTROL_REG register is set and if PASS_CRC is clear, otherwise they are dropped. This means that packets shorter than 64-Bytes are dropped if the PASS_CRC info bit is set regardless of P0_RX_PAD bit (packets are padded only if they are short and do not have CRC).

A RX INFO word () is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Note

RX Control Data Words [0..2] are mapped to Host Packet Descriptor Protocol Specific Words if (TCHAN[a]_TCFG.tx_filt_pswords = 0) and (Host PD Word 1.Protocol Specific Region Location.bit[28] = 0h) and (Host PD Word 1.Protocol Specific Valid Word Count.bits[22-27] = 4h)

CHECKSUM_RESULT								CHECKSUM_START_BYTE							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CHECKSUM_INV	RESERVED	CHECKSUM_BYTECOUNT													

Bit	Field	Description
31-24	CHECKSUM_RESULT	This is the packet byte number where the checksum result will be placed in the egress packet. The first packet byte which is the first byte of the destination address is Byte 1 (not byte zero).
23-16	CHECKSUM_START_BYTE	This is the packet byte number to start the checksum calculation on. The first packet byte is Byte 1.
15	CHECKSUM_INV	When set, a zero checksum value will be inverted and sent as FFFFh.
14	RESERVED	Reserved.
13-0	CHECKSUM_BYTECOUNT	This is the number of bytes to calculate the checksum on. The outgoing Ethernet packet will have a checksum inserted when this value is non-zero.

Other INFO words are not taken into account.

12.2.1.2.8.3 CPPI Checksum Offload

The CPPI host port can be enabled to perform checksum offload on host port packet ingress and egress. UDP (User Datagram Protocol) and TCP (Transmission Control Protocol) over IPV4 and IPV6 are supported. For the purposes of checksum description, the first packet byte (the first byte of the destination address) is byte 1 (not byte 0). That is, a 64 byte packet goes from byte 1 to byte 64. For all packet types, the S_CN_SWITCH bit in the CPSW_CONTROL_REG register must be set for the Outer VLAN L type to be supported.

12.2.1.2.8.3.1 CPPI Transmit Checksum Offload

IPV4 and IPV6 UDP and TCP packets that are received on any Ethernet port and destined for port 0 egress are checked for correct checksum as described below. The byte counts below are shown for packets with no VLAN's. The byte counts vary with one or two packet VLAN's. Packets received on an Ethernet port with errors are not checked for a correct checksum if they are passed to the host.

12.2.1.2.8.3.1.1 IPV4 UDP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no UDP header).
- Byte 24 = 0x11 for UDP protocol.
- Received packet UDP checksum of zero means that there is no IPV4 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

12.2.1.2.8.3.1.2 IPV4 TCP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a

nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no TCP header).

- Byte 24 = 0x06 for TCP protocol.

12.2.1.2.8.3.1.3 IPV6 UDP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x11 for UDP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x11). Middle and last fragments have a fragment extension header followed by data only (no UDP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.
- Received packet UDP checksum of zero means that there is no IPV6 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

12.2.1.2.8.3.1.4 IPV6 TCP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x06 for TCP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x06). Middle and last fragments have a fragment extension header followed by data only (no TCP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.

12.2.1.2.8.4 CPPI Receive Checksum Offload

Packets sent from host port 0 (switch ingress) to any Ethernet port can have a checksum calculated and inserted into the Ethernet egress packet. The RX_CHECKSUM_EN bit in the CPSW_P0_CONTROL_REG register must be set for receive checksum operation to be enabled. When bit RX_CHECKSUM_EN is enabled, Control Data Word 2 input on CPPI receive PSI interface determines how the checksum is calculated. The CHECKSUM_RESULT field in Control Data Word 2 determines where the checksum is inserted. The checksum result location is adjusted by the egress port if a VLAN is to be inserted or removed on Ethernet port egress.

12.2.1.2.8.5 Egress Packet Operations

Each CPSW egress port (Ethernet and Host) is capable of performing egress packet processing operations (CPSW_ALE_EGRESSOP). IntraVLAN processing either adds, removes, or replaces VLAN information or does nothing. InterVLAN routing allows hardware routing between a limited number of VLANs - thereby allowing high-bandwidth or other routing operations to be offloaded from software to the CPSW (hardware). IntraVLAN processing and InterVLAN routing operations are mutually exclusive. In addition, the packet source and destination addresses can be swapped on egress to facilitate OAM or generic testing operations.

12.2.1.2.9 MII Management Interface (MDIO)

The MII Management interface module implements the 802.3 serial management interface to interrogate and control external Ethernet PHY using a two-wire bus.

12.2.1.2.9.1 MDIO Frame Formats

Table 12-140 shows the address, Table 12-141 shows the read format and Table 12-142 shows the write format of the supported Clause 45 MII Management interface frames. Post-increment accesses are not supported.

Table 12-140. MDIO Clause 45 Address Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	00	AAAAA	RRRRR	10	AAAA.AAAA.AAAA.AAAA

Table 12-141. MDIO Clause 45 Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	11	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 12-142. MDIO Clause 45 Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction. The MDIO CPSW_MDIO_USER_ADDR0_REG register must be written before a read or write operation is performed to set the address used in the operation. Each read or write operation has a preceeding address frame.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization. The preamble is required in clause 45 operation.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 00 pattern.

Operation Code

The operation code for an address transaction is 00. The operation code for a read is 11, while the operation code for a write is a 01.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

MMD Number

The MMD number is the 5 bits allowing 32 unique values. The first bit transmitted is the MSB.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Address

The address field is 16 bits on address operations. The first bit transmitted is the MSB of the address word. Each read/write operation initiated has an automatic address operation initiated first that uses the MDIO CPSW_MDIO_USER_ADDR0_REG/ CPSW_MDIO_USER_ADDR1_REG register values as the 16-bit address.

Data

The Data field is 16 bits on read and write operations. The first bit transmitted and received is the MSB of the data word.

12.2.1.2.9.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the CPSW_MDIO_CONTROL_REG register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO CPSW_MDIO_LINK_REG register. Individual PHY's can be enabled or disabled for polling the associated bit in the CPSW_MDIO_POLL_EN_REG register. The CPSW_MDIO_LINK_REG and CPSW_MDIO_ALIVE_REG register bit values are updated on the poll of each PHY. The LINKSEL bit in the CPSW_MDIO_USER_PHY_SEL_REG_k register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO CPSW_MDIO_LINK_INT_RAW_REG register and the MDIO CPSW_MDIO_LINK_INT_MASKED_REG register, if enabled by the LINKINT_ENABLE bit in the CPSW_MDIO_USER_PHY_SEL_REG_k register.

The MDIO CPSW_MDIO_ALIVE_REG register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO CPSW_MDIO_ALIVE_REG register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a CPSW_MDIO_USER_ACCESS_REG_k register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW field in the CPSW_MDIO_USER_INT_RAW_REG register corresponding to the CPSW_MDIO_USER_ACCESS_REG_k register being used. The corresponding bit in the CPSW_MDIO_USER_INT_MASKED_REG register may also be set depending on the mask setting in the MDIO CPSW_MDIO_USER_INT_MASK_SET_REG and CPSW_MDIO_USER_INT_MASK_CLEAR_REG registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different CPSW_MDIO_USER_ACCESS_REG_k registers. The host should check the status of the GO bit in the MDIO CPSW_MDIO_USER_ACCESS_REG_k register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO CPSW_MDIO_USER_ACCESS_REG_k register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the CPSW_PN_MAC_CONTROL_REG register in the corresponding MAC.

12.2.1.3 CPSW Programming Guide

12.2.1.3.1 Initialization and Configuration of CPSW Subsystem

To configure the CPSW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (RMII, or RGMII) Mode. See the CTRLMMR_MCU_ENET_CTRL[1-0] MODE_SEL register.
2. Configure pads (pin muxing), as per the interface selected. Refer to *Pad Configuration Registers* and the device-specific Datasheet.
3. Enable the CPSW Ethernet Subsystem clocks. See *CPSW Integration*
4. Ensure that at least 2000 CPPI_ICLK periods are run after reset is de-asserted.
5. Configure the CPSW_CONTROL_REG register
6. Configure the Ethernet Port Source Address registers (CPSW_PN_SA_L_REG and CPSW_PN_SA_H_REG)
7. Configure the CPSW statistic port enable register CPSW_STAT_PORT_EN_REG

8. Configure the ALE (*Address Lookup Engine*)
9. Configure the MDIO (*Initializing the MDIO Module*)
10. Configure Ethernet port, as per the desired mode of operations

12.2.1.3.2 CPSW Reset

To reset the Ethernet port, the host must perform the following:

1. Set CMD_IDLE bit to 1h in the Ethernet port control register: CPSW_PN_MAC_CONTROL_REG.
2. Wait for IDLE bit to be set to 1h, which is indicated in the Ethernet port status register: CPSW_PN_MAC_STATUS_REG.
3. Set SOFT_RESET bit to 1h in the Ethernet port software reset register: CPSW_PN_MAC_SOFT_RESET_REG.
4. Wait for SOFT_RESET bit in the CPSW_PN_MAC_SOFT_RESET_REG registers to be cleared to confirm reset completion.
5. Configure the Ethernet ports.
6. Re-configure registers reset to default value by CPSW_PN_MAC_SOFT_RESET_REG.

12.2.1.3.3 MDIO Software Interface

12.2.1.3.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CPSW_MDIO_CONTROL_REG).
2. Enable the MDIO module by setting the ENABLE bit in CPSW_MDIO_CONTROL_REG.
3. The MDIO PHY alive status register (MDIO CPSW_MDIO_ALIVE_REG) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO CPSW_MDIO_LINK_REG) can determine whether this PHY already has a link.
4. Set the appropriate PHY addresses in the MDIO user PHY select register (CPSW_MDIO_USER_PHY_SEL_REG_k, where k = 0 or 1), and set the LINKINT_ENABLE bit to enable a link change event interrupt if desirable.
5. Set the appropriate LINKSEL bit in the CPSW_MDIO_USER_PHY_SEL_REG_k register (where k = 0 or 1).
6. Set the appropriate USERINTMASKSET bit field in the CPSW_MDIO_USER_INT_MASK_SET_REG register.
7. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO CPSW_MDIO_USER_INT_MASK_SET_REG) to use the MDIO user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1).

12.2.1.3.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO CPSW_MDIO_USER_ACCESS_REG_k corresponding to the PHY and PHY register SW wants to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO CPSW_MDIO_USER_ACCESS_REG_k for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_RAW_REG) corresponding to MDIO CPSW_MDIO_USER_ACCESS_REG_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW_MDIO_USER_INT_MASK_SET_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_MASKED_REG) and an interrupt is triggered on the host processor.

12.2.1.3.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) is cleared.

2. Write to the GO, REGADR, and PHYADR bits in the CPSW_MDIO_USER_ACCESS_REG_k register corresponding to the PHY and PHY register SW wants to read.
3. The read data value is available in the DATA bit field in MDIO CPSW_MDIO_USER_ACCESS_REG_k register after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in CPSW_MDIO_USER_ACCESS_REG_k register. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_RAW_REG) corresponding to MDIO CPSW_MDIO_USER_ACCESS_REG_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW_MDIO_USER_INT_MASK_SET_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_MASKED_REG) and an interrupt is triggered on the host processor.

12.2.2 Gigabit Ethernet Switch (CPSW0)

This chapter describes the Gigabit Ethernet Switch (CPSW0) subsystem in the device.

12.2.2.1 CPSW0 Overview

The 9-port Gigabit Ethernet Switch (CPSW0) subsystem provides Ethernet packet communication for the device and can be configured as an Ethernet switch.

CPSW0 features the Serial Gigabit Media Independent Interface (SGMII), Reduced Gigabit Media Independent Interface (RGMII), Reduced Media Independent Interface (RMII) and the Management Data Input/Output (MDIO) interface for physical layer device (PHY) management.

Figure 12-87 shows the CPSW0 module overview.

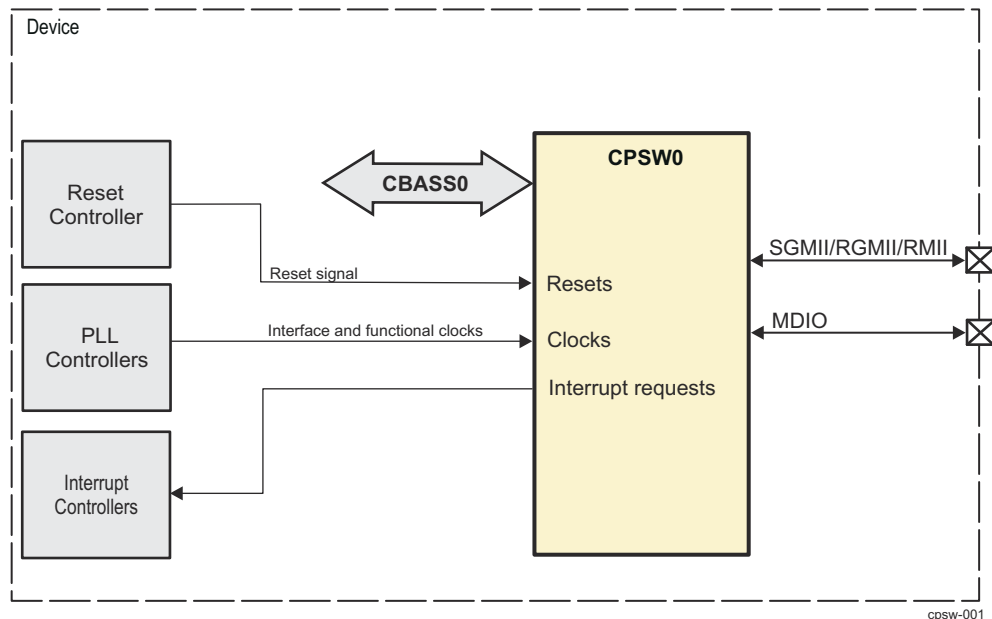

Figure 12-87. CPSW0 Overview

12.2.2.1.1 CPSW0 Features

The 9-port CPSW0 subsystem provides the following features:

- Eight Ethernet ports with selectable SGMII(1G,2.5G), QSGMII, USXGMII/XFI, RGMII, and RMII interfaces and an internal Communications Port Programming Interface (CPPI) port (port 0)
- Synchronous 10M/100M/1000M/10G operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0 and 802.1Qaz)
- Ethernet port reset isolation
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
 - Timestamp module capable of time stamping external timesync events like Pulse-Per-Second and also generating Pulse-Per-Second outputs
 - CPTS module that supports time stamping for IEEE1588 with support for 8 hardware push events and generation of compare output pulses
- DSCP Priority Mapping (IPv4 and IPv6)
- IPV4/IPV6 UDP/TCP checksum offload
- Priority Based Flow Control (802.1QBB) and Flow Control (802.3x) Support
- Wire rate switching (802.1d)
- Store and Forward Switching
- Non-Blocking switch fabric
- Time Sensitive Network Support

- IEEE P802.3br/D2.0 Interspersing Express Traffic
- IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE)
 - 1024 ALE table entries
 - Parameterized number of addresses plus VLANs (total)
 - Wire rate lookup
 - LAN support
 - Host controlled time-based aging and/or auto-aging
 - Spanning tree support
 - L2 address lock and L2 filtering support
 - MAC authentication (802.1x)
 - Receive-based or destination-based Multicast and Broadcast rate limits
 - MAC address blocking
 - Source port locking
 - OUI (Vendor ID) host accept/deny feature
 - Configurable number of classifier/policers (96)
 - Port and VLAN, OUI, or address traffic mirroring
 - Port trunking for up to four trunks across any port combination
 - Policing of ingress data flows
 - Castagnoli or Ethernet CRC selectable per port
- EtherStats and 802.3 Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Maximum frame size of 2020 bytes
- Management Data Input/Output (MDIO) module for PHY Management
- Host port CPPI Streaming Packet Interface (CPPI_GCLK)
- Digital loopback and FIFO loopback modes supported
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECCED)

12.2.2.1.2 CPSW0 Not Supported Features

The following features are not supported for 9-port CPSW0 switch:

- MII and GMII Mode
- Gigabit half-duplex in 1Gbit or 10Gbit modes.
- Software reset on CPRGMII, CPRMII, PCSR submodules
- Interspersed Express Traffic (IET) in RMII mode
- Jumbo sized packets (9600 bytes)
- Rate limiting in half-duplex mode
- Dual VLAN switch operations
- MACSEC
- Synchronous Ethernet
- Cut Through Switching
- RGMII Internal Delay Mode disabled

12.2.2.1.3 Terminology

Terminology:

AVB	Audio Video Bridging
AVBTP	Audio Video Bridging Transport Protocol
BMCA	Best Master Clock Algorithm
CFI	Canonical Format Indicator
CPPI	Communications Port Programming Interface
CPSW	Common Platform Switch
DLR	Device Level Ring
DSCP	Differentiated Services Code Point
EEE	Energy Efficient Ethernet
EMAC	Ethernet Media Access Control
EOP	End of Packet
EOQ	End of Queue
IPG	Inter-Packet Gap
LPI	Low Power Indicator
MDIO	Management Data Input/Output
MOF	Middle of Frame
OUI	Organizationally Unique Identifier
PFC	Priority based Flow Control
PTP	Precision Time Protocol
RMON	Remote Monitoring
RTCP	RTP Control Protocol
RTP	Real-time Transport Protocol
SCR	Switched Central Resource
SRP	Stream Reservation Protocol
TOS	Type of Service
VLAN	Virtual Local Area Network

12.2.2.1.4 CPSW Ports

Table 12-143. CPSW Clocks and Resets

Clocks	
Module Clock Input	Description
CPPI_ICLK	CPPI packet streaming interface clock (320-MHz). Main clock for CPSW0.
GMII_RFT_CLK	125-MHz GMII Gigabit mode clock.
RGMII_MHZ_5_CLK	5-MHz RGMII reference clock.
RGMII_MHZ_50_CLK	50-MHz RGMII reference clock.
RGMII_MHZ_250_CLK	250-MHz RGMII reference clock.
RMII_MHZ_50_CLK	50-MHz RMII reference clock.
CPTS_RFT_CLK	CPTS IEEE 1588 clock.
GMII1_MT_CLK	
GMII2_MT_CLK	
GMII3_MT_CLK	
GMII4_MT_CLK	
GMII5_MT_CLK	
GMII6_MT_CLK	
GMII7_MT_CLK	
GMII8_MT_CLK	
GMII1_MR_CLK	
GMII2_MR_CLK	
GMII3_MR_CLK	
GMII4_MR_CLK	
GMII5_MR_CLK	
GMII6_MR_CLK	
GMII7_MR_CLK	
GMII8_MR_CLK	
RGMII_RXC_I	RGMII reference clock that provides the timing reference for receive operations.
RGMII_TXC_O	RGMII transmit reference clock.
MDIO_MCLK	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
Resets	
Module Reset Input	Description
CPSW0_RST	Module Reset

Table 12-144. CPSW Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
CPSW0_STAT_PEND_0	CPSW0 statistic pending interrupt 0	Level
CPSW0_MDIO_PEND_0	CPSW0 MDIO interrupt	Level
CPSW0_EVNT_PEND_0	CPSW0 event pending interrupt	Level
CPSW0_ECC_SEC_PEND_0	CPSW0 SEC ECC error interrupt	Level
CPSW0_ECC_DED_PEND_0	CPSW0 DED ECC error interrupt	Level
Time Sync and Compare Events		
Module Event	Description	Type
CPSW0_CPTS_COMP_0	CPSW0 compare event interrupt	Edge
CPSW0_CPTS_GENF0_0	CPSW0 CPTS generator function event interrupt 0	Edge

Table 12-144. CPSW Hardware Requests (continued)

CPSW0_CPTS_GENF1_0	CPSW0 CPTS generator function event interrupt 1	Edge
CPSW0_CPTS_SYNC_0	CPSW0 CPTS sync event interrupt	Edge

12.2.2.2 CPSW0 Environment

This section describes the CPSW0 external connections (environment).

12.2.2.2.1 CPSW0 RMII Interface

Figure 12-88 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system. The individual CPSW0 and MDIO signals for the RMII interface are summarized in Table 12-145.

The CPSW0 module integrated in the device supports internal and external clock sources in RMII mode. Figure 12-88 shows the internal clock source for RMII_MHZ_50_CLK clock. It is 50 MHz clock source that is provided on the CLKOUT device pin. For more details see *CPSW0 Integration*. This clock has to be routed on the PCB to the RMII_REF_CLK device pin and the external PHY, RMII clock input (shared by all RMII ports).

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

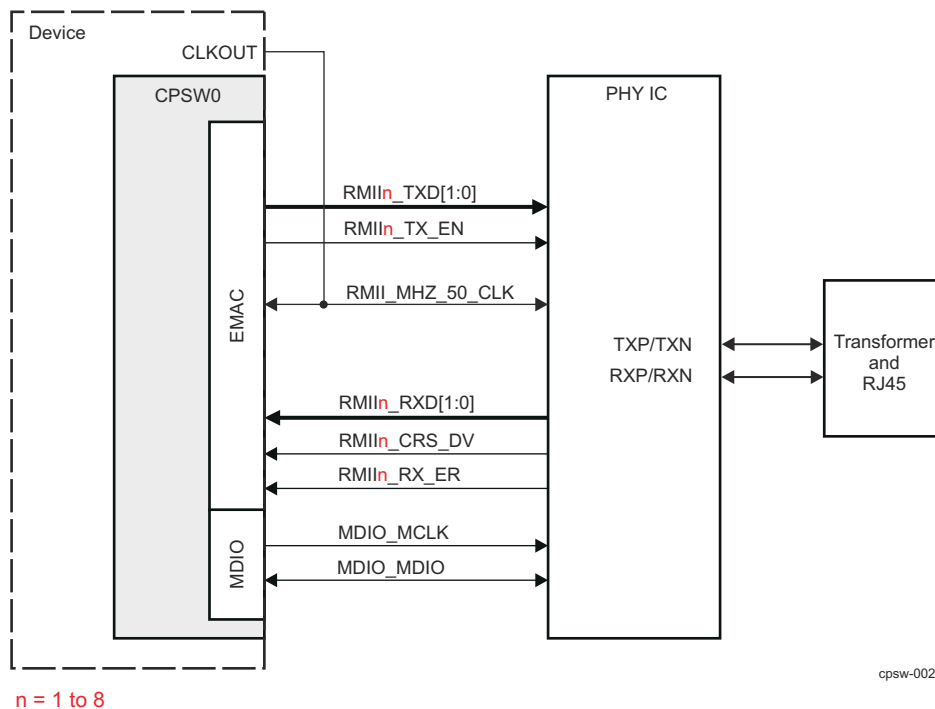

Figure 12-88. RMII Interface Typical Application (Internal Clock Source)

Figure 12-89 shows the external clock source for RMII_MHZ_50_CLK clock. In this case a 50 MHz clock is available on the PCB and it can be sourced from an oscillator or from the Ethernet PHY. This externally generated clock has to be routed to both RMII_REF_CLK device pin and the external PHY, RMII clock input.

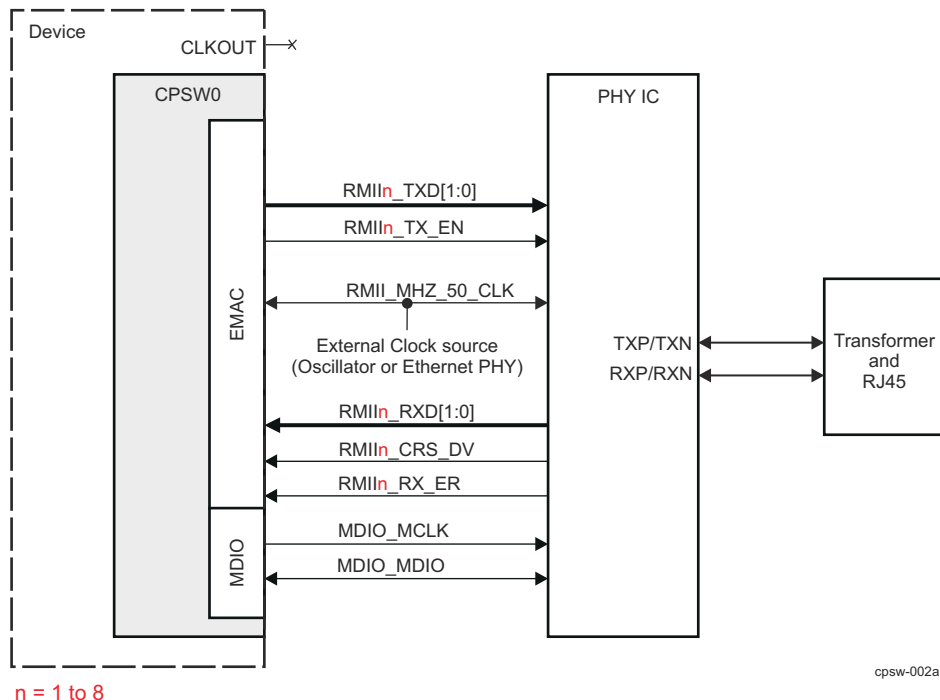

Figure 12-89. RMII Interface Typical Application (External Clock Source)

Table 12-145. RMII I/O Description

Signal ⁽²⁾	I/O ⁽¹⁾	Description
RMII _n _TXD[1:0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII _n _TX_EN is asserted.
RMII _n _TX_EN	O	RMII transmit enable. The transmit enable signal indicates that the RMII _n _TXD[1:0] pins are generating data for use by the PHY. RMII _n _TX_EN is synchronous to RMII_MHZ_50_CLK.
RMII_MHZ_50_CLK	I	RMII 50MHz reference clock. The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RMII _n _RXD[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII _n _CRS_DV is asserted and RMII _n _RX_ER is de-asserted.
RMII _n _CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RMII _n _RX_ER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MCLK	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO0_MDIO data pin.
MDIO_MDIO	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO0_MDIO pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

(2) n = 1 to 8

12.2.2.2.2 CPSW0 RGMII Interface

Figure 12-90 shows a device with integrated EMAC and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW0 and MDIO signals for the RGMII interface are summarized in Table 12-146.

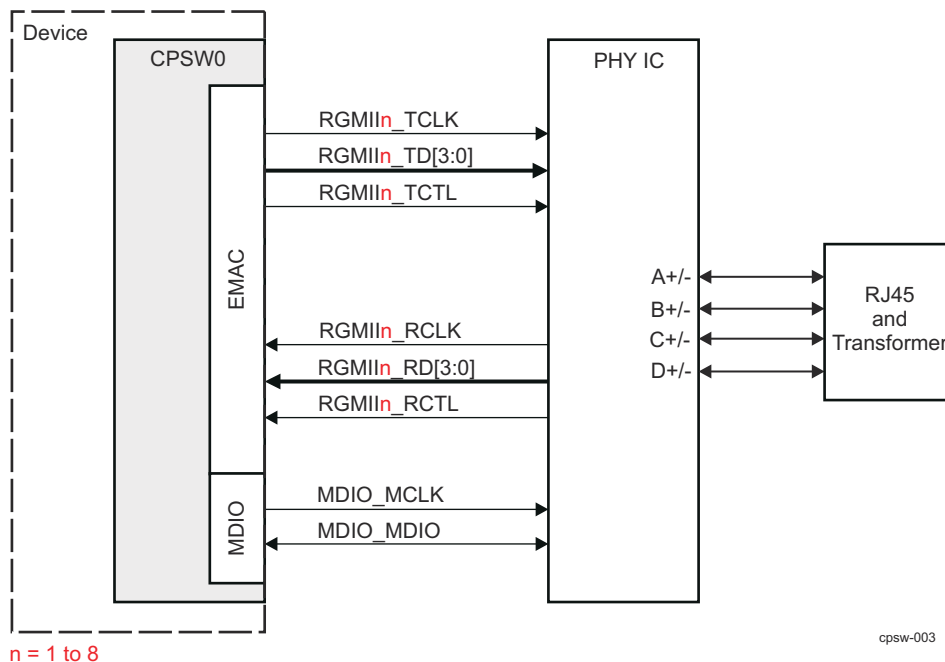

Figure 12-90. RGMII Interface Typical Application

Table 12-146. RGMII I/O Description

Signal ⁽²⁾	I/O ⁽¹⁾	Description
RGMII _n _TD[3:0]	O	The transmit data pins are a collection of 4 bits of data. TD0 is the least-significant bit (LSB). The signals are valid only when RGMII _n _TCTL is asserted.
RGMII _n _TCTL	O	Transmit Control/enable. The transmit enable signal indicates that the TD pins are generating data for use by the PHY.
RGMII _n _TCLK	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RGMII _n _RD[3:0]	I	The receive data pins are a collection of 4 bits of data. RD0 is the least-significant bit (LSB). The signals are valid only when RGMII _n _RX_CTL is asserted
RGMII _n _RCTL	I	The receive data valid/control signal indicates that the RD pins are nibble data for use by the EMAC.
RGMII _n _RCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MCLK	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO0_MDIO pin.
MDIO_MDIO	I/O	The MDIO0_MDIO pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO0_MDIO pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

(2) n 1 to 8

Note

The Control Module registers assign the specific function to the device pads. For more information on Control Module settings, see Pad Configuration Registers in *Control Module (CTRL_MMR)* and the device-specific Datasheet.

12.2.2.3 CPSW0 Functional Description

The 9-port switch Ethernet subsystem module (CPSW) is compliant to the IEEE Std 802.3 Specification. CPSW top level functional block diagram is shown in Figure 12-91.

12.2.2.3.1 Functional Block Diagram

The 9-port Ethernet subsystem consists of:

- CPSW_9G
- One RGMII_n (where n = 1 to 8) interface module
- One SGMII_n (where n = 1 to 8) interface modules
- One RMII_n (where n = 1 to 8) interface module
- One Host Port 0 CPPI Packet Streaming Interface
- CPSW subsystem control registers (REG)
- One MDIO interface module
- One Interrupt Controller module

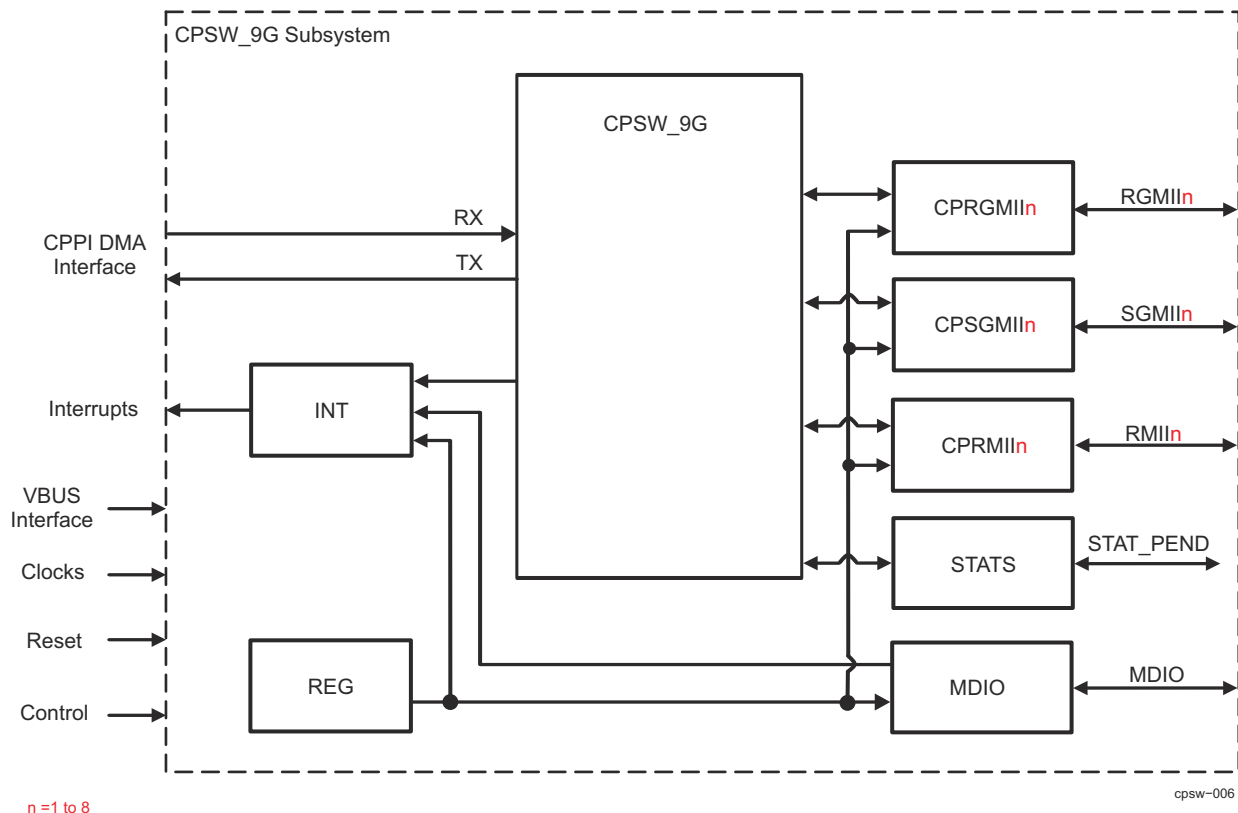

Figure 12-91. CPSW Top Level Block Diagram

12.2.2.3.2 CPSW Ports

The Ethernet Subsystem has 9 ports. Port 0 is the Host port (internal to the Subsystem). Port 1 to Port 8 are the external ports connected to RGMII, SGMII or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the CPPI Host Port
- Port1 to Port8 is referred to the interfaces RGMII/SGMII/RMII

12.2.2.3.2.1 Interface Mode Selection

The 9-port switch (CPSW) Ethernet Subsystem has eight 10/100/1000 Ethernet ports with selectable RMII, RGMII and SGMII interfaces.

The interface modes for all 8 Ethernet ports are selected by configuring the Ethernet interface mode selection bitfield (PORT_MODE_SEL) in the CTRLMMR_ENET1_CTRL to CTRLMMR_ENET8_CTRL registers.

See the device-specific Datasheet for configuring the pin mux mode as per the interface selected.

12.2.2.3.3 Clocking

12.2.2.3.3.1 Subsystem Clocking

CPSW clocking summary is shown in *CPSW0 Integration*.

12.2.2.3.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

12.2.2.3.3.2.1 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

12.2.2.3.3.2.2 RMII Interface Clocking

RMII interface clock RMII_50MHZ_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

RMII_REF_CLK from device pin or internal RGMII_MHZ_50_CLK clock (default clock) can be used as the clock source for RMII interface. For more details on RMII clocking, please see *CPSW0 Integration*

CTRLMMR_CLKOUT_CTRL[4]CLK_EN and CTRLMMR_CLKOUT_CTRL[0]CLK_SEL bits are used to enable and select the clock source for CLKOUT device pin.

12.2.2.3.3.2.3 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (CPPI_ICLK) clock. The application software or driver must control the divide-down value.

See the CPSW_MDIO_CONTROL_REG register for configuring the Clock Divider ([15-0]CLKDIV) value.

12.2.2.3.4 Software IDLE

The submodule software idle register bits enable CPSW operation to be completely or partially suspended by software control. There are two CPSW submodules that contain software idle register bits. Each of the two submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW module enters the idle state when all two submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the two submodule idle bits. The CPSW_9G is in the idle state when all two submodules are in the idle state. The CPSW_SOFT_IDLE_REG[0] SOFT_IDLE bit may be set if desired after the submodules are in the idle state. The SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

12.2.2.3.5 Interrupt Functionality

CPSW Ethernet Subsystem has six interrupt outputs:

- EVNT_PEND - CPTS Event Pending Interrupt
- STAT_PEND0 – Statistics Pending Interrupts
- ECC_DED_INT - ECC DED Level Interrupt
- ECC_SEC_INT - ECC SEC Level Interrupt
- MDIO_INTR - MDIO Pending Interrupt (combined MDIO_LINKINT and MDIO_USERINT events)

12.2.2.3.5.1 EVNT_PEND Interrupt

See [Section 12.2.2.3.7, Common Platform Time Sync \(CPTS\)](#) for more details on this interrupt.

12.2.2.3.5.2 Statistics Interrupt (STAT_PEND0)

The statistics level interrupt (STAT_PEND0) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement any statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The statistics are mapped into internal memory space and are 32-bits wide. The raw and masked statistics interrupt status may be read by reading the CPSW_CPTS_INTSTAT_RAW_REG and CPSW_CPTS_INTSTAT_MASKED_REG registers, respectively.

The statistics interrupt is enabled by setting to 1h the TS_PEND_EN bit in the CPSW_CPTS_INT_ENABLE_REG register.

12.2.2.3.5.3 ECC DED Level Interrupt (ECC_DED_INT)

Level interrupt (ECC_DED_INT) indicating an ECC double error has been detected.

12.2.2.3.5.4 ECC SEC Level Interrupt (ECC_SEC_INT)

Level interrupt (ECC_SEC_INT) indicating an ECC single error has been detected and corrected.

12.2.2.3.5.5 MDIO Interrupts

Normal Mode: (CPSW_MDIO_POLL_REG[30] STATECHANGEMODE = 0h)

MDIO_LINKINT event is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR_MON field of the CPSW_MDIO_USER_PHY_SEL_REG_k register and the corresponding LINKINT_ENABLE bit is set. The MDIO_LINKINT event is also captured in the MDIO CPSW_MDIO_LINK_INT_MASKED_REG register. When the GO bit in the CPSW_MDIO_USER_ACCESS_REG_k register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the CPSW_MDIO_USER_INT_MASK_SET_REG register is set, the MDIO_USERINT signal is asserted. The MDIO_USERINT event is also captured in the CPSW_MDIO_USER_INT_MASKED_REG register.

State Change Mode: (CPSW_MDIO_POLL_REG[30] STATECHANGEMODE = 1h)

In State Change Mode, the MDIO will assert MDIO_LINKINT[0] when any bit in the MDIO CPSW_MDIO_ALIVE_REG or CPSW_MDIO_LINK_REG registers changes due to MDIO operations. The MDIO_LINKINT event is also captured in the CPSW_MDIO_LINK_INT_MASKED_REG register. MDIO_LINKINT[1] output is unused in State Change Mode. The CPSW_MDIO_USER_PHY_SEL_REG_k registers are unused in state change mode.

Manual Mode: (CPSW_MDIO_POLL_REG[31] MANUALMODE = 1h)

Manual Mode allows software to directly control the MDIO serial clock output (CPSW_MDIO_MANUAL_IF_REG[2] MDIO_MDCLK_O) and the MDIO serial data output enable (CPSW_MDIO_MANUAL_IF_REG[1] MDIO_OE). Manual Interface Mode is enabled when the MANUALMODE bit is set in the CPSW_MDIO_POLL_REG register. Manual Mode is intended to be used by software for slow speed general purpose IO operations and not for MDIO PHY operations.

12.2.2.3.6 CPSW_9G

The CPSW_9G RMII/ RGMII interface is compliant to the IEEE Std 802.3 Specification.

The CPSW_9G contains one Ethernet port interface (Ethernet port 1), one CPPI packet streaming interface host port (port 0), Common Platform Time Sync (CPTS), ALE Engine and Statistics (STATS). A top-level block diagram of the CPSW_9G is shown in [Figure 12-92](#).

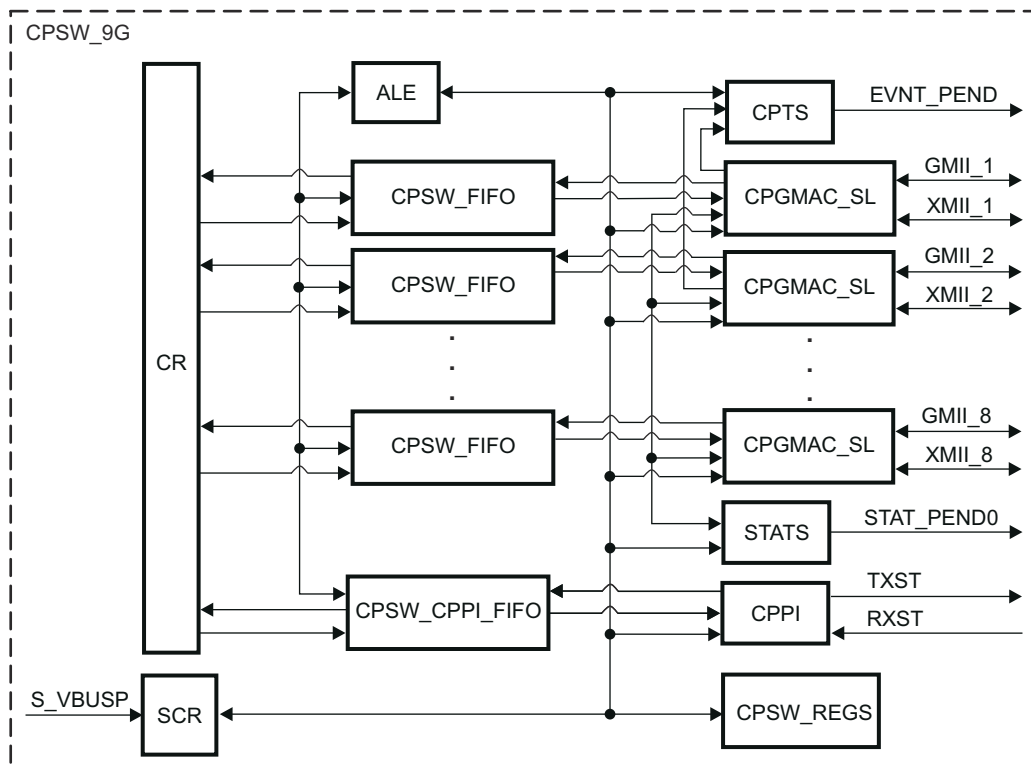

Figure 12-92. CPSW_9G Block Diagram

12.2.2.3.6.1 Address Lookup Engine (ALE)

The Address Lookup Engine (ALE) is a sub-block of the CPSW Switch and it processes all received packets and determines the packet destination port(s). The ALE uses the incoming packet data: received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the `ENABLE_ALE` bit in the `CPSW_ALE_CONTROL` register is set. All packets are dropped when the `ENABLE_ALE` bit is cleared to 0h.

12.2.2.3.6.1.1 Error Handling

In normal operation, the Ethernet port modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a MAC control packet. However, when the `CPSW_PN_MAC_CONTROL_REG_k` configuration bit(s) `RX_CEF_EN`, `RX_CSF_EN`, or `RX_CMF_EN` are set, error frames, short frames or MAC control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a MAC control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). Packets with errors that are forwarded to the host have no VLAN untagging or drop due to rate limiting. No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address. Directed packets from the host are not learned, updated, or touched.

12.2.2.3.6.1.2 Bypass Operations

The ALE may be configured to operate in bypass mode by setting the `ENABLE_BYPASS` bit in the `CPSW_ALE_CONTROL` register. When in bypass mode, all Ethernet port received packets are forwarded only to the host port (port 0). In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

12.2.2.3.6.1.3 OUI Deny or Accept

The ALE may be configured to operate in OUI deny mode by setting the `ENABLE_OUI_DENY` bit in the `CPSW_ALE_CONTROL` register. When in OUI deny mode, a packet with a non-matching OUI source address

will be dropped unless the destination address matches a multicast table entry with the SUPER bit set. When ENABLE_OUI_DENY bit is cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory address table entry. Broadcast packets will be dropped unless the broadcast address is entered into the table with the SUPER bit set. Unicast packets will be dropped unless the unicast address is in the table with BLOCK and SECURE both set (supervisory unicast packet).

12.2.2.3.6.1.4 Statistics Counting

ALE sends many statistics along with the frame routing so the CPSW can count them on a per port basis. There are many reasons to drop frames the below drop events are individually counted in CPSW per port statistics counters.

Table 12-147. Learned Address Control Bits

Abbreviation	Description
vddc	Dual VLAN or Double VLAN drop counter.
frdc	IPv4 fragmented drop counter.
nldc	IPv4 Protocol or IPv6 Next Header drops due to next header limit drop counter.
etdc	Ether Type field is ≤ 1500 and the frame size is too small drop counter.
smdc	The Source Address has bit 40 set drop counter.
badc	The Source or Destination Address blocked drop counter.
svdc	The Source Address is locked to a different port drop counter.
des	The Source and Destination are equal and the Source Address is not in the table drop counter.
adc	The Source Address is not in the table in authentication mode drop counter.
vicdc	The VLAN ingress check failed drop counter.
rlcd	Rate Limit Drop Counter.
over	Lookup Overflow, the rate of the ALE clock is not sufficient to handle the incoming frame rate (Should never happen).
drop	Packet is dropped and not forwarded.

12.2.2.3.6.1.5 Automotive Security Features

The ALE has many automotive security features that most enterprise switches do not require.

- VLANs can be configured to not allow fragmented IPv4 frames. That is a VLAN can be configured to not allow fragmented IPv4 traffic.
- VLANs can be configured to only allow up to four different IPv4 Protocols or IPv6. Next Header values, for example a VLAN can be configured to only allow TCP traffic in both IPv4 and IPv6 packets.
- Drop invalid Source Addresses, that is drop Source Addresses with bit 40 set (Multicast/Broadcast indicator on Destination Addresses)
- IEEE802.3 Length Check, drop frames that the IEEE802.3 Length is not contained within the frame. (Ether Types 0-1500)
- Any Source Address can be secured to a port dropping any attempts from other ports to masquerade as a service.
- Any source or destination address can be blocked.
- Per Port or Per VLAN ingress checking, dropping traffic from non-member ports.
- Classification, Policing on L2 and L3 information.

12.2.2.3.6.1.6 CPSW Switching Solutions

The host port can operate in many different modes as well depending on the functionality of the host. It is important to understand the modes and configure them properly.

The ALE Table is designed to maximize the modes without compromise of the system functionality as well.

12.2.2.3.6.1.6.1 Basics of 5-port Switch Type

The 5-port switch has a host port, and that port can operate in two fundamental modes. Bridge mode allows the host to extend the switched domain to another network like Wi-Fi or another multi-port switch. In this case the host must be able to see unknown unicast addresses so they can be broadcast to the other network. In Port mode the host need not see any unknown unicast traffic. The CPSW_ALE_CONTROL[8] EN_HOST_UNI_FLOOD bit determines the host mode for unknown unicast traffic. This bit should only be set if you are bridging two or more networks together.

In 5-port switch, the ALE table is shared between the host port and the network.

12.2.2.3.6.1.7 VLAN Routing and OAM Operations

12.2.2.3.6.1.7.1 InterVLAN Routing

The CPSW module supports wire rate InterVLAN routing for a small number of routes, that is the host will setup an ALE classifier with an associated egress operation that will cause the CPSW to perform particular egress operations. The ALE can optionally check time to live validity as well.

The ALE uses the classifier along with an egress opcode, destination port mask and TTL check field to tell the CPSW to manipulate the packet on the egress. The CPSW will use the opcode along with a per port operation table to process the packet. By setting up the CPSW egress operation table you can replace the DA, SA and VLAN along with optionally updating the time to live IP header field. This allows the CPSW to perform the routing function for a small set of routes without getting the local host/CPU involved.

The Egress opcode will only be used for a classifier match and the packet would normally be sent only to the host. That is the host would have routed the packet but the CPSW has been configured to do the work instead. In the event that the time-to-live check feature is enabled and the time-to-live is either 0 or 1, the packet will not get the egress opcode and instead be sent to the host as if the route is not setup. This allows the host to deal with invalid TTL fields.

12.2.2.3.6.1.7.2 OAM Operations

The ALE supports OAM loopback on ports so that a remote link can be tested. That is a port placed in OAM loopback will echo packets received on a port back to the port with an egress op of 0xFF which will swap the SA and DA on egress in the CPSW.

Any supervisory packet will not be affected, so the spanning tree and other bridging functions are not affected.

Packets will only be echoed if the port is in OAM loopback mode, the received packet is not a supervisor packet. The port is in a forwarding state and the packet received DA!=SA and there are no errors in the packet.

When a port is in OAM loopback the port will not egress traffic from other ports, no address for loop backed traffic will be learned if enabled. Any packet received on the OAM loopback port with an error will be processed as if the port is not in OAM. That is if the host has enabled copy errored frames the errored frames will be sent to the host instead.

12.2.2.3.6.1.8 Supervisory packets

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise blocked to be forwarded for special purposes. For example the BPDU packets that are sent during link start up must also be seen on ports in a blocking state. This allows the bridge software to remove loops in the fabric.

12.2.2.3.6.1.9 Address Table Entry

The ALE table contains multiple table entry types. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 12-148. Learned Address Control Bits

Bit(s)	Value
AGEABLE	1
Touch	1
BLOCK	0
SECURE	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40**.

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40**.

12.2.2.3.6.1.9.1 Free Table Entry

Table 12-149. Free (Unused) Address Table Entry Bit Values

74:62	61:60	59:0
RESERVED	ENTRY_TYPE (00)	RESERVED

12.2.2.3.6.1.9.2 Multicast Address Table Entry (Bit 40 == 0)

Table 12-150. Multicast Address Table Entry Bit Values

74	73:70	69:66	65	64	63	62	61:60	59:48	47:0
TRUNK	RESERVED	PORT_NUMBER	BLOCK	SECURE	TOUCH	AGEABLE	ENTRY_TYPE (01)	RESERVED	MULTICAST_ADDRESS

Trunk Indicator (TRUNK)

0h = The port bits in the entry are the port number

1h = The port bits in the entry are the trunk number

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0h = Address is not blocked.

1h = Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0h = Received port number is a don't care.

1h = Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Touch Indicator (TOUCH)

Only valid when AGEABLE is a 1h.

0h = Ageable unicast address has not been touched

1h = Ageable unicast address that has been touched

Ageable (AGEABLE)

This bit indicates that the address is ageable.

0h = Unicast address that is not ageable

1h = Unicast address that is ageable

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

12.2.2.3.6.1.9.3 Multicast Address Table Entry (Bit 40 == 1)

Table 12-151. VLAN/Multicast Address Table Entry Bit Values

74:66	65	64	63:62	61:60	59:48	47:0
PORT_MASK	SUPER	IGNMBITS	FWDSTLVL	ENTRY_TYPE (1h)	RESERVED	MULTICAST_ADDRESS

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0h = Non-supervisory packet

1h = Supervisory packet

Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

Forward State Level (FWDSTLVL)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s).

A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

0h = Forwarding

1h = Blocking/Forwarding/Learning

2h = Forwarding/Learning

3h = Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

3h = VLAN address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

12.2.2.3.6.1.9.4 VLAN Unicast Address Table Entry (Bit 40 == 0)

Table 12-152. Unicast Address Table Entry Bit Values

74	73:70	69:66	65	64	63	62	61:60	59:48	47:0
TRUNK	RESERVED	PORT_NUM BER	BLOCK	SECURE	TOUCH	AGEABLE	ENTRY_TY PE (11)	VLAN_ID	UNICAST_A DDRESS

Trunk Indicator (TRUNK)

0h = The port bits in the entry are the port number

1h = The port bits in the entry are the trunk numbe

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0h = Address is not blocked.

1h = Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/

Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0h = Received port number is a don't care.

1h = Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Touch Indicator (TOUCH)

Only valid when AGEABLE is a 1h.

0h = Ageable unicast address has not been touched

1h = Ageable unicast address that has been touched

Ageable (AGEABLE)

This bit indicates that the address is ageable.

0h = Unicast address that is not ageable

1h = Unicast address that is ageable

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

1h = Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

12.2.2.3.6.1.9.5 OUI Unicast Address Table Entry

Table 12-153. OUI Unicast Address Table Entry Bit Values

74:64	63:62	61:60	59:48	47:24	23:0
RESERVED	UNICAST_TYPE (2h)	ENTRY_TYPE (1h)	RESERVED	UNICAST_OUI	RESERVED

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

0h = Unicast address that is not ageable.

1h = Ageable unicast address that has not been touched.

2h = OUI address - lower 24-bits are don't cares (not ageable).

3h = Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

1h: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

12.2.2.3.6.1.9.6 VLAN/Unicast Address Table Entry (Bit 40 == 0)

Table 12-154. Unicast Address Table Entry Bit Values

74	73:70	69:66	65	64	63	62	61:60	59:48	47:0
TRUNK	RESERVED	PORT_NUMBER	BLOCK	SECURE	TOUCH	AGEABLE	ENTRY_TYPE (3h)	VLAN_ID	UNICAST_ADDRESS

Trunk Indicator (TRUNK)

0h = The port bits in the entry are the port number

1h = The port bits in the entry are the trunk number

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0h = Address is not blocked.

1h = Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0h = Received port number is a don't care.

1h = Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Touch Indicator (TOUCH)

Only valid when AGEABLE is a 1h.

0h = Ageable unicast address has not been touched

1h = Ageable unicast address that has been touched

Ageable (AGEABLE)

This bit indicates that the address is ageable.

0h = Unicast address that is not ageable

1h = Unicast address that is ageable

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

3h: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

12.2.2.3.6.1.9.7 VLAN/ Multicast Address Table Entry (Bit 40 == 1)

Table 12-155. Multicast Address Table Entry Bit Values

74:66	65	64	63:62	61:60	59:48	47:0
PORT_MASK	SUPER	IGNMBITS	FWDSTLVL	ENTRY_TYPE (3h)	VLAN_ID	UNICAST_ADD RESS

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0h = Non-supervisory packet

1h = Supervisory packet

Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

Forward State Level (FWDSTLVL)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s).

A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

0h = Forwarding

1h = Blocking/Forwarding/Learning

2h = Forwarding/Learning

3h = Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

3h = VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The VLAN ID associated with the Address entry.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

12.2.2.3.6.1.9.8 Inner VLAN Table Entry

Table 12-156. Inner VLAN Table Entry

74:66	65	64:62	61:60	59:48	47	46:45	44:36
-------	----	-------	-------	-------	----	-------	-------

Table 12-156. Inner VLAN Table Entry (continued)

NO_LEARN_MASK	VLAN_FORCE_INGRESS_CHECK	RESERVED	ENTRY_TYPE (1h)	VLAN_ID	NOFRAG	RESERVED	REG_MCAST_FLOOD_INDEX
35:33	32:24	23	22:21	20:12	11:9	8:0	
RESERVED	FORCE_UNTAGGED_EGRESS	LMTNXTHDR	RESERVED	UREGMSK	RESERVED	VLAN_MEMBER_LIST	

No Learn Mask (NO_LEARN_MASK)

When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

VLAN Force Ingress Check (VLAN_FORCE_INGRESS_CHECK)

If the receive port is not a member of this VLAN then the packet is dropped. This is similar to the `ly_REG_Py_VID_INGRESS_CHECK` bit in the `CPSW_ly_ALE_PORTCTL0_y` registers except this check is for this VLAN only (not all VLANs).

Table Entry Type (ENTRY_TYPE)

2h: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

(NOFRAG)

VLAN No IPv4 Fragmented frames Control - Causes IPv4 fragmented IP frames to be dropped.

Registered Multicast Flood Index (REG_MCAST_FLOOD_INDEX)

Index into `CPSW_ALE_MSK_MUX0` to `CPSW_lx_ALE_MSK_MUXx` register array that is used to create the registered multicast flood mask.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress for the specified port(s) (except on port 0).

VLAN Limit Next Header Control (LMTNXTHDR)

This bit causes frames to be dropped if the Protocol/Nxt Header does not match the `CPSW_ALE_NXT_HDR` register values.

VLAN Unregister Multicast Mask (UREGMSK)

This field indicates which port(s) are the unregistered multicast flood mask.

VLAN Member List (VLAN_MEMBER_LIST)

This field indicates which port(s) are members of the associated VLAN. One bit per port.

12.2.2.3.6.1.9.9 Outer VLAN Table Entry

Table 12-157. Outer VLAN Table Entry

74:66	65	64:62	61:60	59:48	47	46:45	44:36
NO_LEARN_MASK	VLAN_FORCE_INGRESS_CHECK	RESERVED	ENTRY_TYPE (2h)	VLAN_ID	NOFRAG	RESERVED	REG_MCAST_FLOOD_INDEX
35:33	32:24	23	22:21	20:12	11:9	8:0	
RESERVED	FORCE_UNTAGGED_EGRESS	LMTNXTHDR	RESERVED	UREGMSK	RESERVED	VLAN_MEMBER_LIST	

No Learn Mask (NO_LEARN_MASK)

When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

VLAN Force Ingress Check (VLAN_FORCE_INGRESS_CHECK)

If the receive port is not a member of this VLAN then the packet is dropped. This is similar to the ly_REG_Py_VID_INGRESS_CHECK bit in the CPSW_ly_ALE_PORTCTL0_y registers except this check is for this VLAN only (not all VLANs).

Table Entry Type (ENTRY_TYPE)

2h: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

(NOFRAG)

VLAN No IPv4 Fragmented frames Control - Causes IPv4 fragmented IP frames to be dropped.

Registered Multicast Flood Index (REG_MCAST_FLOOD_INDEX)

Index into CPSW_ALE_MSK_MUX0 to CPSW_lx_ALE_MSK_MUXx register array that is used to create the registered multicast flood mask.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress for the specified port(s) (except on port 0).

VLAN Limit Next Header Control (LMTNXTHDR)

This bit causes frames to be dropped if the Protocol/Nxt Header does not match the CPSW_ALE_NXT_HDR register values.

VLAN Unregister Multicast Mask (UREGMSK)

This field indicates which port(s) are the unregistered multicast flood mask.

VLAN Member List (VLAN_MEMBER_LIST)

This field indicates which port(s) are members of the associated VLAN. One bit per port.

12.2.2.3.6.1.9.10 EtherType Table Entry

Table 12-158. EtherType Table Entry

74:65	64:62	61:60	59:16	15:0
RESERVED	RESERVED	ENTRY_TYPE (1h)	RESERVED	ETHERTYPE

Table Entry Type (ENTRY_TYPE)

2h: VLAN entry

Ether Type (ETHERTYPE)

16-bits Ether Type field.

12.2.2.3.6.1.9.11 IPv4 Table Entry

Table 12-159. IPv4 Table Entry

74:70	69:65	64:62	61:60	59:32	31:0
RESERVED	IGNMBITS	RESERVED	ENTRY_TYPE (2h)	RESERVED	IPv4ADR

Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

Table Entry Type (ENTRY_TYPE)

2h: VLAN entry

IPv4 Address (IPV4ADR)

32-bit IPv4 Address. Any ignored bits must be zero value in the table entry.

12.2.2.3.6.1.9.12 IPv6 Table Entry High

Table 12-160. IPv6 Table Entry High

74:71	70:64	63	62	61:60	59:0
RESERVED	IGNMBITS	RESERVED	(1h)	ENTRY_TYPE (2h)	IPV6ADR[127:68]

Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

Table Entry Type (ENTRY_TYPE)

2h: VLAN entry

IPv6 Address - upper 64 bits (IPV6ADR[127:68])

This address is split into three fields in the IPv6 High and IPv6 Low table entry. Any ignored bits must be zero in the table entry(s).

12.2.2.3.6.1.9.13 IPv6 Table Entry Low

Table 12-161. IPv6 Table Entry Low

74:71	70:63	62	61:60	59:0
RESERVED	IPV6ADR[67:60]	RESERVED	ENTRY_TYPE (2h)	IPV6ADR[59:0]

Table Entry Type (ENTRY_TYPE)

2h: VLAN entry

IPv6 Address - upper 8 bits (IPV6ADR[67:60])

IPv6 Address - upper 60 bits (IPV6ADR[59:0])

This address is split into three fields in the IPv6 High and IPv6 Low table entry. Any ignored bits must be zero in the table entry(s).

Note: IPV6 table address entries operate differently than all other table entry types. IPV6 table entries have a high entry concatenated with a low entry. The high entry must have an entry_pointer value of the low entry_pointer plus 0x40. Bit six of the entry_pointer must be set for the high entry and must be zero for the low entry.

12.2.2.3.6.1.10 Multicast Address

Multicast addresses are addresses with bit 40 set. Only destination addresses can be Multicast addresses. The group bit (bit 40) of the source address is reserved in the IEEE standard.

A multicast address of all ones is the broadcast address which can be added to the lookup table if forwarding of broadcast packets need be modified.

12.2.2.3.6.1.10.1 Multicast Ranges

Added IgnMbits to indicate at least one bit of the multicast address is ignored. Up to 10 bits of the multicast address can be ignored to provide the ability to create multiple multicast address ranges.

if ((IgnMbits)&(MultiCastAddress[0] == 0x000)) { MultiCastAddress[0] is ignored in compare}

if ((IgnMbits)&(MultiCastAddress[1:0] == 0x001)) { MultiCastAddress[1:0] is ignored in compare}

if ((IgnMbits)&(MultiCastAddress[2:0] == 0x003)) { MultiCastAddress[2:0] is ignored in compare}

```

if ((IgnMbits)&(MultiCastAddress[3:0]==0x007)) { MultiCastAddress[3:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[4:0]==0x00F)) { MultiCastAddress[4:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[5:0]==0x01F)) { MultiCastAddress[5:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[6:0]==0x03F)) { MultiCastAddress[6:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[7:0]==0x07F)) { MultiCastAddress[7:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[8:0]==0x0FF)) { MultiCastAddress[8:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[9:0]==0x1FF)) { MultiCastAddress[9:0] is ignored in compare}

```

Below is 'C' code to modify ALE MultiCastAddress and IgnMbits when iNumOfBitsToIgnore is greater than zero. Where fGenMask(iOffset,iBitsToMask) creates a Mask for the value provided. For example fGenMask(0,5) will return 0x1F.

```

if(iNumOfBitsToIgnore)
{
    int iIgnClrMsk,iIgnSetMsk;
    iIgnClrMsk=fGenMask(0, iNumOfBitsToIgnore);
    iIgnSetMsk=fGenMask(0, iNumOfBitsToIgnore -1);
    MultiCastAddress &= ~iIgnClrMsk;
    MultiCastAddress |= iIgnSetMsk;
    IgnMbits = 1;
}
else
{
    IgnMbits = 0;
}

```

Multicast Addresses or Ranges can overlap, in the event of an overlap; the higher ALE index will be used.

12.2.2.3.6.1.11 Supervisory Packets

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise blocked to be forwarded for special purposes. For example the BPDU packets that sent during link start up must also be seen on ports in a blocking state. This allows the bridge software to remove loops in the fabric.

12.2.2.3.6.1.12 Aging and Auto Aging

The ALE supports software control or automatic aging of agable addresses.

Any time an agable address is seen as a source address entering from a port the source address entry will be marked as touched.

If the aging timer expires or the software sets the [29] AGE_OUT_NOW bit in the CPSW_ALE_CONTROL, the aging process will be started.

The aging process will read each ALE entry and for all entries that are an address with or without VLAN that is also agable, the touch check process will be done.

The touch check process will test the TOUCH bit and if clear, the entry will be marked as free, else the TOUCH bit will be cleared.

What this means is that if the aging interval was programmed as one second, any unused entry could stay in the ALE table for 1.000001 to 1.999999 seconds

12.2.2.3.6.1.13 ALE Policing and Classification

The ALE has a number of configurable classifier engines (policers) that can be used for classification. Classification is a subset of the policing function and uses a policer without the color marking or rate limiting functions. A policer is a hardware engine that is used for policing. The POLCNTDIV8 field in the CPSW_ALE_STATUS register indicates the number of policers available to be used for classification. Each policer can be enabled to match on one or more of any of the below packet fields for classification. All but Port and Priority are index references to the ALE table entries.

- Port Number
- Priority extracted from VLAN, mapped from DSCP if enabled, or Default Port Priority
- Organization Network Unique identifier - ONU
- Destination Address - DA
- Source Address - SA
- Outer VLANID -S-VLANID
- Inner VLANID -C-VLANID
- Ether Type
- IP Source Address - IPSA with full CIDR masking for IPv4 and IPv6
- IP Destination Address - IPSA with full CIDR masking for IPv4 and IPv6
- Support Host Thread/Flow ID mapping based on any packet classification above

12.2.2.3.6.1.13.1 ALE Policing

The policing function on each policer engine is implemented as dual-counter three-color marking engine as described in the IETF RFC2698. The first counter is the Committed Information Rate (CIR) counter and the second counter is the Peak Information Rate (PIR) counter. The policing function can use either or both counters. Based on the counter values the packet color is determined. The color is used to determine whether the packet is dropped or forwarded. The ALE has a local feature that can drop packets regardless of queue state.

The policing rates are determined by the below equations:

CIR policing rate in Mbit/s = ((ALE frequency in Mhz) * CPSW_ALE_POLICECFG7[31-0] CIR_IDLE_INC_VAL) / 32768

PIR policing rate in Mbit/s = ((ALE frequency in Mhz) * CPSW_ALE_POLICECFG6[31-0] PIR_IDLE_INC_VAL) / 32768

Each policer has 10 different match operations (see [Section 12.2.2.3.6.1.13](#)). Since multiple policing entries can be hit on a single packet this provides the ability to create precise traffic stream control.

Packets are colored at ALE lookup time. Packets can be colored RED, YELLOW, or GREEN. If multiple policers are configured for a packet stream then the packet color is merged from all matching (hit) policers. If any policer is RED then the packet is marked RED. Else if any policer is YELLOW then the packet is marked YELLOW. Otherwise the packet is marked GREEN.

The Policing engine supports several modes such that packets that don't hit a policing/classifier match can be treated as RED, YELLOW, GREEN or policer 0 color. Using policer 0 allows for a system to regulate unregulated traffic.

12.2.2.3.6.1.13.2 Classifier to Host Thread Mapping

The ALE module allows Host Thread mapping based on any packet classification. That is the ALE can generate a thread ID used by the host based on ALE classifier matches.

When enabled the highest classifier match can map to a particular thread ID value.

The ALE also supports an optional default Thread ID value in the event that no classifier match.

Each Thread ID including the default thread ID has an enable such that if no matches occur with the enable bit set are seen the default is used, if the default is not enabled, the switch will use the {port,priority} value instead. If multiple classifier matches occur, the highest matching entry with a thread enable bit set will be used.

Three registers are used for ALE classification thread mapping configuration (CPSW_ALE_THREADMAPDEF, CPSW_ALE_THREADMAPCTL and CPSW_ALE_THREADMAPVAL). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW_ALE_THREADMAPCTL register allows the CPSW_ALE_THREADMAPVAL register contents to be written to the selected classifier. There is a CPSW_ALE_THREADMAPDEF register that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

12.2.2.3.6.1.13.3 ALE Classification

When the policers are configured as classifiers, the color marking and policing functions of the policing/classifier engines are not used. One or multiple classifiers can be configured to match on a single packet. For example, a classifier can be enabled to match on priority while another classifier could match IP address.

12.2.2.3.6.1.13.3.1 Classifier to CPPI Transmit Flow ID Mapping

The ALE can generate a 6-bit transmit CPPI Flow ID based on classifier matches that can be used instead of the switch default transmit Flow ID mapping. The switch default flow ID is the remapped received packet priority (0 to 7). Thread and flow ID are used interchangeably for this since there is a single hardware thread (TXST_THREAD_MREADY) but there are 6-bits of FLOW_ID in the transmit CPPI INFO word 0. When enabled, the highest classifier match can map to a particular 6-bit flow ID value that is associated with the classifier. The ALE also supports an optional ALE default thread/flow ID value in the event that no classifiers match. Each thread/flow ID, including the ALE default thread/flow ID, has an enable such that the ALE default thread/Flow ID is used if enabled and if no matches occur (instead of the remapped received packet priority). If the ALE default is not enabled and no matches occur then the switch default value will be used. If multiple classifier matches occur, the highest match with a thread enable bit set will be used. The resultant flow ID has the CPSW_P0_FLOW_ID_OFFSET_REG register value added to it to determine the actual value in the INFO 0 Flow ID field.

Three registers are used for ALE classification thread/flow ID mapping configuration (CPSW_ALE_THREADMAPDEF, CPSW_ALE_THREADMAPCTL and CPSW_ALE_THREADMAPVAL). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW_ALE_THREADMAPCTL register allows the CPSW_ALE_THREADMAPVAL register contents to be written to the selected classifier. There is a single CPSW_ALE_THREADMAPDEF that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

12.2.2.3.6.1.14 Mirroring

The ALE supports three mirroring modes: destination port, source port and or table entry.

Destination port mirroring allows packets from any ingress port or trunk which ends up switching to a particular egress destination port or trunk to be mirrored to yet another egress destination port or trunk. For example any traffic from any port that is switched to port 'A' can be also mirrored to port 'B'. (MIRROR_DP=A, MIRROR_DEN=1h, MIRROR_TOP=B in the CPSW_ALE_CONTROL register).

Source port mirroring allows packets received on any enabled ingress source port or trunk to be switched to the mirror egress port as well as the actual egress destination ports. For example traffic received on ingress port 'A' can be switched to egress port 'B' as well as the intended egress destination port. (ly_REG_Py_MIRROR_SP=1h in the CPSW_ly_ALE_PORTCTL0_y register, MIRROR_SEN=1h, MIRROR_TOP=B in the CPSW_ALE_CONTROL register).

Table entry mirroring allows for any MAC Address, MAC Address with VLAN, ONU Address or VLAN entry that matches on ingress to be switched to the egress destination as well as the actual egress destination. For example all traffic for VLAN ID of 35 can be mirrored to port 'B'. That is any traffic switched on VLAN ID of 35 will be mirrored. ({VLAN ID of 35 in ALE Table entry index=C}, MIRROR_MIDX=C, MIRROR_MEN=1h, MIRROR_TOP=B)

In the event that mirrored packets are mirrored to or from a port that is also the mirror port the packet will not be duplicated or marked as a mirror packet since the packet has already been on the port as ingress or egress. The packet sent to the mirror port may have modified VLAN info based on the port and VLAN lookup table entries. The mirror port need not be a member of the VLAN ID it is mirroring, the ALE will forward traffic to the mirror port after ingress and egress filters are applied.

The switch may decide to drop any mirror traffic based on switch buffer thresholds as to prevent required traffic from becoming congested.

Port mirroring is controlled by register fields in CPSW_ALE_CONTROL, CPSW_ALE_CTRL2 and the port control registers.

- MIRROR_DP - The destination port that will have its traffic mirrored (CPSW_ALE_CONTROL register).
- MIRROR_TOP - The port to which mirrored traffic is sent (CPSW_ALE_CONTROL register).
- MIRROR_MEN - The enable for mirroring traffic that matches a supported lookup table entry (CPSW_ALE_CONTROL register).
- MIRROR_DEN - The Enable for destination port mirroring (CPSW_ALE_CONTROL register).
- MIRROR_SEN - The Enable for source port mirroring (CPSW_ALE_CONTROL register).
- MIRROR_MIDX - The index of a lookup table entry that will be mirrored CPSW_ALE_CTRL2 register).
- ly_REG_Py_MIRROR_SP - The enable for the Source port to be mirrored. Although multiple source ports can be mirrored concurrently, a mirror traffic bandwidth issue may occur on the mirror egress port (CPSW_ly_ALE_PORTCTL0_y register).

12.2.2.3.6.1.15 Trunking

The ALE supports port trunking of any port in any of four trunk groups. That is, four trunk groups can be supported with up to eight ports in each trunk group. There are no port adjacency rules for trunk groups. When ports are a member of a trunk group, addresses added and used in the lookup table will refer to the trunk group rather than port as indicated in the lookup table entries. If ports are removed from a trunk group, the ALE will redistribute the traffic based on the crc polynomial of enabled fields and the remaining ports within the trunk group. A trunk group may contain only one port. Packet priority, DA, SA, C-VLAN ID, IPv4SA, IPv4DA, IPv6SA, and/or IPv6DA can be used in the hash to generate destination port within the trunk group. If all hash enables are disabled, the packet can be directed to a particular port within the trunk group which allows for testing paths etc. A host directed frame is directed to the directed port regardless of trunk group settings.

Trunking is controlled through fields in the CPSW_ALE_CTRL2 register and in each ALE CPSW_ly_ALE_PORTCTL0_y register:

- TRK_EN_DST - Enable destination address hashing for trunk port calculation.
- TRK_EN_SRC - Enable source address hashing for trunk port calculation.
- TRK_EN_PRI - Enable priority hashing for trunk port calculation.
- TRK_EN_IVLAN - Enable inner C-VLAN ID hashing for trunk port calculation.
- TRK_EN_SIP - Enable source IP address hashing for trunk port calculation.
- TRK_EN_DIP - Enable destination IP address hashing for trunk port calculation.
- TRK_BASE - Hashing formula starting value and test port offset.
- ly_REG_Py_TRUNKEN - Enable this port as a trunk group
- ly_REG_Py_TRUNKNUM - Trunk group number defines this port as a member of a particular trunk group.

12.2.2.3.6.1.16 DSCP

The ALE can map DSCP field to priority prior to classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See CPSW_P0_RX_DSCP_MAP_REG_y and CPSW_PN_RX_DSCP_MAP_REG_k_y registers in the Register Manual section for DSCP mapping.

12.2.2.3.6.1.17 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are *Ingress Filtering*, *VLAN_Aware Lookup*, and *Egress*.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The MCAST_FWD_STATE indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The BLOCK and SECURE bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the Ethernet port to the ALE. Packets with errors may be passed to the host (not aborted) by a Ethernet port port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set in the CPSW_PN_MAC_CONTROL_REG_k register. Error packets that are passed to the host by the Ethernet port are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with long or short errors received by the host are dropped. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPSW_PN_MAC_CONTROL_REG_k register:

- [22] RX_CEF_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX_CSF_EN - enables short frames to be forwarded
- [24] RX_CMF_EN - enables MAC control frames to be forwarded.

12.2.2.3.6.1.17.1 Ingress Filtering Process

Condition and action
If ((ALE BYPASS) and (host port is not the receive port)) then use host portmask and go to Egress process
if (directed packet) then use directed port number and go to Egress process
If (Rx ly_REG_Py_PORTSTATE is Disabled) then discard the packet
if ((ALE BYPASS or error packet) and (host port is not the receive port)) then use host portmask and go to Egress process
if (((BLOCK) and (unicast source address found)) or ((BLOCK) and (unicast destination address found))) then discard the packet
if ((ENABLE_RATE_LIMIT) and (rate limit exceeded) and (not BCAST_MCAST_CTL)) then if (((Multicast/Broadcast destination address found) and (not SUPER)) or (Multicast/Broadcast destination address not found)) then discard the packet
if ((not forward state test valid) and (destination address found)) then discard the packet to any port not meeting the requirements <ul style="list-style-type: none"> • Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward state test.
if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding))) then discard the packet to any ports not meeting the above requirements

if (source address found) and (secure) and (not block) and (receive port number != port_number)) then discard the packet
if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode))) then discard the packet
If (VLAN_Unaware) CPSW_ALE_UVLAN_UNTAG = "000000" CPSW_ALE_UVLAN_URCAST = "111111" CPSW_ALE_UVLAN_URCAST = "111111" UVLAN_MEMBER_LIST = "111111" else if (VLAN not found) CPSW_ALE_UVLAN_UNTAG = CPSW_ALE_UVLAN_UNTAG CPSW_ALE_UVLAN_RMCAST = CPSW_ALE_UVLAN_RMCAST CPSW_ALE_UVLAN_RMCAST = CPSW_ALE_UVLAN_RMCAST CPSW_ALE_UVLAN_MEMBER = CPSW_ALE_UVLAN_MEMBER else CPSW_ALE_UVLAN_UNTAG = found CPSW_ALE_UVLAN_UNTAG CPSW_ALE_UVLAN_URCAST = found CPSW_ALE_UVLAN_URCAST CPSW_ALE_UVLAN_RMCAST = found CPSW_ALE_UVLAN_RMCAST UVLAN_MEMBER_LIST = found UVLAN_MEMBER_LIST
if ((not SUPER) and (ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member)) then discard the packet
if ((ENABLE_AUTH_MODE) and (source address not found) and not(destination address found and (SUPER))) then discard the packet
if (destination address equals source address) then discard the packet
if (VLAN_AWARE) goto VLAN_Aware_Lookup process else goto VLAN_Unaware_Lookup process

12.2.2.3.6.1.17.2 VLAN_Aware Lookup Process

Condition and action
if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of the PORT_NUMBER and UVLAN_MEMBER_LIST less the host port and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of the PORT_NUMBER and the UVLAN_MEMBER_LIST and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (SUPER)) then portmask is the PORT_NUMBER and goto Egress process
if (Unicast packet) # destination address not found then portmask is VLAN member LIST less host port and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of CPSW_ALE_UVLAN_URCAST and found destination address/VLAN portmask (PORT_MASK) and UVLAN_MEMBER_LIST and goto Egress process

if ((Multicast packet) and (destination address found with or without VLAN) and (SUPER))
then portmask is the PORT_MASK and goto Egress process
if (Multicast packet) # destination address not found
then portmask is the logical "AND" of CPSW_ALE_UVLAN_URCAST and UVLAN_MEMBER_LIST
then goto Egress process
if (Broadcast packet)
then use found UVLAN_MEMBER_LIST and goto Egress process

Note

The UVLAN_MEMBER_LIST, UVLAN_UNREG_MCAST_FLOOD_MASK, UVLAN_REG_MCAST_FLOOD_MASK and UVLAN_FORCE_UNTAGGED_EGRESS are set in the [Section 12.2.2.3.6.1.17.1 Ingress Filtering Process](#), based on VLAN_Unaware, Unknown_VLAN rules and VLAN table entries.

12.2.2.3.6.1.17.3 Egress Process

Condition and action
Clear Rx port from portmask (don't send packet to Rx port).
Clear disabled ports from portmask.
if ((ENABLE_OUI_DENY) and (OUI source address not found) and (not ALE BYPASS) and (not error packet) and ((not mcast destination address) and (SUPER)))
then Clear host port from portmask
if ((not ENABLE_OUI_DENY) and (OUI source address found) and (not ALE BYPASS) and (not error packet) and not ((mcast destination address) and (SUPER)))
then Clear host port from portmask
if ((ENABLE_RATE_LIMIT) and (BCAST_MCAST_CTL))
then if (not SUPER) and (rate limit exceeded on any tx port)
then clear rate limited tx port from portmask
If address not found then SUPER cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

12.2.2.3.6.1.17.4 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

12.2.2.3.6.1.17.4.1 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

Condition and action
If (directed) then do not learn, update, or set touched else continue
If (not (Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_LEARN))
then do not learn address

if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not learn address
if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not learn address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address found) and (receive port_number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address else continue
if ((source address found) and (receive port number != PORT_NUMBER)) then update address else continue
if ((source address not found) and (VLAN_AWARE) and not (LEARN_NO_VLANID)) then learn address with VLAN
if ((source address not found) and ((not VLAN_AWARE) or (VLAN_AWARE and LEARN_NO_VLANID))) then learn address without VLAN

12.2.2.3.6.1.17.4.2 Updating Process

Condition and action
if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_SA_UPDATE)) then do not update address
if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not update address
if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not update address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER)) then update address

12.2.2.3.6.1.17.4.3 Touching Process

if ((source address found) and (ageable) and (not touched)) then set touched

12.2.2.3.6.1.18 VLAN Aware Mode

The CPSW is in VLAN aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL_REG register.

In VLAN aware mode, transmitted packet data is changed depending on the packet type (PKT_TYPE), packet priority (PKT_PRI), and VLAN information.

The VLAN_LTYPE_SEL value is selected by the S_CN_SWITCH bit in the CPSW_CONTROL_REG register and is either the VLAN_LTYPE_INNER (8100h default) or VLAN_LTYPE_OUTER (88A8h default) value.

12.2.2.3.6.1.19 VLAN Unaware Mode

An egress port is operating in the VLAN unaware mode when the VLAN_AWARE bit in the CPSW_CONTROL_REG register is cleared to 0h. In VLAN unaware mode, transmit (egress) packets are not modified on egress.

12.2.2.3.6.2 Packet Priority Handling

Packets are received on 9 ports, eight Ethernet ports and one CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN_LTYPE_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP_IPV4_EN is set in CPSW_P0_CONTROL_REG or CPSW_PN_CONTROL_REG_k, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP_IPV6_EN is set in CPSW_P0_CONTROL_REG or CPSW_PN_CONTROL_REG_k, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority.

The received packet priority is mapped through the receive ports associated packet-priority-to-header-packet-priority-mapping register (CPSW_PN_RX_PRI_MAP_REG_k) to obtain the header packet priority. The header packet priority is the hardware switch priority. The header packet priority is also used as the actual transmit packet priority if the VLAN information is to be sent on egress.

The header packet priority is mapped at each destination FIFO through the CPSW_PN_RX_PRI_MAP_REG_k register (header priority to switch priority mapping register) to obtain the hardware switch priority (hardware queue 0 through 7).

12.2.2.3.6.2.1 Priority Mapping and Transmit VLAN Priority

There are three priorities that are used inside the Gigabit Ethernet Switch: **packet priority**, **header packet priority**, and **switch priority**. The **header packet priority** is used as the outgoing VLAN priority if the packet is egressing from the switch with a VLAN tag. The **switch priority** determines which of the 8 FIFO priority queues the packet uses during egress.

[Figure 12-93](#) below, as well as the corresponding explanation that follows, explains each of the priorities, how they are determined, and how they are used. A number in parentheses in the figure indicates a process (Ethernet port ingress, host port egress, etc.). Each bullet in the text following the diagram explains one of the 5 processes pointed out in the figure.

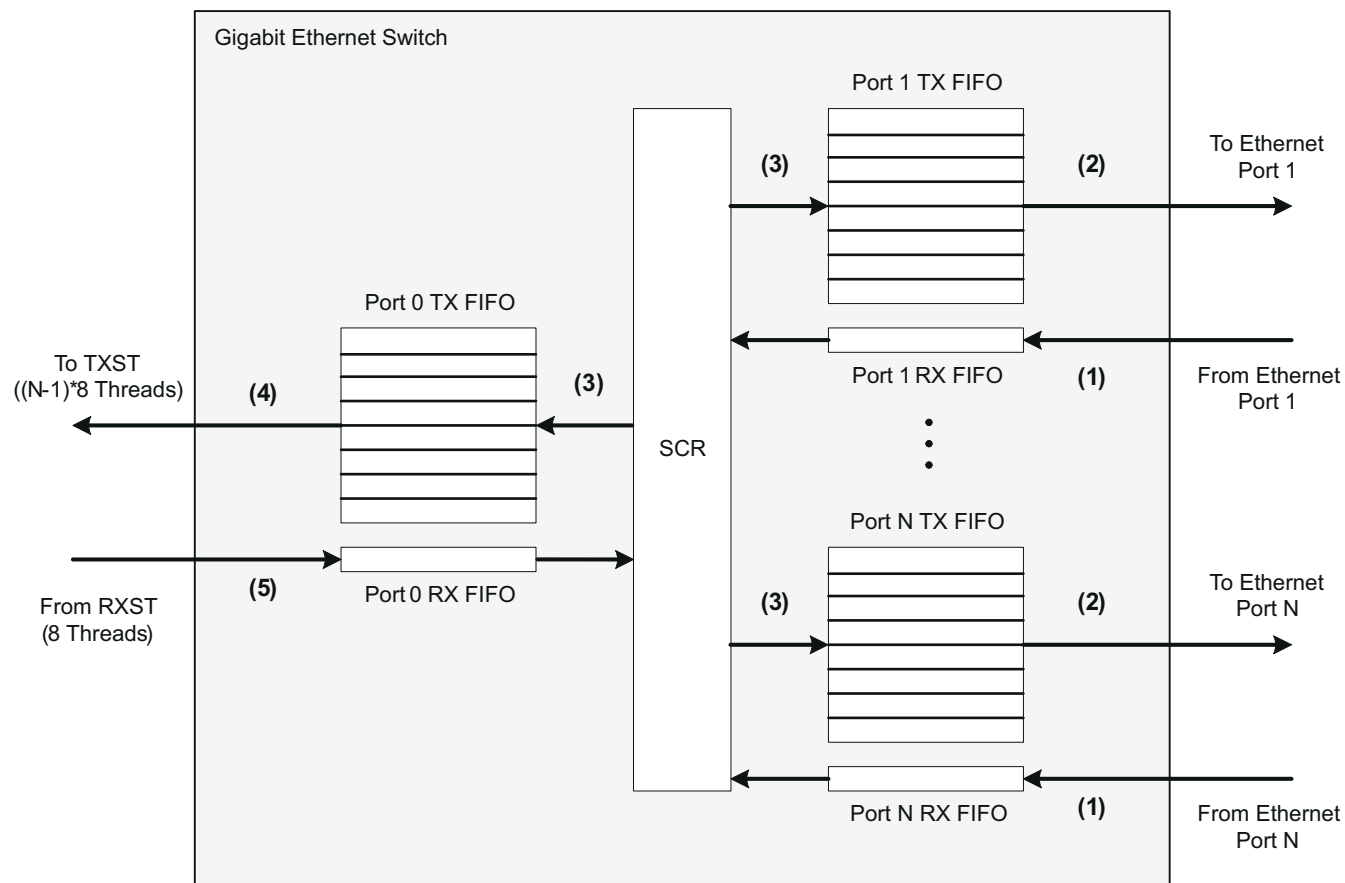

Figure 12-93. Gigabit Ethernet Switch Priority Mapping and Transmit VLAN Processing

From [Figure 12-93](#) above:

- (1) is the ingress process that occurs at the external Ethernet ports
 - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the ingress port's priority. This **packet priority** is then mapped to a **header packet priority** using the CPSW_PN_RX_PRI_MAP_REG_k register where N is the port where the packet entered the switch. This process is explained in further detail in [Section 12.2.2.3.6.2](#).
- (2) is the egress process that occurs at the external Ethernet ports
 - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1) or (5). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.2.3.6.4.1](#).
- (3) is the process by which it is decided which priority TX queue to place the packet on in the Port N TX FIFO during egress
 - Each Port's TX FIFO has 8 queues that each correspond to a priority that is used when determining which packet will egress from the switch next at that port. The **header packet priority** (Ethernet port ingress, process (1)) or the receive packet thread (host port 0 ingress, process (5)) gets mapped through the CPSW_PN_RX_PRI_MAP_REG_k register (where N is the egress port number) to determine the **switch priority** of the packet. The **switch priority** determines which TX FIFO queue to place the packet in. The FIFO architecture is described in [Section 12.2.2.3.6.10.11](#). The header packet priority to switch priority mapping is discussed in [Section 12.2.2.3.6.2](#).
- (4) is the egress process that occurs at Host Port 0 toward the transmit streaming interface (TXST)
 - The TXST has 8 egress threads for each external Ethernet port (32 threads in a 5-port switch and 64 threads in a 9-port switch). The TX thread that is selected for a packet is determined by the Ethernet port of ingress and the **switch priority** of the packet that was determined in process (3).
 - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.2.3.6.4.1](#).
- (5) is the ingress process that occurs at Host Port 0
 - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the host port's priority. This packet priority is then mapped to a **header packet priority** using the CPSW_PN_RX_PRI_MAP_REG_k register.
 - Host port 0 also has a received packet thread. The receive packet thread is based on either the packet's VLAN priority, IPv4 or IPv6 DSCP value, or the streaming interface (RXST) thread that the packet entered host port 0 on.

12.2.2.3.6.3 CPPI Port Ingress

Packets received on the CPPI host port have a received packet priority (0 to 7 with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN_LTYPE_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP_IPV4_EN is set in CPSW_P0_CONTROL_REG or CPSW_PN_CONTROL_REG_k register, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP_IPV6_EN is set in CPSW_P0_CONTROL_REG or CPSW_PN_CONTROL_REG_k register, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority

The CPPI Port (port 0) also has a received packet thread. The received packet thread is determined exactly as the received packet priority except for untagged packets. For untagged packets, the received packet thread is the packet streaming interface thread that the packet was received on (instead of the port VLAN priority or DSCP

priority). The received packet thread is the hardware switch priority. The received packet thread only determines which hardware switch priority the packet should be sent to, the egress VLAN rules are identical to packets that were received on Ethernet ports (as determined by the header packet priority).

For CPPI ingress packets, the destination port hardware switch priority is the below selected value remapped through CPSW_PN_RX_PRI_MAP_REG_k:

1. If the ingress packet is priority tagged or vlan tagged:
 - If RX_REMAP_VLAN in CPSW_P0_CONTROL_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
 - If RX_REMAP_VLAN in CPSW_P0_CONTROL_REG register is set then the destination hardware switch priority is the packet priority value. Port transmit remapping (CPSW_PN_RX_PRI_MAP_REG_k should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
2. Else if the ingress packet has the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP_IPV4_EN is set in CPSW_P0_CONTROL_REG register:
 - If RX_REMAP_DSCP_V4 bit in CPSW_P0_CONTROL_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
 - If RX_REMAP_DSCP_V4 bit in CPSW_P0_CONTROL_REG register is set then the destination hardware switch priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPv4 packet). Port 1 transmit remapping (CPSW_PN_RX_PRI_MAP_REG_k should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
3. Else if the ingress packet has the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP_IPV6_EN is set in CPSW_P0_CONTROL_REG register:
 - If RX_REMAP_DSCP_V6 bit in CPSW_P0_CONTROL_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
 - If RX_REMAP_DSCP_V6 bit in CPSW_P0_CONTROL_REG register is set then the destination hardware switch priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet). Port 1 transmit remapping (CPSW_PN_RX_PRI_MAP_REG_k should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
4. Else the ingress packet is non-tagged and the destination hardware switch priority is the CPPI receive thread number.

12.2.2.3.6.4 Packet CRC Handling

The P0_TX_CRC_REMOVE bit in the CPSW_CONTROL_REG register determines if host port egress packets have CRC included or not. If P0_TX_CRC_REMOVE is set to 1h then all packets that are transmitted from port 0 do not contain CRC. If P0_TX_CRC_REMOVE bit is cleared to 0h then all packets that are transmitted from port 0 contain CRC. The CRC type, if present, is determined by the CRC_TYPE bit in the CPSW_PN_MAC_CONTROL_REG_k register. If the CRC_TYPE bit is cleared to 0h then the CRC present in each packet after host port egress is Ethernet CRC. If the CRC_TYPE bit is set to 1h then the CRC present in each packet after host port egress is Castagnoli CRC.

Note

The CRC type present in the packet after host port egress is determined solely by the CRC_TYPE bit in the CPSW_PN_MAC_CONTROL_REG_k register regardless of the CRC type present in the packet during Ethernet port ingress.

12.2.2.3.6.4.1 Transmit VLAN Processing

Transmit packets are NOT modified during switch egress when the VLAN_AWARE bit in the CPSW_CONTROL_REG register is cleared to 0h. This means that the switch is not in VLAN-aware mode.

The next three sections cover transmit processing when the switch is in VLAN-aware mode for different packet types. The Gigabit Ethernet switch is in VLAN-aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL_REG register. While in VLAN-aware mode, VLAN is added, removed, or replaced according

to the type of packet as well as the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the packet header as explained below.

12.2.2.3.6.4.1.1 Untagged Packets (No VLAN or Priority Tag Header)

Untagged packets are all packets that are not a VLAN packet or a priority tagged packet. According to the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the packet header the packet may exit the switch with a VLAN tag inserted or the packet may leave the switch unchanged. The two cases are discussed below.

- Insert VLAN Case:

Untagged input packets have the header packet VLAN inserted when the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the transmit packet header is de-asserted. For untagged packets, the VLAN EtherType = 0x8100 is inserted after the source address followed by the two byte header packet VLAN. The header packet VLAN is composed of the header packet priority along with the PORT_CFI and PORT_VID values from the CPSW_PN_PORT_VLAN_REG_k register (where N is the port that the untagged packet entered the switch) through. The packet length/type field is output four bytes later than it is input and is not removed or replaced. If the CRC is present in the packet data (PASS_CRC is asserted), then the packet CRC is replaced with a hardware generated CRC.

- No Change Case:

Untagged input packets are output unchanged when the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS transmit packet header bit is asserted.

12.2.2.3.6.4.1.2 Priority Tagged Packets (VLAN VID == 0 && EN_VID0_MODE == 0h)

Priority tagged packets are packets that contain a VLAN header with VID = 0. According to the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the packet header, priority tagged packets may exit the switch with their VLAN ID and priority replaced or they may have their priority tag completely removed. The two cases are discussed below.

Note

In order for a priority tagged packet to fall into this category the ENABLE_VID0_MODE bit in the CPSW_ALE_CONTROL register must also be set to 0h. If the ENABLE_VID0_MODE bit in the CPSW_ALE_CONTROL register is set to 1h, then packets with a VLAN VID of 0 will fall into the VLAN Tagged Packets category in [Section 12.2.2.3.6.4.1.3](#) below.

- Replace Priority and VLAN ID Case:

Priority tagged input packets have the packet VLAN ID and the packet priority replaced with the header packet VLAN ID and the header packet priority when the transmit packet header CPSW_FORCE_UNTAGGED_EGRESS_REG[1-0] MASK bit is de-asserted. The header packet VLAN ID comes from the PORT_VID bits in the CPSW_PN_PORT_VLAN_REG_k register (where N is the port where the packet entered the switch). The header packet priority is based on the packet priority to header packet priority mapping in the CPSW_PN_RX_PRI_MAP_REG_k register (where N is the port where the packet entered the switch).

- Remove VLAN Header Case:

Priority tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority-tagged packets use all four input CRC bytes as pad, input 65-byte priority-tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS_CRC input bit is not asserted - input 64-67 byte (on the wire) priority-tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

12.2.2.3.6.4.1.3 VLAN Tagged Packets (VLAN VID != 0 || (EN_VID0_MODE == 1h && VLAN VID == 0))

VLAN tagged packets are packets that contain a VLAN header specifying the VLAN the packet belongs to (VID), the packet priority (PRI), and the drop eligibility indicator (CFI). According to the CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit in the packet header, VLAN tagged packets may exit the switch with their VLAN priority replaced or they may have their VLAN header completely removed. The two cases are discussed below.

- Replace Priority Case:

VLAN tagged input packets are output with the packet priority replaced with the header packet priority when the transmit packet header CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit is deasserted. The header packet priority is based on the packet priority to header packet priority mapping in the CPSW_PN_RX_PRI_MAP_REG_k register (where N is the port where the packet entered the switch). If the CRC is present in the packet data (PASS_CRC is asserted), then the packet CRC is replaced with a generated CRC.

- Remove VLAN Header Case:

VLAN tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW_ALE_UVLAN_UNTAG[1-0] UVLAN_FORCE_UNTAGGED_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority tagged packets use all four input CRC bytes as pad, input 65-byte priority tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS_CRC input bit is not asserted - input 64-67 byte (on the wire) priority tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

12.2.2.3.6.4.2 Ethernet Port Ingress Packet CRC

All Ethernet ports check the ingress packet CRC in all modes/speeds. The receive port can check either Ethernet CRC or Castagnoli CRC as determined by the CRC_TYPE bit in the CPSW_PN_MAC_CONTROL_REG_k register.

12.2.2.3.6.4.3 Ethernet Port Egress Packet CRC

Ethernet ports transmit each egress packet with the CRC selected by the CRC_TYPE bit in the CPSW_PN_MAC_CONTROL_REG_k register, regardless of the type of CRC that the packet had on ingress to the switch. At the egress port after passing through the switch, the packet CRC is checked for correctness and if the CRC is correct then the packet is output with the generated selected output CRC. If the packet CRC is incorrect, due either to a bit flip in a memory or an error CRC passed in on host ingress, then the generated egress CRC type is used with at least a single byte of the CRC inverted to indicate the error. If the packet length including CRC is divisible by 4 then all 4 CRC bytes will be inverted on error. If there are three bytes remainder after dividing the packet length by 4 then three bytes will be inverted (and so on down to one byte remainder).

12.2.2.3.6.4.4 CPPI Port Ingress Packet CRC

CPPI port ingress packets can be passed in with or without a CRC. The host port is Ethernet CRC only. CPPI ingress packets are not checked for CRC correctness on CPPI ingress, however they are checked for correctness on Ethernet egress and are output with a CRC error if they came in with a CRC error. If a CPPI ingress packet does not have the INFO0 PASSED_CRC bit set then a CRC will be generated for the packet on CPPI ingress. If the PASSED_CRC bit is set then the packet is received and forwarded unchanged. The CRC type is input in the INFO0 word CRC_TYPE bit and must be Ethernet CRC.

12.2.2.3.6.4.5 CPPI Port Egress Packet CRC

The P0_TX_CRC_REMOVE bit in the CPSW_CONTROL_REG register determines if CPPI egress packet have an Ethernet CRC included or not.

12.2.2.3.6.5 FIFO Memory Control

Each of the two CPSW_9G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each FIFO memory

contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX_MAX_BLKs field in the FIFOs associated CPSW_PN_MAX_BLKs_REG register determines the maximum number of 1k FIFO memory blocks to be allocated to the eight logical transmit queues (transmit total). The RX_MAX_BLKs field in the FIFOs associated CPSW_PN_MAX_BLKs_REG register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX_MAX_BLKs value plus the RX_MAX_BLKs value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports is Port1.

Each transmit FIFO contains a configurable number of blocks (20 max) that are either 1k or 4k byte blocks that can be allocated to any priority.

12.2.2.3.6.6 FIFO Transmit Queue Control

There are eight transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPPI receive (also switch egress). The CPPI nomenclature is reversed from the Ethernet port nomenclature due to legacy reasons.

12.2.2.3.6.6.1 CPPI Port Receive Rate Limiting

Port 0 receive operations can be configured to rate limit the host ingress data for each receive thread (priority). CPPI Receive has 8 threads for QOS. There is a committed information rate (CPSW_P0_PRI_CIR_REG_y, where y = 0 to 7) and an excess information rate for each thread (CPSW_P0_PRI_EIR_REG_y, where y = 0 to 7). Rate limiting is enabled for a thread when the committed information rate for the thread is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited threads does impact the excess information rates. No bulk thread will be enabled to send unless there are CPSW_PN_PRI_CTL_REG_k[15-12] TX_HOST_BLKs_REM number of unused blocks remaining in each of the Ethernet port transmit FIFOs. The "blocks remaining check" ensures that bulk traffic from the host will not block rate-limited traffic from the host. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then threads 7 and 6 should be configured for committed information (and excess information if desired). When any channels are configured to be rate-limited, the priority type must be fixed for receive. Round-robin priority type is not allowed when rate-limiting is configured for any thread. The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to receive is controlled by the below equation. If the configured excess information rate is zero, then only the committed information rate is transferred:

Priority Transfer rate [Mbit/s] = (((Frequency in MHZ) * CPSW_P0_PRI_CIR_REG_y) / 32768) + (((Frequency in MHZ) * CPSW_P0_PRI_EIR_REG_y) / 32768))

Where the *frequency* is the CPPI_ICLK frequency (in MHz) and priority 0 to 7.

For example, 10Mbps on priority 7 would give the below:

10Mbps = ~ ((350 * 936) / 32768), at 350Mhz and CPSW_P0_PRI_CIR_REG_y[27-0] PRI_CIR value = 936 (no excess information rate)

12.2.2.3.6.6.2 Ethernet Port Transmit Rate Limiting

Ethernet port transmit operations can be configured to rate limit egress data for each egress priority. There is a committed information rate (CPSW_P0_PRI_CIR_REG_y, where y = 0 to 7) and an excess information rate for each priority (CPSW_P0_PRI_EIR_REG_y, where y = 0 to 7). Rate limiting is enabled for a priority when the committed information rate for the priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured

non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited threads does impact the excess information rates. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to send is controlled by the below equation. If the excess information rate is disabled then the committed information rate only is transferred:

$$\text{Priority Transfer rate [Mbit/s]} = (((\text{Frequency in MHz}) * \text{CPSW_P0_PRI_CIR_REG_y}) / 32768) + (((\text{Frequency in MHz}) * \text{CPSW_P0_PRI_EIR_REG_y}) / 32768))$$

Where the *frequency* is the CPPI_ICLK frequency (in MHz) and priority 0 to 7.

12.2.2.3.6.7 Interspersed Express Traffic (IET – P802.3br/D2.0)

When IET is enabled through CPSW_CONTROL_REG[17] IET_ENABLE = 1h and configured, IET allows preemptable traffic on selected transmit priorities to be preempted by express traffic on selected express priorities. Received traffic is separated onto express and preempt receive queues. When IET is disabled (IET_ENABLE = 0h), all Ethernet traffic is express traffic and switch operation is as if IET does not exist. Traffic is only intended to be moved to the preempt queue after preemption is verified and enabled.

12.2.2.3.6.7.1 IET Configuration

- Using the preempt receive queue requires more blocks to be allocated to the ports receive FIFO. Write a value of decimal 7 to the CPSW_PN_MAX_BLKES_REG[7-0] RX_MAX_BLKES bit field, and a value of decimal 13 to the CPSW_PN_MAX_BLKES_REG[15-8] TX_MAX_BLKES register for every port to be enabled for IET.
- Write the [23-0]MAC_VERIFY_CNT bit field in the Ethernet port CPSW_PN_IET_VERIFY_REG_k register to set the verify/response timeout count. The default is 10ms for Gigabit mode. For other time values or link speeds the verify count should be updated. If CPSW_PN_IET_CONTROL_REG_k[2] MAC_DISABLEVERIFY bit is to be set (this is forced mode) then this step is unneeded.
- The receive FIFO block allocation is insufficient if CPSW_STAT_RX_BOTTOM_OF_FIFO_DROP_k[31-0] COUNT is nonzero, indicating that receive packets are being dropped due to FIFO block allocation.
- Write the CPSW_PN_IET_CONTROL_REG_k register in the Ethernet port as below:
 - Set the CPSW_PN_CONTROL_REG_k[16] IET_PORT_EN bit. The port will not actually be enabled until bit IET_ENABLE is set in the CPSW_CONTROL_REG.
 - The CPSW_PN_IET_CONTROL_REG_k[0] MAC_PENABLE bit can be set as desired. No effect will occur until IET_ENABLE is set. This bit enables preemptable packets to be preempted by express traffic but does not preclude packets from being sent to the preempt queue.
 - If verify/response is desired then CPSW_PN_IET_CONTROL_REG_k[3] MAC_LINKFAIL should be cleared by software to enable verify and response packets. Otherwise, MAC_DISABLEVERIFY bit should be set for forced mode. Verification and response will occur immediately after clearing this bit.
 - Configure the remaining CPSW_PN_IET_CONTROL_REG_k register bits as desired.
- Set the IET_ENABLE bit in the CPSW_CONTROL_REG register to enable IET operations.
- After preemption has been verified, the CPSW_PN_IET_CONTROL_REG_k[23-16] MAC_PREMPT field is written to configure the FIFO priorities to be sent to the preempt queue (the other priorities with cleared bits go to the express queue). The hardware switch for each queue from express to preempt happens only when there are no packets queued on the priority.

12.2.2.3.6.8 Enhanced Scheduled Traffic (EST – P802.1Qbv/D2.2)

12.2.2.3.6.8.1 Enhanced Scheduled Traffic Overview

- When enabled and configured, EST allows express queue traffic to be scheduled (placed) on the wire at specific repeatable time intervals.
- EST operates on a repeating time interval generated by the CPTS EST function generator. For example, a 125us repeating time interval can be configured.
- Each Ethernet port has 128 EST fetch commands maximum in the global EST fetch RAM.
- Each 22-bit fetch command consists of a 14-bit fetch count (14 MSB's) and an 8-bit priority fetch allow (8 LSB's) that will be applied for the fetch count time in wireside clocks.

- The configured port fetch commands are executed in sequence, beginning at port address zero each time through the time interval beginning at cycle start.
- EST allows non-scheduled express and preempt queue traffic to be cleared from the wire to ensure that the scheduled traffic is transmitted at the proper time (zero allow).
- EST can be used with or without preemption. The CPSW_PN_IET_CONTROL_REG_k[23-16] MAC_PREMPT value determines whether the priority is enabled on the express or preempt queue. Whether a priority is on the express or preempt queue only effects the wire clear time from an EST operation perspective.
- Software should not move priorities to the preempt queue unless preemption is configured, enabled, and verified allowing preemption to occur.
- Express packet time stamp events can be enabled to assist software in configuring and timing EST operations.

12.2.2.3.6.8.2 Enhanced Scheduled Traffic Fetch RAM

- The EST fetch RAM is read/writable in the CPSW configuration address space.
- Each Ethernet transmit port has 128 locations in the global EST fetch RAM.
 - Ethernet port 1 has EST fetch RAM addresses 0x080-0x0FF, and so on.
- **One buffer operation:** When CPSW_PN_EST_CONTROL_REG_k[0] EST_ONEBUF is set to 1h, the 128 port locations operate as one buffer. The EST_BUFFACT bit in CPSW_PN_FIFO_STATUS_REG_k register is the upper address bit of the port's fetch RAM address indicating whether operation is currently in the upper or lower 64 locations of the port's fetch RAM.
- **Two buffer operation:** When CPSW_PN_EST_CONTROL_REG_k[0] EST_ONEBUF is cleared there are two 64-location buffers with CPSW_PN_EST_CONTROL_REG_k[1] EST_BUFSEL selecting the buffer to be used. When the buffer is switched by changing the CPSW_PN_EST_CONTROL_REG_k[1] EST_BUFSEL value, the actual switch occurs on cycle start. The actual buffer being used is indicated by the EST_BUFFACT bit in CPSW_PN_FIFO_STATUS_REG_k. Software should avoid writing the switched out buffer fetch RAM locations until it detects that the actual switch has occurred.
- The first address location in the port's fetch RAM space (location zero) is read at the beginning of each EST time interval (cycle start). Addresses are then read in ascending order for the duration of the interval. The port address zero is then read again at the beginning of the next cycle repeating the time interval packet operations.

12.2.2.3.6.8.3 Enhanced Scheduled Traffic Time Interval

- Each Ethernet port has an Enhanced Scheduled Traffic Function (ESTF) generator in the CPTS submodule.
- The EST function generator generates the EST time interval as a configured number of CPTS reference clocks (CPTS_RFT_CLK).
- The EST function generator rising edge is the cycle start time and the cycle repeats (cycle start occurs) after every time interval.
- The first fetch allowed value is at the port base address zero in the EST fetch RAM and is actually applied 16 wireside clocks after cycle start. The 16 clock cycle delay allows the first fetch value time to be fetched from the EST fetch RAM (prefetch time at cycle start).
- Each successive fetch allow is applied for the associated fetch count thereafter. The minimum non-zero fetch count is 16. The minimum value of 16 guarantees that the next fetch value has time to be fetched before the current fetch count is over. There are 64 maximum fetch values when CPSW_PN_EST_CONTROL_REG_k[0] EST_ONEBUF = 0h, and 128 maximum fetch values when CPSW_PN_EST_CONTROL_REG_k[0] EST_ONEBUF = 1h.
- The next cycle start then causes the fetch to once again start at the port address zero.

12.2.2.3.6.8.4 Enhanced Scheduled Traffic Fetch Values

- The 22-bit fetch value is made up of the 14-bit fetch count and the 8-bit fetch allow.
- The fetch time indicates the number of wireside clocks that the fetch allow will be active.
- The fetch count is in Ethernet wireside clocks which is bytes in Gigabit mode (CPSW_PN_MAC_CONTROL_REG_k[7] GIG = 1h) and nibbles in 10/100Mbps mode.
- When a fetch allow bit is set, the corresponding priority is enabled to begin packet transmission on an allowed priority subject to rate limiting. The actual packet transmission on the wire may carry over into the next fetch count and is the reason for the wire clear time in the fetch zero allow.

- When a fetch allow bit is cleared, the corresponding priority is not enabled to transmit for the fetch count time.
- A non-zero fetch allow value with a non-zero fetch count causes the fetch allow value to be applied for the fetch count number of wireside clocks.
- A zero fetch count causes the associated fetch allow to be held for the duration of the cycle (until the next cycle start).
- A zero fetch allow with a non-zero fetch count is intended to clear the wire for a scheduled (timed) express packet in the next fetch. A zero fetch allow indicates that no packet can be started for transmission for the associated fetch count. The associated fetch count must be sufficient to guarantee that the wire is cleared given that a packet on an allowed priority in the previous fetch could have been started on the previous clock and that there is hardware latency in the clear time. The timed packet should be sent on a priority that is enabled in the next fetch but disabled in the current zero allow fetch. The fetch allow previous to a zero allow should have only preempt priorities enabled or only express priorities enabled but not both.
- The number of clocks required to clear the wire varies depending Ethernet wire speed and on whether express or preempt priorities were allowed in the previous fetch command.

12.2.2.3.6.8.5 Enhanced Scheduled Traffic Packet Fill

Packet fill can be enabled (CPSW_PN_EST_CONTROL_REG_k[8] EST_FILL_EN = 1h) to occur in the fetch count time associated with a fetched zero allow. The intention with fill is that a smaller packet on a non-timed priority might be able to be inserted on the wire during the wire clear time which would increase wire utilization. Fill is intended to be used with either only express priorities in the previous non-zero fetched allow, or only preempt priorities in the previous non-zero fetched allow but not both. Fill must be configured to ensure that any fill packet does not conflict with the timed express packet allowed in the next fetch.

- **Express fill:**

1. CPSW_PN_EST_CONTROL_REG_k[8] EST_FILL_EN is set and
2. A fetch contains a non-zero fetch count with a zero fetch allow, and
3. The previous allow contained only express priorities.
4. The fetch count loaded should be at least TBD clocks and the CPSW_PN_EST_CONTROL_REG_k[25-16] EST_FILL_MARGIN should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
5. The fetch count loaded should be at least TBD clocks and the CPSW_PN_EST_CONTROL_REG_k[25-16] EST_FILL_MARGIN should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

- **Preempt fill:**

1. CPSW_PN_EST_CONTROL_REG_k[8] EST_FILL_EN is set and
2. A fetch contains a non-zero fetch count with a zero fetch allow, and
3. The previous allow contained only preempt priorities
4. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
5. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

- **Express non-fill:**

1. CPSW_PN_EST_CONTROL_REG_k[8] EST_FILL_EN is clear and
2. The previous allow contained only express priorities.
3. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
4. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

- **Preempt non-fill:**

1. CPSW_PN_EST_CONTROL_REG_k[8] EST_FILL_EN is clear and
2. The previous allow contained only preempt priorities.
3. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
4. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

12.2.2.3.6.8.6 Enhanced Scheduled Traffic Time Stamp

The EST can be configured to generate CPTS timestamp events for selected express traffic. The EST timestamp events use the CPTS host event type (CPSW_CPTS_EVENT_1_REG[23-20] EVENT_TYPE = 7 decimal). The EST timestamps will not override host sent timestamps for packets that were sent from the host with an enabled host timestamp.

- EST Events (host events) contain the below information:
 - Time Stamp of the selected express packet.
 - The event CPSW_CPTS_EVENT_1_REG[28-24] PORT_NUMBER indicates the transmit port number.
 - The event CPSW_CPTS_EVENT_1_REG[23-20] EVENT_TYPE is decimal 7 (host event).
 - The event CPSW_CPTS_EVENT_1_REG[23-20] MESSAGE_TYPE indicates the packet transmit hardware switch priority.
 - The event CPSW_CPTS_EVENT_1_REG[15-0] SEQUENCE_ID upper nibble indicates the packet receive port number.
 - The event CPSW_CPTS_EVENT_1_REG[15-0] SEQUENCE_ID lower byte indicates the sequence number of the express packet in numerical order. The first event is event one, the second is event two and so on. The sequence ID rolls over to zero after 0xFF (8-bits).
 - The event domain is the value from the CPSW_EST_TS_DOMAIN_REG[7-0] EST_TS_DOMAIN register.
- When CPSW_PN_EST_CONTROL_REG_k[2] EST_TS_EN is set, timestamp events will be generated on selected express traffic.
- When CPSW_PN_EST_CONTROL_REG_k[3] EST_TS_FIRST is also set, events will be generated only on the first express packet in each time interval. If CPSW_PN_EST_CONTROL_REG_k[4] EST_TS_ONEPRI is also set then the event will only be on the first CPSW_PN_EST_CONTROL_REG_k[7-5] EST_TS_PRI express packet in the time interval. If CPSW_PN_EST_CONTROL_REG_k[4] EST_TS_ONEPRI is clear then the event will be generated on the first express packet in the time interval on any priority.
- When CPSW_PN_EST_CONTROL_REG_k[3] EST_TS_FIRST is clear, events will be generated on every express packet. If CPSW_PN_EST_CONTROL_REG_k[4] EST_TS_ONEPRI is set then the event will be generated on every CPSW_PN_EST_CONTROL_REG_k[7-5] EST_TS_PRI express packet. If CPSW_PN_EST_CONTROL_REG_k[4] EST_TS_ONEPRI is clear then event will be generated on every express packet on any priority.

12.2.2.3.6.9 Audio Video Bridging

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks*". a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams*."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)*."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

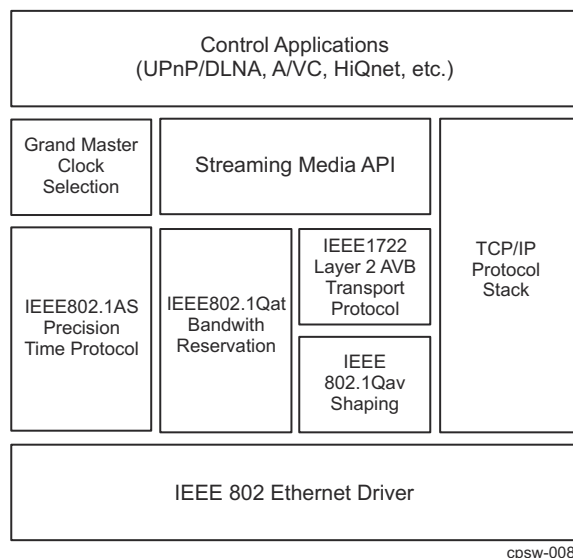

Figure 12-94. The Network Static with AVB

The following sections describe the media transport protocols that work within the AVB framework.

12.2.2.3.6.9.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))

The protocol defined by 802.1AS automatically selects a device to be the master clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

Note

The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

Based on IEEE 1588:2002, PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock master selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2-in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock master, the Best Master Clock Algorithm (BMCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandmaster. Once a Grandmaster has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Slave nodes compare the value of their RTC against the PTP Grandmaster and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1-μs accuracy over seven network hops.

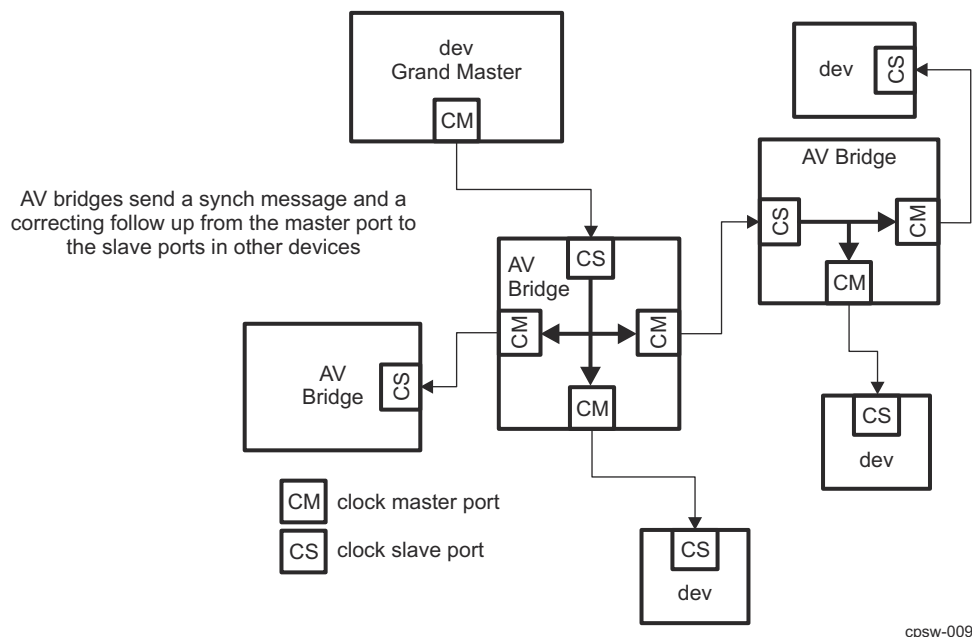

Figure 12-95. AVB Network & PTP Clock Entities

The media transport protocols that work within the AVB framework are:

12.2.2.3.6.9.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in Figure 12-96 and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

IEEE 1722 Packet Construction

Figure 12-96. IEEE 1722 Packets

1722 or AVBTP Presentation Time and Synchronization:

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

12.2.2.3.6.9.1.1 Cross-timestamping and Presentation Timestamps

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandmaster. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. Figure 12-97 illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

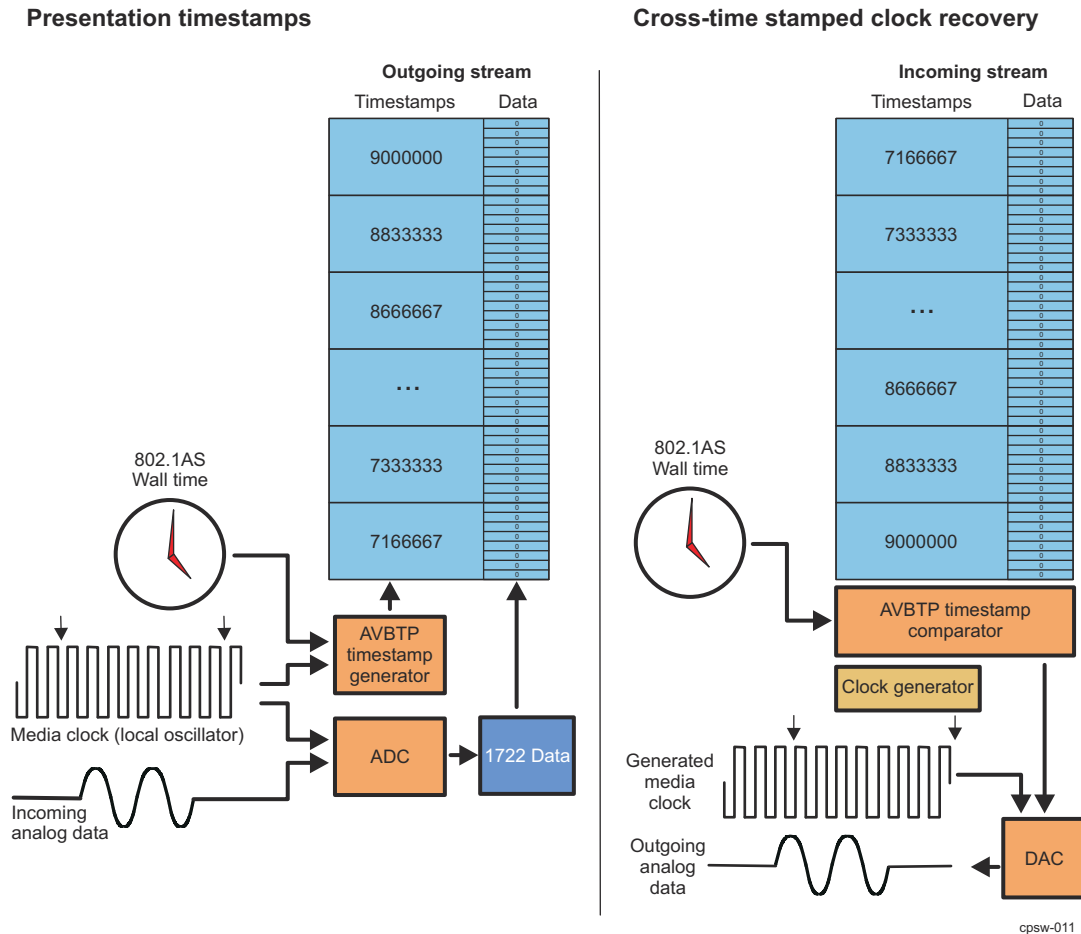

Figure 12-97. Cross Time Stamping and Presentation Timestamps

12.2.2.3.6.9.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/Video Bridging (AVB) protocols.

12.2.2.3.6.9.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
 - Receive policing
 - Transmit rate control.

End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like [Figure 12-98](#).

Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

cpsw-012

Figure 12-98. AV Stream Queuing/Policing

12.2.2.3.6.9.2.1 Configuring the Device for 802.1Qav Operation

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW_9G that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
 - CPPI TX and RX descriptors
 - VLAN and Priority tags

Table 12-162. Example of TX Configuration

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

Table 12-163. Example of RX Configuration

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
 - ALE in VLAN-ware mode, Non-ALE in bypass mode.

12.2.2.3.6.10 Ethernet MAC Sliver

The Ethernet port peripheral is compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation
- RMII/RGMII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control
- Programmable Inter Packet Gap (IPG).

12.2.2.3.6.10.1 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS_CRC bit is 0h. For the Ethernet port generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS_CRC bit is set.

12.2.2.3.6.10.2 MTXER

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

12.2.2.3.6.10.3 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX_PACE bit in the CPSW_PN_MAC_CONTROL_REG_k register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

12.2.2.3.6.10.4 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96-bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRC is de-asserted within approximately 48-bit times of MTXEN being de-asserted, then 96-bit times is measured from MTXEN. If the frame suffered a collision, or if MCRC is not de-asserted until more than approximately 48-bit times after MTXEN is de-asserted, then 96-bit times (approximately, but not less) is measured from MCRC.

The Ethernet port transmit inter-packet gap (IPG) may be shortened by eight bit times when short gap is enabled and triggered. Setting the [10] TX_SHORT_GAP_ENABLE bit in the CPSW_PN_MAC_CONTROL_REG_k register enables the gap to be shortened when triggered. The condition is triggered when the ports associated transmit packet FIFO has a user defined number of FIFO blocks used. The associated transmit FIFO blocks used value determines if the gap is shortened, and so on. The CPSW_GAP_THRESH_REG register value determines the short gap threshold. If the FIFO blocks used is greater than or equal to the GAP_THRESH value then short gap is triggered.

12.2.2.3.6.10.5 Back Off

The Gigabit Ethernet Mac Sliver implements the 802.3 binary exponential back-off algorithm.

12.2.2.3.6.10.6 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the CPSW_PN_MAC_CONTROL_REG_k register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

12.2.2.3.6.10.7 Speed, Duplex and Pause Frame Support Negotiation

The Ethernet port can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

12.2.2.3.6.10.8 RMII Interface

The CPRMII peripheral is compliant to the RMII specification document.

12.2.2.3.6.10.8.1 Features

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

12.2.2.3.6.10.8.2 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMII_RXER on any di-bit in the received packet will cause an MII_RXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMII_CRS_DV toggle will issue an MII_RXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMII_CRS_DV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

12.2.2.3.6.10.8.3 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the CPGMAC MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The CPGMAC does not source the transmit error (MII_TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMII_TXD[1:0] for each clock that RMII_TXEN is de-asserted.

12.2.2.3.6.10.9 RGMII Interface

The CPRGMII peripheral is compliant to the RGMII specification document.

12.2.2.3.6.10.9.1 Features

- Supports 1000/100/10 Mbps speed
- Full and Half Duplex support (CPGMAC supports only Full duplex in Gigabit mode).
- MII mode support
- Energy Efficient Ethernet Support

12.2.2.3.6.10.9.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

12.2.2.3.6.10.9.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the RGMII_RX_INBAND input is asserted. RGMII_RX_INPUT is asserted by configuring the CTL_EN bit to 1h of the CPSW_PN_MAC_CONTROL_REG_k register. The link status, duplexity, and speed are determined from the RGMII input data stream RXD[3:0] when RX_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in [Table 12-164](#).

Table 12-164. In-Band Data

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0h: half-duplex	0h: 10-Mbps mode	2.5 MHz	0h: Link is down
1h: full-duplex	1h: 100-Mbps mode	25 MHz	1h: Link is up
	2h: 1000-Mbps mode	125 MHz	
	3h: Reserved	Reserved	

12.2.2.3.6.10.9.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the RGMII_RX_INBAND input is deasserted by setting to 0h bit CTL_EN of the CPSW_PN_MAC_CONTROL_REG_k register. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the CPSW_PN_MAC_CONTROL_REG_k[0] FULLDUPLEX and CPSW_PN_MAC_CONTROL_REG_k[7] GIG bits. If bit [7] GIG = 1h, then CPRGMII is operating in Gigabit mode. If bit [7] GIG is cleared (0h), then CPRGMII is operating in 100 Mbps mode.

12.2.2.3.6.10.9.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRGMII module.

In 10/100 Mbps mode, the TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 Mbps mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII_LINK. Packet transmission will begin on the first TX_CTL rising edge after the 4096 transmit clock count has expired.

12.2.2.3.6.10.10 Frame Classification

Received frames are proper (good) frames if they are between 64 and CPSW_P0_RX_MAXLEN_REG[13:0] RX_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the CPSW_P0_RX_MAXLEN_REG/ CPSW_PN_RX_MAXLEN_REG_k register. The register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames. If RX_CSF_EN bit in CPSW_PN_MAC_CONTROL_REG_k is set to 1h, undersized frames from 33 to 63 bytes will be forwarded only to the host on a best effort basis (meaning that the ALE may or may not be able to keep up with the packet rate and the short packet may be dropped due to bandwidth limitations). If RX_CSF_EN and RX_CEF_EN in CPSW_PN_MAC_CONTROL_REG_k are set, fragment frames from 33 to 63 bytes will also be forwarded only to the host on a best effort basis. Ethernet port received frames shorter than 33 bytes are dropped in all cases.

A received long packet will always contain RX_MAXLEN number of bytes transferred to memory (if CPSW_PN_MAC_CONTROL_REG_k[22]RX_CEF_EN = 1h). An example with RX_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

12.2.2.3.6.10.11 Receive FIFO Architecture

This section describes the architecture of the Ethernet port's receive FIFOs. Internal to the Gigabit Ethernet switch, all Ethernet ports have an identical associated packet FIFO. Each transmit packet FIFO contains eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each transmit FIFO memory contains 81,920 bytes total organized as 2560 by 256-bit words. Each FIFO also contains a single memory for the receive queue. Each receive FIFO memory contains a total of 32768 bytes total organized as 1024 by 256-bit words.

12.2.2.3.6.11 Embedded Memories

Table 12-165. Embedded Memories

Memory Type Description	Number of Instances	
Single-port 3072-word × 64 RAM	1	(Combined FIFO RAM)
Single-port 128-word × 28-bit RAM	1	1 (EST)

12.2.2.3.6.12 Memory Error Detection and Correction

The CPSW_9G error detection and correction logic uses the ECC Aggregator Module.

The ECC CPSW_ECC_VECTOR register is used to select which ECC RAM's status and control registers are currently being read or written as shown in [Table 12-166](#). The CPSW FIFO RAMs implement ECC only on packet headers. The packet data is protected by Ethernet CRC. The ALE and EST RAMs have complete ECC as normal.

Table 12-166. ECC RAM to CPSW RAM Mapping

ECC RAM Number	CPSW RAM
0	ALE RAM
1	Port 0 FIFO RAM

12.2.2.3.6.12.1 Packet Header ECC

Only packet headers bits are protected by ECC in the FIFO RAMs. The ECC_ERR_CTRL1[31-0] ECC_ROW bit is used to activate a row address where force single-bit error or force double-bit error needs to be applied. ECC_ERR_CTRL2 [15-0] ECC_BIT1 is implemented to determine which bit of the header is flipped for an SEC error when the ECC_CRC_MODE bit is cleared in the CPSW_CONTROL_REG register. The ECC status registers return the RAM row address where the single or double-bit error has occurred (ECC_ERR_STAT2[31-0] ECC_ROW) along with the bit position in the RAM data that is in error (ECC_ERR_STAT1[31-16] ECC_BIT1 value). Forcing double-bit errors in testing can cause indeterminate operation if multiple used packet header bits are flipped given that only single-bit errors are fixed by the ECC logic. Header bits 207 down to 200 are not currently used in the CPSW and may be used to test double bit errors without the possibility of requiring a reset for the switch to recover from the double bit error. No header bits are flipped when ECC_CRC_MODE is set to 1h. Either the RX_ECC_ERR_EN (enable receive ECC error operations) or the TX_ECC_ERR_EN (enable transmit ECC error operations) bits must be set in the CPSW_P0_CONTROL_REG register to test ECC header errors.

The header ECC code is stored in bits 255 down to 208. If any bit is flipped in the ECC code, the flipped bit will be corrected, but the index of the flipped bit will be reported as bit zero. This implies that when the aggregator reports that there is a SEC on bit 0, it can mean two things: either SEC on data bit 0 or SEC somewhere inside the ECC code. Any packet header with ECC error issues a pulse interrupt (ECC_PULSE_INTR) as does an ALE RAM ECC error.

12.2.2.3.6.12.2 Packet Protect CRC

Each packet received without error is passed through the CPSW_9G memories with a generated Ethernet protect CRC. The protect CRC is checked on egress for correctness and removed. If the CRC is correct (no RAM bit errors), then the packet is output with the selected port CRC type. If a protect CRC error is detected on host egress then the TXST_DROP signal will be asserted so that the packet is dropped to the host. If a protect CRC error is detected on Ethernet egress then the egress CRC will be generated on the packet and at least one byte of the CRC will be inverted on output. CRC memory protect errors do not assert the ECC_PULSE_INTR signal. CRC memory protect errors are counted in the associated port statistics registers and issue an interrupt on STAT_PEND_INTR if any CRC memory protect error occurs (and the statistics for that port are enabled). When the ECC_CRC_MODE bit in the CPSW_CONTROL_REG register is set, the ECC_ERR_CTRL2 [15-0] ECC_BIT1 bit field will flip the associated column bit in any FIFO memory read operation, inducing a CRC protect error when the protect CRC is checked. No header bits are flipped when ECC_CRC_MODE is set. Either the RX_ECC_ERR_EN or the TX_ECC_ERR_EN bits must be set in the CPSW_P0_CONTROL_REG register to test packet CRC errors.

12.2.2.3.6.12.3 Aggregator RAM Control

The ECC logic for each FIFO RAM (receive and transmit) is divided into eight separate ECC encoders/decoders that encode/decode 26-bits of data each. Each of the 8 encoders (0 to 7) generates 6-bits of ECC code (48 code bits total), and each of the eight decoders (0 to 7) checks 6-bits of ECC code across the 26-bits of data (208 data bits total). The 48-bits of ECC code are passed through the RAM in the upper 48 unused bits in the header word. The header data bits and ECC code bits are shown in [Table 12-167](#). The [15-0] ECC_BIT1 value returned on

error is a 16-bit value that is the concatenation of 5 bits of zero, 3 bits of the encoder/decoder number (0 to 7), 3 bits of zero, and 5 bits of index into the indicated 26-bit encoder/decoder.

For example, an ECC_BIT1 value of 0x0308 is bit 8 of encoder/decoder 3, which is header bit 86 (that is, $(26 \times 3) + 8$).

Table 12-167. ECC Submodule Header Data Bit to Encoder/Decoder Mapping

Header Data Bits	Encoder/Decoder
25:0	Encoder/Decoder 0 Data
51:26	Encoder/Decoder 1 Data
77:52	Encoder/Decoder 2 Data
103:52	Encoder/Decoder 3 Data
129:104	Encoder/Decoder 4 Data
155:130	Encoder/Decoder 5 Data
181:156	Encoder/Decoder 6 Data
207:182	Encoder/Decoder 7 Data
213:208	Encoder/Decoder 0 ECC
219:214	Encoder/Decoder 1 ECC
225:220	Encoder/Decoder 2 ECC
231:226	Encoder/Decoder 3 ECC
237:232	Encoder/Decoder 4 ECC
243:238	Encoder/Decoder 5 ECC
249:244	Encoder/Decoder 6 ECC
255:250	Encoder/Decoder 7 ECC

12.2.2.3.6.13 Ethernet Port Flow Control

The Ethernet port have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The Ethernet port have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an Ethernet port can be sent to the CPPI port. The destination port can trigger the receive Ethernet port flow control. An Ethernet destination port triggers another Ethernet receive flow control when the destination port is full.

When a packet is received on an Ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the Ethernet port will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX_BLK_CNT = 0h). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX_FLOW_EN bit in CPSW_PN_MAC_CONTROL_REG_k be set to 1h. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit.

12.2.2.3.6.13.1 Ethernet Receive Flow Control

For every Ethernet port to be configured for full-duplex receive flow control, write a value of decimal 7 to the CPSW_PN_MAX_BLKES_REG[7-0] RX_MAX_BLKES bit field, and a value of decimal 13 to the CPSW_PN_MAX_BLKES_REG[15-8] TX_MAX_BLKES register. This re-allocation allows for flow control runout on the receive FIFO at the expense of FIFO memory on the Ethernet transmit side. 10/100Mbps half-duplex

collision based receive flow control does not need this re-allocation. Receive flow control is enabled by the RX_FLOW_EN bit in the CPSW_PN_MAC_CONTROL_REG_k register.

12.2.2.3.6.13.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in CPSW_PN_MAC_CONTROL_REG_k). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

12.2.2.3.6.13.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX bit is set in the CPSW_PN_MAC_CONTROL_REG_k register). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The Ethernet port will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full at which time the receive FIFO will overrun and CPSW_STAT_RX_BOTTOM_OF_FIFO_DROP_k[31-0] COUNT value will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The Ethernet port will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL_SA[47-0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The Ethernet port will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If CPSW_PN_MAC_CONTROL_REG_k[3] RX_FLOW_EN is cleared to 0h while the pause time is nonzero, then the pause time will be cleared to 0h and a 0 count pause frame will be sent.

12.2.2.3.6.13.2 Qbb (10/100/1G/10G) Receive Priority Based Flow Control (PFC)

IEEE 802.1Qbb based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX bit must be set in the CPSW_PN_MAC_CONTROL_REG_k register). When receive PFC (Priority based Flow Control) flow control is enabled and triggered for a priority, the port will transmit a PFC pause frame to request that the sending station stop transmitting on that priority (and perhaps others) for the period indicated within the transmitted pause frame (FFFFh pause time). When the triggering condition is removed, or when PFC flow control is disabled, the port will transmit a pause frame to cancel the pause request (00.00 pause time). Priority based pause frames can have one to eight priorities

enabled as determined by the priority enable vector in the pause frame. Pause frames can give some priorities pause on and others pause off in the same frame. An enabled priority will have either a pause on value (FFFFh) or a pause off value (00.00). Priorities with a zero enable bit in the pause frame priority enable vector are unchanged by the pause frame on the sending station side. The [23-16] RX_FLOW_PRI value in the CPSW_PN_PRI_CTL_REG_k register indicates which port receive priorities are enabled for PFC. The priority enable vector in the pause frame only refers to the priorities that have a valid pause on or pause off sent in the sent pause frame.

The Ethernet port will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh) on each priority to be paused along with a set priority enable vector bit. The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control trigger is removed for a specific priority, the MAC will transmit a pause frame with a set priority enable vector bit and a zero pause time on that priority to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the Rx FIFO is not full at which time the receive FIFO will overrun and CPSW_STAT_RX_TOP_OF_FIFO_DROP_k[31-0] COUNT value will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame on the priority to be paused or not.

The Ethernet port will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL_SA[47-0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 01.01
- The 16-bit priority enable vector. The lower 8-bits are used for priorities 7 down to 0.
- A 16-bit pause time value for each priority. The pause on value is FFFFh and the pause off value is 00.00. A pause-quantum is 512 bit-times.
- Zero padding to 64-byte data length (The Ethernet port will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX_FLOW_EN bit in the CPSW_PN_MAC_CONTROL_REG_k is cleared to 0h while the pause time is nonzero, then the pause time will be cleared to zero and a zero count pause frame will be sent. For any priority that has flow control enabled then associated priority in the CPSW_PN_TX_BLKs_PRI_REG_k register should be written with zero.

12.2.2.3.6.13.3 Ethernet Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the Ethernet port from transmitting any further frames. Incoming pause frames are only acted upon when the [0] FULLDUPLEX and [4] TX_FLOW_EN bits in the CPSW_PN_MAC_CONTROL_REG_k register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the [24] RX_CMF_EN (RX Copy MAC Control Frames Enable) bit in the CPSW_PN_MAC_CONTROL_REG_k register is set. The [4] TX_FLOW_EN and [0] FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- [4] TX_FLOW_EN is set in CPSW_PN_MAC_CONTROL_REG_k register, and
- the RX maximum frame length is 64 bytes inclusive (CPSW_PN_RX_MAXLEN_REG_k[13-0] RX_MAXLEN), and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If [4] TX_FLOW_EN in CPSW_PN_MAC_CONTROL_REG_k register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
 - The reserved multicast destination address 01.80.C2.00.00.01, or the Ethernet port SL_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit CPSW_PN_MAC_TX_PAUSETIMER_REG_k[15:0] TX_PAUSETIMER. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 Bytes. The standard allows pause frames longer than 64 Bytes to be discarded or interpreted as valid pause frames. The Ethernet port will recognize any pause frame between 64 Bytes and CPSW_PN_RX_MAXLEN_REG_k[13:0] RX_MAXLEN bytes in length.

12.2.2.3.6.14 PFC Trigger Rules

There are five rules that can each set and clear a PFC (Priority based Flow Control) trigger condition for each enabled priority. The five rules are the destination based rule, the sum of outflows rule, the sum of blocks per port rule, the sum of blocks total rule, and the top of receive FIFO rule. Ethernet ports issue transmit PFC pause frames when any priority is triggered for any rule. Port 0 issues flow control on the associated receive thread when any priority is triggered for any rule. There are no pause frames sent on port 0 transmit (no port 0 outflow). Receive priority remapping is taken into account for all rules on all ports. Transmit priority remapping is taken into account for the sum of outflows rule, the sum of blocks per port rule, and the destination based rule. Transmit priority remapping is not taken into account for the sum of blocks total rule or the top of receive FIFO rule. The intent of PFC is to shutdown lower priorities as traffic congestion increases so that the higher priorities can continue to operate. Systems with only 1518 byte packets may only need to configure the destination based rule.

12.2.2.3.6.14.1 Destination Based Rule

The destination based rule is the primary rule for PFC and should be configured when PFC is enabled. The rule is evaluated for PFC trigger when the destination ports are determined on address lookup at packet reception (bottom of receive FIFO). The conditions of all packet destination port transmit FIFO's at packet reception determine whether or not one or more receive port priorities will be triggered. Each packet destination port is evaluated for each priority and the results are combined to produce the priority flow control trigger(s) on the receive port. A priority trigger is cleared at any time the clear condition is satisfied for that priority on all destination port FIFO's (all transmit FIFO's that set the trigger). The intent of the rule is to progressively

trigger receive PFC with decreasing priority as the FIFO allocated blocks (CPSW_PN_BLK_CNT_REG_k[12-8] TX_BLK_CNT) increases, and have the effect of priority outflow increase with decreasing priority. The add amount for outflow is zero if the outflow is not set and CPSW_PN_TX_D_OFLOW_ADDVAL_L_REG_k/ CPSW_PN_TX_D_OFLOW_ADDVAL_H_REG_k if the outflow is set for a particular priority.

A PFC priority is triggered by conditions in any destination transmit FIFO by the below equation at packet reception:

$$\text{priX_trig_set} = ((\text{addvalX}[4:0] \& \{5\{\text{tx_d_trig_setX}\}\}) + \text{pn_tx_blk_cnt}[4:0]) \geq \text{tx_d_thresh_setX}[4:0]$$

A PFC priority is cleared by conditions in all destination transmit FIFO's by the below equation at any time after the set has occurred:

$$\text{priX_trig_clr} = ((\text{addvalX}[4:0] \& \{5\{\text{tx_d_trig_setX}\}\}) + \text{pn_tx_blk_cnt}[4:0]) \leq \text{tx_d_thresh_clrX}[4:0]$$

Where,

- **X** is the priority
- **addvalX** is from CPSW_PN_TX_D_OFLOW_ADDVAL_L_REG_k and CPSW_PN_TX_D_OFLOW_ADDVAL_H_REG_k registers and has a maximum value of 11 decimal
- **tx_d_trig_setX** is set when transmit flow control (outflow) is triggered on the destination TX FIFO priority (by receiving a pause frame with the associated priority paused).
- **pn_tx_blk_cnt** is the total number of blocks allocated on all priorities in the destination transmit FIFO (0 to 20).
- **tx_d_thresh_setX** is from CPSW_PN_TX_D_THRESH_SET_L_REG_k and CPSW_PN_TX_D_THRESH_SET_H_REG_k registers
- **tx_d_thresh_clrX** is from CPSW_PN_TX_D_THRESH_CLR_L_REG_k and CPSW_PN_TX_D_THRESH_CLR_H_REG_k registers
- **tx_d_thresh_setX** must be greater than **tx_d_thresh_clrX**

12.2.2.3.6.14.2 Sum of Outflows Rule

The Sum of Outflows rule is a global control that sets and clears PFC triggers on a receive port due to conditions in all other Ethernet port transmit FIFOs regardless of receive traffic. An outflow is set for a transmit FIFO priority when a PFC pause frame is received on the port with a non-zero pause quanta for that priority indicating that the port should not transmit on that priority. An outflow is clear for a priority when the transmit pause condition is removed either due to receiving a pause frame with a zero pause quanta or by the pause timer expiring for the priority. Port 0 does not have transmit flow control. The sum of outflows rule is intended to be used in some systems to pass along outflow on lower priorities with larger packet sizes. Triggering PFC on priorities due to this rule also prevents packet transmission from Ethernet ports to the host for the duration of the pause time on the triggered priorities. When configured to trigger due to this rule, pause frames will be sent on Ethernet ports regardless of receive traffic.

A PFC priority is triggered by conditions in all other Ethernet transmit FIFOs by the below equation at any time:

$$\text{priX_trig_set} = \text{sum of all other Ethernet port priX_outflows} \geq \text{tx_g_oflow_thresh_setX}[4:0]$$

A PFC priority is cleared by conditions in all other Ethernet transmit FIFO's by the below equation at any time:

$$\text{priX_trig_clr} = \text{sum of all other Ethernet port priX_outflows} \leq \text{tx_g_oflow_thresh_clrX}[4:0]$$

Where,

- **X** is the priority
- **tx_g_oflow_thresh_setX** is from CPSW_TX_G_OFLOW_THRESH_SET_REG
- **tx_g_oflow_thresh_clrX** is from CPSW_TX_G_OFLOW_THRESH_CLR_REG
- **tx_g_oflow_thresh_setX** must be greater than **tx_g_oflow_thresh_clrX**.

12.2.2.3.6.14.3 Sum of Blocks Per Port Rule

The Sum of Blocks Per Port rule is an aggressive global control that sets and clears PFC triggers on receive ports due to conditions in any other port transmit FIFO regardless of receive traffic. When any transmit FIFO has a trigger condition set, all other receive ports will trigger PFC for that priority. This rule is intended to be configured in systems with high traffic rate jumbo packets on lower priorities.

A PFC priority is triggered by conditions in any other transmit FIFO by the below equation at any time:

$$\text{priX_trig_set when the sum of all Tx FIFO blocks allocated on the port} \geq \text{thresh_setX}[4:0]$$

A PFC priority is cleared when conditions in all other Ethernet transmit FIFO's satisfy the below equation at any time:

priX_trig_clr when the sum of all tx FIFO blocks allocated on the port \leq **thresh_clrX[4:0]**

Where,

- **X** is the priority
- **thresh_setX** is from CPSW_PN_TX_G_BUF_THRESH_SET_L_REG_k/
CPSW_PN_TX_G_BUF_THRESH_SET_H_REG_k (or CPPI port0
CPSW_P0_TX_G_BUF_THRESH_SET_L_REG/ CPSW_P0_TX_G_BUF_THRESH_SET_H_REG)
- **thresh_clrX** is from CPSW_PN_TX_G_BUF_THRESH_CLR_L_REG_k/
CPSW_PN_TX_G_BUF_THRESH_CLR_H_REG_k (or CPPI port0
CPSW_P0_TX_G_BUF_THRESH_CLR_L_REG/ CPSW_P0_TX_G_BUF_THRESH_CLR_H_REG)
- **thresh_setX** must be greater than **thresh_clrX** for each priority.

12.2.2.3.6.14.4 Sum of Blocks Total Rule

The Sum of Blocks Total rule is an extremely aggressive global control that sets and clears PFC triggers on receive ports due to conditions in all transmit FIFOs regardless of receive traffic. When any priority has a trigger condition set, all receive ports will trigger PFC for that priority. The intent of this rule is to shutdown lower priorities with jumbo packets as the total switch congestion increases.

A PFC priority is triggered by conditions in all transmit FIFO by the below equation at any time:

priX_trig_set = sum of all tx FIFO blocks allocated in all ports \geq **thresh_setX[4:0]**

A PFC priority is cleared when conditions in all transmit FIFO's satisfy the below equation at any time:

priX_trig_clr = sum of all tx FIFO blocks allocated in all ports \leq **thresh_clrX[4:0]**

Where,

- **X** is the priority
- **thresh_setX** is from CPSW_TX_G_BUF_THRESH_SET_L_REG/
CPSW_TX_G_BUF_THRESH_SET_H_REG
- **thresh_clrX** is from CPSW_TX_G_BUF_THRESH_CLR_L_REG/
CPSW_TX_G_BUF_THRESH_CLR_H_REG
- **thresh_setX** must be greater than **thresh_clrX** for each priority.

12.2.2.3.6.14.5 Top of Receive FIFO Rule

The Top of Receive FIFO Rule sets PFC triggers on the associated receive port for all priorities. This rule requires no configuration and is enabled when PFC flow control is enabled. The Top of Receive FIFO rule triggers when a received packet cannot be transferred to an intended destination port due to insufficient space in that destination port transmit FIFO. The receive FIFO exists to accept flow control runout (especially for 802.3 flow control). The trigger condition for this rule is cleared when the receive FIFO is emptied after runout. Preferable PFC configurations preclude this rule from triggering. If a lower priority packet triggers this rule then higher priority packets could be in the runout after the lower priority packet(s), which would increase the switch latency of the higher priority packets. This rule ensures that there is no packet loss on any priority in any configuration. However, PFC configuration should ensure that this rule is triggered only by high priority packets or preferably not at all. The [27] TORF bit in the CPSW_PN_MAC_STATUS_REG_k register indicates that this rule has triggered. The CPSW_PN_MAC_STATUS_REG_k[26-24] TORF_PRI field indicates the lowest priority that has triggered this rule since the last clearing of the status register fields. More aggressive shutdown of lower priorities in the other rules is preferable to having this rule trigger.

12.2.2.3.6.15 Energy Efficient Ethernet Support (802.3az)

Energy Efficient Ethernet (EEE) allows the LPSC to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. The module EEE clock stop interface is used by the external controller to control module EEE operations. EEE operations are configured as shown below:

1. The 12-bit EEE clock pre-scale value is written to the CPSW_EEE_PRESCALE_REG register. The pre-scaler is used to clock all EEE-related counters

2. The port Idle to LPI count values (CPSW_PN_IDLE2LPI_REG_k[23-0] COUNT) are written with the desired values
3. The port LPI to Wake count values (CPSW_PN_LPI2WAKE_REG_k[23-0] COUNT) are written with the desired values
4. The [0] EEE_EN bit is set in the switch CPSW_SS_CONTROL_REG register

EEE operation can begin after configuration. The host allows (through LPSC) the CPSW to enter a low power state by asserting the EEE_CLKSTOP_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert EEE_CLKSTOP_REQ to the CPSW.

Each Ethernet port has a transmit and a receive LPI (low power indicate) state. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the CPSW_PN_IDLE2LPI_REG_k value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPPI (port 0) LPI state includes transmit and receive. The CPPI LPI state is entered when the CPPI transmit and receive have both been idle for the Idle to LPI time (CPSW_P0_IDLE2LPI_REG). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

Note

External PHY signaling has the following conditions:

- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX_CTL at the rising and the falling TXC edges, respectively. RXDV and RXER are the sampled values of RX_CTL at the rising and the falling RXC clock edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the EEE_CLKSTOP_ACK signal is asserted, and the LPSC is allowed to stop the module clock. When EEE_CLKSTOP_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the CPSW memory address space, and then turn off the clock again while EEE_CLKSTOP_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting EEE_CLKSTOP_REQ. There must be at least one rising edge of the clock before EEE_CLKSTOP_REQ is de-asserted. The module EEE_CLKSTOP_ACK output signal will be deasserted on the clock after the de-assertion of EEE_CLKSTOP_REQ. The host may queue CPPI receive packets at any time without regard to the CPSW module LPI state. The Host must deassert EEE_CLKSTOP_REQ on wakeup for a minimum of two clock periods. If EEE_CLKSTOP_REQ is deasserted for less than 5 clock periods for a wakeup event from the host to a particular Ethernet port (or visa versa), then the wakeup event will not cause the other Ethernet port to awaken.

The external Ethernet PHY's can also wakeup the LPSC by removing the Ethernet receive LPI indication. If the CPSW module is in Idle state with EEE_CLKSTOP_ACK asserted and the receive LPI indication is removed, the EEE_CLKSTOP_WAKEUP signal will be asynchronously asserted. On wakeup, the LPSC restarts the clock and de-assert the EEE_CLKSTOP_REQ signal. The EEE_CLKSTOP_WAKEUP signal will be synchronously deasserted with EEE_CLKSTOP_ACK. Upon the deassertion of EEE_CLKSTOP_REQ, the Ethernet ports will count the CPSW_PN_LPI2WAKE_REG_k time for each port at which time the port is available for transmit.

12.2.2.3.6.16 Ethernet Switch Latency

When CPSW is configured as a store and forward switch, the switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

The store and forward latency is shown in [Table 12-168](#):

Table 12-168. Switch Latency

Mode	Latency
Gig (1000)	880 ns
100	1.3 μ s
10	6.5 μ s

12.2.2.3.6.17 MAC Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW operation to be completely or partially suspended. Each Ethernet port has associated emulation control registers (CPSW_EM_CONTROL_REG and CPSW_PN_MAC_EMCONTROL_REG_k). The submodule emulation control registers must be accessed to facilitate CPSW emulation control. The CPSW module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

Ethernet port Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the CPSW_PN_MAC_EMCONTROL_REG_k register) allow Ethernet port operation to be suspended. When the emulation suspend state is entered, the Ethernet port will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the Ethernet port after the suspend state is entered are ignored.

Table 12-169 shows the operations of the emulation control input and register bits.

Table 12-169. Emulation Control Input

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

12.2.2.3.6.18 MAC Command IDLE

The CMD_IDLE bit in the CPSW_PN_MAC_CONTROL_REG_k register allows MAC operation to be suspended. When the idle state is commanded, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the MAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

12.2.2.3.6.19 CPSW Network Statistics

The CPSW has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of CPSW0_RST. When one or more port enable (Pn_STAT_EN) bits in the CPSW_STAT_PORT_EN_REG register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STAT_PEND0) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

[Table 12-170](#) and [Table 12-171](#) summarize network statistics.

12.2.2.3.6.19.1 Rx-only Statistics Descriptions

12.2.2.3.6.19.1.1 Good Rx Frames (Offset = 3A000h)

All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Had a length of 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the [Section 12.2.2.3.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.3.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.2.3.6.19.1.2 Broadcast Rx Frames (Offset = 3A004h)

All ports

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for address FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the [Section 12.2.2.3.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.3.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.2.3.6.19.1.3 Multicast Rx Frames (Offset = 3A008h)

All ports

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.2.3.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.3.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.2.3.6.19.1.4 Pause Rx Frames (Offset = 3A00Ch)

Ethernet port N (where N = 1 to 8)

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (TX_FLOW_EN = 1h).

The port could have been in either half or full-duplex mode.

See the [Section 12.2.2.3.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.3.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.2.3.6.19.1.5 Rx CRC Errors (Offset = 3A010h)

All ports

The total number of frames received on the port that experienced a CRC error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX_MAXLEN bytes inclusive
- Had no code/align error
- Had a CRC error

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- A frame containing an even number of nibbles, and
- Failing the Frame Check Sequence test.

12.2.2.3.6.19.1.6 Rx Align/Code Errors (Offset = 3A014h)

Ethernet port N (where N = 1 to 8)

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX_MAXLEN bytes inclusive
- Had either an alignment error, or a code error.

Overruns have no effect upon this statistic.

An alignment error is defined to be:

- A frame containing an odd number of nibbles
- Failing the Frame Check Sequence test if the final nibble is ignored

A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

Note

RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing Rx Align/Code Errors and Rx CRC errors.

12.2.2.3.6.19.1.7 Oversize Rx Frames (Offset = 3A018h)

All ports

The total number of oversized frames received on the port. An oversized frame is defined to be:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX_MAXLEN in bytes
- Had no CRC error, alignment error, or code error.

See the [Section 12.2.2.3.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.3.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.2.3.6.19.1.8 Rx Jabbers (Offset = 3A01Ch)

All ports

The total number of jabber frames received on the port. A jabber frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX_MAXLEN in bytes
- Had no CRC error, alignment error or code error

See the [Section 12.2.2.3.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.3.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.2.3.6.19.1.9 Undersize (Short) Rx Frames (Offset = 3A020h)

All ports

The total number of undersized frames received on the port. An undersized frame is defined to be:

- Was any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes
- Had no CRC error, alignment error, or code error

See the [Section 12.2.2.3.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.3.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.2.3.6.19.1.10 Rx Fragments (Offset = 3A024h)

Ethernet port N (where N = 1 to 8)

The total number of frame fragments received on the port. A frame fragment is defined to be:

- Any data frame (address matching does not matter)
- Less than 64 bytes long
- Having a CRC error, an alignment error, or a code error
- Not the result of a collision caused by half-duplex, collision-based flow control

See the [Section 12.2.2.3.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.3.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.2.3.6.19.1.11 RX IPG Error

The total number of 10G frames received on a port that had a correct preamble but did not have at least five bytes of IDLE preceding the frame. This does not indicate if the frame with the IPG error was kept or ignored.

12.2.2.3.6.19.1.12 ALE Drop (Offset = 3A028h)

All ports

The total number of frames received on a port such that the destination address was not equal to the source address and the packet was not destined to the port it was received on, but the frame was not forwarded to any port (the PORT_MASK was zero).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was not equal to the source address
- the packet was not destined for the port it was receive on
- had a zero PORT_MASK

12.2.2.3.6.19.1.13 ALE Overrun Drop (Offset = 3A02Ch)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to exceeding the maximum ALE lookup rate (Port 0 should not have ALE Overrun Drops because the ingress rate is controlled to prevent it). This statistic should be zero and when non-zero indicates a system clock issue or indicates that short packets were sent with RX_CSF_EN at a rate that exceeded the maximum lookup rate.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- the maximum ALE lookup rate was exceeded so the lookup was aborted and the packet was dropped.

12.2.2.3.6.19.1.14 Rx Octets (Offset = 3A030h)

All ports

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Of length 64 to RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.2.3.6.19.1.6](#), Rx Align/Code Errors and [Section 12.2.2.3.6.19.1.5](#), Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

12.2.2.3.6.19.1.15 Rx Bottom of FIFO Drop (Offset = 3A084h)

Ethernet port N (where N = 1 to 8)

The total number of frames received on a port that overran the port's receive FIFO and were dropped (bottom of receive FIFO). Port 0 (CPPI receive port) should not drop packets on receive because port 0 receive flow control should be enabled. The Ethernet ports will only drop packets in the receive FIFO when receive flow control is enabled and the sending port ignores sent pause frame and then overruns the receive FIFO. An overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- Was dropped on port 0 due to a lack of memory space in the receive FIFO.

Note

This statistic should be zero if proper flow control is being followed.

Host port 0

This statistic also counts frames dropped on port 0 that were 17 to 63 bytes (only for port 0). For Ethernet ports, the drop count for frames shorter than 33 bytes is included in the undersized or fragment count. Port 0 simply gives an indication that a packet was dropped. No other statistics are counted for frames shorter than 33 bytes.

12.2.2.3.6.19.1.16 Portmask Drop (Offset = 3A088h)

All ports

The total number of frames received on a port that were dropped by the ALE (the ALE did not forward the packet to any port). Port mask drop frame is defined to be:

- Any data or MAC control frame
- Any length greater than 32 bytes
- Was dropped by the ALE due to PORT_MASK=0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

Note

This statistic does not count in the overall total as it includes every packet received greater than 32 bytes that had a zero PORT_MASK.

12.2.2.3.6.19.1.17 Rx Top of FIFO Drop (Offset = 3A08Ch)

All ports

The total number of frames received on a port that had a start-of-frame (SOF) overrun on any destination port egress (when attempting to load the packet from the top of the ingress port receive FIFO into any other port's transmit FIFO). If a multicast/broadcast packet is dropped by multiple destination ports then this statistic will increment by the number of ports that dropped the packet. Rx Top Of FIFO Drop is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error or code error
- had a SOF of frame overrun on another port egress.

12.2.2.3.6.19.1.18 ALE Rate Limit Drop (Offset = 3A090h)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to receive rate limiting on this port or due to transmit rate limiting on any destination port (not sent to all expected destination ports if transmit rate limiting).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the receive rate was exceeded and the packet was dropped, or the transmit rate was exceeded to any destination port and the packet was dropped to one or more expected destination ports (indicates that the destinations were reduced due to rate limiting).

12.2.2.3.6.19.1.19 ALE VLAN Ingress Check Drop (Offset = 3A094h)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to VLAN ingress check failure.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the VLAN ID ingress check failed (the receive port was not in the group)
- The address lookup did not return a match with the SUPER bit set.

12.2.2.3.6.19.1.19.1 ALE DA=SA Drop (Offset = 3A098h)

All ports

The total number of frames received on a port that were dropped (zero PORT_MASK) due to destination address equal to source address.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was equal to the source address
- the source address was not an entry in the table.

12.2.2.3.6.19.1.19.2 Block Address Drop (Offset = 3A09Ch)

The total number of frames received on a port that were dropped (zero PORT_MASK) due to the destination or source address being blocked.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source or destination address matched a table entry with the block bit set.

12.2.2.3.6.19.1.19.3 ALE Secure Drop (Offset = 3A0A0h)

The total number of frames received on a port that were dropped (zero port_mask) due to a secure violation (the source address is owned by a different receive port).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source address is an entry in the table with the SECURE bit set and a port number for a different receive port.

12.2.2.3.6.19.1.19.4 ALE Authentication Drop (Offset = 3A0A4h)

The total number of frames received on a port that were dropped (zero port_mask) due to authentication failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- CPSW_ALE_CONTROL[1] ENABLE_AUTH_MODE is set to 1h, and
- the source address is not equal to the destination address, and
- the source address is not a table entry, and
- the destination address is not a table entry with the SUPER bit set.

12.2.2.3.6.19.1.19.5 ALE Unknown Unicast (Offset = 3A0A8h)

All ports

The total number of frames received on a port that had a unicast destination address with an unknown source address.

- was any data frame with a unicast destination address
- the source address was not a table entry
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

Note: The ALE Unknown Unicast Bytecount statistic is the number of bytes contained in the ALE Unknown Unicast frames.

12.2.2.3.6.19.1.19.6 ALE Unknown Unicast Bytecount (Offset = 3A0ACh)

The total number of bytes received on a port that had a unicast destination address with an unknown source address.

12.2.2.3.6.19.1.19.7 ALE Unknown Multicast (Offset = 3A0B0h)

The total number of frames received on a port that had a multicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Multicast Bytecount statistic is the number of bytes contained in the ALE Unknown Multicast frames.

12.2.2.3.6.19.1.19.8 ALE Unknown Multicast Bytecount (Offset = 3A0B4h)

The total number of bytes received on a port that had a multicast destination address with an unknown source address.

12.2.2.3.6.19.1.19.9 ALE Unknown Broadcast (Offset = 3A0B8h)

The total number of frames received on a port that had a broadcast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Broadcast Bytecount statistic is the number of bytes contained in the ALE Unknown Broadcast frames.

12.2.2.3.6.19.1.19.10 ALE Unknown Broadcast Bytecount (Offset = 3A0BCh)

The total number of bytes received on a port that had a broadcast destination address with an unknown source address.

12.2.2.3.6.19.1.19.11 ALE Policer/Classifier Match (Offset = 3A0C0h)

All ports

The total number of frames received on a port that matched a policer. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

12.2.2.3.6.19.2 ALE Policer Match Red (Offset = 3A0C4h)

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

12.2.2.3.6.19.3 ALE Policer Match Yellow (Offset = 3A0C8h)

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

12.2.2.3.6.19.4 IET Receive Assembly Error (Offset = 3A140h)

The total number of pretable received frames with IET assembly errors.

- any frame received
- was any size, and
- was a non-initial fragment that mismatched the frame count or fragment count (went to the assembly error state in the IET receive state machine)

12.2.2.3.6.19.5 IET Receive Assembly OK (Offset = 3A144h)

The total number of correctly received and re-assembled pre-emptable frames.

- any pre-emptable frame received
- was any size, and
- was correctly received and re-assembled without error

12.2.2.3.6.19.6 IET Receive SMD Error (Offset = 3A148h)

The total number of received frames rejected due to an unknown SMD value or received frames rejected with an SMD-C when no frame is in progress.

- any frame received
- was any size, and
- was rejected because of an unknown SMD value or SMD-C with no frame in progress.

Note: If IET_ENABLE is not set, this statistic counts any received frame with any non-express SMD.

12.2.2.3.6.19.7 IET Receive Merge Fragment Count (Offset = 3A14Ch)

The total number of received non-initial fragments that did not have an assembly error. The IET stat CPSW_STAT_RXFRAGMENTS_k is derived by adding the Receive Assembly Error count to this value.

- any frame received
- was any size, and
- was a non-initial fragment that did not contain an assembly error

12.2.2.3.6.19.8 Tx-only Statistics Descriptions

The maximum and minimum transmit frame size is software-controllable.

12.2.2.3.6.19.8.1 Good Tx Frames (Offset = 3A034h)

All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

12.2.2.3.6.19.8.2 Broadcast Tx Frames (Offset = 3A038h)

All ports

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

12.2.2.3.6.19.8.3 Multicast Tx Frames (Offset = 3A03Ch)

All ports

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

12.2.2.3.6.19.8.4 Pause Tx Frames (Offset = 3A040h)

Ethernet port N (where N = 1 to 8)

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex, carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64-byte multicast frames so will appear in the *Tx Multicast Frames* and *64octet Frames* statistics.

12.2.2.3.6.19.8.5 Deferred Tx Frames (Offset = 3A044h)

Ethernet port N (where N = 1 to 8)

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic.

12.2.2.3.6.19.8.6 Collisions (Offset = 3A048h)

Ethernet port N (where N = 1 to 8)

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
 - Was destined for any unicast, broadcast or multicast address
 - Was any size
 - Had no carrier loss and no underrun
 - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions)

CRC errors have no effect upon this statistic.

2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

12.2.2.3.6.19.8.7 Single Collision Tx Frames (Offset = 3A04Ch)

Ethernet port N (where N = 1 to 8)

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

12.2.2.3.6.19.8.8 Multiple Collision Tx Frames (Offset = 3A050h)

Ethernet port N (where N = 1 to 8)

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

12.2.2.3.6.19.8.9 Excessive Collisions (Offset = 3A054h)

Ethernet port N (where N = 1 to 8)

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

12.2.2.3.6.19.8.10 Late Collisions (Offset = 3A058h)

Ethernet port N (where N = 1 to 8)

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The *Late Collisions* statistic dominates over the single-, multiple-, and excessive- collision statistics. If a late collision occurs, the frame will not be counted in any of these other three statistics.

CRC errors have no effect upon this statistic.

12.2.2.3.6.19.8.11 Carrier Sense Errors (Offset = 3A060h)

Ethernet port N (where N = 1 to 8)

The total number of frames on the port that experienced carrier loss. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.

CRC errors have no effect upon this statistic.

12.2.2.3.6.19.8.12 Tx Octets (Offset = 3A064h)

All ports

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Was any size
- Had no late or excessive collisions, no carrier loss and no underrun.

12.2.2.3.6.19.8.13 Transmit Priority 0-7 (Offset = 3A180h to 3A1A8h)

The total number of frames transmitted on the port from transmit FIFO priority 0-7. Collision retries do not affect this statistic. Pause frames do not affect this statistic.

- Any frame transmitted from priority 0-7, and
- Was less than or equal to CPSW_TX_PRI0_MAXLEN_REG to CPSW_TX_PRI7_MAXLEN_REG
- Collision retries are not counted in this statistic.
- Pause frames are not counted in this statistic.
- Carrier sense errors do not affect this statistic.

Note: The Transmit Priority 0-7 Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 statistic.

12.2.2.3.6.19.8.14 Transmit Priority 0-7 Drop (Offset = 3A1C0h to 3A1E8h)

The total number of transmit frames on the port that overran the transmit FIFO priority 0-7 and were dropped. This count includes frames dropped due to CPSW_TX_PRI0_MAXLEN_REG to CPSW_TX_PRI7_MAXLEN_REG.

- Any frame destined to be transmitted from priority 0-7, and
- Was any size, and
- Was dropped due to priority 0-7 FIFO overrun (Start of packet overrun).
- Was dropped due to frame size larger than CPSW_TX_PRI0_MAXLEN_REG to CPSW_TX_PRI7_MAXLEN_REG.

Note: The Transmit Priority 0-7 Drop Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 Drop statistic.

12.2.2.3.6.19.8.15 Tx Memory Protect Errors (Offset = 3A17Ch)

All ports

The total number of transmit frames on the port that had a memory protect CRC error on egress:

- Any frame destined to be transmitted,
- Was any size
- Had a memory protect CRC error on egress.

Note

- Frames to the host with memory protect errors are dropped via TXST_DROP. Ethernet frames will have at least one byte of the generated port type CRC inverted on egress.
- This statistic is 8-bits wide only and will not rollover but will limit at 0xFF.
- A non-zero value in this statistic will issue a STAT_PEND0 interrupt for the associated port.

12.2.2.3.6.19.8.16 IET Transmit Merge Fragment Count (Offset = 3A14Ch)

The total number of non-initial preemptable transmit fragments on preemptable transmit.

- Any frame destined to be transmitted on the preemptable port, and
- Was any size, and
- was a non-initial fragment.

12.2.2.3.6.19.8.17 IET Transmit Merge Hold Count (Offset = 3A150h)

The total number of preemptable frames that were preempted and reassembled by the assertion of MAC_HOLD in the CPSW_PN_IET_CONTROL_REG_k register or were preempted by Enhanced Scheduled Traffic (EST). The IET statistic can be derived and maintained by software.

- Any frame destined to be transmitted on the preemptable port, and
- was any size, and
- was preempted by the assertion of MAC_HOLD.
- was preempted by Enhanced Scheduled Traffic (EST).

12.2.2.3.6.19.9 Rx- and Tx (Shared) Statistics Descriptions

Table 12-170. Rx Statistics Summary

Rx Statistic	Frame/ Oct	Rx/ Rx+ Tx	Frame Type					Frame Size (bytes)							Event					
			MAC control		Data ⁽⁵⁾			<64	64	65-127	128-255	256-511	512-1023	1024-rx_max len	>rx_max len	Flow Coll. ⁽⁸⁾	CRC Error	Alignment/ Code	Overrun	Address Disc.
			Pause frame	Non-pause ⁽⁴⁾	Multicast	Broadcast	Unicast													
Good Rx Frames	F	Rx	(y ⁽¹⁾	y	y	y	y)	n	(y	y	y	y	y	y)	n	- ⁽²⁾	n	n	-	n
Broadcast Rx Frames	F	Rx	(% ⁽⁶⁾	%	n	y)	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n

Table 12-170. Rx Statistics Summary (continued)

Rx Statistic	Frame/ Oct	Rx/ Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data ⁽⁵⁾			<64	64	65-127	128-255	256-511	512-1023	1024-rx_max len	>rx_max len	Flow Coll. (8)	CRC Error	Align/ Code	Overrun	Add. Disc.
			Pause frame	Non-pause ⁽⁴⁾	Multicast	Broadcast	Unicast													
Multicast Rx Frames	F	Rx	(%	%	y)	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Pause Rx Frames	F	Rx	y	n	n	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	-
Rx CRC Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	-	y	-	n
Oversized Rx Frames	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	(y	y)	-	n
Undersized Rx Frames	F	Rx	n	n	(y	y	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	Rx	n	n	(y	y	y)	y ⁽⁷⁾	n	n	n	n	n	n	n	-	(y	y)	-	-
Rx Overruns ⁽⁹⁾	F	Rx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	y)	-	-	-	y	n
64octet Frames	F	Rx+Tx ⁽³⁾	(y	y	y	y	y)	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	y	n	n	n	n	-	-	-	-	n
256-511octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Net Octets	O	Rx+Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y	y)	y)	-	-	-	-

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
- (5) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
- (6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (7) "y^" Frame fragments are not counted if less than 8 bytes.
- (8) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
- (9) The rx_overruns stat is for RX_MOF_OVERRUNS and RX_SOF_OVERRUNS added together.

Table 12-171. Tx Statistics Summary

Tx Statistic ⁽⁹⁾	Frame Type							Frame Size (bytes)							Event									
	Fra me/ Oct	Tx/ Rx +Tx	MAC control (4)		Data			64	65- 127	128- 255	256- 511	512- 1023	1024- 535	>1535	CRC Error	Collision Type					No Carrier	Queue d	Def err ed	Un der run
			Pause- MAC	Any- CPU	Multi- cast	Broad- cast	Uni- cast																	
																Flow ⁽⁸⁾	1	2-15	16	Late				
Good Tx Frames	F	Tx	(y ⁽¹⁾)					(y)	(y)	(y)	(y)	(y)	(y)	(y)	- ⁽²⁾	-	-	-	n	n	n	-	-	n
Broadcast Tx Frames	F	Tx	n	(% ⁽⁵⁾)	n			(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	-	-	-	n	n	n	-	-	n
Multicast Tx Frames	F	Tx	(y)	%				(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	-	-	-	n	n	n	-	-	n
Pause Tx Frames	F	Tx	y	n	n	n		y	n	n	n	n	n	n	-	-	-	-	-	-	-	-	-	-
Collisions	F	Tx	n	(y				(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	(+ ⁽⁶⁾)	+	+	+	+	n	-	-	-
Single Collision Tx Frames	F	Tx	n	(y				(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	-	y	n	n	n	n	-	-	-
Multiple Collision Tx Frames	F	Tx	n	(y				(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	-	n	y	n	n	n	-	-	-
Excessive Collisions	F	Tx	n	(y				(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	-	n	n	y	n	n	-	-	-
Late Collisions	F	Tx	n	(y				n	(y						-	-	-	-	-	y	-	-	-	-
Deferred Tx Frames	F	Tx	n	(y				(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	-	n	n	n	n	n	-	y	n
Carrier Sense Errors	F	Tx	(y					(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	-	-	-	-	-	y	-	-	-
64octet Frames	F	Rx+ Tx ⁽³⁾	(y					y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
65-127octet Frames	F	Rx+ Tx	(y					n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
128-255octet Frames	F	Rx+ Tx	(y					n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-
256-511octet Frames	F	Rx+ Tx	(y					n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-
512-1023octet Frames	F	Rx+ Tx	(y					n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-
1024-UPoctet Frames	F	Rx+ Tx	(y					n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-
Tx Octets	O	Tx	(y					(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	-	-	-	n	n	n	-	-	n
Net Octets	O	Rx+ Tx	(y					(y)	(y)	(y)	(y)	(y)	(y)	(y)	-	-	\$ ⁽⁷⁾	\$	\$	\$	\$	-	-	-

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
- (5) "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (6) "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.

- (7) "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
- (8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See *Rx Statistics Summary*.)
- (9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

12.2.2.3.6.19.9.1 Rx + Tx 64 Octet Frames (Offset = 3A068h)

All ports

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

12.2.2.3.6.19.9.2 Rx + Tx 65–127 Octet Frames (Offset = 3A06Ch)

All ports

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 65 to 127 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.2.3.6.19.9.3 Rx + Tx 128–255 Octet Frames (Offset = 3A070h)

All ports

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 128 to 255 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.2.3.6.19.9.4 Rx + Tx 256–511 Octet Frames (Offset = 3A074h)

All ports

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 256 to 511 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.2.3.6.19.9.5 Rx + Tx 512–1023 Octet Frames (Offset = 3A078h)

All ports

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error

- Was 512 to 1023 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.2.3.6.19.9.6 Rx + Tx 1024_Up Octet Frames (Offset = 3A07Ch)

All ports

The total number of frames of size 1024 to RX_MAXLEN bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 1024 to RX_MAXLEN bytes long on receive, or any size on transmit

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

12.2.2.3.6.19.9.7 Net Octets (Offset = 3A080h)

All ports

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter)
- Any length (including less than 64 bytes and greater than RX_MAXLEN bytes)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced, (that is, multiple retries are counted each time)
- Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting)

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of Ethernet utilization.

12.2.2.3.7 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

Main features of CPTS module are:

- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling
- Supports up to 4 hardware timestamp push inputs
- Supports timestamp counter compare output (CPTS_COMP)
- Supports timestamp counter bit output (CPTS_SYNC)
- Supports a configurable number of timestamp Generator bit outputs (CPTS_GENFn).
- Supports Ethernet Enhanced Scheduled Traffic Operations (CPTS_ESTFn).
- 32-bit and 64-bit timestamp modes with PPM and nudge adjustment.

12.2.2.3.7.1 CPSW0 CPTS Integration

This section describes CPTS module integration in the CPSW0 module, including information about clocks, resets, and hardware requests.

[Figure 12-99](#) shows CPTS integration in the device CPSW0 module.

Figure 12-99. CPSW0 CPTS Integration

CPTS IEEE 1588 clock (RCLK) is selected through the CTRLMMR_MCU_ENET_CLKSEL register.

Note

For more information about CPTS clocks and resets, see *MCU_CPSW0 Clocks and Resets* in *CPSW0 Integration*.

12.2.2.3.7.2 CPTS Architecture

Figure 12-100 shows the architecture of the CPTS module inside the CPSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the CPSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWN_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value through the Event FIFO. The reference clock used for the time stamp (CPTS_RFT_CLK) can be derived from several sources.

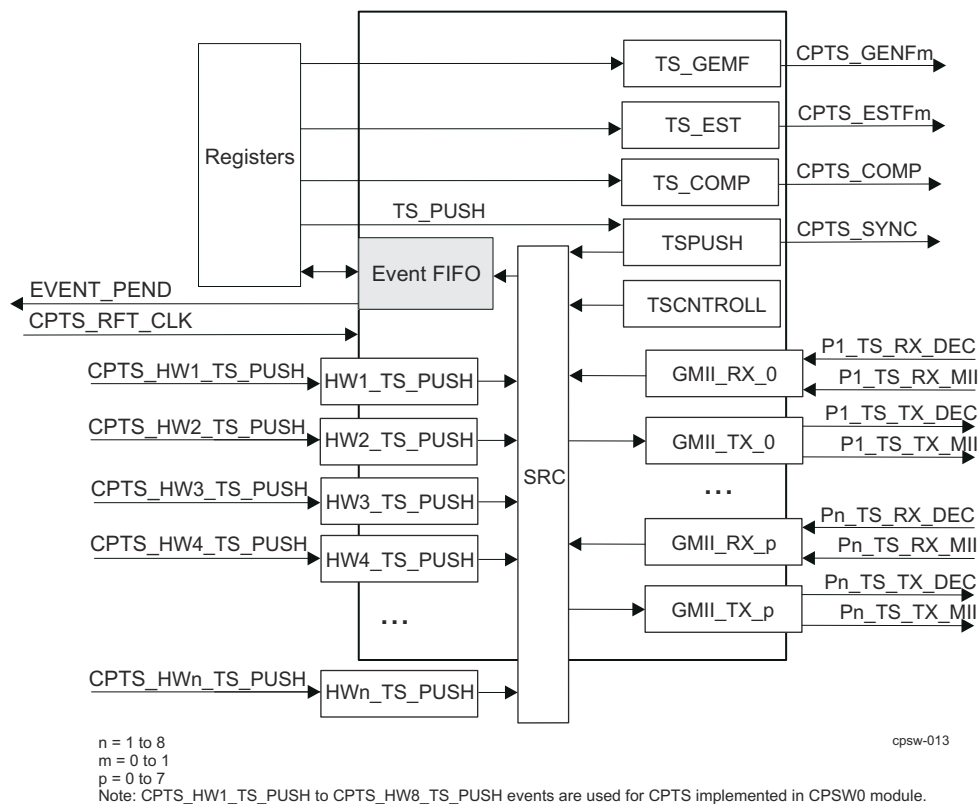

Figure 12-100. CPTS Block Diagram

Note

See [Section 12.2.2.3.7.1, CPSW0 CPTS Integration](#) for CPTS integration in the device CPSW0 module.

12.2.2.3.7.3 CPTS Initialization

The CPTS module should be configured as follows:

1. Reset the CPTS module.
2. Write the CPTS_CLKSEL value in the CTRLMMR_CPSW_CLKSEL register with the desired reference clock selection. This value is allowed to be written only when the CPTS_EN bit in the CPSW_CPTS_CONTROL_REG register is cleared to zero.
3. Set the CPTS_EN bit in the CPSW_CPTS_CONTROL_REG register.
4. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPSW_CPTS_INT_ENABLE_REG register.

12.2.2.3.7.4 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS_RFT_CLK rising edge when CPTS_EN bit is set to 1h. When CPTS_EN bit is cleared to 0h, the time stamp value is reset to 0h.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPSW_CPTS_TS_LOAD_VAL_REG / CPSW_CPTS_TS_LOAD_HIGH_VAL_REG and CPSW_CPTS_TS_LOAD_EN_REG registers).

12.2.2.3.7.5 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each CPTS_RFT_CLK rising edge when CPTS_EN bit is set to 1h. When CPTS_EN bit is cleared to 0h, the time stamp value is reset to 0h.

64-bit mode is selected when CPSW_CPTS_CONTROL_REG[5] MODE bit set to 1h.

For test purposes, the time stamp value can be written via the time stamp load function (CPSW_CPTS_TS_LOAD_EN_REG, CPSW_CPTS_TS_LOAD_VAL_REG, and CPSW_CPTS_TS_LOAD_HIGH_VAL_REG registers). The CPSW_CPTS_TS_ADD_VAL_REG feature is included to allow 1ns timestamp operations with an CPTS_RFT_CLK rate less than 1Ghz. Table 12-172 shows the CPTS_RFT_CLK and CPSW_CPTS_TS_ADD_VAL_REG values for 1ns operations.

Table 12-172. ADD_VAL feature

CPTS_RFT_CLK (MHz)	CPSW_CPTS_TS_ADD_VAL_REG[2-0] ADD_VAL
1000 MHz	0
500 MHz	1
333.33 MHz	2
250 MHz	3
200 MHz	4
166.66 MHz	5
142.85714 MHz	6
125 MHz	7

12.2.2.3.7.6 64-Bit Timestamp Nudge

The 64-bit TIME_STAMP value can be adjusted by writing the CPSW_CPTS_TS_NUDGE_VAL_REG[7-0] TS_NUDGE_VAL bit field value which is a two's complement value. A value of FFh will subtract 1 clock cycle from the next incremented 64-bit time stamp value (CPSW_CPTS_EVENT_0_REG[31-0] TIME_STAMP and CPSW_CPTS_EVENT_3_REG[31-0] TIME_STAMP value). A nudge value of 1h will add 1 clock cycle to the next incremented TIME_STAMP[63-0] value. For example, if the current TIME_STAMP value is F06h, and CPSW_CPTS_TS_ADD_VAL_REG[2-0] ADD_VAL = 3h, the next incremented timestamp value would be F0Ah without a nudge and F0Ah +/- [7-0] TS_NUDGE_VAL with a nudge. The [7-0] TS_NUDGE_VAL value is cleared to zero when the nudge has occurred.

12.2.2.3.7.7 64-bit Timestamp PPM

The 64-bit TIME_STAMP can be adjusted by parts per million or by parts per hour. Writing a non-zero value to the CPSW_CPTS_TS_PPM_LOW_VAL_REG[31-0] TS_PPM_LOW_VAL (Time stamp PPM Low value) and CPSW_CPTS_TS_PPM_HIGH_VAL_REG[9-0] TS_PPM_HIGH_VAL (Time stamp PPM High value) enables PPM operations. The adjustment is up or down depending on the [7] TS_PPM_DIR bit in the CPSW_CPTS_CONTROL_REG register. The TIME_STAMP value is increased by the PPM value when [7] TS_PPM_DIR bit is cleared. The TIME_STAMP value is decreased by the PPM value when [7] TS_PPM_DIR bit is set.

Parts Per Million example:

To adjust for 100 parts per million the configured value for TS_PPM[41-0] (through CPSW_CPTS_TS_PPM_LOW_VAL_REG[31-0] TS_PPM_LOW_VAL and CPSW_CPTS_TS_PPM_HIGH_VAL_REG[9-0] TS_PPM_HIGH_VAL) is:
 $1,000,000/100 = 10,000(\text{decimal})$

Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS_RFT_CLK the configured value for TS_PPM[41-0] (through CPSW_CPTS_TS_PPM_LOW_VAL_REG[31-0] TS_PPM_LOW_VAL and CPSW_CPTS_TS_PPM_HIGH_VAL_REG[9-0] TS_PPM_HIGH_VAL) is:
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600 \text{ seconds/hour}) = 34630\text{B8A000} (\text{hex})$

12.2.2.3.7.8 Event FIFO

All time sync events are pushed onto the Event FIFO. There are 10 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

12.2.2.3.7.9 Timestamp Compare Output

CPTS features one Time Stamp Compare (CPTS_COMP) output. The CPTS_COMP function is a software oriented feature that is intended to be replaced going forward by the hardware oriented GENF function. CPTS_COMP is not compatible with timestamp PPM or a non-zero CPSW_CPTS_TS_ADD_VAL_REG[2-0] ADD_VAL value.

12.2.2.3.7.9.1 Non-Toggle Mode: 32-bit

The CPTS_COMP output is asserted for CPSW_CPTS_TS_COMP_LEN_REG[31-0] TS_COMP_LENGTH periods when the CPSW_CPTS_EVENT_0_REG[31-0] TIME_STAMP value (lower 32-bits) compares with the CPSW_CPTS_TS_COMP_VAL_REG[31-0] TS_COMP_VAL and the length value is non-zero. The CPTS_COMP rising edge occurs three CPTS_RFT_CLK clock periods after the values compare. A timestamp compare event is pushed into the event FIFO when CPTS_COMP is asserted. The polarity of the CPTS_COMP output is determined by the CPSW_CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit. The output is asserted low when the polarity bit is 0h.

12.2.2.3.7.9.2 Non-Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIME_STAMP are used (CPSW_CPTS_EVENT_0_REG and CPSW_CPTS_EVENT_3_REG). In 32-bit mode only the lower 32-bits (CPSW_CPTS_EVENT_0_REG) are used.

12.2.2.3.7.9.3 Toggle Mode: 32-bit

The CPTS_COMP output is asserted (CPSW_CPTS_TS_COMP_LEN_REG[31-0] TS_COMP_LENGTH) for CPTS_RFT_CLK clock periods when the TIME_STAMP[31:0] value compares with the CPSW_CPTS_TS_COMP_VAL_REG and the length value is non-zero. The CPTS_COMP toggles thereafter on CPSW_CPTS_TS_COMP_VAL_REG[31-0] TS_COMP_LENGTH for CPTS_RFT_CLK periods. The length high or low can be adjusted by writing the CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE bit field value which is a two's complement value. A value of FFh will subtract one CPTS_RFT_CLK period from the CPSW_CPTS_TS_COMP_VAL_REG[31-0] TS_COMP_LENGTH value. A value of 0x01h will add one CPTS_RFT_CLK period to the CPSW_CPTS_TS_COMP_LEN_REG[31-0] TS_COMP_LENGTH value. Only a single high or low time is adjusted (nudged) and the CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred. The CPTS_COMP output is asserted low when the CPSW_CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit is 0h. No compare events and no CPTS_EVNT interrupts are generated in toggle mode. The CPSW_CPTS_CONTROL_REG[6] TS_COMP_TOG bit must be set for toggle mode (value 1h). Note this bit must be set before writing a non-zero value to CPSW_CPTS_TS_COMP_VAL_REG register.

12.2.2.3.7.9.4 Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIMESTAMP are used (CPSW_CPTS_EVENT_0_REG and CPSW_CPTS_EVENT_3_REG). In 32-bit mode only the lower 32-bits (CPSW_CPTS_EVENT_0_REG) are used.

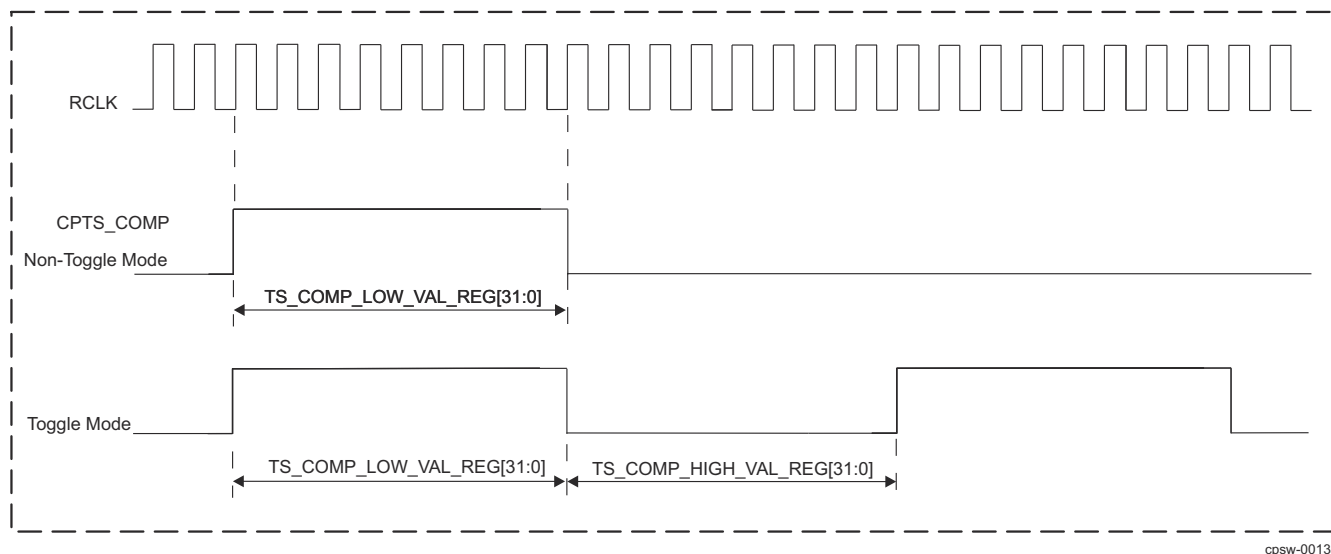

Figure 12-101. CPTS_COMP Output in Toggle and Non-Toggle Mode

12.2.2.3.7.10 Timestamp Sync Output

The CPTS_SYNC output is a selected bit of the [31:0]TIME_STAMP counter value. One of bits 17-31 can be selected in CPSW_CPTS_CONTROL_REG[31:28] TS_SYNC_SEL. The CPTS_SYNC output is disabled when CPSW_CPTS_CONTROL_REG[31:28] TS_SYNC_SEL is zero.

If the selected counter bit is 1 at the time when TS_SYNC_SEL value is written then a rising edge will not occur on the CPTS_SYNC output. A rising edge will occur on the CPTS_SYNC output upon the next transition to 1 of the selected counter bit. The TS_SYNC_SEL value must be written to zero before changing to a different non-zero value. No events are generated due to the CPTS_SYNC operation. The CPTS_SYNC output is two CPTS_RFT_CLK periods after the actual count value.

12.2.2.3.7.11 Timestamp GENFn Output

The CPTS_GENFn outputs have a programmable cycle (frequency) with a PPM feature and software nudge feature. The CPTS_GENFn output cycle is CPSW_GENF0_LENGTH_REG/ CPSW_GENF1_LENGTH_REG[31:0] LENGTH CPTS_RFT_CLK periods (which is different than CPTS_COMP operation). [Figure 12-102](#) represents the CPTS_GENFn output signal.

The CPTS_GENFn output cycle is CPSW_GENF0_LENGTH_REG/ CPSW_GENF1_LENGTH_REG[31:0] CPTS_RFT_CLK periods beginning when the 64-bit TIME_STAMP value compares with the 64-bit GENFn_COMP value (CPSW_GENF0_COMP_LOW_REG and CPSW_GENF0_COMP_HIGH_REG registers) and the length value is non-zero. The CPTS_GENFn output cycle repeats thereafter every CPSW_GENF0_LENGTH_REG/ CPSW_GENF1_LENGTH_REG[31:0] CPTS_RFT_CLK periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the CPSW_CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit is low. No compare events and no CPTS_EVNT interrupts are generated.

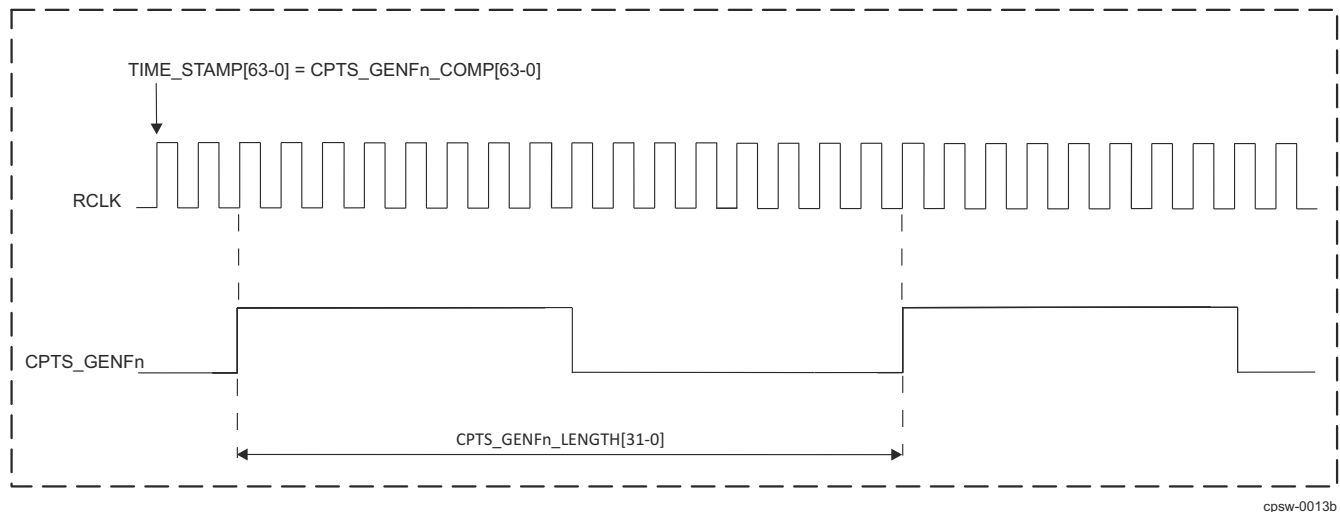

Figure 12-102. CPTS_GENFn Output Signal Diagram

12.2.2.3.7.11.1 GENFn Nudge

The cycle length can be adjusted by writing the CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE register value which is a two's complement value. A value of FFh will subtract 1 CPTS_RFT_CLK from the CPSW_GENF0_LENGTH_REG/ CPSW_GENF1_LENGTH_REG[31-0] value. A value of 1h will add 1 CPTS_RFT_CLK to the CPSW_GENF0_LENGTH_REG/ CPSW_GENF1_LENGTH_REG[31-0] value. The CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred.

12.2.2.3.7.11.2 GENFn PPM

The CPTS_GENFn output cycle can be adjusted by parts per million or by parts per hour. Writing a non-zero value to CPSW_GENF0_PPM_LOW_REG/ CPSW_GENF0_PPM_HIGH_REG enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single CPTS_RFT_CLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPSW_GENF0_CONTROL_REG/ CPSW_GENF1_CONTROL_REG[0] PPM_DIR bit. When PPM_DIR bit is set a single CPTS_RFT_CLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM_DIR bit is cleared a single CPTS_RFT_CLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

Parts Per Million example:

To adjust for 100 parts per million the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG and CPSW_GENF0_PPM_HIGH_REG) is:
 $1,000,000/100 = 10,000(\text{decimal})$

Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS_RFT_CLK the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG and CPSW_GENF0_PPM_HIGH_REG) is:
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600 \text{ seconds/hour}) = 34630\text{B8A000} (\text{hex})$

12.2.2.3.7.12 Timestamp ESTFn

Each Ethernet port has a dedicated ESTFn generator which operates identically to the GENFn function.

12.2.2.3.7.13 Time Sync Events

Time Sync events are 96-bit values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPSW_CPTS_EVENT_0_REG through CPSW_CPTS_EVENT_3_REG hold the data of a time sync event. There are eight types of sync events:

- Time Stamp Push Event
- Time Stamp Counter Rollover Event (32-bit mode only)
- Time Stamp Counter Half-rollover Event (32-bit mode only)

- Hardware Time Stamp Push Event
- Ethernet Receive Event
- Ethernet Transmit Event
- Time Stamp Compare Event
- Host Transmit Event

12.2.2.3.7.13.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the [0]TS_PUSH bit of the CPSW_CPTS_TS_PUSH_REG register. The time stamp value is returned in the event, along with a time stamp push event code. The upper 32-bits (CPSW_CPTS_EVENT_3_REG register) of the timestamp are zero in 32-bit mode.

12.2.2.3.7.13.2 Time Stamp Counter Rollover Event (32-bit mode only)

The CPTS module contains a 32-bit time stamp value (CPSW_CPTS_EVENT_0_REG). The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented. This event occurs only in 32-bit mode.

12.2.2.3.7.13.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value (CPSW_CPTS_EVENT_0_REG[31:0] TIME_STAMP) has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. This event occurs only in 32-bit mode.

The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 12-103](#) shows a misalignment condition. This misaligned event condition arises because an Ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

Host software must detect and correct for misaligned event conditions. For every event time stamp after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

When a rollover occurs, software increments the software time stamp upper value. The misaligned case indicates to software that the misaligned event time stamp has a valid upper value that is pre-increment, so one must be subtracted from the upper value to allow software to calculate the correct time for the misaligned event.

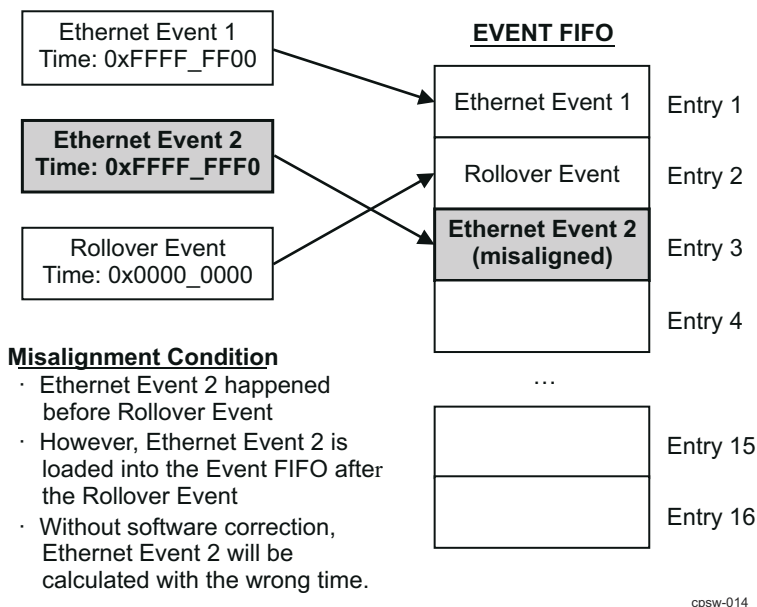

Figure 12-103. Event FIFO Misalignment Condition

12.2.2.3.7.13.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (CPTS_HW[1:4]_TS_PUSH events) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in [Figure 12-99](#). The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPSW_CPTS_EVENT_1_REG register indicates the hardware push input that caused the event (encoded).

The hardware time stamp inputs are asynchronous and are low frequency signals. The CPTS logic synchronizes and performs a rising edge detect on the incoming asynchronous input.

Each hardware time stamp input must be asserted for at least 10 periods of the selected CPTS_RFT_CLK clock. Each input can be enabled or disabled by setting the respective bits in the CPSW_CPTS_CONTROL_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

12.2.2.3.7.13.5 Ethernet Port Events

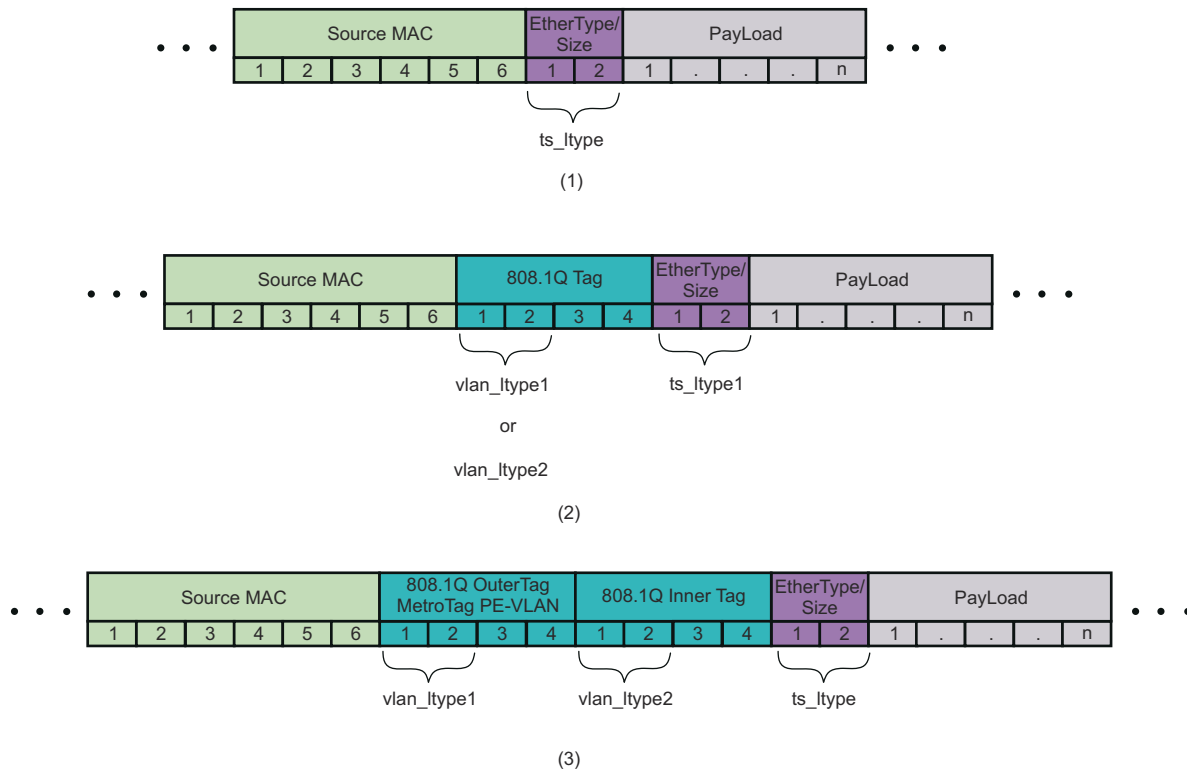

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in [Figure 12-104](#). For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field in the CPSW_PN_TS_SEQ_LTYPE_REG_k or the TS_LTYPE2 field in CPSW_PN_TS_CTL_LTYPE2_REG_k register (depending on which enable bit was set) , which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in [Figure 12-104](#). To indicate to the CPTS hardware that a virtual LAN is in use, the TS_TX_VLAN_LTYPE1_EN (or TS_TX_VLAN_LTYPE2_EN) enable bit must be set in the CPSW_PN_TS_CTL_REG_k register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the TS_VLAN_LTYPE1 (or TS_VLAN_LTYPE2 depending on which enable

bit was set) field in the CPSW_PN_TS_VLAN_LTYPE_REG_k register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 12-104. In this case, both TS_VLAN_LTYPE1 and TS_VLAN_LTYPE2 must be enabled. The outer tag must match the value of the TS_VLAN_LTYPE1 field, and the inner tag must match the value of the TS_VLAN_LTYPE2 field.

cpsw-015

Figure 12-104. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)

12.2.2.3.7.13.5.1 Ethernet Port Receive Event

This section describes Ethernet port receive events. Ethernet port generates time synchronization events for valid received time sync packets. For every packet received on the Ethernet port, a timestamp will be captured by the receive module inside the CPTS for the corresponding port. The time stamp will be captured by the receive module regardless of whether or not the packet is a time synchronization packet to make sure that the time stamp is captured as soon as possible. The packet is sampled on both the rising and falling edges of the CPTS_RFT_CLK, and the time stamp will be captured once the start of frame delimiter for the receive packet is detected.

After the time stamp has been captured, the receive interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPSW decoder determines if the packet is a valid Ethernet receive time synchronization event. The receive interface for the port will use the following criteria to determine if the packet is a valid Annex D, Annex E, or Annex F time synchronization Ethernet receive event:

Annex D (IPv4)

1. Receive annex D time sync is enabled (TS_RX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG_k register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x0800

- b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches 0x0800
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches 0x0800
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
 5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG_k register is cleared to 0h, or byte 22 contains any value if CPSW_PN_TS_CTL_LTYPE2_REG_k is set to 1h. Byte 22 is the TTL/HOP field.
 6. Byte 23 contains 0x11 (Next Header UDP Fixed).
 7. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is cleared to 0h and Bytes 30 through 33 contain:
 - a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set
- OR-
- The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set -OR-
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set.
 9. The PTP message begins in byte 42.
 10. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG_k register.
 11. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex E (IPv6)

1. Receive annex E time sync is enabled (TS_RX_ANNEX_E_EN bit is set in the switch CPSW_PN_TS_CTL_REG_k register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x86dd.
 - b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches 0x86dd
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches 0x86dd
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the

- f. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG_k register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register.
- g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the third packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG_k register.
- h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG_k register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register
3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG_k register.
5. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

If all of the criteria described above are met for either Annex D, Annex E, or Annex F, and the packet is determined to be a valid time synchronization packet, then the RX interface will push an Ethernet receive event into the event FIFO.

12.2.2.3.7.13.5.2 Ethernet Port Transmit Event

This section describes Ethernet port transmit events. For every packet transmitted on the Ethernet ports, the port transmit interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPTS transmit interface for the port will use the following criteria to determine if the packet is a valid time synchronization Ethernet transmit event. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. To be a valid Ethernet transmit time synchronization event, the conditions listed below must be true for either Annex D, Annex E, or Annex F:

Annex D (IPv4)

1. Transmit time sync is enabled (TS_TX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG_k register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x0800
 - b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches 0x0800
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches 0x0800
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG_k register is cleared to 0h, or byte 22 contains any value if TS_TTL_NONZERO is set to 1h. Byte 22 is the TTL/HOP field.

6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is cleared to 0h and Bytes 30 through 33 contain:
 - a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - f. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG_k register.
11. The packet was sent by host port 0.

Annex E (IPv6)

1. Transmit annex E time sync is enabled (TS_TX_ANNEX_E_EN bit is set in the switch CPSW_PN_TS_CTL_REG_k register).
2. One of the sequences below is true.
 - a. The first packet LTYPE matches 0x86dd.
 - b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches 0x86dd
 - c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches 0x86dd
 - d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG_k register is cleared to 0h, or byte 21 contains any value if TS_TTL_NONZERO is set to 1h. Byte 21 is the TTL/HOP field..
6. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is cleared to 0 and Bytes 38 through 53 contain:
 - a. FF0M:0:0:0:0:0:0:0181 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - b. FF0M:0:0:0:0:0:0:0182 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - c. FF0M:0:0:0:0:0:0:0183 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - d. FF0M:0:0:0:0:0:0:0184 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - e. FF0M:0:0:0:0:0:0:006B and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set

Note

All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_PN_TS_CTL2_REG_k register.

-OR-

The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set to 1h and Bytes 38 through 53 contain any value.

7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
 - a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set, or
 - b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG_k register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG_k register.
10. The packet was sent by host port 0.

Annex F (IEEE 802.3)

1. Transmit time sync is enabled (TS_TX_ANNEX_F_EN is set in the switch CPSW_PN_TS_CTL_REG_k register).
2. One of the sequences below is true:
 - a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG_k register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
 - b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG_k register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register.
 - c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG_k register.
 - d. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG_k register.
 - e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG_k register.
 - f. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG_k register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register.
 - g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG_k register.
 - h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG_k register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG_k register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG_k register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG_k register.
3. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG_k register.
4. The packet was sent by host port 0.

If all of the criteria described above are met, and the packet is determined to be a valid time synchronization packet, then the time stamp for the transmit event will not be generated until the start of frame delimiter of the

packet is actually transmitted. The start of frame delimiter will be sampled on every rising and falling edge of the CPTS_RFT_CLK. Once the packet is transmitted, then the TX interface will push an Ethernet transmit event into the event FIFO.

Table 12-173. Values of Message Type Field

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4:7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E:F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPSW_CPTS_EVENT_1_REG register contains the Message Type and Sequence ID values from the original time sync packet. The CPSW_CPTS_EVENT_0_REG (and CPSW_CPTS_EVENT_3_REG) register contains the time stamp value when the packet arrived at the corresponding port.

12.2.2.3.7.14 Timestamp Compare Event

Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode.

12.2.2.3.7.14.1 32-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 32-bit time stamp value (CPSW_CPTS_EVENT_0_REG) compares with the CPSW_CPTS_TS_COMP_VAL_REG register and the CPSW_CPTS_TS_COMP_LEN_REG value is non-zero. The CPSW_CPTS_TS_COMP_LEN_REG value should be written by software after the CPSW_CPTS_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

12.2.2.3.7.14.2 64-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 64-bit time stamp value (CPSW_CPTS_EVENT_0_REG and CPSW_CPTS_EVENT_3_REG) compares with the CPSW_CPTS_TS_COMP_VAL_REG and CPSW_CPTS_TS_COMP_HIGH_VAL_REG registers and the CPSW_CPTS_TS_COMP_LEN_REG value is non-zero. The CPSW_CPTS_TS_COMP_LEN_REG value should be written by software after the CPSW_CPTS_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

12.2.2.3.7.15 Host Transmit Event

The host can send a packet to be transmitted on an Ethernet port that will generate a time synchronization event. The host sets the TSTAMP_EN bit and sends the DOMAIN, MESSAGE_TYPE, and SEQUENCE_ID in the additional control information that resides in the protocol specific section of the descriptor that is transmitted

to the CPSW_9G. An event is then generated and placed on the event FIFO once the packet is transmitted. Host events allow the user to timestamp exactly when a software generated packet exits the device.

12.2.2.3.7.16 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPSW_CPTS_INT_ENABLE_REG register.
2. Upon interrupt, read the CPSW_CPTS_EVENT_0_REG through CPSW_CPTS_EVENT_3_REG registers values.
3. Set the CPSW_CPTS_EVENT_POP_REG[0] EVENT_POP bit to 1h to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPSW_CPTS_INT_ENABLE_REG
2. Upon interrupt, enter the CPTS service routine.
3. Read the CPSW_CPTS_EVENT_0_REG through CPSW_CPTS_EVENT_3_REG registers values.
4. Set the CPSW_CPTS_EVENT_POP_REG[0] EVENT_POP bit to 1h to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than four CPTS_RFT_CLK periods plus four CPPI_ICLK periods.
6. Read the TS_PEND_RAW bit in the CPSW_CPTS_INTSTAT_RAW_REG register to determine if another valid event is in the event FIFO. If bit TS_PEND_RAW is asserted, go to step 3. If bit TS_PEND_RAW is not asserted proceed with step 7.
7. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPSW_CPTS_INTSTAT_RAW_REG register to determine if a valid event is on the event FIFO.

12.2.2.3.8 CPPI Streaming Packet Interface

The receive streaming interface on port 0 of the CPSW is responsible for receiving packet for Ethernet egress data from the packet streaming switch in the NAVSS. The CPPI receive port is equivalent to an Ethernet port with the difference being that the data is provided to the CPSW in the 128-bit streaming interface data format instead RGMII data format.

In addition to the packet data, the receive streaming interface also can provide additional control information that resides in the information words of the descriptor that was transmitted to the CPSW.

The tables below show the information that may be passed along with which descriptor information word to put it in.

12.2.2.3.8.1 Port 0 CPPI Transmit Packet Streaming Interface (CPSW_9G Egress)

The CPSW2G has a single transmit packet streaming interface. All Ethernet packet data destined for the host (Port 0) is transferred on the transmit packet streaming interface. The transmit packet streaming interface is equivalent to an Ethernet MAC output with the difference being that 128-bit streaming interface data is output. Egress packet data is packed on the 128-bit data bus with all words having 16-bytes except possibly the last packet data word which is the word previous to the EOP word. INFO Word 0–3 is transferred on SOP. The EOP word contains the packet status 0–3 (data type 24) which includes the timestamp and checksum data. Packets are not dropped on the transmit streaming interface due to pushback, but packets may be dropped in the associated priority FIFO.

INFO Word 0–3 and Status Data Word 0–3 (on EOP) are the only non-payload data word types that are transferred. Long packets are truncated at the CPSW_PN_RX_MAXLEN_REG_k[13-0] RX_MAXLEN byte value of the ingress port (only the CPSW_PN_RX_MAXLEN_REG_k number of bytes are kept if long packets are transferred due to CPSW_PN_MAC_CONTROL_REG_k register copy error frames

set - RX_CEF_EN). MAC control frames are only transferred if the receiving Ethernet port has the CPSW_PN_MAC_CONTROL_REG_k[24] RX_CMF_EN bit set.

The error encoding on the TXST_PKT_ERR[3:0] output is shown in [Table 12-174](#):

Table 12-174. Error Encoding on the TXST_PKT_ERR[3:0] Output

TXST_PKT_ERR[3:0]	Description
0000	No Error
0001	CRC Error
0010	Code or alignment error
0011	Short (no code/align/crc error)
0100	FragCRC (short with crc error)
0101	Frag Code/Align (short with code/align error)
0110	Long
0111	Jabber CRC (long with crc error)
1000	Jabber Code/Align (long with code/align error)
1001	Mac onl control packet (CPSW_PN_MAC_CONTROL_REG[24] RX_CMF_EN set on ingress Ethernet port)
1010	Mac control CRC
1011	Mac control Code/Align
1100	Mac control short/frag (short MAC control frame with CRC/Code/Align)
1101	Mac control long/jabber (long MAC control frame with CRC/Code/Align)
1110	Reserved
1111	Reserved

The CPPI Port 0 transmit packet streaming interface has a single output thread. If a packet transmission has begun then the entire packet will be transmitted before the next packet is sent (packet data from multiple packets are not interleaved on the transmit streaming interface). The default egress flow is the port number minus 1, concatenated with the 3-bit Port 0 transmit FIFO hardware switch priority. For example, a packet that was received on port 4 with a Port 0 transmit FIFO hardware switch priority of 5 would be sent on flow 29 (decimal) or flow 0b0011101 (binary). Priority remapping on ingress and Port 0 transmit egress effects the output flow.

INFO Words () are a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

RESERVED								FLOW_ID							

Bit	Field	Description
31-27	PKT_TYPE	Always set to 0b00111. Host PD (Packet Descriptor) Word 2. Packet Type: bits[31-27].
26-24	RESERVED	Reserved.
23	PASS_CRC	This bit is cleared to zero (no CRC passed) when the P0_TX_CRC_REMOVE bit in the CPSW_CONTROL_REG register is set (and the egress packet has no errors). When the remove bit is cleared to zero then this bit is cleared and no CRC is passed with the output packet. The packet length includes the CRC if it is present.

Bit	Field	Description
22	CRC_TYPE	The packet CRC type. The type of CRC passed is determined by CRC_TYPE field in the CPSW_PN_MAC_CONTROL_REG_k register (not by the type of CRC the packet had on Ethernet port ingress). Host PD Word 1. Protocol Specific Flags: bits[27-24]. 0h: Ethernet CRC 1h: Castagnoli CRC
21-8	RESERVED	Reserved.
7-0	FLOW_ID	This is the packet output transmit streaming interface flow. The default flow ID can be overridden by ALE classification (Thread mapping). The switch default flow is the 3-bit “From Port” value concatenated with the 3-bit “Switch Priority” {From_Port[2:0], Switch_Priority[2:0]} as shown below: Host PD (Packet Descriptor) Word 1. Flow ID: bits[13-0]. 0h: The packet was received on Ethernet port 1 1h: The packet was received on Ethernet port 2 Switch Priority – The actual hardware switch priority that the packet was stored in on the CPPI transmit FIFO.

0		PKT_LENGTH													

Bit	Field	Description
31-20	FIXED_PS_SIZE	Fixed packet size: 0x4
19-14	RESERVED	Reserved.
13-0 (Host PD (Packet Descriptor) Word 1. Packet Length: bits[21-0])	PKT_LENGTH	Specifies the number of bytes in the entire packet. Offset bytes are not included. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

12.2.2.3.8.2 CPPI Receive Packet Streaming Interface (CPSW Ingress)

Info Word 0/1/2/3 (INFO1 and INFO3 are ignored) are transferred on SOP. If a timestamp word (Extended Packet Info Word 0/1/2/3) is to be transferred it must be after SOP and before any packet data is transferred. Any following non-data type words will be dropped. The EOP word must be payload data.

Input receive packets cannot be aborted by the host. The INFO Word bit descriptions and Extended Packet INFO Word bit descriptions are shown below. The PASS_CRC bit indicates that the CRC is passed with the packet data. Packets that have a passed CRC that is an error CRC will be output on the Ethernet port with at least one CRC byte inverted to indicate the error if P0_RX_PASS_CRC_ERR bit is set, otherwise they are dropped. The packet is a directed packet when any of the TO_PORT bits are nonzero. A packet may be directed only to a single port. The packet will be sent to the port number indicated. For directed packets the lookup process is skipped to determine the destination. However, in vlan aware mode (when VLAN_AWARE bit in the CPSW_CONTROL_REG register is set to 1h) the lookup is performed to determine untagged egress. Packets longer than the value in CPSW_P0_RX_MAXLEN_REG[13-0] RX_MAXLEN bit field are dropped. Packets shorter than 60-Bytes are padded to 64-Bytes (after adding pad and CRC) if P0_RX_PAD bit in the CPSW_CONTROL_REG register is set and if PASS_CRC is clear, otherwise they are dropped. This means that packets shorter than 64-Bytes are dropped if the PASS_CRC info bit is set regardless of P0_RX_PAD bit (packets are padded only if they are short and do not have CRC).

A RX INFO word () is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Note

RX Control Data Words [0..2] are mapped to Host Packet Descriptor Protocol Specific Words if (TCHAN[a]_TCFG.tx_filt_pswords = 0) and (Host PD Word 1.Protocol Specific Region Location.bit[28] = 0h) and (Host PD Word 1.Protocol Specific Valid Word Count.bits[22-27] = 4h)

CHECKSUM_INV	RESERVED	CHECKSUM_BYTECOUNT
Bit	Field	Description
31-24	CHECKSUM_RESULT	This is the packet byte number where the checksum result will be placed in the egress packet. The first packet byte which is the first byte of the destination address is Byte 1 (not byte zero).
23-16	CHECKSUM_START_BYTE	This is the packet byte number to start the checksum calculation on. The first packet byte is Byte 1.
15	CHECKSUM_INV	When set, a zero checksum value will be inverted and sent as FFFFh.
14	RESERVED	Reserved.
13-0	CHECKSUM_BYTECOUNT	This is the number of bytes to calculate the checksum on. The outgoing Ethernet packet will have a checksum inserted when this value is non-zero.

Other INFO words are not taken into account.

12.2.2.3.8.3 CPPI Checksum Offload

The CPPI host port can be enabled to perform checksum offload on host port packet ingress and egress. UDP (User Datagram Protocol) and TCP (Transmission Control Protocol) over IPV4 and IPV6 are supported. For the purposes of checksum description, the first packet byte (the first byte of the destination address) is byte 1 (not byte 0). That is, a 64 byte packet goes from byte 1 to byte 64. For all packet types, the S_CN_SWITCH bit in the CPSW_CONTROL_REG register must be set for the Outer VLAN L type to be supported.

12.2.2.3.8.3.1 CPPI Transmit Checksum Offload

IPV4 and IPV6 UDP and TCP packets that are received on any Ethernet port and destined for port 0 egress are checked for correct checksum as described below. The byte counts below are shown for packets with no VLAN's. The byte counts vary with one or two packet VLAN's. Packets received on an Ethernet port with errors are not checked for a correct checksum if they are passed to the host.

12.2.2.3.8.3.1.1 IPV4 UDP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no UDP header).
- Byte 24 = 0x11 for UDP protocol.
- Received packet UDP checksum of zero means that there is no IPV4 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

12.2.2.3.8.3.1.2 IPV4 TCP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no TCP header).

- Byte 24 = 0x06 for TCP protocol.

12.2.2.3.8.3.1.3 IPV6 UDP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x11 for UDP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x11). Middle and last fragments have a fragment extension header followed by data only (no UDP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.
- Received packet UDP checksum of zero means that there is no IPV6 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

12.2.2.3.8.3.1.4 IPV6 TCP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x06 for TCP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x06). Middle and last fragments have a fragment extension header followed by data only (no TCP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.

12.2.2.3.8.4 CPPI Receive Checksum Offload

Packets sent from host port 0 (switch ingress) to any Ethernet port can have a checksum calculated and inserted into the Ethernet egress packet. The RX_CHECKSUM_EN bit in the CPSW_P0_CONTROL_REG register must be set for receive checksum operation to be enabled. When bit RX_CHECKSUM_EN is enabled, Control Data Word 2 input on CPPI receive PSI interface determines how the checksum is calculated. The CHECKSUM_RESULT field in Control Data Word 2 determines where the checksum is inserted. The checksum result location is adjusted by the egress port if a VLAN is to be inserted or removed on Ethernet port egress.

12.2.2.3.8.5 Egress Packet Operations

Each CPSW egress port (Ethernet and Host) is capable of performing egress packet processing operations (CPSW_ALE_EGRESSOP). IntraVLAN processing either adds, removes, or replaces VLAN information or does nothing. InterVLAN routing allows hardware routing between a limited number of VLANs - thereby allowing high-bandwidth or other routing operations to be offloaded from software to the CPSW (hardware). IntraVLAN processing and InterVLAN routing operations are mutually exclusive. In addition, the packet source and destination addresses can be swapped on egress to facilitate OAM or generic testing operations.

12.2.2.3.9 MII Management Interface (MDIO)

The MII Management interface module implements the 802.3 serial management interface to interrogate and control external Ethernet PHY using a two-wire bus.

12.2.2.3.9.1 MDIO Frame Formats

Table 12-175 shows the address, Table 12-176 shows the read format and Table 12-177 shows the write format of the supported Clause 45 MII Management interface frames. Post-increment accesses are not supported.

Table 12-175. MDIO Clause 45 Address Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	00	AAAAA	RRRRR	10	AAAA.AAAA.AAAA.AAAA

Table 12-176. MDIO Clause 45 Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	11	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 12-177. MDIO Clause 45 Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction. The MDIO CPSW_MDIO_USER_ADDR0_REG register must be written before a read or write operation is performed to set the address used in the operation. Each read or write operation has a preceeding address frame.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization. The preamble is required in clause 45 operation.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 00 pattern.

Operation Code

The operation code for an address transaction is 00. The operation code for a read is 11, while the operation code for a write is a 01.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

MMD Number

The MMD number is the 5 bits allowing 32 unique values. The first bit transmitted is the MSB.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Address

The address field is 16 bits on address operations. The first bit transmitted is the MSB of the address word. Each read/write operation initiated has an automatic address operation initiated first that uses the MDIO CPSW_MDIO_USER_ADDR0_REG/ CPSW_MDIO_USER_ADDR1_REG register values as the 16-bit address.

Data

The Data field is 16 bits on read and write operations. The first bit transmitted and received is the MSB of the data word.

12.2.2.3.9.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the CPSW_MDIO_CONTROL_REG register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO CPSW_MDIO_LINK_REG register. Individual PHY's can be enabled or disabled for polling the associated bit in the CPSW_MDIO_POLL_EN_REG register. The CPSW_MDIO_LINK_REG and CPSW_MDIO_ALIVE_REG register bit values are updated on the poll of each PHY. The LINKSEL bit in the CPSW_MDIO_USER_PHY_SEL_REG_k register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO CPSW_MDIO_LINK_INT_RAW_REG register and the MDIO CPSW_MDIO_LINK_INT_MASKED_REG register, if enabled by the LINKINT_ENABLE bit in the CPSW_MDIO_USER_PHY_SEL_REG_k register.

The MDIO CPSW_MDIO_ALIVE_REG register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO CPSW_MDIO_ALIVE_REG register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a CPSW_MDIO_USER_ACCESS_REG_k register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW field in the CPSW_MDIO_USER_INT_RAW_REG register corresponding to the CPSW_MDIO_USER_ACCESS_REG_k register being used. The corresponding bit in the CPSW_MDIO_USER_INT_MASKED_REG register may also be set depending on the mask setting in the MDIO CPSW_MDIO_USER_INT_MASK_SET_REG and CPSW_MDIO_USER_INT_MASK_CLEAR_REG registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different CPSW_MDIO_USER_ACCESS_REG_k registers. The host should check the status of the GO bit in the MDIO CPSW_MDIO_USER_ACCESS_REG_k register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO CPSW_MDIO_USER_ACCESS_REG_k register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the CPSW_PN_MAC_CONTROL_REG_k register in the corresponding MAC.

12.2.2.4 CPSW0 Programming Guide

12.2.2.4.1 Initialization and Configuration of CPSW Subsystem

To configure the CPSW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (RMII, RGMII, SGMII, QSGMII or QSGMII_SUB) Mode.
See CTRL_MMR0_ENET1_CTRL[2-0] PORT_MODE_SEL to CTRL_MMR0_ENET8_CTRL[2-0] PORT_MODE_SEL registers.
2. Configure pads (pin muxing), as per the interface selected. Refer to *Pad Configuration Registers* and the device-specific Datasheet.
3. Enable the CPSW Ethernet Subsystem clocks. See *CPSW Integration*
4. Ensure that at least 2000 CPPI_ICLK periods are run after reset is de-asserted.
5. Configure the CPSW_CONTROL_REG register
6. Configure the Ethernet Port Source Address registers (CPSW_PN_SA_L_REG_k and CPSW_PN_SA_H_REG_k)

7. Configure the CPSW statistic port enable register CPSW_STAT_PORT_EN_REG
8. Configure the ALE ([Section 12.2.2.3.6.1, Address Lookup Engine](#))
9. Configure the MDIO ([Section 12.2.2.4.3.1, Initializing the MDIO Module](#))
10. Configure Ethernet port, as per the desired mode of operations

12.2.2.4.2 Ethernet MAC Reset or XGMII/GMII Mode Change Configuration

To reset the Ethernet port, the host must perform the following:

1. Set CMD_IDLE bit to 1h in the Ethernet port control registers: CPSW_PN_MAC_CONTROL_REG_k.
2. Wait for IDLE bit to be set to 1h, which is indicated in the Ethernet port status registers: CPSW_PN_MAC_STATUS_REG_k.
3. Set SOFT_RESET bit to 1h in the Ethernet port software reset registers: CPSW_PN_MAC_SOFT_RESET_REG_k.
4. Wait for SOFT_RESET bit in the CPSW_PN_MAC_SOFT_RESET_REG_k registers to be cleared to confirm reset completion.
5. Configure the Ethernet ports.

12.2.2.4.3 MDIO Software Interface

12.2.2.4.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CPSW_MDIO_CONTROL_REG).
2. Enable the MDIO module by setting the ENABLE bit in CPSW_MDIO_CONTROL_REG.
3. The MDIO PHY alive status register (MDIO CPSW_MDIO_ALIVE_REG) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO CPSW_MDIO_LINK_REG) can determine whether this PHY already has a link.
4. Set the appropriate PHY addresses in the MDIO user PHY select register (CPSW_MDIO_USER_PHY_SEL_REG_k, where k = 0 or 1), and set the LINKINT_ENABLE bit to enable a link change event interrupt if desirable.
5. Set the appropriate LINKSEL bit in the CPSW_MDIO_USER_PHY_SEL_REG_k register (where k = 0 or 1).
6. Set the appropriate USERINTMASKSET bit field in the CPSW_MDIO_USER_INT_MASK_SET_REG register.
7. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO CPSW_MDIO_USER_INT_MASK_SET_REG) to use the MDIO user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1).

12.2.2.4.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO CPSW_MDIO_USER_ACCESS_REG_k corresponding to the PHY and PHY register SW wants to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO CPSW_MDIO_USER_ACCESS_REG_k for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_RAW_REG) corresponding to MDIO CPSW_MDIO_USER_ACCESS_REG_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW_MDIO_USER_INT_MASK_SET_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_MASKED_REG) and an interrupt is triggered on the host processor.

12.2.2.4.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) is cleared.

2. Write to the GO, REGADR, and PHYADR bits in the CPSW_MDIO_USER_ACCESS_REG_k register corresponding to the PHY and PHY register SW wants to read.
3. The read data value is available in the DATA bit field in MDIO CPSW_MDIO_USER_ACCESS_REG_k register after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in CPSW_MDIO_USER_ACCESS_REG_k register. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_RAW_REG) corresponding to MDIO CPSW_MDIO_USER_ACCESS_REG_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW_MDIO_USER_INT_MASK_SET_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_MASKED_REG) and an interrupt is triggered on the host processor.

12.2.3 Peripheral Component Interconnect Express (PCIe) Subsystem

This chapter describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) subsystem.

12.2.3.1 PCIe Subsystem Overview

The Peripheral Component Interconnect Express (PCIe) subsystem is built around a multi-lane dual-mode PCIe controller that provides low pin-count, high reliability, and high-speed data transfers at rates of up to 8.0 Gbps per lane for serial links on backplanes and printed wiring boards.

Figure 12-117 provides PCIe subsystem overview.

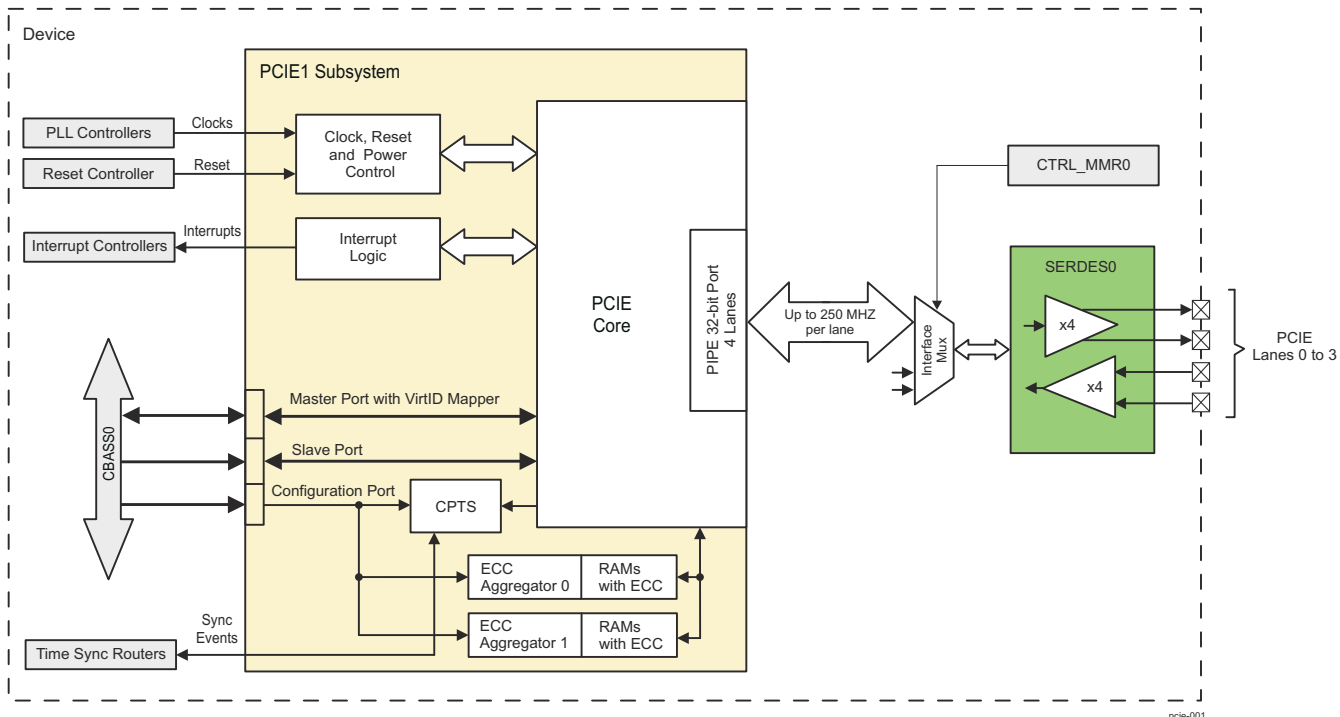

Figure 12-117. PCIe Subsystem Overview

12.2.3.1.1 PCIe Subsystem Features

Each PCIe subsystem supports the following main features:

- Compliance to PCIe® Base Specification, Revision 4.0 (Version 0.7)
- 4-lane configuration with up to 8.0 Gbps/lane (Gen3). Can be used in 1x4, 1x2, 1x1 modes.
- Gen3 (8 Gbps 128/130-bit encoding), Gen2 (5 Gbps 8/10-bit encoding), and Gen1 (2.5 Gbps 8/10-bit encoding) with auto-negotiation
- 62.5/125/250MHz operation on PIPE interface for Gen1/Gen2/Gen3, respectively
- Constant 32-bit PIPE width for Gen1/2/3 modes
- Dynamic PIPE width change when switching between Gen1/2/3 modes
- Dual mode: Root Port (RP) or End Point (EP) operation modes
- Maximum payload size of 256 bytes
- Maximum remote read request size of 4K bytes
- Four virtual channels (VC)
- Four traffic classes (TC)
- PCI Power Management states are:
 - L1 Active State Power Management
 - L1 Power Management substates support
 - D1 Device Power Management state
- Maximum number of non-posted outstanding transactions: 32
- Resizable BAR capability

- Separate Reference Clock with Independent Spread (SRIS)
- Legacy, MSI and MSI-X Interrupt Support
- 32 outbound address translation regions
- Precision time measurement (PTM)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.2.3.1.2 PCIe Subsystem Ports

This section describes PCIe subsystem ports related to clocks, resets, and hardware requests.

Table 12-178. PCIe Subsystem Clocks and Resets

Clocks	
Module Clock Input	Description
PCIE_FICLK	PCIE interface bus clock (CBA_CLK).
PCIE_PM_CLK	PCIE core free-running clock used for low power state transitions and clock control generation.
PCIE_CPTS_RCLK	PCIE CPTS reference clock (RCLK). The CPTS RCLK clock frequency should be greater than or equal to the PCIE CBA_CLK clock frequency. Otherwise, the software will have to add some wait cycles before a correct event is generated by the CPTS module. Additionally, the CPTS RCLK should be set to same frequency as the PCIe core clock.
PCIE_LANE0_TXMCLK	PCIE core clock (CORE_CLK) driven by SERDES via lane 0. In multi-lane modes, only PCIE1_LANE0_TXMCLK is used as the core clock input for all lanes. The TXMCLKs for the rest of the lanes are left unconnected
PCIE_LANE0_RXCLK	PCIE PIPE interface clock driven by SERDES via lane 0. In multi-lane modes, only PCIE1_LANE0_RXCLK is used as the PIPE interface clock for all lanes. The RXCLKs for the rest of the lanes are left unconnected.
SERDES0_IP2_LN0_TXCLK	PCIE lane 0 PIPE/RAW TX return clock.
SERDES0_IP2_LN1_TXCLK	PCIE lane 1 PIPE/RAW TX return clock.
SERDES0_IP2_LN2_TXCLK	PCIE lane 2 PIPE/RAW TX return clock.
SERDES0_IP2_LN3_TXCLK	PCIE lane 3 PIPE/RAW TX return clock.
Resets	
Module Reset Input	Description
PCIE_RST	PCIE reset

Table 12-179. PCIe Subsystem Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
PCIE_DOWNSTREAM_PULSE_0	PCIE downstream interrupt	Pulse
PCIE_ERROR_PULSE_0	PCIE error interrupt	Pulse
PCIE_FLR_PULSE_0	PCIE function level interrupt	Pulse
PCIE_HOT_RESET_PULSE_0	PCIE hot reset interrupt	Pulse
PCIE_LEGACY_PULSE_0	PCIE legacy interrupt	Pulse
PCIE_LINK_STATE_PULSE_0	PCIE link state interrupt	Pulse
PCIE_LOCAL_LEVEL_0	PCIE local interrupt	Level
PCIE_PWR_STATE_PULSE_0	PCIE power state interrupt	Pulse
PCIE_PHY_LEVEL_0	PCIE PHY interrupt	Level
PCIE_PTM_VALID_PULSE_0	PCIE PTM valid interrupt	Pulse
PCIE_ECC0_CORR_LEVEL_0	PCIE ECC AGGR 0 correctable error interrupt	Level
PCIE_ECC0_UNCORR_LEVEL_0	PCIE ECC AGGR 0 uncorrectable error interrupt	Level
PCIE_ECC1_UNCORR_LEVEL_0	PCIE ECC AGGR 1 uncorrectable error interrupt	Level
PCIE_ASF_NONFATAL_LEVEL_0	PCIE active internal diagnostics interrupt	Level
PCIE_ASF_FATAL_LEVEL_0	PCIE active internal diagnostics interrupt	Level
PCIE_CPTS_PEND_0	PCIE timesync interrupt	Level
PCIE_DPA_PULSE_0	PCIE dynamic power allocation interrupt	Pulse
DMA Events		
Module DMA Event	Description	Type
-	The PCIe subsystem does not provide built-in DMA capabilities	-

Table 12-179. PCIe Subsystem Hardware Requests (continued)

Time Sync and Compare Events (Output)		
Module Event	Description	Type
PCIE_CPTS_HW1_PUSH_0	PCIE CPTS hardware push event (HW1_TS_PUSH)	Edge
PCIE_CPTS_COMP_0	PCIE CPTS compare output interrupt	Edge
PCIE_CPTS_SYNC_0	PCIE CPTS sync output interrupt	Edge
PCIE_CPTS_GENF_0	PCIE CPTS GENF0 output interrupt	Edge
Time Sync Events (Input)		
Module Event	Description	Type
PCIE_CPTS_HW2_PUSH_0	PCIE CPTS hardware time stamp push event (HW2_TS_PUSH)	Edge

12.2.3.2 PCIe Environment

This section describes the PCIe subsystem application fields from an environment point of view (external connections).

[Table 12-180](#) describes the SERDES signal names at device level related to PCIe subsystem and specifies their functions.

Table 12-180. PCIe Subsystem I/O Signals

Device Level Signal	I/O ⁽¹⁾	Description
RXN0	I	PCIe Lane 0 Receive Differential Data (-)
RXP0	I	PCIe Lane 0 Receive Differential Data (+)
TXN0	O	PCIe Lane 0 Transmit Differential Data (-)
TXP0	O	PCIe Lane 0 Transmit Differential Data (+)
RXN1	I	PCIe Lane 1 Receive Differential Data (-)
RXP1	I	PCIe Lane 1 Receive Differential Data (+)
TXN1	O	PCIe Lane 1 Transmit Differential Data (-)
TXP1	O	PCIe Lane 1 Transmit Differential Data (+)
RXN2	I	PCIe Lane 2 Receive Differential Data (-)
RXP2	I	PCIe Lane 2 Receive Differential Data (+)
TXN2	O	PCIe Lane 2 Transmit Differential Data (-)
TXP2	O	PCIe Lane 2 Transmit Differential Data (+)
RXN3	I	PCIe Lane 3 Receive Differential Data (-)
RXP3	I	PCIe Lane 3 Receive Differential Data (+)
TXN3	O	PCIe Lane 3 Transmit Differential Data (-)
TXP3	O	PCIe Lane 3 Transmit Differential Data (+)
CLKREQn	I/O	PCIe sideband signal for negotiation of L1 Substate entry/exit. The PCIE1_CLKREQn pin operates as an active low open-drain bidirection reference clock request pin. 1 = no request for clock; 0 = request for clock

(1) I = Input; O = Output.

12.2.3.3 PCIe Subsystem Functional Description

12.2.3.3.1 PCIe Subsystem Block Diagram

The block diagram of PCIe subsystem is shown in Figure 12-118. The subsystem comprises of these major components – the PCIe Core with AXI interfaces, bridges to connect to the system CBASS0 interconnect master and slave interfaces, bridges to connect the system CBASS0 configuration interfaces, additional logic to implement the Precision Time Measurement (PTM), user configuration and interrupt, and RAMs to support the controller FIFOs.

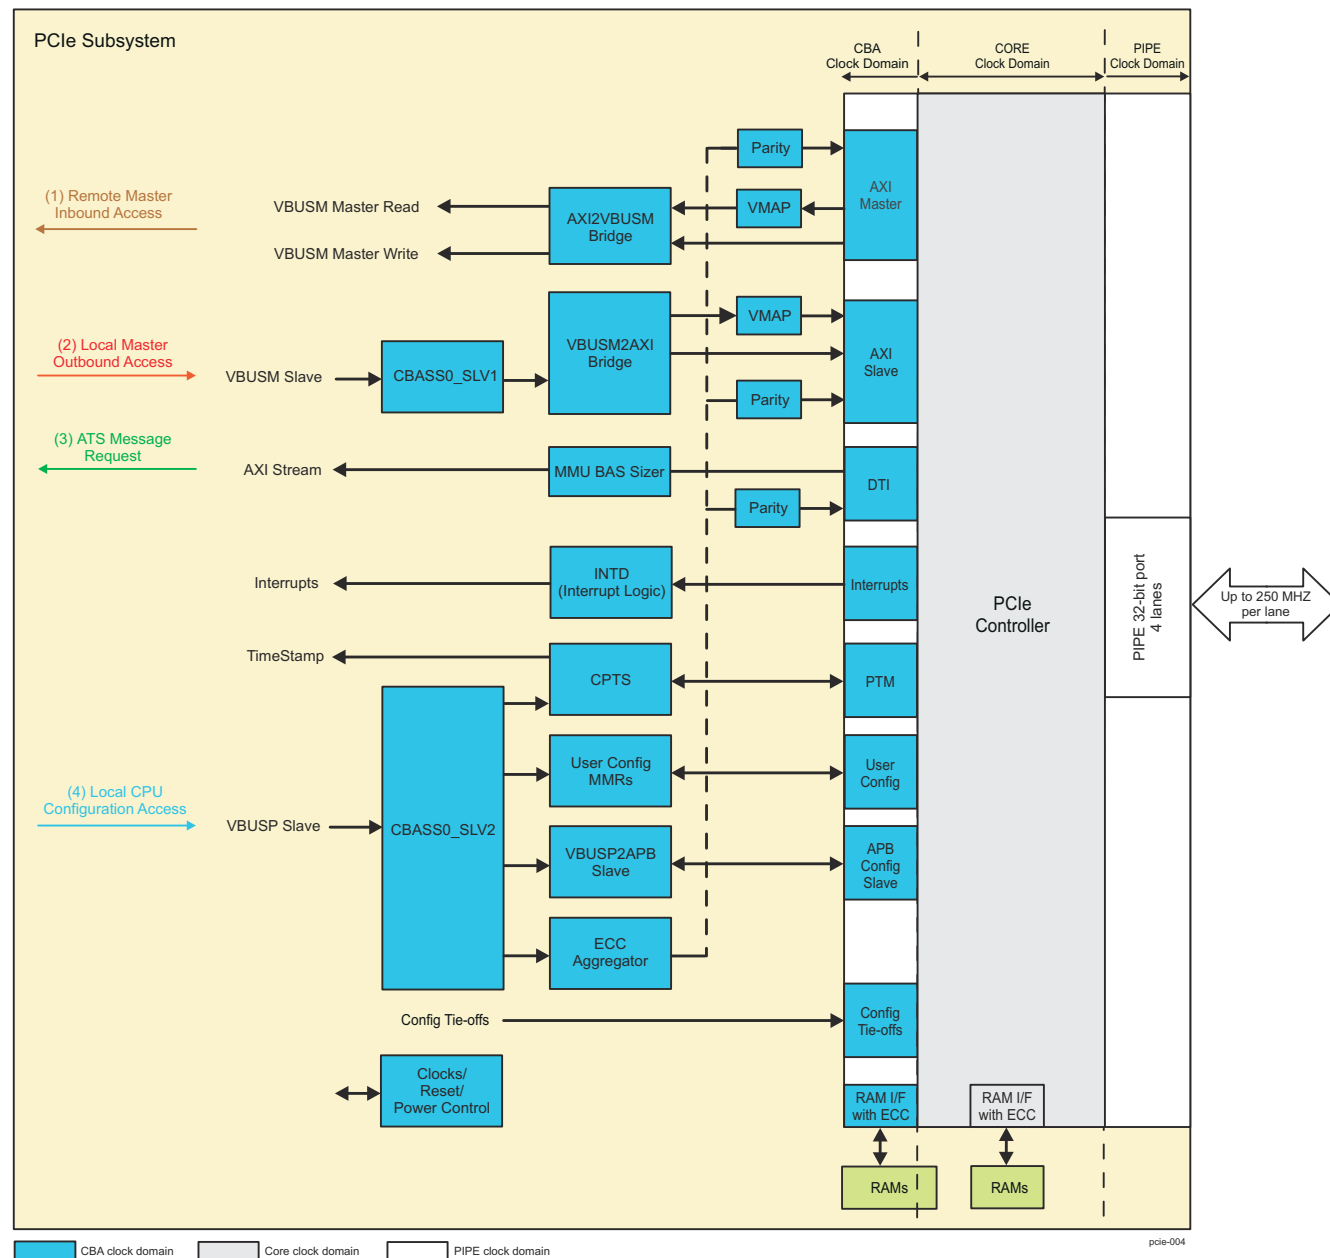

Figure 12-118. PCIe Subsystem Block Diagram

Figure 12-118 also shows some example data flows in the PCIe subsystem, such as:

1. A remote master issues a read or write access over PCIe to the local device. This will create a command to be issued on the PCIe VBUSM master read or write interface.
2. A master in the local device issues a read or write access over PCIe to the remote device. This will create a command to be issued on the PCIe VBUSM slave read or write interface.

3. A remote endpoint issues an Address Translation Request (ATS). This will create an inbound transaction on the AXI DTI interface.
4. A master in the local device wants to access the local PCIe configuration registers, the ECC aggregator registers or the CPTS registers. This will create a transaction over the PCIe VBUSP slave interface.

12.2.3.3.1.1 PCIe Core Module

The PCIe Core module supports dual mode of operation - it can be configured as an End Point (EP) and also as a Root Port (RP). The operational mode is selected with the CTRLMMR_PCIE1_CTRL[7] MODE_SEL register bit within the device Control Module (CTRL_MMR0). It is expected that the MODE_SEL bit is programmed during initial power up based on settings in the SoC boot configuration or a non-volatile storage such as eFuse or Flash memory.

It is not expected that the MODE_SEL setting would have to change during a full power cycle of the device. It is more likely that the operational mode of a SoC will stay as EP or RP for a particular end product's life cycle. It is not expected to switch back and forth during operation without a reset cycle.

The PCIe core module supports four virtual channels (VC) and four transfer classes (TC). The VCs can be used to implement Quality-of-Service (QoS) mechanism by enabling priority or round-robin arbitration. Typically, the highest numbered enabled VC is assigned the highest priority.

The PCIe core module is configured to support Single Root I/O virtualization (SR-IOV). It supports 6 Physical Functions (PF) and 16 Virtual Functions (VF).

There is one AXI master port and one AXI slave port in the PCIe core. All ingress data traffic regardless of the VC assigned will be delivered on the AXI master port. Similarly, all egress data that is presented on AXI slave port of the PCIe core will be assigned VCs through the outbound address translation registers.

12.2.3.3.1.2 PCIe PHY Interface

The PCIe subsystem incorporates a 4-lane PCIe compliant PHY (PIPE) interface to connect to a SERDES-based PHY. The PCIe PHY module consist of a SERDES module and a PCIe PCS (Physical Coding Sub-block) module. The SERDES module converts parallel data into PCIe serial signals and the PCIe PCS module provides an industry standard PIPE Interface to PCIe MAC. The frequency of the PIPE interface can be 62.5MHz, 125MHz or 250MHz depending on whether the system is operating in Gen1, Gen2 or Gen3 mode. The width of the PIPE interface remains constant at 32-bits for all modes of operation. The PCIe controller Lane 0 will always be the master lane for any lane width. For more information on the SERDES module, see *Serializer/Deserializer (SerDes)*.

12.2.3.3.1.3 CBA Infrastructure

The PCIe subsystem includes two CBASS modules (CBASS_SLV1 and CBASS_SLV2) to provide access to the various sub-components.

The CBASS_SLV1 is used to access the PCIe egress data region through the VBUSM2AXI bridge and the AXI slave port of the PCIe controller. There are three data regions implemented in the CBASS_SLV1. The PCIE_DAT0 region provides a region with 27 bits of address and PCIE_DAT1 region provides a region with 32 bits of address. These regions are provided to ensure separate memory spaces for 32-bit and 64-bit maps at the SoC level. The PCIE_DAT2 region provides a region with 48 bits of address. This is used to route all requests with *case/* not equal to zero to the PCIe controller slave port. The destination for all these three regions is the AXI slave port of the PCIe controller.

The CBASS_SLV2 provides multiple regions to access the VBUSP configuration ports of the sub-components of the PCIe sub-system like the PCIe controller configuration port, USER_CFG, VMAP, CPTS and the ECC aggregators. Having multiple regions on the VBUSP configuration port enables the SoC infrastructure to have hardware firewalls that can provide secure access to configuration registers.

The SERDES PLL should be initialized prior to accessing the PCIe core and ECC_AGGR1 configuration registers. Any accesses to these two regions prior to initializing the SERDES PLL will complete with a read/write status error in CBASS_SLV2.

12.2.3.3.1.4 VBUSM to AXI Bridges

A VBUSM2AXI protocol conversion bridge is attached to the each AXI slave port. This bridge translates all incoming data requests and sends them to the AXI slave port of the PCIe controller core. Wherever required, it also generates side band signals that the AXI bridge needs based upon the address and the address space of the transaction on the device's native bus.

12.2.3.3.1.5 AXI to VBUSM Bridges

The AXI master port of the PCIe core has an AXI2VBUSM bridge that is used for high speed data transfer during data read/write transactions originated by remote devices over the PCIe link. This bridge provides the protocol translation between the AXI master interface of the PCIe controller core and the VBUSM interface used in the device.

12.2.3.3.1.6 VBUSP to APB Bridge

A VBUSP2APB bridge is used to convert the device VBUSP configuration access to the APB protocol supported by the PCIe controller core.

12.2.3.3.1.7 Custom Logic

The PCIe subsystem includes custom logic to implement Precision Time Management (PTM), interrupts and user configuration registers.

12.2.3.3.2 PCIe Subsystem Reset Schemes

This section describes the reset schemes supported by PCIe Base Specification and the way these resets are supported by the PCIe Subsystem. PCIe Base Specification specifies two mechanisms for performing reset – Conventional Reset mechanism and Functional Level Reset mechanism.

12.2.3.3.2.1 PCIe Conventional Reset

There are three distinct types of Conventional Reset and each of these causes the hardware state machines, hardware logic, port states and configuration registers to be initialized to their default values.

1. Cold Reset – The reset occurring at power-up of the device is referred to as Cold Reset. Cold Reset is triggered by the PERSTn signal being asserted. PERSTn signal is an auxiliary signal in PCIe Specification and can be used at power on reset for the device that has PCIe as its primary bus interface to rest of the system. The device is allowed to generate its own power-on reset as long as the PCIe requirements for PERSTn are met. See PCIe Base Specifications for details.
2. Warm Reset – A reset can be triggered by the hardware without the removal of power from the device. This reset is referred to as Warm Reset. The hardware implementation is not specified by the PCIe Specification.
3. Hot Reset – The PCIe Specifications provides an in-band mechanism to propagate a Conventional Reset across a Link. This reset, called the Hot Reset, propagates via the transmission of TS1 Ordered Sets. In general, Hot Reset is software controlled procedure and can only be issued by Root Port in a PCIe network as the propagation is downstream only. PCIe subsystem translates the received in-band hot reset into an interrupt that can then be used by software to reset the PCIe subsystem.

After a conventional reset, the software must wait at least 100 ms before attempting any PCIe transaction on the device that has been reset. If the downstream device does not respond to transaction packets, it must not give up until 1 second plus an additional 50% (0.5 second) time is lapsed.

12.2.3.3.2.2 PCIe Function Level Reset

The Function Level Reset (FLR) is an optional in-band reset mechanism that is used to reset one particular function in a PCIe device. The PCIe core will initiate the appropriate function level reset process when it receives the FLR message. The PCIe subsystem will raise an interrupt to the SoC, based on the FLR_IN_PROGRESS[5:0] and VF_FLR_IN_PROGRESS[15:0] status outputs from the PCIe core. Software can update the PCIE_USER_FLR_DONE[5-0] FLR_DONE and/or PCIE_USER_VF_FLR_DONE[15-0] VF_FLR_DONE register bits to signal to the PCIe core that the application layer FLR processing is complete.

12.2.3.3.2.3 PCIe Reset Isolation

It can be important to isolate reset of PCIe subsystem from reset of the rest of the device. The procedure to implement this depends upon what functionality the PCIe subsystem is providing – Root Port or End Point.

12.2.3.3.2.3.1 Root Port Reset with Device Not Reset

When PCIe subsystem is operating as a Root Port, it is the master controller on the PCIe subsystem. When PCIe subsystem is to be reset in this operating mode, the link to the downstream device will get disconnected. To accomplish this reset, the PCIe subsystem RP should issue a hot reset to End Point or Switch downstream. It should also stop any ongoing transactions. Then, a PCIe subsystem reset can be issued. The sequence of events is outlined below:

1. Stop transactions at system and application level. This is recommended for graceful suspension of activity at system level. It is not required by PCIe subsystem though. Not choosing to gracefully stop transaction would cause some of the outstanding transactions to complete in error and it may be harmful from software stability standpoint.
2. Disable “Bus Master Enable” for End Points (see [Section 12.2.3.3.6.2, PCIe Transaction Limitations](#)). Note that a hand shake with EP Software may be required as not all End Point application software will automatically become aware of this disable action from RP.
3. Optionally, issue Hot Reset to End Point devices via PCIE_USER_RSTCMD[0] INIT_HOT_RESET bit . Note that the link will be getting disconnected. So, a reset may be happening regardless of the Hot Reset command from RP. It depends on the architecture of the other (external) device. In devices with PCIe subsystem, link disconnection automatically results in a reset request interrupt. A PCIe subsystem reset is required to get the memory buffers out of internal flush modes.
4. Initiate Clock Stop sequence and wait for Acknowledgement. For more information, see [Section 12.2.3.3.3.1, CBA Power Management](#).
5. Issue reset to PCIe subsystem (local reset).
6. Reinitialize PCIe subsystem and downstream devices. PCIe bus enumeration must be performed again.

Note that it is possible for Root Port to occasionally see the downstream device going down for some reason and disconnecting. Such events typically occur due to an internal error condition in the End Point. When such an event occurs, the sequence of events for the Root Port will be as follows:

1. The PCIe subsystem in RP mode will issue the “Reset Request” interrupt when it detects link getting disconnected unexpectedly.
2. The PCIe subsystem will flush all master transactions and any completion data from pending transactions. It will also start completing slave transactions with error completions.
3. After servicing the interrupt and disabling further interrupts, the system software must reset PCIe subsystem Root Port (see steps #4 and later specified previously in this section).

12.2.3.3.2.3.2 Device Reset with Root Port Not Reset

As a Root Port, PCIe core is the master of PCIe subsystem. If the device hardware and the software is reset and re-initialized, the system does not get additional benefit of keeping the PCIe subsystem alive as all context information is lost. So, this mode is not supported.

12.2.3.3.2.3.3 End Point Device Reset with Root Port Not Reset

It may be desirable to isolate the reset only to PCIe subsystem when it is operating as an End Point. Such resets may be implemented when a Hot Reset command is received from upstream device (Root Port or Switch). The sequence to be followed is as outlined below.

1. Hot Reset is received. The “Request Reset” interrupt is triggered.
2. The PCIe subsystem will automatically enter Flush Mode. The PCIe Link Training and Status State Machine (LTSSM) will be disabled automatically.
3. PCIe subsystem will complete all master transactions and any completion data from pending transactions will be accepted and discarded. It will also start issuing error response for new slave transactions.
4. Upon receipt of the reset interrupt from PCIe subsystem, the system software must immediately start preparing for shut down of PCIe subsystem. The DMA or software process accessing PCIe subsystem should gracefully suspend operations. Otherwise, step #3 may continue for unduly long time and Root Port may assume that the EP is non-responsive to its link re-training attempts.
5. Read the Reset Command register (PCIE_USER_RSTCMD) to check if the bridge activity flush bit is zero. This indicates that it is safe to issue warm reset to PCIe subsystem.
6. Initiate Clock Stop sequence. This will ensure no outstanding transactions exist.
7. Issue a PCIe subsystem Reset.

8. Resume initialization sequence.

12.2.3.3.2.3.4 Device Reset with End Point Device Not Reset

As an End Point, the PCIe subsystem does not need to stay operational when the device reset is happening. Upon detecting the link disconnection, the upstream port will re-train the link when Root Port issues a link retrain command to itself or to a switch port next to the EP.

If it is required that the PCIe subsystem be operational (without any transactions though), the End Point must negotiate with the other devices (primarily Root Port) to stop activity. Otherwise, if the End Point goes into force idle/standby or clock stop modes without properly managing the process, there will be timeouts or errors on incoming read transactions and writes will be completely lost. In such situation, the Root Port will encounter excessive errors and may issue a hot reset to the End Point anyway.

12.2.3.3.2.4 PCIe Reset Limitations

Once a reset situation occurs, the PCIe subsystem prepares for reset assertion from the device level reset controller. In this mode, all outbound write transactions are discarded and all outbound reads are returned with error. Similarly, all inbound reads/writes are discarded and any pending reads are completed but data is discarded. Additionally, any register reads on local or remote registers regions are returned in error even through data may be correct. Register writes on local registers are executed correctly.

Whenever the reset interrupt is asserted by PCIe subsystem, the host controller should clear the interrupt, perform a clock stop request/ack sequence and issue a local reset to PCIe subsystem.

12.2.3.3.2.5 PCIe Reset Requirements

Whenever link goes from connected to disconnected state, the PCIe subsystem requires re-initialization based on the events occurring in PCIe core. A request for reset is typically going to be issued and will manifest as a link down interrupt. Since loopback requires transitions through link connect and disconnect, it will generate a link down interrupts. Typically, issuing the warm reset (module reset for CBA) would be sufficient.

12.2.3.3.3 PCIe Subsystem Power Management

PCIe has multiple power management protocols. Some of them are invoked by the hardware, such as Active State Power Management (ASPM), while others are activated at higher levels via software.

The PCIe core supports D0, D1 and D3-Hot power states.

Link power states L0, L0s, L1, L1s are supported.

L0s entry and exit is managed by the PCIe core if ASPM L0s is enabled.

L1 entry and exit is also managed by the PCIe core if ASPM L1 is enabled. Software can force the exit from L1 by writing to the PCIE_USER_PMCMD[0] CLIENT_REQ_EXIT_L1 bit in the PCIe subsystem. Entry into L1 can also be blocked by setting the PCIE_USER_PMCMD[0] CLIENT_REQ_EXIT_L1 bit.

L1s support requires that the CLKREQ pin be connected to the remote peer. L1s power state is entered when the link is in L1 and CLKREQ pin is de-asserted. Software can force the exit from L1s by writing to either the PCIE_USER_PMCMD[0] CLIENT_REQ_EXIT_L1 or PCIE_USER_PMCMD[1] CLIENT_REQ_EXIT_L1_SUBSTATE bits in the PCIe subsystem.

12.2.3.3.3.1 CBA Power Management

The power management for PCIe subsystem with CBA interface is primarily accomplished through the clock stop protocol. Any time the clock stop protocol is initiated, the PCIe subsystem will acknowledge after making sure that there are no outstanding transactions. If there are any pending transactions in the subsystem, then the clock stop acknowledgement procedure cannot be completed. Therefore, it is necessary that the system software first suspend activity on the serial link as well as on the CBA interface. To do so, it is expected that the devices communicating with the device on which clock stop procedure is to be performed agree to stop transactions targeted to the device in question. Similarly, it is required that the outgoing transactions also be stopped to successfully complete the clock stop sequence. The PCIe subsystem will guarantee that in the event there are pending transactions that are still in process of draining will prevent the clock-stop acknowledgement to be issued to CBA subsystem power management logic.

Note

The PCIe subsystem does not have ability to terminate the clock stop state. Therefore, any wakeup sequence can only be initiated through other means such as software driven timers or software detected events occurring outside of PCIe subsystem.

12.2.3.3.4 PCIe Subsystem Interrupts

The PCIe subsystem provides a mix of interrupts from the PCIe controller interrupt, CPTS interrupts, and interrupts generated in the subsystem using the internal Interrupt Distributor (CP_INTD) module.

The CP_INTD module is used to generate and aggregate interrupts from various status signals of the PCIe core. Interrupts from the PCIe core and CPTS module are ported out directly to the PCIe subsystem boundary without any aggregation. [Table 12-181](#) shows the details on the PCIe subsystem interrupt outputs.

Table 12-181. PCIe Subsystem Interrupt Events

Interrupt Name	Clock Dependency	Description
PCIE_LEGACY_PULSE	CBA_CLK	PCIe legacy interrupt. INTA_OUT, INTB_OUT, INTC_OUT and INTD_OUT status outputs from the PCIe core are aggregated. Note: Valid in RP mode only.
PCIE_ERROR_PULSE	CBA_CLK	PCIe error interrupt. FATAL_ERROR_OUT, NON_FATAL_ERROR_OUT and CORRECTABLE_ERROR_OUT status outputs from the PCIe core are aggregated. Note: Valid in both RP and EP modes.
PCIE_ASF_FATAL_LEVEL	CBA_CLK	PCIe internal diagnostics fatal interrupt. The ASF_INT_FATAL from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_ASF_NONFATAL_LEVEL	CBA_CLK	PCIe internal diagnostics nonfatal interrupt. The ASF_INT_NONFATAL from the PCIe controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_FLR_PULSE	CBA_CLK	PCIe Function Level interrupt. FLR_IN_PROGRESS[5:0] and VF_FLR_IN_PROGRESS[15:0] status outputs from the PCIe core are aggregated. Note: Valid in EP mode only.
PCIE_DOWNSTREAM_PULSE	CBA_CLK	PCIe downstream interrupt. <ul style="list-style-type: none"> F0_VSEC_INTERRUPT_OUT, F1_VSEC_INTERRUPT_OUT, F2_VSEC_INTERRUPT_OUT, F3_VSEC_INTERRUPT_OUT, F4_VSEC_INTERRUPT_OUT and F5_VSEC_INTERRUPT_OUT status outputs from the PCIe controller are aggregated. Note: Valid in EP mode only
PCIE_HOT_RESET_PULSE	CBA_CLK	PCIe hot reset interrupt. HOT_RESET_OUT status output from the PCIe controller is aggregated. Note: Valid in EP mode only.
PCIE_LINK_STATE_PULSE	CBA_CLK	PCIe link state interrupt. LINK_DOWN_RESET_OUT status from the PCIe core is aggregated. Note: Valid in both RP and EP modes.
PCIE_PWR_STATE_PULSE	CBA_CLK	PCIe power state interrupt. POWER_STATE_CHANGE status output from the PCIe core are aggregated. Note: Valid in both EP and RP modes.
PCIE_DPA_PULSE	CBA_CLK	PCIe dynamic power allocation interrupt. DPA_INTERRUPT[5:0] status output from the PCIe core are aggregated. Note: Valid in both EP and RP modes.

Table 12-181. PCIe Subsystem Interrupt Events (continued)

Interrupt Name	Clock Dependency	Description
PCIE_LOCAL_LEVEL	CBA_CLK	PCle local interrupt. The LOCAL_INTERRUPT from the PCle controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_PHY_LEVEL	CBA_CLK	PCle PHY interrupt. The PHY_INTERRUPT_OUT from the PCle controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.
PCIE_PTM_VALID_PULSE	CBA_CLK	PCle PTM valid interrupt. PTM_LOCAL_TIMER_OUT_VALID status output from the PCle controller is aggregated. Note: Valid only in EP mode.
PCIE_ECC0_UNCORR_PULSE	CBA_CLK	PCle ECC Aggregator0 uncorrected pulse interrupt.
PCIE_ECC0_UNCORR_LEVEL	CBA_CLK	PCle ECC Aggregator0 uncorrected level interrupt.
PCIE_ECC0_CORR_PULSE	CBA_CLK	PCle ECC Aggregator0 corrected pulse interrupt.
PCIE_ECC0_CORR_LEVEL	CBA_CLK	PCle ECC Aggregator0 corrected level interrupt.
PCIE_ECC1_UNCORR_PULSE	LANE0_TXMCLK	PCle ECC Aggregator1 uncorrected pulse interrupt.
PCIE_ECC1_UNCORR_LEVEL	LANE0_TXMCLK	PCle ECC Aggregator1 uncorrected level interrupt.
PCIE_CPTS_PEND_INTR	CBA_CLK	PCle CPTS level interrupt.

12.2.3.3.4.1 Interrupts Aggregation

The PCIe subsystem includes the CP_INTD module to aggregate some of the PCIe controller signals into the subsystem interrupts indicated in [Table 12-181](#). The interrupt aggregator takes both level and pulse signals from the PCIe core and produces the aggregated pulse interrupt outputs.

The aggregator also supports the End of Interrupt (EOI) feature. EOI can be used to re-trigger a pulse interrupt output, if a PCIe controller level signal is still asserted at the end of interrupt processing. The re-triggering of the the pulse interrupt can be achieved by writing the specified EOI vector value to the PCIE_USER_EOI_VECTOR register.

Table 12-182. PCIe Controller Interrupts Aggregation - 1

Aggregated Interrupt	CP_INTD Registers and Bits Mapping		EOI_VECTOR	PCIe Controller Signal	Description

(1) EOI is not used since the input signal is of type 'pulse'.

12.2.3.3.4.2 Interrupt Generation in EP Mode

When PCIe subsystem is operating as an End Point (EP), either the legacy interrupts, MSI or MSI-X interrupts can be triggered to the upstream ports (eventually leading to an interrupt in RP device). As per PCIe Specifications, each PCIe function may generate only one of the Legacy or MSI interrupt types as decided during configuration period.

12.2.3.3.4.2.1 Legacy Interrupt Generation in EP Mode

The End Point (EP) can trigger generation of a PCI Legacy Interrupt at the Root Port via an in-band Assert_INTx / Deassert_INTx messages (where x = A, B, C, or D). Software can write to the PCIE_USER_LEGACY_INTR_SET register to trigger the required INTx (where x = A, B, C, or D) assert and de-assert message from the PCIe core. Once an assert message has been generated, it cannot be generated again until a deassert message is generated. Thus, only one interrupt can be pending at a time.

There is no hardware input port provided that will allow generation of legacy interrupts on the EP port.

Note

The interrupt messaging mechanism makes it unfeasible to guarantee a time of delivery of the interrupt unlike in conventional designs where the interrupt line is often electrically connected to the final destination.

12.2.3.3.4.2.2 MSI and MSI-X Interrupt Generation

In the case of MSI interrupts signaling, the interrupt conditions are communicated from the EP to the RP via messages. Thus, upon the occurrence of an interrupt condition, a message is sent by the EP with information that identifies the origin of the interrupt. Each message is in the form of a memory write request, containing an address and a data value to be written. Each PCI function supported by a device can be assigned a separate memory address, thus providing separate virtual channels for signaling interrupts generated by each function. In addition, the MSI mechanism allows a maximum of 32 distinct data patterns in the messages generated by each PCI function, and each pattern can be assigned to an interrupt condition within the function.

In the case of MSI-X interrupts signaling, the operation is similar to the MSI mode, except that the mechanism allows a much larger number of distinct interrupt conditions as many as 2048 per function to be communicated, and enables a distinct address to be defined for each of these conditions. This mechanism requires two tables to be stored in the EP memory. The MSI-X table contains the address/data patterns to be used for each interrupt condition (as many as 2048 per function) as well as individual enable/mask bits, and the Pending Bit Array (PBA) stores the status of each interrupt condition. Interrupt conditions are communicated from the EP to the RP via messages (write requests), as in the case of the MSI mode.

12.2.3.3.4.3 Interrupt Reception in EP Mode

The PCIe specification does not have provision for End Points to receive legacy interrupts. As a result, only events other than these are used to map to interrupts.

12.2.3.3.4.3.1 PCIe Core Downstream Interrupts

The Vendor Specific Capability signals of the PCIe core
- F0_VSEC_INTERRUPT_OUT, F1_VSEC_INTERRUPT_OUT, F2_VSEC_INTERRUPT_OUT, F3_VSEC_INTERRUPT_OUT, F4_VSEC_INTERRUPT_OUT and F5_VSEC_INTERRUPT_OUT, are used to generate interrupts to the EP from the RP. The F0_VSEC_INTERRUPT_OUT represents the interrupt for the EP Physical Function 0, the F1_VSEC_INTERRUPT_OUT is the interrupt output for EP Physical Function 1 and so on. These signals are aggregated into the PCIE_DOWNSTREAM_PULSE interrupt to the local host.

The RP can write to the Vendor Specific Control registers (PCIE_CORE_PFn_I_VENDOR_SPECIFIC_CONTROL_REG) to assert these signals at the EP and this will trigger the PCIE_DOWNSTREAM_PULSE interrupt to the EP host.

12.2.3.3.4.3.2 PCIe Core Function Level Reset Interrupts

The PCIE_FLR_PULSE interrupt is asserted to indicate to the host that the PCIe controller has received a function-level reset request from the remote side. The PCIE_FLR_PULSE interrupt is an

aggregation of the FLR_IN_PROGRESS[5:0] and VF_FLR_IN_PROGRESS[15:0] signals from the PCIe core. Each bit of FLR_IN_PROGRESS[5:0] represents Physical Function0 through 5 and each bit of the VF_FLR_IN_PROGRESS[15:0] represents Virtual Function0 through 15.

Upon assertion of the function level reset interrupt, software will need to write to the PCIE_USER_FLR_DONE[5:0] FLR_DONE bit field within 100ms to acknowledge to the PCIe core that all the application level processing related to the function level reset is complete. Similarly, software will need to acknowledge virtual function level reset completion by writing to the PCIE_USER_VF_FLR_DONE[15:0] VF_FLR_DONE bit field within 100ms of the virtual function level reset being asserted.

12.2.3.4.3.3 PCIe Core Power Management Event Interrupts

The PCIE_PWR_STATE_PULSE interrupt is generated to let the software know of the power management events. The PCIE_PWR_STATE_PULSE interrupt is generated by the POWER_STATE_CHANGE_INTERRUPT output of the PCIe core. This interrupt is asserted when the power state of a physical or virtual function is being changed to D1 or D3 state by writing into their Power Management Control register (PCIE_CORE_PFn_I_PWR_MGMT_CTRL_STAT_REP or PCIE_CORE_VFm_I_PWR_MGMT_CTRL_STAT_REP, respectively).

Software can check the PCIE_USER_LINKSTATUS[23:16] POWER_STATE_CHANGE_FUNCTION_NUM register field to determine the physical function for which power state change occurred. The PCIE_USER_PMCMD[2] POWER_STATE_CHANGE_ACK register bit can be used to acknowledge the POWER_STATE_CHANGE_INTERRUPT.

The PCIE_DPA_PULSE interrupt is generated by aggregating the PCIe controller DPA_INTRs interrupt status outputs. This interrupt is asserted in EP mode when there is a configuration write to the dynamic power allocation control register (PCIE_CORE_PFn_I_DPA_CTRL_STATUS_REG) to modify the DPA power state of the device. The DPA_INTR0 is asserted for such an event for PF0, the DPA_INTR1 for PF1 and so on.

12.2.3.4.3.4 PCIe Core Hot Reset Request Interrupt

When the link is down, the Root Port may request reset of the End Point. This request is terminated as an PCIE_HOT_RESET_PULSE interrupt to the End Point host software. All outstanding transactions are completed in error on slave port and further transactions are not generated on the master port. Once the transactions are completely stopped, the software should issue a local reset to PCIe subsystem. The re-initialization process may then be started.

The PCIE_HOT_RESET_PULSE interrupt is generated from the HOT_RESET_OUT output of the PCIe core.

12.2.3.4.3.5 PTM Valid Interrupt

In EP mode, the PCIe subsystem will generate the PCIE_PTM_VALID_PULSE interrupt to the local CPU after a PTM dialog between the PTM requester (EP) and the PTM responder (RP). The PTM valid interrupt indicates to the CPU in the EP that the local timers have been updated with the timestamp data obtained from the RP. The CPU can read the timer registers inside the EP to determine the current timebase.

The PCIE_PTM_VALID_PULSE interrupt is generated from the PTM_LOCAL_TIMER_OUT_VALID signal from the PCIe core.

12.2.3.4.4 Interrupt Generation in RP Mode

As per PCIe Base Specifications, Root Port ports only receive interrupts. There is no mechanism to generate interrupts from RP port to EP mode as per PCIe specification.

However, PCIe subsystem does support generation of interrupts from RP to EP. The downstream interrupts described in [Section 12.2.3.4.3.1, PCIe Core Downstream Interrupts](#) provides a mechanism for the RP to generate software triggered interrupts to the EP.

12.2.3.4.5 Interrupt Reception in RP Mode

12.2.3.4.5.1 PCIe Legacy Interrupt Reception in RP Mode

The RP can receive any of the four legacy INTx interrupts from the EP. These will trigger the PCIE_LEGACY_PULSE interrupt to the host CPU.

The PCIE_LEGACY_PULSE interrupt is an aggregation INTA_OUT, INTB_OUT, INTC_OUT and INTD_OUT signals from the PCIe core.

12.2.3.3.4.5.2 MSI/MSI-X Interrupt Reception in RP Mode

The PCIe core decodes all MSI and MSI-X messages received from the link and forwards them on the low-priority AXI master interface. These messages must then be routed to the system interrupt controller by the SoC interconnect (CBASS0).

12.2.3.3.4.5.3 Advanced Error Reporting Interrupt

If enabled by software at the time of enumeration, PCIe subsystem will generate this interrupt to indicate occurrence of errors of various levels of severity. The software can choose not to enable Advanced Error Reporting but if it enables, it must process the interrupt as per PCIe Specifications.

The advanced error reporting interrupt is signaled by the PCIE_ERROR_PULSE interrupt. The PCIE_ERROR_PULSE is an aggregation of the FATAL_ERROR_OUT, NON_FATAL_ERROR_OUT and CORRECTABLE_ERROR_OUT from the PCIe core.

12.2.3.3.4.6 Common Interrupt Reception in RP and EP Modes

These interrupts are common to both RP and EP modes of operation.

12.2.3.3.4.6.1 PCIe Local Interrupt

The LOCAL_INTERRUPT from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

12.2.3.3.4.6.2 PHY Interrupt

The PHY_INTERRUPT_OUT from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

12.2.3.3.4.6.3 Link down Interrupt

If the PHY link is disconnected, the PCIE_LINK_STATE_PULSE interrupt will be generated. The expected course of action is to reset the entire PCIe subsystem and restart. All application states must also be initialized so that the operations can resume following the reset and renegotiation of the link.

The PCIE_LINK_STATE_PULSE interrupt is generated from the LINK_DOWN_RESET_OUT output of the PCIe core.

12.2.3.3.4.6.4 Transaction Error Interrupts

If there is a timeout on PCIe or an abort, PCIE_PHY_LOCAL_LEVEL interrupt will be issued. The PCIE_PHY_LOCAL_LEVEL interrupt is generated by the aggregation of the LOCAL_INTERRUPT and PHY_INTERRUPT_OUT signals from the PCIe core. For more details, see the PCIe specification.

12.2.3.3.4.6.5 Power Management Event Interrupt

This PCIE_PWR_STATE_PULSE interrupt is generated to let the software know of the power management events. The PCIE_PWR_STATE_PULSE interrupt is generated by aggregating the POWER_STATE_CHANGE_INTERRUPT and DPA_INTERRUPT outputs of the PCIe core.

In EP mode, software can check the PCIE_USER_LINKSTATUS[23-16] POWER_STATE_CHANGE_FUNCTION_NUM bit field to determine the physical function for which power state change occurred.

The PCIE_USER_PMCMD[2] POWER_STATE_CHANGE_ACK bit can be used to acknowledge the POWER_STATE_CHANGE_INTERRUPT.

12.2.3.3.4.6.6 Active Internal Diagnostics Interrupts

The active internal diagnostics interrupt is signaled by the PCIE_ASF_PULSE interrupt. This is an aggregation of the ASF_CSR_ERR, ASF_DAP_ERR, ASF_INTEGRITY_ERR, ASF_INT_FATAL, ASF_INT_NONFATAL, ASF_PROTOCOL_ERR, ASF_SRAM_CORR_ERR, ASF_SRAM_UNCORR_ERR, and ASF_TRANS_TO_ERR signals from the PCIe core.

12.2.3.3.4.7 ECC Aggregator Interrupts

The PCIE_ECC0_UNCORR_PULSE/PCIE_ECC0_UNCORR_LEVEL and PCIE_ECC0_CORR_PULSE/PCIE_ECC0_CORR_LEVEL interrupts are asserted by the CBA clock domain ECC Aggregator. The PCIE_ECC1_UNCORR_PULSE/PCIE_ECC1_UNCORR_LEVEL interrupts are asserted by the Core clock domain ECC Aggregator. The Core clock domain ECC Aggregator correctable interrupts are not exported since this aggregator is only connected to the parity injection logic and the correctable interrupts for this module will never fire.

12.2.3.3.4.8 CPTS Interrupt

The PCIE CPTS_PEND_INT interrupt is asserted by the CPTS module in the PCIe subsystem to signal a TimeStamp event.

12.2.3.3.5 PCIe Subsystem DMA Support

The PCIe Subsystem has different requirements based upon whether it is operated in Root Port (RP) or End Point (EP) mode. The PCIe subsystem does not have DMA capabilities built into it. It has internal slave and master ports connected to the device-level interconnect.

An external DMA engine can make burst data read/writes on the slave port and the master port on PCIe subsystem can initiate reads/writes to memory on behalf of a remote PCIe device.

The PCIe subsystem does not specify the DMA protocol that is used for data transfers. The software implementations on the two ends of the PCIe link implement a data transfer protocol that is compatible with each other.

As a result, there will be several software drivers required – one driver that will manage the PCIe subsystem in RP mode and another set of drivers that will run on the RP side and will manage each of the End Points connected to the PCIe subsystem RP.

Similarly, when PCIe subsystem is operating as an End Point, there are two drivers – one to manage the PCIe subsystem from the device side and another driver that will run on the device operating as the Root Port.

12.2.3.3.5.1 PCIe DMA Support in RP Mode

When operating in Root Port mode, a DMA controller internal to the device (outside PCIe subsystem) can perform DMA to and from any remote device located on the PCIe subsystem. The memory address of such devices is available to the software via the PCIe bus enumeration procedure. In addition, the PCIe subsystem has a provision to perform memory address translation on outbound requests. Thus, the software is able to map different memory regions in its memory map to correspond to different addresses (and different access types) on the PCIe side.

12.2.3.3.5.2 PCIe DMA Support in EP Mode

When operating as a PCIe End Point, the device will be located in PCIe memory map at location programmed in the Base Address Registers by the PCIe Root device. Any PCIe transactions destined for the device from the upstream ports will get transferred to the master port on the PCIe subsystem. Similarly, any transactions originating from the software will be sent over to PCIe link.

In End Point mode, the PCIe subsystem provides address translation functionality. It is possible to map memory accesses originating on PCIe side to memory accesses with different address on the CBA bus side. These address ranges are configurable through application registers.

12.2.3.3.6 PCIe Subsystem Transactions

12.2.3.3.6.1 PCIe Supported Transactions

PCIe subsystem supports the following transactions:

1. Memory Read/Write in inbound/outbound direction in Root Port (RP) and End Point (EP) modes.
2. I/O Read/Write in outbound direction in RP mode.
3. Configuration Read/Write in outbound direction in RP mode.
4. Configuration Read/Write in inbound direction in EP mode.
5. Message Transactions for interrupts and power management in RP and EP modes.

The following transactions are not supported:

1. Locked Read transactions and associated messages.
2. Inbound I/O Transaction Layer Packets (TLPs).
3. User defined messages.

12.2.3.3.6.2 PCIe Transaction Limitations

Added

There are some limitations that must be adhered to while issuing transactions to PCIe subsystem internal bus interface.

- System Initialization

CAUTION

The PCIe subsystem operation is completely dependent upon the availability of the SERDES module for PCIe transactions. The SERDES module must be configured and corresponding PLLs must be locked before the PCIe subsystem is able to process any data transactions. Any data accesses to the PCIe subsystem prior to this initialization may result in an internal bus hang condition.

- Remote Configuration and I/O Requests

Since the remote configuration and I/O transaction windows are directly mapped to internal bus space, the software must care to not access these spaces when there is no operational PCIe link. No response may be generated for such transactions. It is recommended that checks be built into software to avoid remote accesses in the absence of an operational link.

- Byte Strobe Limitations

For any type of write transactions, the byte enables can only have a single unbroken string of 1s. In other words, in a transaction, if a byte's write strobe is set, then all following bytes must have write strobe set until the last byte with write enabled. "Holes" or "Zeros" in between the byte enables are not allowed.

Since the internal bus width is greater than 32-bit, the TLP (Transaction Layer Packets) size will not be 1 (PCIe counts in 32-bit units) and therefore, it is through the FBE/LBE (First/Last Byte Enable) that the actual data transfer size is controlled.

- Burst Type Limitations

The PCIe core and respectively the PCIe subsystem does not support 'fixed' or 'wrap' burst types on its Slave or Master port. Transactions that require any burst type other than incremental burst type will result in unspecified behavior, possibly bus lock up.

- Transaction Address Alignment

The PCIe subsystem imposes a limitation of a maximum of 128-byte outbound read/write command. However, if the starting address is not aligned to an 8-byte boundary, then the maximum transaction size is reduced to 120 bytes. This limitation is placed to avoid arithmetic overflow in computing transaction length from CBA to AXI. Unspecified behavior will occur, if misaligned transactions in outbound direction are not limited to a maximum of 120 bytes.

- Read Interleaving

Read interleaving refers to the process of returning split read responses from multiple transactions. This implies that read data is not guaranteed to be sent in sequential order (data for one transaction to be sent completely before the next). The PCIe core will not interleave read responses, if the outbound read command/transaction size does not exceed the maximum transaction size configured in the PCIe core.

12.2.3.3.7 PCIe Subsystem Address Translation

The PCIe subsystem uses the address translation registers in the PCIe core to translate outbound system addresses to PCIe space and inbound PCIe address to a valid system address. Note that internal address translation is different from the Address Translation Services (ATS).

12.2.3.3.7.1 PCIe Inbound Address Translation

12.2.3.3.7.1.1 Root Port Inbound PCIe to AXI Address Translation

The Root Port inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the BAR match of the incoming TLP. In Root Port mode there are 2 bars, so BAR 0 and BAR1 registers are implemented. There is a BAR7 register which is used as a no match BAR address translation register. In Root Port mode there are 2 bars but a BAR value of 7 will be indicated by HAL2AXI when BAR matching is disabled. Any address that does not match the Root Port BARs will be sent out as a BAR7 TLP. Each BAR register is implemented as two 32-bit registers which are named addr0 and addr1. The "Root Port Inbound PCIe to AXI Address Translation Logic" takes the upper bits from the "Root Port Inbound PCIe to AXI Address Translation Registers" and the lower bits are taken from the inbound PCIe address to form the AXI address. An addr0 [5:0] + 1 number of lower bits are passed from the inbound PCIe address to AXI address. In other words, the number of bits taken from inbound PCIe address is given by the addr0[5:0] + 1 value.

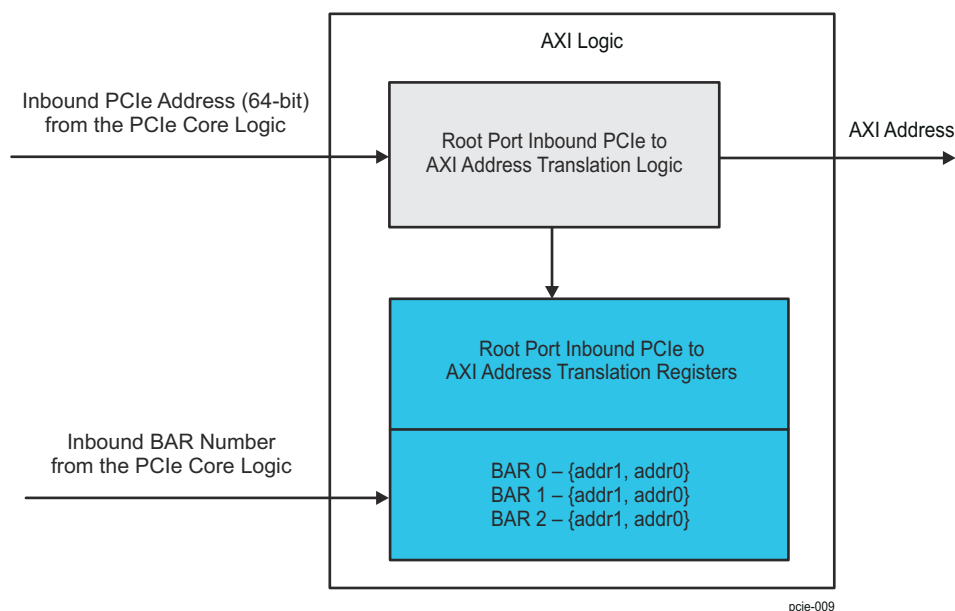

Figure 12-119. PCIE Root Port Inbound PCIe to AXI Address Translation

A set of registers corresponding to one Root Port BAR is shown in [Table 12-185](#).

Table 12-185. PCIE Root Port Inbound PCIe to AXI Address Translation Registers for one BAR

Register Name	Bits	Description	Default Value
addr1 (where BAR can be bar0, bar1 or bar7)	31:0	Upper [63:32] bits of the AXI address.	32'd0
addr0 (where BAR can be bar0, bar1 or bar7)	31:8	Lower [31:8] bits of the AXI address.	24'd0
	7:6	Reserved	2'd0
	5:0	Number of address bits passed through from PCIe to AXI. The PCIe controller passes the programmed value + 1 bits from PCIe to AXI. Minimum value to be programmed into this field is 7 as the lower 8 bits of the base address programmed in these registers (AXI) are replaced by zeros by the Root Port Inbound PCIe to AXI Address Translation Logic.	6'd0

12.2.3.3.7.1.2 End Point Inbound PCIe to AXI Address Translation

The End Point Inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the function number and BAR match of the incoming TLP. In End Point mode there are 7 bars per function, so 7 sets of registers are

implemented per function, each BAR having two 32-bit registers (addr0 and addr1). The "End Point Inbound PCIe to AXI Address Translation Logic" takes the upper bits from the "End Point Inbound PCIe to AXI Address Translation Registers" and the lower bits are taken from the Inbound PCIe Address to form the AXI address. The number of bits to pass from Inbound PCIe Address to AXI is decided by the Inbound BAR aperture.

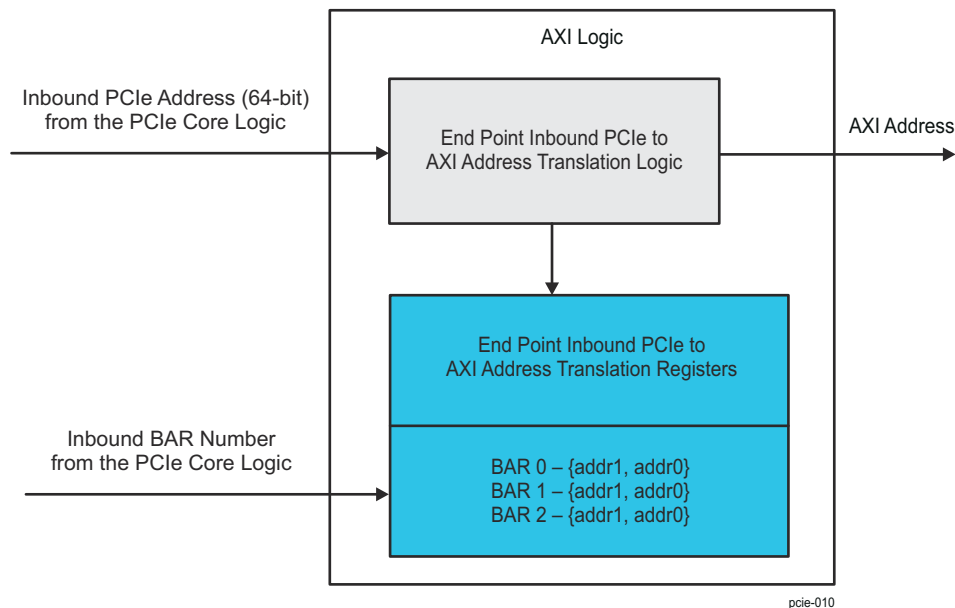

Figure 12-120. PCIe End Point Inbound PCIe to AXI Address Translation

A set of registers corresponding to one End Point BAR is shown in [Table 12-186](#).

Table 12-186. PCIe End Point Inbound PCIe to AXI Address Translation Registers for one BAR

Register Name	Bits	Description	Default Value
addr1 (where BAR can be bar0, bar1, bar2,...bar7, and PF can be pf0, pf1, pf2,... pf21)	31:0	Upper [63:32] bits of the AXI address.	32'd0
addr0 (where BAR can be bar0, bar1, bar2,...bar7, and PF can be pf0, pf1, pf2,... pf21)	31:0	Lower [31:0] bits of the AXI address.	32'd0

12.2.3.3.7.2 PCIe Outbound Address Translation

The PCIe Subsystem allows mapping of PCIe addresses to/from the internal bus addresses of the device. This is accomplished by using internal address translation unit (iATU) in the PCIe core. For each outbound read/write request, the address translation module within PCIe subsystem can convert a VBUSM address to a PCIe address of memory Read/Write type.

If a transaction is large enough that it goes past the address translation region, unspecified behavior may occur. The address translation only works at the time a command is issued. So, a memory write, for example, will not automatically go to next translation region, if it starts in the previous one and is bigger than the remaining size in the starting translation region.

The "Dynamic Method: Sideband Descriptor Based" outbound address translation mechanism is used to bypass the outbound address translation unit under certain conditions. For more details on the bypass operation, see [Section 12.2.3.3.7.2.1, PCIe Outbound Address Translation Bypass](#).

12.2.3.3.7.2.1 PCIe Outbound Address Translation Bypass

The PCIe subsystem supports bypassing the outbound address translation in the PCIe controller when the *case/* value on the VBUSM slave interface is non-zero.

The device UDMA has the ability to send transactions to alternate address maps which are external to the local device. This is achieved by using casel identifier in the DMA descriptors. There are three requirements that need to be met in the PCIe subsystem when using this mode in the DMA, namely:

- Block transactions based on initiator credentials to support FFI (Freedom from Interference)
- Bypass the Address Translation Unit (ATU) inside the PCIe controller since the transaction address is external to the local device
- Assign the correct Bus, Device, Function (BDF) and Traffic Class (TC) values to the transaction

To meet these requirements, the PCIe subsystem uses the *cvirtid* values on the VBUSM slave interface to filter transactions based on initiator credentials. The VMAP block in the PCIe subsystem has a *virtid* match register (PCIE_VMAP_OB_VIRTID_MATCH) and a set of 32 registers that can be used to program the descriptor fields when the ATU logic in the PCIe controller is bypassed.

The PCIe subsystem will filter outbound VBUSM slave transactions that have a non-zero casel value. If the *cvirtid*[11:5] attribute of the VBUSM slave transaction matches the value programmed in the PCIE_VMAP_OB_VIRTID_MATCH register, the credentials of the transaction initiator are verified. The *cvirtid*[11:5] value should also be non-zero for a successful match.

When the credentials match, the ATU of the PCIe controller is bypassed. The *cvirtid*[4:0] is used to select one of the 32 PCIE_VMAP_DESC_j descriptor registers. These registers can be programmed to assign the BDF and TC values to the outbound PCIe transaction. If the PCIE_VMAP_DESC_j[16] BD_EN0 register bit is set, then the bus, device and function numbers are all set from the external descriptor registers. If the BD_EN bit is not set, then the bus and device numbers are assigned by the PCIe controller using the values captured during enumeration. If ARI mode is enabled (in the PCIE_CORE_PFn_I_SRIOV_CTRL_STATUS_REG register), the function number uses the PCIE_VMAP_DESC_j[7:0] DEV_FUNC_NUM register field. If ARI mode is not enabled, the device number uses PCIE_VMAP_DESC_j[7:4] DEV_FUNC_NUM field and the function number uses the [3:0] DEV_FUNC_NUM field. The ARI mode is a PCIe controller hardware configuration option that is enabled for PCIe endpoints that support SR-IOV.

If the credentials of the initiator fail to match the programmed value in the PCIE_VMAP_OB_VIRTID_MATCH register, the VBUSM slave transaction is then flushed by the bridge and is not submitted to the PCIe controller. The VBUSM2AXI2 bridge will return a protection error status for both read and write transactions. In addition, the write data is discarded and the correct number of read data phases with data value of zero are returned.

12.2.3.3.8 PCIe Subsystem Virtualization Support

The PCIe subsystem supports Address Translation Request (ATS) messages in Root Port mode. All PCIe ATS requests are forwarded to the SMMU. The ATS response sent back by the SMMU is forwarded to the remote PCIe requestor.

In End Point mode, the PCIe subsystem supports SR-IOV with 6 physical functions (PF), and 4 virtual functions (VF) per physical function for PF0-PF3 only (6PF/16VF).

12.2.3.3.8.1 End Point SR-IOV Support

In End Point (EP) mode, the PCIe subsystem supports Single Root I/O Virtualization (SR-IOV) with four physical functions (PF) and four virtual functions (VF) per physical function for PF0-PF3 only.

12.2.3.3.8.2 Root Port ATS Support

In Root Port (RP) mode, the PCIe subsystem has an AXI streaming interface (DTI) to connect to the system level SMMU. The Address Translation Messages (ATS) from the End Point is routed to the SMMU over the DTI interface. The translated address and any invalidation requests from the SMMU, sent to the PCIe over the DTI interface, is converted to ATS messages and sent to the End Point.

12.2.3.3.8.3 VirtID Mapping

The PCIe subsystem includes the VMAP module that can be programmed to map (convert) the incoming 16-bit PCIe requestID + 2-bit PCIe AT bits to the 16-bit CBA virtID + 2-bit CBA atype attributes.

Figure 12-121 shows the block diagram of the VMAP module. The blocks shown in the diagram are replicated for the read and write AXI channels. However, there is only one set of configuration registers in the VMAP module and these are shared by both the read and write channel logic.

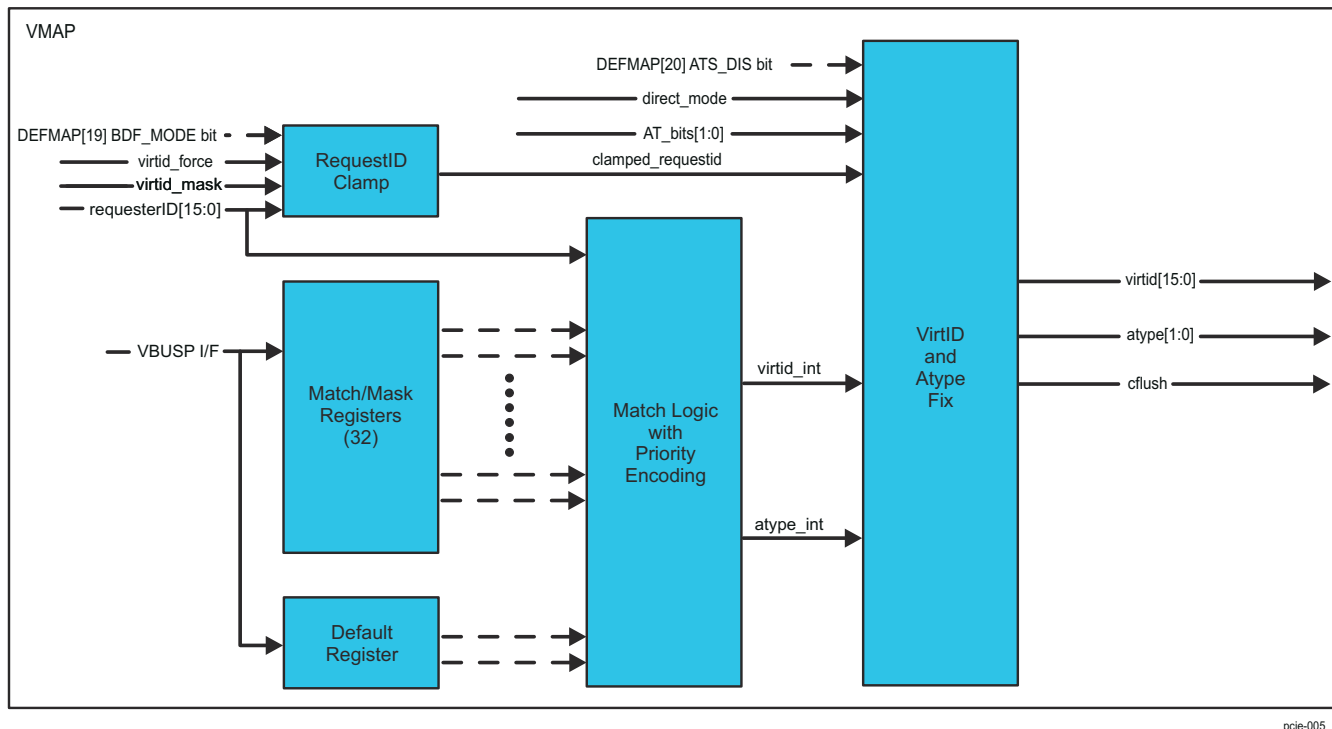

Figure 12-121. PCIe Subsystem VirtID Mapper

The RequestID Clamp block is used to clamp the incoming requestID to a maximum value. This block compares the incoming PCIe requestID[15:12] masked with the virtid_mask[3:0] to an expected value. Bit [19] BDF_MODE in PCIE_VMAP_DEFMAP is used to set the value to virtid_force[3:0] or 4'h0. The clamped_requestid is set to the maximum value of FFFFh if the comparison is false. The clamped_requestid value is later used downstream by the PVU or SMMU in the SoC.

Each of the VMAP modules includes a set of 32 match and mask registers. Software can enable the registers to be used for the mapping by setting the [0] EN bit in PCIE_VMAP_CTRL_j registers. Software can also program the [15-0] RID and [31-16] MASK bit fields in PCIE_VMAP_REQID_j registers to indicate the incoming PCIe requestid that needs to be matched. The [11-0] VID and [17-16] ATYPE bit fields in PCIE_VMAP_VIRTID_j registers are used to program the required CBA virtID and Atype fields in case of a match. In order to prevent a spurious match, the [15-0] RID and [31-16] MASK bit fields in PCIE_VMAP_REQID_j registers should be set up before the [0] EN bit in PCIE_VMAP_CTRL_j registers is set. The same sets of registers are used for both read and write transactions.

The Match logic with Priority Encoding block compares the incoming PCIe requestID with the values programmed in the VMAP control registers and sets the value of the virtid_int and atype_int variables. For every incoming PCIe transaction, the incoming PCIe requestID[11:0] bits are masked with the PCIE_VMAP_REQID_j[31-16] MASK bit field and compared against each of the thirty two values indicated by PCIE_VMAP_REQID_j[15-0] RID that are enabled. The location of the first match of this comparison operation is used to select the [11-0] VID and [17-16] ATYPE bit fields in PCIE_VMAP_VIRTID_j registers. This is used as the virtid_int and atype_int values for the downstream logic. In case none of the enabled [15-0] RID and [31-16] MASK bit fields in PCIE_VMAP_REQID_j registers pairs match the incoming requestID, the value in [11-0] DEF_VID and [17-16] DEF_ATYPE bit fields in PCIE_VMAP_DEFMAP registers is used.

The VirtID and Atype Fix block uses the incoming PCIe AT_bits along with the matched and clamped values of the requestID from the downstream blocks to set the final values of the virtID, catype and cflush attributes for the particular CBA transaction. The values of the virtID, catype and cflush are determined based on the following criteria:

1. If the incoming PCIe TLP has a translated address, as indicated by the PCIe AT_bits equal to 2 and if the match operation results in an expected atype value of 2 and Address Translation Services (ATS) is enabled

in the system, as indicated by the PCIE_VMAP_DEFMAP[20] ATS_DIS register bit, the virtID is set to the *clamped_requestid* and the *catype* value is set to 2. This enables the PCIe subsystem to pass along the full incoming requestID[15:0] to the upstream SMMU/PVU. The incoming transaction is flushed if it fails this criteria by setting the cflush attribute to 1. The PCIe EP initiating this transaction will be sent a Completion Abort (CA) response for a read request, if the transaction is flushed.

2. If the incoming PCIe TLP does not have a translated address, as indicated by the PCIe AT_bits equal to 0, the virtID can be set to the output of the mask/match registers or the *clamped_requestid*. The *catype* attribute for this transaction can be set to the value from the mask/match registers.

Note

The PCIe implementation in the device uses the *direct_mode* workaround. This forces the *cvirtID* and *catype* to 0 when the incoming transaction matches the criteria outlined in (1) above.

The system Interconnect only supports 12-bits of *virtid*. As a result, only *virtid*[11:0] from the PCIe VMAP module will be used in the system and *virtid*[15:12] is not connected.

The pseudo-code for the virtID mapping algorithm implemented is described below.

```
// Requestid Clamp
// Note: only the low 4 bits of virtid_force & virtid_mask are used in the current PCIe wrapper
// virtid_mask[7:4] should always be 1
// virtid_mask[n] of 1 means use the virtid_force value for this bit
// virtid_mask[n] of 0 means use the requestID value for this bit, virtid_force[n] should be 0
// Bit [19] BDF_MODE in PCIE_VMAP_DEFMAP specifies if we are using
// 0 based bus numbers (0) or offset bus numbers (1)
expected_value[3:0] = PCIE_VMAP_DEFMAP[19] BDF_MODE ? virtid_force[3:0] : 4'h0;
if (requestID[15:12] & virtid_mask[3:0] == expected_value[3:0] )
{
    clamped_requestID[15:0] = requestID[15:0];
}
else
{
    clamped_requestID[15:0] = FFFFh;
}
// Match Logic with Priority Encoding
for n in 0 to 31 do
if (PCIE_VMAP_CTRL_j[0] EN == 1h &&
(requestID & PCIE_VMAP_REQID_j[31:16] MASK) == PCIE_VMAP_REQID_j[15:0] RID )

}
else
{
// this is not SMMU, use the value from the register
virtid[11:0] = virtid_int[11:0];
virtid[15:12] = 4'h0;
}
}
}

```

12.2.3.3.9 PCIe Subsystem Quality-of-Service (QoS)

The Virtual Channel/Transfer Class (VC/TC) feature in the PCIe core, in conjunction with the device system CBASS Quality-of-Service (QOS) capabilities, provide a mechanism for supporting differentiated QOS within the PCIe subsystem. The policy for traffic differentiation is determined by the Transfer Class (TC) and Virtual Channel (VC) mapping and VC-based arbitration mechanism.

A Virtual Channel is established when one or more TCs are associated with a physical resource designated by a VC ID. Every Traffic Class that is supported on a given path within the subsystem must be mapped to one of the enabled Virtual Channels. Every Port must support the default TC0/VC0 pair – this is “hardwired.” Any additional TC mapping or additional VC resource enablement is optional. The number of VC resources provisioned within a component or enabled within a given subsystem may vary due to implementation and usage model requirements.

The PCIe core in the PCIe subsystem is configured to support four virtual channels (4VC/4TC). For both ingress and egress traffic, VC3, the highest numbered virtual channel, has the highest priority.

For ingress traffic, the TC information from each transaction on the AXI master information is mapped to the CCHANID signal of the VBUSM master interface. The system level interconnect can use the CCHANID along with the ORDERID for QoS purposes. [Table 12-187](#) shows the TC mapping to the 12-bit CCHANID of each VBUSM master interface.

Table 12-187. PCIe Subsystem QoS Ingress CCHANID Mapping

TC Value	CCHANID[11:0]
0	{9'd0, 3'b000}
1	{9'd0, 3'b001}
2	{9'd0, 3'b010}
3	{9'd0, 3'b011}
4	{9'd0, 3'b110}
5	{9'd0, 3'b101}
6	{9'd0, 3'b110}
7	{9'd0, 3'b111}

For egress traffic requiring the highest priority it should be mapped to VC=3 in the PCIe controller. The VC mapping is done using the AXI outbound descriptor registers in the PCIe controller.

12.2.3.3.10 PCIe Subsystem Precision Time Measurement (PTM)

The Precision Time Measurement (PTM) enables precise coordination of events across multiple components with independent local time clocks. Ordinarily, such precise coordination would be difficult given that individual time clocks have differing notions of the value and rate of change of time. To work around this limitation, PTM enables components to calculate the relationship between their local times and a shared PTM Master Time: an independent time domain associated with a PTM Root.

The PTM defines the following components:

- PTM Requester - A Function capable of using PTM as a consumer associated with an Endpoint.
- PTM Responder - A Function capable of using PTM to supply PTM Master Time associated with a RP.
- Time Source - A local clock associated with a PTM Responder.
- PTM Root – The source of PTM Master Time for a PTM hierarchy. A PTM Root must also be a Time Source and is typically also a PTM Responder.

When using PTM between two components on a Link, the EP sends PTM requests to the RP on the same link. During each dialog, the RP populates the PTM Response message based on timestamps stored during previous PTM dialogs. Once each component has historical timestamps from the preceding dialog, the EP can combine its timestamps with those passed in the PTM Response message to calculate the PTM Master Time.

The PCIe core implements all of the features required to handle the PTM conversation between the requestor and responder in hardware. In addition, an internal TimeStamp module (CPTS) is connected to the timestamp interface of the PCIe core so that events can be logged.

The Precision Time Measurement (PTM) support in the PCIe subsystem is handled by the combination of the PCIe core and the CPTS module.

The PCIe core controller handles the PCIe conversation to exchange timestamps between the RP and EP. It also includes logic to calculate the timestamp differences as specified in the PCIe standard. A 64-bit timer that is the master clock is included in the PCIe core. The PCIe controller can be programmed to initiate the PTM conversation automatically by setting the [0] PTMRQM bit in the PCIE_CORE_LM_I_PT_M_LOCAL_CONTROL_REG register.

In EP mode, there are two methods to register a CPTS HW1 push timestamp that is needed to transfer the PCIe PTM timebase to the local system time base.

1. The first method involves the PTM_LOCAL_TIMER_OUT_VALID and PTM_EP_TIMER. The PTM_LOCAL_TIMER_OUT_VALID output from the PCIe controller will be asserted when the PTM conversation is complete and the EP local timer has been updated. The adjusted value of the EP 64-bit timer is available in the PTM_LOCAL_TIMER_OUT output of the controller. A second 64-bit free running timer, PTM_EP_TIMER, is used to shadow the value of the EP timebase. The PTM_EP_TIMER is loaded with the value of the PTM_LOCAL_TIMER_OUT[63:0] when PTM_LOCAL_TIMER_OUT_VALID is high. When PTM_LOCAL_TIMER_OUT_VALID is low, PTM_EP_TIMER will be free running based on the same PCIE_CORE_CLK that drives the PTM_LOCAL_TIMER_OUT. The increment value of PTM_EP_TIMER can be adjusted by writing to the PCIE_USER_PT_M_CFG[10-8] PTM_EP_TIMER_ADJ register field. The increment value is one by default. The value of the PTM_EP_TIMER will not be updated to the RP timebase until the first PTM dialog has occurred. Software can set the PCIE_USER_PT_M_CFG[6-0] PTM_CLK_SEL register field value between 0 and 63 to choose a particular bit of the PTM_EP_TIMER as the source for the CPTS HW1 time stamp push event.
2. The second method to register the CPTS HW1 push timestamp involves only the PTM_LOCAL_TIMER_OUT_VALID output from the PCIe controller. Software can set the PCIE_USER_PT_M_CFG[6-0] PTM_CLK_SEL register field value to 64 to select the PTM_LOCAL_TIMER_OUT_VALID as the source of the CPTS HW1 time stamp push event. This will create a CPTS HW1 timestamp when there is a PTM dialog between the PCIe End Point and Root Port. The actual value of the EP PTM local timer can be read from the PCIE_USER_PT_M_TIMER_LOW and PCIE_USER_PT_M_TIMER_HIGH registers.

In RP mode, the CPTS can take control of the PTM master time. The 64-bit CPTS timer is continuously loaded into the PCIe PTM master clock by tying high the PTM_TIMER_IN_VALID input of the PCIe controller. This allows for software to adjust the PCIe PTM master clock as necessary using the CPTS module and maintain the PTM master time by monotonically increasing it as required by the PCIe standard. The CPTS HW1_PUSH timestamp input is driven by the particular bit of the PTM_LOCAL_TIMER_IN counter, as selected by the value in the PCIE_USER_PT_M_CFG[6-0] PTM_CLK_SEL register field.

The reference clock (RCLK) for the CPTS can be controlled via the CTRLMMR_PCIE1_CLKSEL[3-0] CPTS_CLKSEL register field in the device Control Module. This enables the SoC flexibility in choosing the CPTS reference clock input. In RP mode, the RCLK needs to be connected to the SERDES PIPE clock since the CPTS will be driving the PTM master clock. For more information on the RCLK source clock selection, see *PCIe Subsystem Integration*.

Figure 12-122 shows the PTM support logic in the PCIe subsystem.

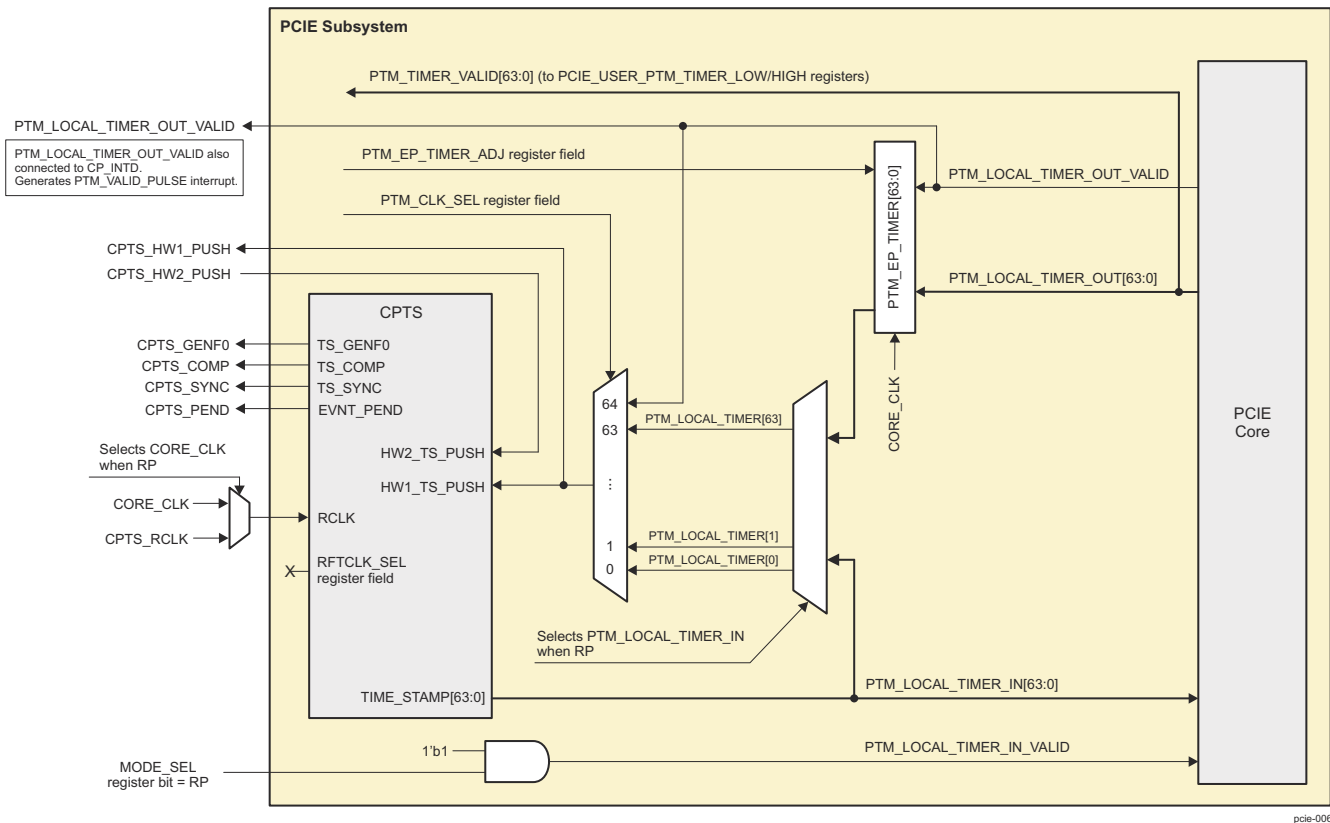

Figure 12-122. PCIe Subsystem PTM Implementation

12.2.3.3.11 PCIe Subsystem Loopback

The PCIe subsystem provides loopback support through PIPE interface (Link Layer).

12.2.3.3.11.1 PCIe PIPE Loopback

The procedure depends upon whether the device is operating in RP or EP Mode. In either case, the PCIe subsystem can be loopback master or loopback slave as outlined in PCIe specifications. A loopback master is the component requesting loopback and transmitting the data. A loopback slave is the component looping back the data.

Note

The PIPE loopback mode cannot be used for looping back transactions.

12.2.3.3.11.1.1 PIPE Loopback Master Mode

The loopback path when PCIe subsystem is loopback master is:

PCIe subsystem (loopback master) -> PIPE (TX) -> PCIe Link -> Loopback -> PCIe Link -> PIPE (RX) -> PCIe subsystem

12.2.3.3.11.1.2 PIPE Loopback Slave Mode

The loopback path when PCIe subsystem is loopback slave is:

Remote device -> PCIe Link -> PIPE (RX) -> Loopback -> PIPE (TX) -> PCIe Link -> Remote device

If the PCIe subsystem is a loopback slave, then the incoming serial data is routed back to the originating device from the PIPE interface as per PCIe loopback requirements. Typically, PCIe test equipment will be used as loopback master and it will transition PCIe subsystem into loopback slave state following which the inbound transactions will be loopback to the test equipment. There is no programming required on PCIe subsystem to enter loopback in slave mode. PHY support is not required to use this loopback mode.

12.2.3.3.12 PCIe Subsystem Error Handling

As an End Point, PCIe subsystem reports errors to root complex so that corrective action may be taken. These messages become error interrupts on the Root Port side. In addition, the errors that are detected by the PCIe subsystem locally are also reported to software via interrupts.

Note that for several errors of the same type that are detected in close succession, the PCIe subsystem will not necessarily send as many error messages to Root Port. It is guaranteed to send at least one such error message.

12.2.3.3.12.1 PCIe AXI to/from VBUSM Bus Error Mapping

[Table 12-188](#) and [Table 12-189](#) show the bus error mapping to/from the AXI interface on the PCIe controller to the system VBUSM interfaces.

The AXI2VBUSM bridge maps the bus errors on the ingress AXI interface to the VBUSM master interface as shown in the table below.

Table 12-188. AXI to VBUSM Bus Error Mapping

VBUSM		AXI	
Code	Error	Code	Error
0 (decimal)	Success	0h	OKAY
1 (decimal)	N/A	3h	N/A
2-3 (decimal) 7 (decimal)	All Others	2h	SLVERR

The VBUSM2AXI bridge maps the bus errors on the egress VBUSM slave interface to the AXI interface as shown in the table below.

Table 12-189. VBUSM to AXI Bus Error Mapping

AXI		VBUSM	
Code	Error	Code	Error
N/A	N/A	2 (decimal)	Protection Error
0h	OKAY	0 (decimal)	Success
3h	DECERR	1 (decimal)	Addressing Error
2h	SLVERR	1 (decimal)	Addressing Error

12.2.3.3.13 PCIe Subsystem Internal Diagnostics Features

12.2.3.3.13.1 PCIe Parity

All the parity inputs on the PCIe controller core are driven by the EDC_INV module. This allows the parity input to the PCIe controller to be inverted and thus inject an error. [Figure 12-123](#) shows the parity logic on the AXI AWADDR port as an example. The parity of the AWADDR inputs to the PCIe controller are calculated as an XOR and this is fed into the PCIe controller using the EDC_INV block. The input AWADDR_par can be inverted using commands from the ECC Aggregator to enable error injection. Similar logic is present on all other parity inputs to the PCIe controller.

Checking input parity and output parity are handled inside the PCIe controller. Any errors in parity are signaled using the PCIe active internal diagnostics interrupt (PCIE_ASF_PEND).

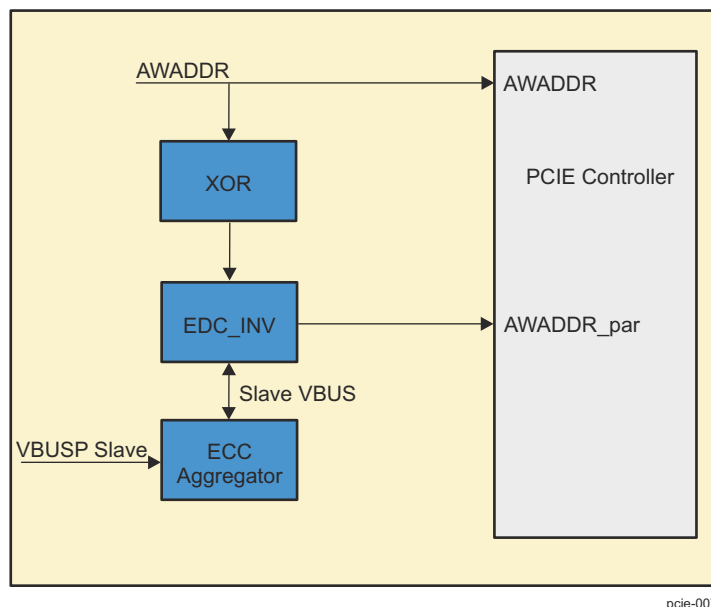

Figure 12-123. Parity Logic on AXI AWADDR Input

12.2.3.3.13.2 ECC Aggregators

The PCIe subsystem instantiates two ECC Aggregators: AXI_ECC_AGGR and CORE_ECC_AGGR.

AXI_ECC_AGGR is connected to the RAMs in PCIe CBA Clock Domain and CORE_ECC_AGGR is connected to the RAMs in the PIPE Clock Domain.

The ECC Aggregator modules integrated within the PCIe subsystem provide a mechanism to control and monitor the ECC RAMs via Single Error Correction (SEC) and Double Error Detection (DED) functions. Each ECC Aggregator module gathers level pending status from the ECC RAMs into two interrupts to system level. One interrupt is for correctable errors (SEC) and the other one for uncorrectable errors (DED). The ECC Aggregator supports software readable status of ECC single/double-bit errors and associated information such as RAM address and data bit(s) that are in error. Write back correction for async read RAMs is not supported.

For more information on the ECC Aggregator operation, see [Section 12.10.6, ECC Aggregator](#).

12.2.3.3.13.3 RAM ECC Inversion

The RAM ECC logic inside the PCIe controller can be tested using the ECC inversion logic.

12.2.3.3.14 LTSSM State Encoding

[Table 12-190](#) is used when the PCIe/M-PCIe core is configured to be operating in PCIe mode.

[Table 12-190](#) provides the encoding of the LTSSM states on the LTSSM_STATE output of the core, as well the state read from the Physical Layer Configuration Register 0.

Table 12-190. LTSSM State Encoding

12.2.4 Universal Serial Bus (USB) Subsystem

This section describes the USB 3.0 Dual-Role-Device (DRD) interface subsystem of the device.

Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

12.2.4.1 USB Overview

Similar to earlier versions of USB bus, USB 3.0 is a general-purpose cable bus, supporting data exchange between a host device and a wide range of simultaneously accessible peripherals.

The device supports these USB subsystems:

- USB3SS0 is SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem with on-chip SS (USB3.0) PHY and HS/FS/LS ¹(USB2.0) PHY

Figure 12-124 shows the USB subsystem highlights.

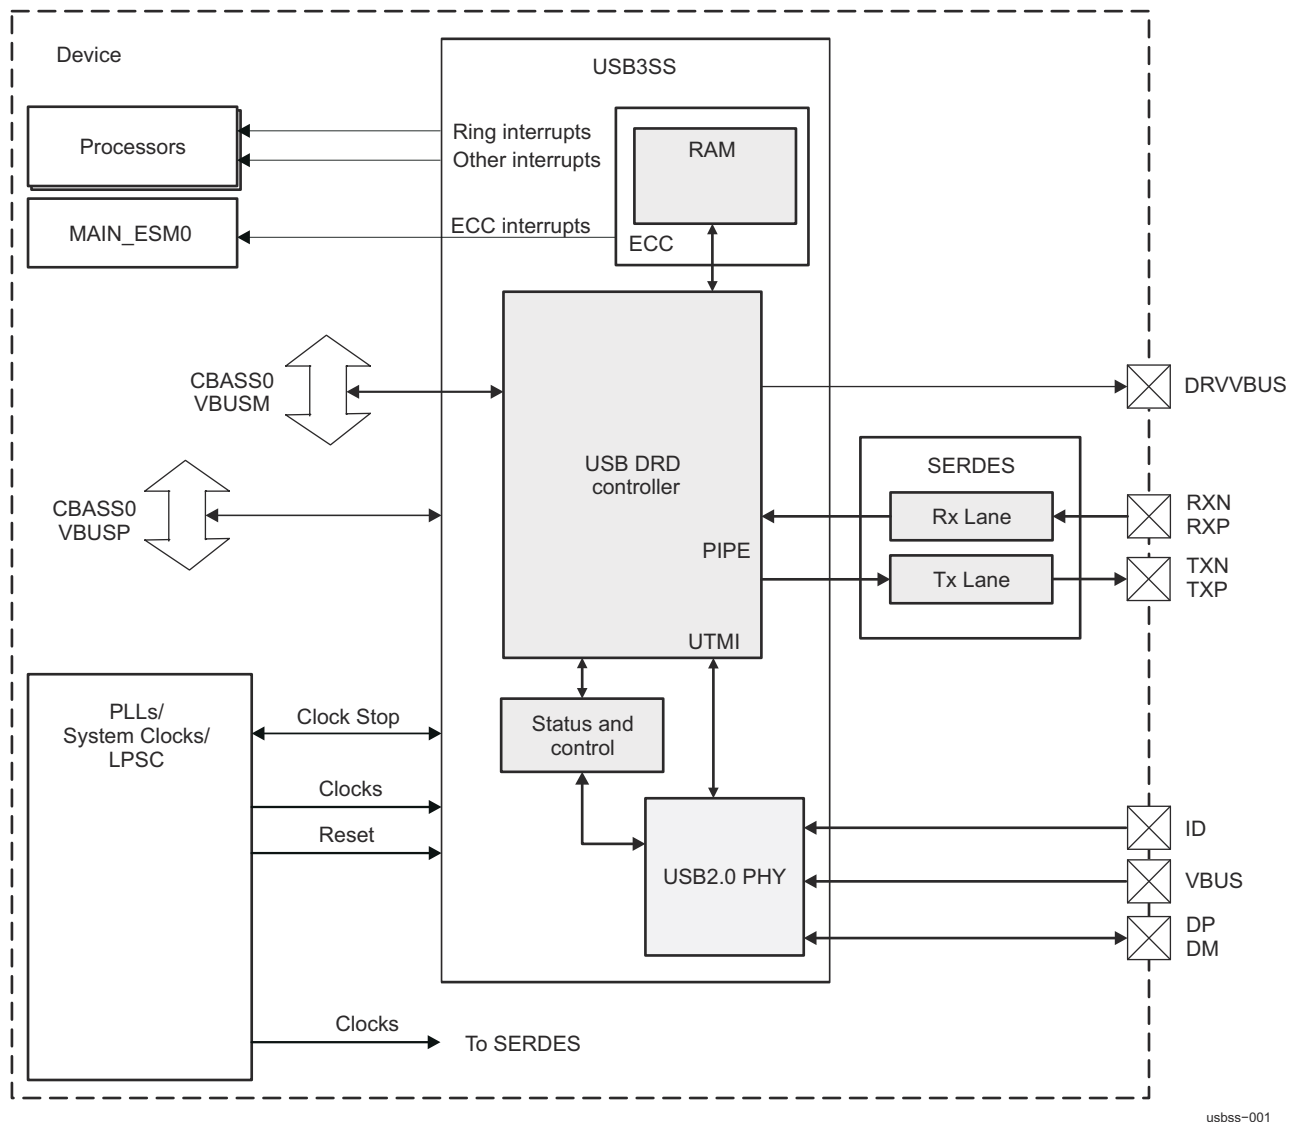

Figure 12-124. USB Subsystem Overview

12.2.4.1.1 USB Features

The USB Dual-Role-Device (DRD) subsystem, supports the following USB features:

- General features:
 - Supports Peripheral (aka Device) mode at Superspeed (5 Gbps), Highspeed (480 Mbps), and Fullspeed (12 Mbps)
 - Supports Host mode at Superspeed (5 Gbps), Highspeed (480 Mbps), Fullspeed (12 Mbps), and Lowspeed (1.5 Mbps)
 - Static peripheral operation
 - Static host operation
 - Compliant with USB 3.1 Gen1 Specification
 - Limited OTG 2.0 functionality
 - Supports VBUS and ID detection
 - Host Negotiation Protocol (HNP) support

¹ LowSpeed (LS) is supported only in host mode.

- Charger Downstream Port (CDP) as per Battery Charging Specification, Revision 1.2
- Each controller instance contains single xHCI with the following features:
 - Compatible to the xHCI specification (revision 1.0)
 - Supports 15 Transmit (TX), 15 Receive (RX) endpoints (EPs), and one EP0 endpoint which is bidirectional
 - Internal scatter-gather DMA controller
 - Dynamic data buffering
 - USB3 power saving states (U1, U2, and U3) and USB2 L1/L2
 - 64 slots supported with 32 endpoints per slot, for host operation
- Operation flexibility:
 - Uniform programming model for SS, HS, FS, and LS operation
 - Multiple interrupt lines:
 - 8 interrupts associated with 8 programmable Event Rings for multi-core support
 - Interrupt for OTG events
- Functional safety:
 - Internal RAM with ECC
 - Hardware transaction timeout monitor
- Supports VBUS and ID detection in the USB2.0 PHY
- External requirements and I/O features:
 - Requires an external charge pump or power switch for VBUS 5-V generation
 - Requires an external circuitry or PMIC to start the battery charging upon Battery Charger (BC) detected event
 - Requires external high-precision resistors for USB2.0 PHY and SERDES termination calibration
 - Supports internal data lane swapping for Type C connector. All other Type C features, like cable detection and CC configuration, have to be implemented using external circuitry
 - Supports short circuit protection to GND and short-term short circuit protection to VBUS on data pins

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.2.4.1.2 USB Ports

This section describes USB module ports related to clocks, resets, and hardware requests.

Table 12-191. USB Clocks and Resets

Clocks	
Module Clock Input	Description
ACLK	VBUSM interface clock
PCLK	VBUSP interface clock
BUFCLK	VBUSM bridge clock
CLK_LPM	Low power clock (24 MHz). This clock has to be free running when USB is enabled.
USB2_REFCLOCK	USB2PHY reference clock. HFOSC selected via CTRLMMR_USB0_CLKSEL. Frequency value must be indicated to PHY via USB3POSS_STATIC_CONFIG.
USB2_APB_PCLK	USB2PHY VBUSP interface clock
Resets	
Module Reset Input	Description
USB_RST	USB3SS0 hardware reset

Table 12-192. USB Hardware Requests

Interrupt Requests		
Module Interrupt	Description	Type
IRQ_[0:7]	8 event ring interrupts in host mode. In device mode, IRQ[6] is device USB interrupt and IRQ[7] is device wakeup request.	Level
HOST_SYSTEM_ERROR	USB host system error	Level
OTGIRQ	USB OTG events	Level

Table 12-192. USB Hardware Requests (continued)

ASF_INT_NONFATAL	USB safety features nonfatal interrupt	Level
ASF_INT_FATAL	USB safety features fatal interrupt	Level
A_ECC_AGGR_CORRECTED_ERR_LEVEL	ECC aggregator interrupt	Level
A_ECC_AGGR_UNCORRECTED_ERR_LEVEL	ECC aggregator interrupt	Level
DMA Events		
Module DMA Event	Description	Type
-	No PDMA channels to external DMA engines. USB has an internal DMA controller.	-

12.2.4.1.3 USB Terminology

The following acronyms and abbreviations are related to USB.

Term	Definition
ADP	Attach Detection Protocol: detects USB OTG attach/detach events.
DRD	Dual Role Device: USB Host and Peripheral capable.
DS	Down Stream (A USB port facing from a Host or Hub to a Device/Peripheral).
EP	Endpoint: USB communication channel between the USB link partners carrying a single transfer type (BULK, ISOCH, INT, or CONTROL) and bus sharing arbitration scheme.
FS	Full-Speed USB data rate (12 Mbps).
HNP	Host Negotiation Protocol, OTG extension to swap USB host and peripheral roles.
HS	High-Speed USB data rate (480 Mbps).
ITP	Isochronous Timestamp Packet: USB SS micro-frame boundary packets.
LMP	Link Management Packet.
LS	Low-Speed USB data rate (1.5 Mbps).
OTG	On-The-Go extension to USB protocol.
PHY	Physical Layer Device.
SS	Super-Speed USB data rate. 5 Gbps (USB3.0 or USB3.1 Gen1)
US	Upstream facing from a device (or hub) to the host (or a hub).
USB IF	USB Implementers Forum. The governing organization that develops and maintains the USB specifications and compliance standard. http://www.usb.org
xHC	Host Controller, designates the USB hardware that implements the xHCI specification.
xHCI	eXtensible Host Controller Interface. The specification that defines the register level interface for host controller.

12.2.4.2 USB Environment

This chapter details the USB subsystem environment.

[Table 12-193](#) describes the external signals of the USB3SS0 subsystem.

Table 12-193. USB3SS Input/Output Description

Device Pin	I/O ⁽¹⁾	Description
DP	I/O	USB2.0 data pins. These are HS/FS/LS bidirectional differential data lane (D+/D-)
DM	I/O	
SSRX1P (SSRX2P)	I	USB3.0 differential data receive lane (RX+ pin)
SSRX1N (SSRX2N)	I	USB3.0 differential data receive lane (RX- pin)
SSTX1P (SSTX2P)	O	USB3.0 differential data transmit lane (TX+ pin)
SSTX1N (SSTX2N)	O	USB3.0 differential data transmit lane (TX- pin)
REXT	A/I	USB3.0 SerDes external calibration resistor. Requires a 3.01 kOhm $\pm 1\%$ accurate off-chip resistor connected from this pin to ground.
ID	A/I	USB cable identifier (A/B-device). Analog ID pin sense with internal pull-up
VBUS	A/I	An 3.3-V analog input for monitoring the voltage on VBUS (VBUS sense). 5-V VBUS must be applied via an external resistive divider /3. For example, R1 = 20 kOhm and R2 = 10 kOhm

Table 12-193. USB3SS Input/Output Description (continued)

Device Pin	I/O ⁽¹⁾	Description
DRVVBUS	O	A digital output signal for VBUS Power Supply Enabling. Used to enable an external charge pump or power switch to supply +5V power to the VBUS port, when appropriate
RCALIB	A/I	External resistor for USB2.0 PHY calibration. Requires a 500 Ohm $\pm 1\%$ off-chip resistor connected from this pin to ground

(1) I = Input; O = Output; A = Analog

12.2.4.3 USB Functional Description

Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

The USB3SS subsystem contains the USB3.0 Dual Role Device (DRD) controller module and a USB2.0 PHY module. A wrapper module is controlling some top-level functions like Host and Device role switch and reset release.

The USB controller uses USB2PHY for USB2.0 operation and one of the device SERDESes for USB3.0 speeds. The SERDES also contains lane swap feature for USB Type-C plug flipping support.

12.2.4.3.1 USB Type-C Connector Support

Lane swapping for Type-C connector support is performed within the SERDES wrapper module. Type-C CC detection and configuration has to be performed by external ICs. Type-C device attachment/detachment and cable orientation have to be communicated using I2C, GPIO, or a similar method.

For USB Type-C support, the SERDES wrapper and SERDES must be programmed for USB protocol on lane 0, lane 1, and/or lane2, and lane 3. Software must hold PHY in reset and then write to the LN10_SWAP and/or LN23_SWAP bit of the to mux the PIPE interface to the other lane. Also the SuperSpeed port in the controller has to be in disabled state when programming LN10_SWAP or LN23_SWAP.

12.2.4.3.2 USB Controller Reset

USB controller has three resets going in, called preset_n, pwrup_rst_n, and aresetn.

- preset_n comes from the mod_g_rst_n input coming from LPSC
- pwrup_rst_n is PWRUP_RST_N register bit in the USB wrapper module (USB3P0SS_W1). This reset has to be deasserted before accessing controller registers. The default value for pwrup_rst_n is 0 (reset asserted). This reset goes to the default asserted state when mod_g_rst_n reset is asserted.
- areset_n comes from PWRUP_RST_N register bit, but the deassertion is synchronized to ACLK.

12.2.4.3.3 Overcurrent Detection

The overcurrent detection circuit is external to the device. Software must specify an overcurrent condition to the controller whenever the overcurrent signal is received from the detection circuit. Software must set the OVERCURRENT_N bit to 0 in the USB3P0SS_W1 register when overcurrent was detected.

12.2.4.3.4 Top-Level Initialization Sequence

The following initialization sequence has to be followed before configuring the controller for USB operation:

1. Software must select and configure the SERDES for USB operation. Some of the registers are shown in . Refer to *Serializer/Deserializer (SerDes)* for more details. USB2.0 PHY contains default configuration that normally does not need change.
2. Software must configure the pseudo-static settings in USB3P0SS_W1 register
3. Software must set PWRUP_RST_N to 1 in order to deassert controller reset

After the above sequence, software can access controller registers.

12.2.5 Serializer/Deserializer (SerDes)

This section describes the Serializer/Deserializer (SerDes) in the device.

12.2.5.1 SerDes Overview

SerDes' goal is to convert device (SoC) parallel data into serialized data that can be output over a high-speed electrical interface. In the opposite direction, SerDes converts high-speed serial data into parallel data that can be processed by the device. To this end, the SerDes contains a variety of functional blocks to handle both the external analog interface as well as the internal digital logic.

Most important building blocks of SerDes are:

- Physical Media Attachment (PMA):
 - Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer, and Clock and Data Recovery (CDR) unit.
 - Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes, and muxes SerDes to peripherals.
- The device contains four 4-lane SERDES.

12.2.5.1.1 SerDes Features

The SERDES module features include:

- Quad lane PHY containing:
 - Transmit and Receive I/Os
 - Serializer
 - Deserializer
 - Clock and data recovery (CDR) unit
- Common Module (CMN)
 - PLLs
 - Master bias
 - Automatic calibration of pin termination resistors
 - Reference clock input buffers
 - Reset and startup management
- Physical Coding Sub-block (PCS)
 - USB3.1 Gen 1 (5 Gbps)
 - PCIe Gen 1 (2.5 Gbps), Gen 2 (5 Gbps), Gen 3 (8 Gbps)
 - Hyperlink (10 Gbps)
 - Display Port / Embedded Display port v1.4
 - SGMII, QSGMI, XAUI (2.5G SGMII), USXGMII(5G/10G), XFI(5G/10G)
 - Symbol alignment
 - Selectable serial pin polarity reversal for both transmit and receive paths
 - Bit stream reordering
- Physical Media Attachment (PMA) layer
 - Transmit equalization
 - Receive equalization
 - Data path BIST with programmable pattern generation and error detection
 - Serial bit stream and parallel word loopback for both line and parallel side
 - 8-bit ADC provides digitized ATB measurement results
 - Supports DC and AC JTAG (boundary scan) per IEEE 1149.6

The SERDES mux (WIZ) module supports the following features:

- Multiplexes device interfaces onto a single SERDES lane (Tx and Rx)
- Provides registers to implement SERDES control and status functions and alignment delays
- Clock generator block for providing MAC transmit clock

- Rx comma align block
 - Performs de-stuffing the Rx data stream in the event that the Rx rate is different from the Tx rate
 - Supports comma detection that is not sensitive to false commas using all 8B/10B character combinations

12.2.5.1.2 Industry Standards Compatibility

All SerDes interfaces are configured as point-to-point connections. It is assumed that the connection is made between the SoC and another device that is compliant to the appropriate industry standard. The list of supported standards is given below.

This chapter deals with the physical layer and, therefore, it is the electrical specifications in these standards that are relevant. For more information regarding protocol compliance ², see the device-specific Datasheet.

- PCIe: This is electrically compliant with Base specification revision 4.0.
- USB: This is electrically compliant with USB 3.1.
- Hyperlink: Electrically compliant to OIF-CEI-11G-SR.
- Display Port/ Embedded Display Port VESA Standard v1.4
- SGMII: Compliant to IEEE 802.3 Clause 70-7
- XAUI: Compliant to IEEE 802.3 Clause 47.3
- QSGMII: Compliant to OIF-CEI 2.0-6G-SR
- USXGMII: Electrically compliant to IEEE 802.3ap Clause 72-7

Table 12-194. SerDes Supported Standards

Standard	Bit Rate (Gbps)	Reference Clock Frequency (MHz)
PCI Express 4.0 Gen1	2.5	100
PCI Express 4.0 Gen2	5.0	100
PCI Express 4.0 Gen3	8.0	100
SGMII	1.0	100
XAUI	2.5G	156.25
QSGMII	5G	100
USXGMII/XFI	5G/10G	156.25
Hyperlink	10.0	100
DP/eDP	1.62-8.1	19.2
USB 3.1 Gen1 SuperSpeed	5.0	100

² Electrical compatibility does not guarantee interoperability with devices

12.2.5.1.3 SerDes Ports

This section describes SerDes module ports related to clocks, resets, and hardware requests.

Table 12-195. SerDes Clocks and Resets

Clocks	
Module Clock Input	Description
SERDES_ICLK	VBUS interface clock
CMN_REFCLK_INT	Internal reference clock from device sources. Software selectable.
Resets	
Module Reset Input	Description
SERDES_RST	Serdes LPSC reset

Table 12-196. SerDes Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
PHY_PWR_TIMEOUT_LVL_0	Lane power timeout interrupt	Level
DMA Events		
Module DMA Event	Description	Type
-	No PDMA channels to external DMA engines	-

12.2.5.1.3.1 WIZ Settings

This section describes the quasi-static settings that software must perform after global resets. These settings are made via registers in the CTRL_MMR0 module. For CTRL_MMR0 description, please refer to *Control Module (CTRL_MMR)*.

12.2.5.1.3.1.1 Interface Selection

SerDeses provide PHY functions for the following high-speed interfaces:

- DP/eDP
- PCIeGen1, Gen2, and Gen3 (one- to four-lane)
- SGMII (1G), XAUI (2.5G), QSGMII(5G), USXGMII/XFI(5G/10G)
- Hyperlink
- USB3.0

Table 12-197 describes the interface combinations supported by SERDES0, SERDES1, SERDES2, and SERDES4.

Note

SERDES 3 does not exist in the device.

Table 12-197. SERDES0/1/2/4 Supported Configurations

Interface Alias	[1:0]		[1:0]		[1:0]		[1:0]	
	LANE_FUNC_SEL	Interface onLane 0	LANE_FUNC_SEL	Interface onLane 1	LANE_FUNC_SEL	Interface onLane 2	LANE_FUNC_SEL	Interface onLane 3

(1) Lane 2 is reserved for USB Type-C lane swap functionality.

12.2.5.1.3.1.2 USB3.0 Double Muxing

USB3.0 pipe interface is connected to both SERDES0.IP3.LN3 and SERDES4.IP3.LN3 (two different SerDes). The USB_SERDES_MUX implements the mapping shown in [Table 12-198](#).

Table 12-198. SerDes USB SERDES Mapping Table

[1:0]MAIN_CTRL_MMR USB0_CTRL.serdes_sel	SERDES connection
0x0	SERDES0.ip3_LN3
0x1	SERDES4.ip3_LN3

1. Programming USB0_CTRL.serdes_sel should align with SERDES0_LN3_CTRL and SERDES4_LN3_CTRL lane_func_sel programming. Refer to the J7AHP MAIN_CTRL_MMR spec.
2. When not selected, the ports should be tied to the BUSDEF default value.

12.2.5.1.3.1.3 Hyperlink SERDES Double Muxing

The vusr_dual ports are connected to both SERDES0 and SERDES4. The VUSR_SERDES_MUX implements the mapping shown in [Table 12-199](#).

Table 12-199. VUSR SERDES Mapping Table

VUSR_Dual_port	MAIN_CTRL_MMR VUSR_CTRL.In#_serdes_sel	SERDES Connection
vusrx_in_0	main_ctrl_mmr.VUSR_CTRL.In0_serdes_sel[0]	SERDES0.ip4_LN0
	main_ctrl_mmr.VUSR_CTRL.In0_serdes_sel[1]	SERDES4.ip4_LN0
vusrx_in_1	main_ctrl_mmr.VUSR_CTRL.In1_serdes_sel[0]	SERDES0.ip4_LN1
	main_ctrl_mmr.VUSR_CTRL.In1_serdes_sel[1]	SERDES4.ip4_LN1
vusrx_in_2	main_ctrl_mmr.VUSR_CTRL.In2_serdes_sel[0]	SERDES0.ip4_LN2
	main_ctrl_mmr.VUSR_CTRL.In2_serdes_sel[1]	SERDES4.ip4_LN2
vusrx_in_3	main_ctrl_mmr.VUSR_CTRL.In3_serdes_sel[0]	SERDES0.ip4_LN3
	main_ctrl_mmr.VUSR_CTRL.In3_serdes_sel[1]	SERDES4.ip4_LN3

1. When not selected, the ports should be tied to the BUSDEF default value. Refer to the J7AHP MAIN_CTRL_MMR.

Follow these programming guidelines for mapping SerDes to VUSR_DUAL lanes:

- Programming VUSR_CTRL.In#_serdes_sel should align with SERDES1_LN#_CTRL and SERDES4_LN#_CTRL lane_func_sel programming. Refer to the J7AHP MAIN_CTRL_MMR.
- When VUSR_CTRL.dual_vusr_en = 0 (single VUSR mode), VUSR_CTRL.In#_serdes_sel must be all 0 or 1. Split VUSR mapping (where some vusr lanes are mapped to SERDES0 and some are mapped to SERDES4) is only allowed in the dual_vusr_en=1 (dual VUSR) mode.

- In dual VUSR mode, all vusrx lanes mapped to one VUSR (within the vusr_dual) must be mapped to the same SerDes.

12.2.5.1.3.1.4 CPSW Channel and SERDES IP Mapping

The cpsw_9xuss SGMII ports [2:1] are connected to both SERDES1 and SERDES2, and ports [8:5] are connected to both SERDES2 and SERDES4. The CPSW_SERDES_MUX implements the mapping shown in Table 12-200.

Table 12-200. CPSW9X Channel and SERDES Mapping

CPSW_9XUSS channel	MAIN_CTRL_MMR SERDES Register Setting	SERDES Connection
1	SERDES2_LN2_CTRL_lane_func_sel[x0],[11]	SERDES1.ip1_LN2
1	SERDES2_LN2_CTRL_lane_func_sel[01]	SERDES2.ip2_LN2
2	SERDES2_LN3_CTRL_lane_func_sel[00],[11]	SERDES1.ip1_LN3
2	SERDES2_LN3_CTRL_lane_func_sel[01]	SERDES2.ip2_LN3
3	-	SERDES1.ip1_LN0
4	-	SERDES1.ip1_LN1
5	SERDES4_LN0_CTRL_lane_func_sel[x0],[11]	SERDES2.ip1_LN0
	SERDES4_LN0_CTRL_lane_func_sel[01]	SERDES4.ip2_LN0
6	SERDES4_LN1_CTRL_lane_func_sel[x0],[11]	SERDES2.ip1_LN1
	SERDES4_LN1_CTRL_lane_func_sel[01]	SERDES4.ip2_LN1
7	SERDES4_LN2_CTRL_lane_func_sel[x0],[11]	SERDES2.ip1_LN2
	SERDES4_LN2_CTRL_lane_func_sel[01]	SERDES4.ip2_LN2
8	SERDES4_LN3_CTRL_lane_func_sel[x0],[11]	SERDES2.ip1_LN3
	SERDES4_LN3_CTRL_lane_func_sel[01]	SERDES4.ip2_LN3

1. Programming USB0_CTRL.serdes_sel should align with SERDES0_LN3_CTRL and SERDES4_LN3_CTRL lane_func_sel programming. Refer to the J7AHP MAIN_CTRL_MMR spec.

12.2.5.1.3.1.5 ACSPCIE Reference Clock Selection

Table 12-201 describes the SERDES ACSPCIE reference clock selection. ACSPCIE buffer clk selection: Needs PCIE_REFCLK1_CLKSEL_OUT_CLK_EN to be enabled for driving the clk out onto the ref clk pins.

Table 12-201. SerDes ACSPCIE Reference Clock Selection

[1:0] CLK_SEL	ACSPCIE Clk Source
0x0	SERDESx_REF_DER_OUT_CLK
0x1	MAIN_PLL2_HSDIV4_CLKOUT ⁽¹⁾
0x2	SERDESx_REF_OUT_CLK
0x3	0

(1) Refer to the CTRL_MMR.

12.2.5.1.3.1.6 Internal Reference Clock Selection

Table 12-202 describes the internal reference clock options for SERDES.

Table 12-202. SerDes Internal Reference Clock Selection

[1:0]CLK_SEL	Internal Clock to SERDES
0x0	HFOSC0_CLKOUT
0x1	HFOSC1_CLKOUT
0x2	MAIN_PLL3_HSDIV4_CLKOUT ¹
0x3	MAIN_PLL2_HSDIV4_CLKOUT ¹

1. Refer to the CTRL_MMR.

12.2.5.2 SerDes Environment

12.2.5.2.1 SerDes I/Os

[Figure 12-125](#) shows the I/O interface signals of SERDES.

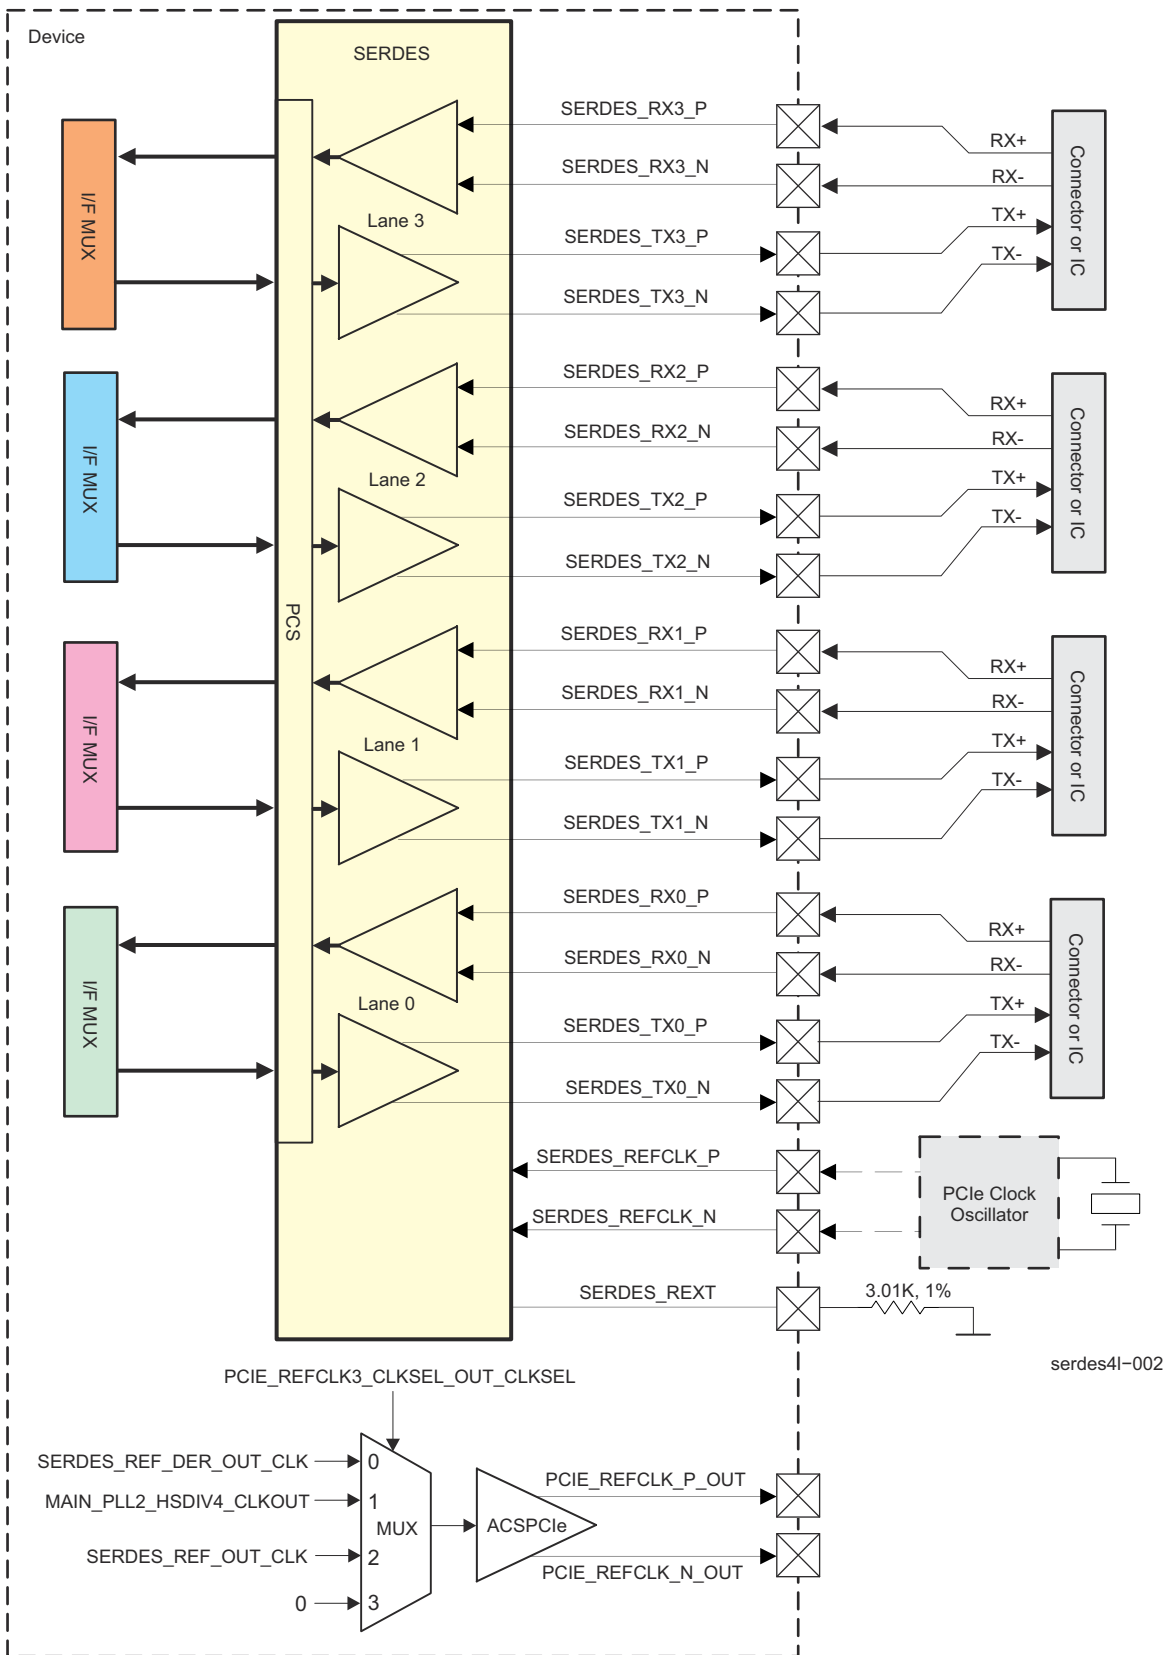

Figure 12-125. SerDes Environment

Note

Although containing some of the basic external components, [Figure 12-125](#) must not be considered as an exhaustive guide for the PCB designer. TI provides additional documents for those who are willing to design PCBs and/or fine tune the SerDes.

[Table 12-203](#) describes the external signals of each SERDES module.

Table 12-203. SerDes Input/Output Description

Device Pin	I/O ⁽¹⁾	Description
SERDES_RX0_P	I	SerDes differential data receive pins. Lane 0
SERDES_RX0_N	I	
SERDES_TX0_P	O	SerDes differential data transmit pins. Lane 0
SERDES_TX0_N	O	
SERDES_RX1_P	I	SerDes differential data receive pins. Lane 1
SERDES_RX1_N	I	
SERDES_TX1_P	O	SerDes differential data transmit pins. Lane 1
SERDES_TX1_N	O	
SERDES_RX2_P	I	SerDes differential data receive pins. Lane 2
SERDES_RX2_N	I	
SERDES_TX2_P	O	SerDes differential data transmit pins. Lane 2
SERDES_TX2_N	O	
SERDES_RX3_P	I	SerDes differential data receive pins. Lane 3
SERDES_RX3_N	I	
SERDES_TX3_P	O	SerDes differential data transmit pins. Lane 3
SERDES_TX3_N	O	
PCIE_REFCLK_P_OUT	O	Serdes Internal reference clock Output
PCIE_REFCLK_N_OUT	O	
SERDES_REFCLK_P	I	SerDes external system reference clock
SERDES_REFCLK_N	I	
SERDES_REXT	A/I	PMA external calibration resistor. Requires a 3.01 kOhm $\pm 1\%$ accurate off-chip resistor connected from this pin to ground.

(1) I = Input; O = Output; A = Analog

12.2.5.3 SerDes Functional Description

12.2.5.3.1 SerDes Block Diagram

Figure 12-126 is a top-level, non-exhaustive diagram of SerDes and WIZ wrapper. Note that only one (Tx + Rx) lane is shown.

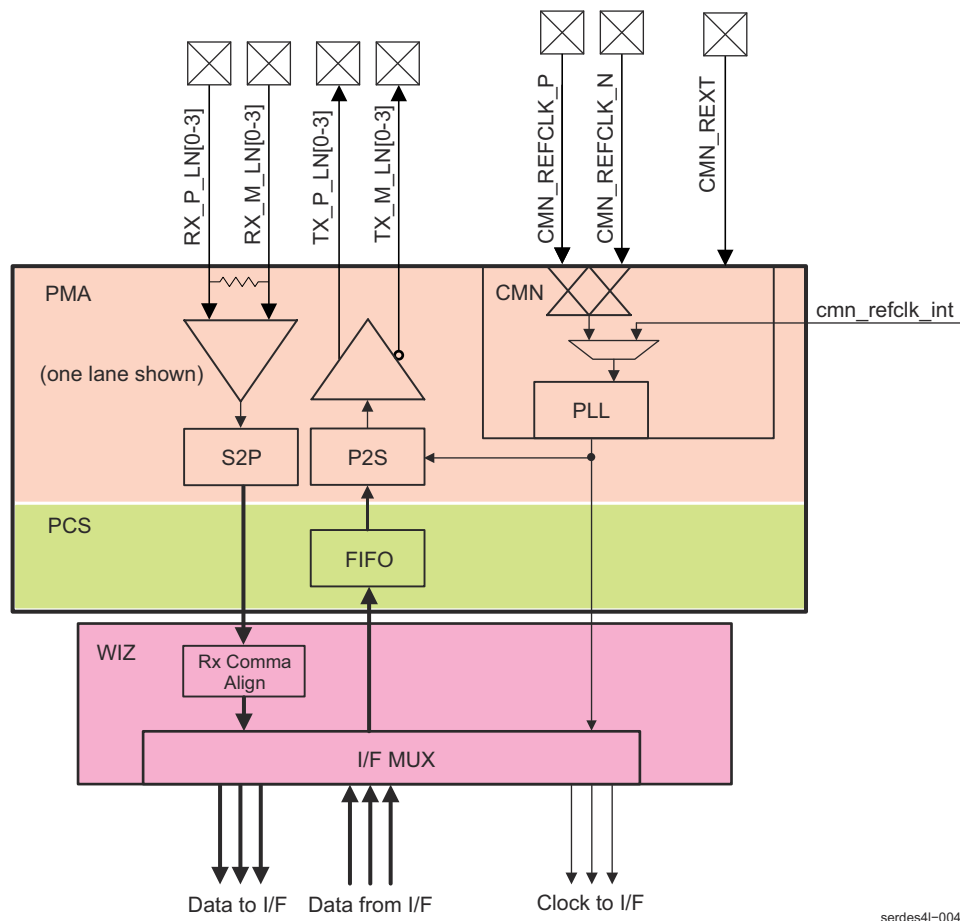

Figure 12-126. SerDes and WIZ Block Diagram

Building blocks of SerDes include:

- Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer (P2S/S2P), and Clock and Data Recovery (CDR) unit. Each SerDes contains one Tx and Rx lane.
- Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Lanes and CMN are parts of the Physical Media Attachment (PMA) layer.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes (register interface), and muxes SerDes to peripherals (USB, PCIe, and others).

12.3 Memory Interfaces

This section describes the memory interfaces in the device.

12.3.1 Flash Subsystem (FSS)

This section describes the Flash Subsystem (FSS) in the device.

12.3.1.1 FSS Overview

The Flash Subsystem (FSS) provides access to external flash devices via Octal SPI (OSPI) and HyperBus™ interface along with encryption/decryption, authentication, and in-line ECC protection.

The FSS includes two OSPI and one HyperBus interface. For more information, see *Octal Serial Peripheral Interface (OSPI)* and *HyperBus Interface*.

Table 12-204. FSS Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
MCU_FSS0	-	✓	-

The first FSS path (FSS0) has access to either OSPI0 or HyperBus interface and can be configured for ECC, authentication, or both. The second FSS path (FSS1) has access only to OSPI1 and can be configured with or without ECC.

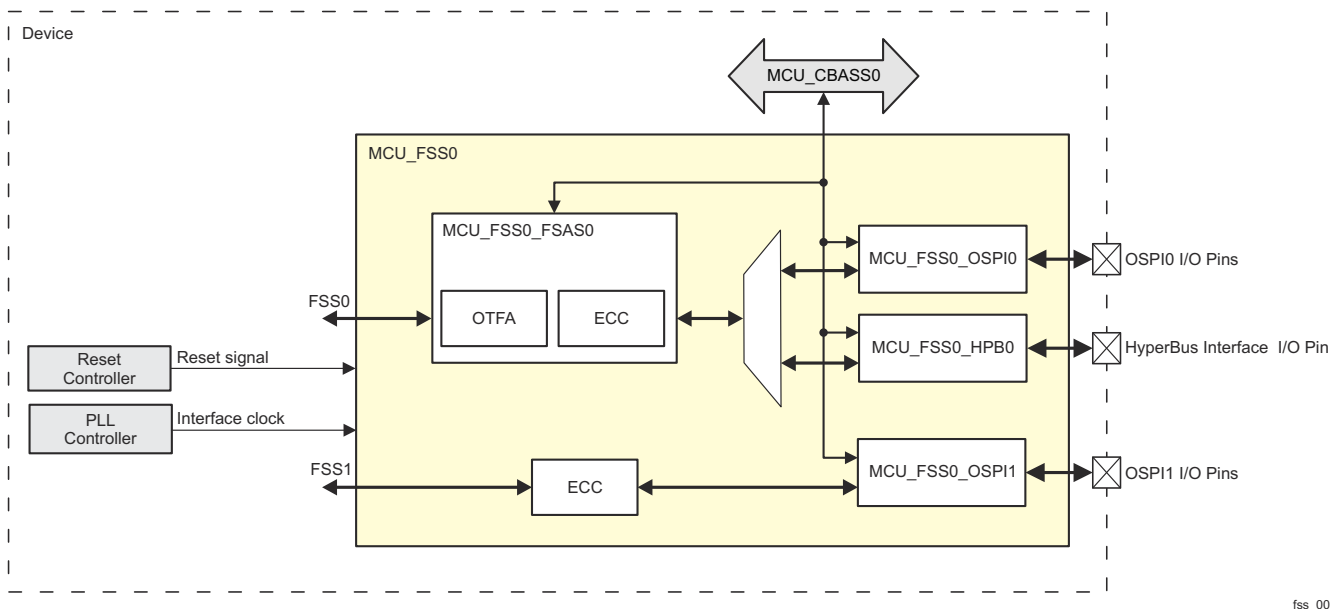

Figure 12-127. FSS Overview

12.3.1.1.1 FSS Features

The FSS has the following features:

- Two simultaneous flash interfaces:
 - Two OSPIs (OSPI0 and OSPI1) OR
 - One HyperBus interface and one OSPI (OSPI1)
- Primary OSPI0/HyperBus interface supports:
 - Execute in place (XIP) operation
 - 32-byte block copy (BC) operation
- Secondary OSPI1 interface supports:
 - 32-byte block copy (BC) operation
 - ECC
- OSPIs support single, dual, quad, or octal SPI devices
- OSPIs support up to 4 devices
- HyperBus interface supports up to 2 devices

- The OSPI and HyperBus interface have independent power management for low power operations

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.3.1.1.2 Flash Ports

HyperBus interface	For more information about HyperBus interface I/O signals, see <i>HyperBus Environment</i> .

12.3.1.3 FSS Functional Description

12.3.1.3.1 FSS Block Diagram

The FSS provides access to external Flash and RAM devices. It supports XIP (Execute-in-Place) and BC (Block Copy) operations.

The FSS consists of two OSPIs and one HyperBus interface. There are two FSS paths - FSS0 and FSS1 (see). The first path (FSS0) includes OSPI0 and HyperBus interface. The second path (FSS1) includes OSPI1. These two FSS paths can be used simultaneously (see *FSS Typical Application*).

Table 12-208 shows the FSS allowed interface combinations.

Table 12-208. FSS Allowed Interface Combinations

Combination	Primary Interface (FSS0)	Secondary Interface (FSS1)
1.	OSPI0 (MCU_FSS0_OSPI0)	Not Used
2.	HyperBus Interface (MCU_FSS0_HPB0)	Not Used
3.	OSPI0 (MCU_FSS0_OSPI0)	OSPI1 (MCU_FSS0_OSPI1)
4.	HyperBus Interface (MCU_FSS0_HPB0)	OSPI1 (MCU_FSS0_OSPI1)
5.	Not Used	OSPI1 (MCU_FSS0_OSPI1)

Figure 12-128 shows the FSS block diagram.

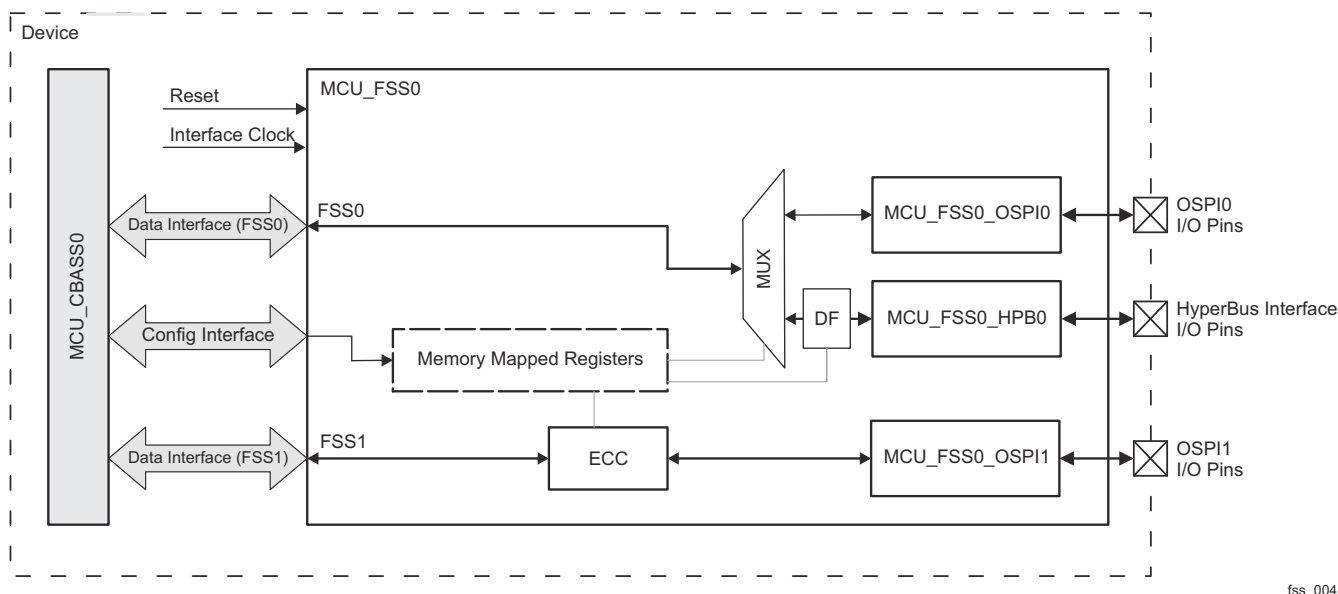

Figure 12-128. FSS Block Diagram

FSS Blocks:

- **MCU_CBASS0:** The MCU_CBASS0 interconnect allows FSS to communicate with the device modules and subsystems.
- **Data Interface (FSS0):** It is 64-bit data/32-bit address multi issue data interface with coherent in-band bypass. It provides accessibility to either the OSPI0 or HyperBus interface.
- **Data Interface (FSS1):** It is 64-bit data/32-bit address multi issue data interface with coherent in-band bypass. It provides accessibility to the OSPI1.
- **Config Interface:** It is used for configuration of the memory mapped registers within the FSS.
- **Interface Clock and Reset:**
 - For more information, see *MCU_FSS0 Clocks and Resets*.
 - For more information, see *MCU_FSS0_OSPI Clocks and Resets*.
 - For more information, see *MCU_FSS0_HPB0 Clocks and Resets*.

- **Memory Mapped Registers:** This block conditionally includes registers from the following blocks: FSS, ECC, MUX, and DF. The configuration of these registers defines which combination of FSS interfaces is selected (see [Table 12-208](#)) and also which FSS features and operation modes are used. For more information, see `MCU_FSS0_SYSCONFIG`.
- **MUX:** The Muxing (MUX) block is used as a software controlled switch in the primary FSS (FSS0) interface. It defines which interface to be used (OSPI0 or HyperBus interface). The MUX block can switch only when the traffic is idle. The software has responsibility to cause the traffic to be stopped.
- **DF:** The Dynamic Fragmenter (DF) module is responsible for fragmenting write data to the flash region so that all writes to the flash region are done in 16-bits chunks (a requirement for HyperFlash). It passes all other transaction through unaffected.
- **FSS Interfaces:**
 - `MCU_FSS0_OSPI0`: The OSPI0 is part of the primary FSS interface (FSS0). It can be configured to use ECC and/or OTFE module.
 - `MCU_FSS0_OSPI1`: The OSPI1 is part of the secondary FSS interface (FSS1). It can be configured with or without ECC.
 - `MCU_FSS0_HPB0`: The HyperBus interface is part of the primary FSS interface (FSS0). It can be configured to use ECC and/or OTFE module.
- **FSS I/O Pins:**
 - **OSPI1 I/O Pins:** All used `MCU_FSS0_OSPI1` interface pins (for more information, see *OSPI I/O Signals*).
 - **HyperBus I/O Pins:** All used `MCU_FSS0_HPB0` interface pins (for more information, see *HyperBus I/O Signals*).

12.3.1.3.2 FSS ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

For more information about ECC, refer to *ECC Aggregator*.

For FSS1 path when the stand-alone ECC module is used:

- The input for the ECC module is 32-byte data block.
- The ECC module generates ECC codes for the 32-byte data block.
- The ECC module packs data + ECC, reformats the address and sends this to the flash controller (OSPI1 flash controller).

For more information, see *ECC Calculation*.

12.3.1.3.3 FSS Modes of Operation

[Table 12-208](#) presents the possible combinations of FSS interfaces.

Both paths (FSS0 and FSS1) support XIP and BC modes.

12.3.1.3.4 FSS Regions

12.3.1.3.4.1 FSS Regions Boot Size Configuration

The boot size for OSPI0/HyperBus defaults to 64 MB but can be configured to be 128 MB. Selection of boot block which will be used is also configurable. For more information see `CTRLMMR_MCU_FSS_CTRL` register in *Control Module (CTRL_MMR)*.

12.3.1.3.5 FSS Memory Regions

[Table 12-209](#) shows the FSS memory regions.

Table 12-209. FSS Memory Regions

Address Range		Size	Description
FSS0 (HyperBus interface or OSPI0)	FSS1 (OSPI1)		
0x04 0000 0000 to 0x04 FFFF FFFF	0x06 0000 0000 to 0x06 FFFF FFFF	4 GB	External Memory Space (Region 0)
0x00 5000 0000 to 0x00 57FF FFFF	0x00 5800 0000 to 0x00 5FFF FFFF	128 MB	Boot Space (Region 1)

Table 12-209. FSS Memory Regions (continued)

Address Range		Size	Description
0x05 0000 0000 to 0x05 FFFF FFFF	0x07 0000 0000 to 0x07 FFFF FFFF	4 GB	External Memory Space (Region 3)

12.3.1.4 FSS Programming Guide**12.3.1.4.1 FSS Initialization Sequence**

Initialization steps:

- Configure the main boot parameters for FSS0 or FSS1):
 - Select the boot block to be used.
 - Select the size of the boot block to be used.
- Enable FSS in PSC.
- Configure the FSS interface which will be used:
 - For FSS0 - OSPI0 or HyperBus interface.
 - For FSS1 - OSPI1.
- Enable the selected FSS interface in PSC.
- Configure the FSS interface:
 - For more information about OSPI configuration, please see *Octal Serial Peripheral Interface (OSPI)*.
 - For more information about HyperBus interface configuration, please see *HyperBus Interface*.
- Configure the ECC region start address and size:
 - MCU_FSS0_ECC_RGSTRT_j
 - MCU_FSS0_ECC_RGSIZ_j
- Enable the ECC option if the target flash device has ECC encoded within.
- If the target device is HyperFlash/SRAM configure fragmentation address boundary:
 - Flash device requires fragmentation.
 - SRAM device does not require fragmentation.
- Enable error interrupts (see MCU_FSS0_ENABLE_SET).

12.3.1.4.2 FSS Real-Time Operation

In the event of an ECC single error detect, the 32-byte block address and associated error bits are stored and an interrupt is generated (if enabled). The CPU can then service the interrupt and determine the error type. If a single error occurs, the CPU can scrub the flash block to determine if the error is permanent and requires reprogramming.

In the event of an ECC double error detect, the 32-byte block address and associated error bits are stored and an interrupt is generated (if enabled). The CPU can then service the interrupt and determine the error type. If the double error detect is within the flash, the region is corrupt and have to be treated as unused.

12.3.1.4.3 FSS Power Up/Down Sequence

There are four PSC controls for the FSS: the FSS itself, OSPI0, HyperBus interface, and OSPI1. The CPU enables the appropriate interfaces before using FSS0 or FSS1 of the FSS.

The FSS0 can be used for HyperBus interface or OSPI0 and only the interface in use has to be enabled. Software should ensure the selected interface is enabled prior to FSS0 transactions.

The FSS1 can only be used to access OSPI1. The FSS1 transaction may be blocked depending on the power state of the OSPI1.

Normal Power Down Sequence:

- Block any new transaction to the particular interface - FSS0 or FSS1.
- Power down the target FSS interface.
- In the event when all targets are powered down, the FSS can then be powered down.

12.3.2 Octal Serial Peripheral Interface (OSPI)

This section describes the Octal Serial Peripheral Interface (OSPI) module for the device.

12.3.2.1 OSPI Overview

The Octal Serial Peripheral Interface (OSPI) module is a kind of Serial Peripheral Interface (SPI) module which allows single, dual, quad or octal read and write access to external flash devices.

The OSPI module is used to transfer data, either in a memory mapped direct mode (for example a processor wishing to execute code directly from external flash memory), or in an indirect mode where the module is set-up to silently perform some requested operation, signaling its completion via interrupts or status registers. For indirect operations, data is transferred between system memory and external flash memory via an internal SRAM which is loaded for writes and unloaded for reads by a device master at low latency system speeds. Interrupts or status registers are used to identify the specific times at which this SRAM should be accessed using user programmable configuration registers.

12.3.2.1.1 OSPI Features

The OSPI modules have the following features:

- Support for single, dual, quad (QSPI mode) or octal (on MCU_FSS0_OSPI0 only) I/O instructions.
- Support dual Quad-SPI mode for fast boot applications.
- Memory mapped 'direct' mode of operation for performing flash data transfers and executing code from flash memory.
- Software triggered 'indirect' mode of operation for performing low latency and non-processor intensive flash data transfers.
- Local SRAM of configurable size to reduce advanced high-performance bus overhead and buffer flash data during indirect transfers.
- Set of software advanced peripheral bus accessible flash control registers to perform any flash command, including data transfers up to 8-bytes at a time.
- Additional addressable memory bank to accommodate more than 8-bytes at a time.
- Support for XIP, sometimes referred to as continuous mode.
- Support for DDR Mode and DTR protocol (including Octal DDR protocol with DQS for Octal-SPI devices)
- Programmable device sizes.
- Programmable write protected regions to block system writes from taking effect.
- Programmable delays between transactions.
- Legacy mode allowing software direct access to low level transmit and receive FIFOs, bypassing the higher layer processes.
- An independent reference clock to decouple bus clock from SPI clock – allows slow system clocks.
- Programmable baud rate generator to generate OSPI clocks.
- Features included to improve high speed read data capture mechanism.
- Option to use adapted clocks or DQS to further improve read data capturing.
- Programmable interrupt generation.
- Up to four external device selects - OSPI and QSPI devices can be mixed:
 - MCU_FSS0_OSPI0 has four chip-selects
 - MCU_FSS0_OSPI1 has two chip-selects.
- Programmable data decoder, enables continuous addressing mode for each of the connected devices and auto-detection of boundaries between devices.
- Support BOOT mode.
- Bidirectional CRC on Multiple-SPI interface.
- Handling ECC errors for flash devices with embedded correction engine.
- Full integration with PHY module dedicated to more flexible and power efficient transfers.
- MCU_FSS0_OSPI0 supports RESET_OUT[1-0] and ECC_FAIL pins for external flash devices where ECC is checked on the flash.
- Automatic Flash device status polling for programming operation (Auto HW Polling)

12.3.2.1.2 OSPI Ports

N_SS_OUT0	O	MCU_FSS0_OSPI1 external flash device chip select 0
N_SS_OUT1	O	MCU_FSS0_OSPI1 external flash device chip select 1
OCLK	O	MCU_FSS0_OSPI1 clock output for the external flash device
	O	MCU_FSS0_OSPI1 external loopback output

Table 12-212. OSPI I/O Signals (continued)

Module Pin	I/O ⁽¹⁾	Description
DQS	I ⁽²⁾	MCU_FSS0_OSPI1 data strobe / external loopback input

(1) I = Input; O = Output

(2) When used as an external loopback input, the DQS signal can alternatively be referred to as LBCLKI. The LBCLKI clock input signal is a looped back version of the LBCLKO clock output signal and facilitates easier timing closure at higher speeds. The loopback has to be at board level in order to support higher OSPI speeds. The source of the loopback clock is defined by CTRLMMR_MCU_OSPIn_CLKSEL[4] LOOPCLK_SEL bit in *Control Module (CTRL_MMR)*.

12.3.2.3 OSPI Functional Description

12.3.2.3.1 OSPI Block Diagram

Figure 12-129 shows the OSPI module block diagram.

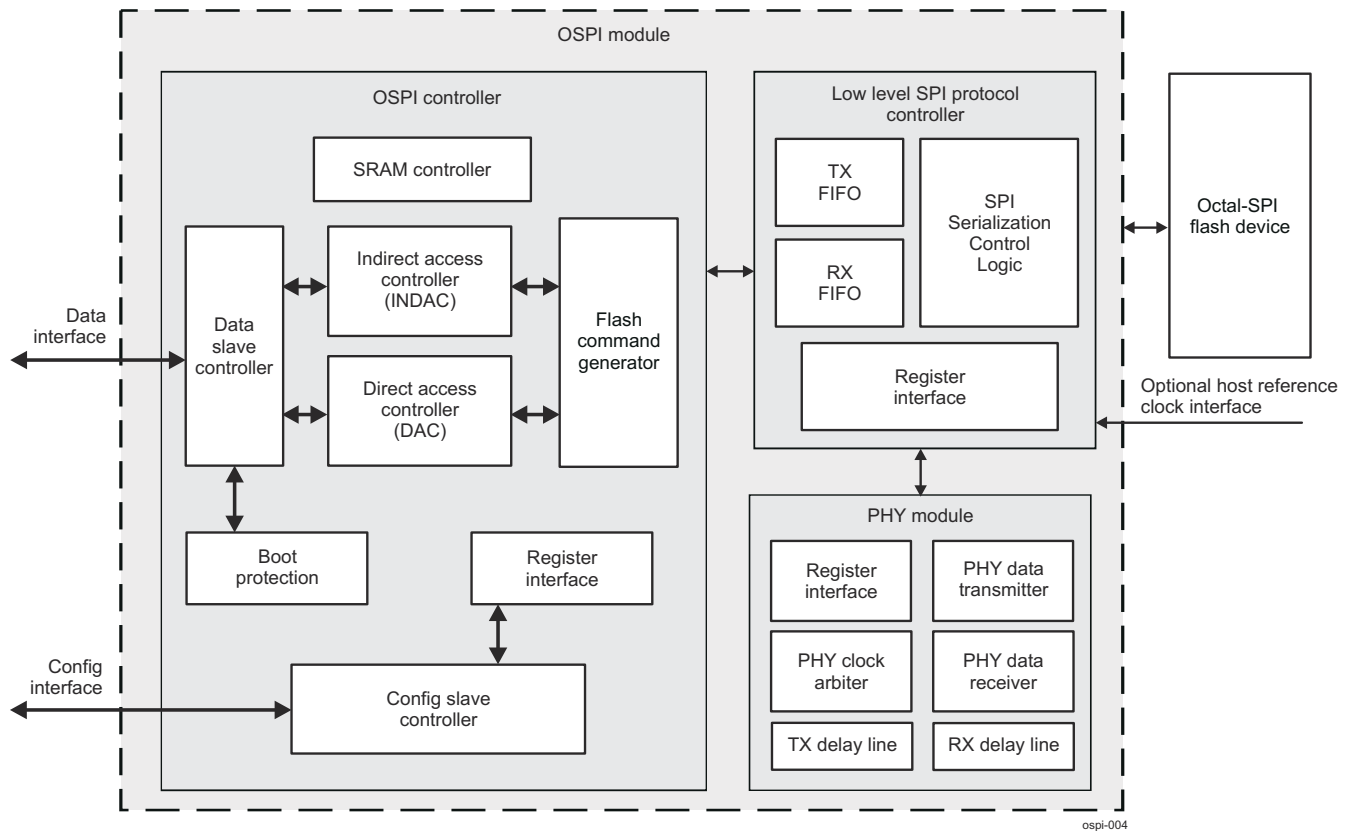

Figure 12-129. OSPI Block Diagram

The OSPI module is composed of three main blocks. The first one is the OSPI controller, the second one is the low level SPI protocol controller, and the third one is the integrated PHY.

The OSPI module has the following two slave interfaces:

- Data slave interface intended for data transfer.
- Configuration slave interface intended for accessing the programmable set of registers.

12.3.2.3.1.1 Data Slave Interface

The data interface is used for data transfer to external flash devices in direct and indirect mode of operation. The data slave controller validates incoming data accesses, responds to invalid requests, performs any required byte and halfword reordering, blocks writes that violate the programmed write protection rules (only for direct access) and forwards the transfer request to either the direct access controller (DAC) or the indirect access controller (INDAC).

The data interface bus is 32-bits wide. Therefore only byte, halfword and word accesses are permitted. When the controller is configured to work in SPI Octal DDR Mode or Octal DDR Protocol (where 2 bytes are collected within single SPI clock cycle what exceeds the size of 1 byte transfer request), 8 bit transfer size is not allowed.

Note

Cache line wrap accesses over the data slave port should be word aligned.

Data slave port doesn't support cache line wrap bursts of 128 bytes.

12.3.2.3.1.2 Configuration Slave Interface

The configuration interface is used to configure the OSPI module and perform software controlled flash accesses using the OSPI_FLASH_CMD_CTRL_REG register (for more information refer to [Section 12.3.2.3.11, Software Triggered Instruction Generator \(STIG\)](#)). Depending on the address it routes the incoming interconnect transfer to the Low level SPI protocol controller or to the ECC aggregator. The configuration port is also used to interact with the OSPI configuration and SRAM ECC registers.

Note

The configuration interface supports only 32-bit accesses. For single byte or halfword manipulations software should perform read-modify-write operations.

12.3.2.3.1.3 OSPI Clock Domains

The OSPI module has two main clock sources for the Octal-SPI controller.

- For interface clocks
- For reference clock

The source for the interface clocks corresponds to the configuration and data buses. The data bus clock (OSPI_HCLK) is the main system clock used to transfer data over the data bus between a master on the system interconnect and the OSPI module. The data bus clock also drives the internal OSPI SRAM. The configuration bus clock (OSPI_PCLK) is used to access the OSPI configuration register and perform basic configuration and for interrupt handling. The OSPI reference clock (OSPI_RCLK) drives the SPI transmit and receive logic in the OSPI module. It is also used to generate the output SPI protocol clock (OSPI_OCLK) and for oversampling of the input data. Using the reference clock (OSPI_RCLK) allows the OSPI module to decouple the frequency of the SPI flash device from the device system clocks, thereby providing more flexible clocking solution.

Note

There is no particular clock ratio requirement between configuration (OSPI_PCLK) and data bus (OSPI_HCLK) clocks.

12.3.2.3.2 OSPI Modes**Note**

Some of the OSPI features described in this section may not be supported on this family of devices. For more information, see *OSPI Not Supported Features*.

The OSPI module supports four SPI modes. These modes are defined through the OSPI_CONFIG_REG[1] SEL_CLK_POL_FLD and OSPI_CONFIG_REG[2] SEL_CLK_PHASE_FLD bits. The SEL_CLK_POL_FLD bit defines the clock polarity and the SEL_CLK_PHASE_FLD bit defines the data launch and data capture relation to the OSPI clock edges. [Table 12-213](#) gives a brief description of these modes.

Table 12-213. OSPI Modes

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
0	0	0	Clock inactive state: low Data launch edge: clock falling edge Data capture edge: clock rising edge
1	0	1	Clock inactive state: low Data launch edge: clock rising edge Data capture edge: clock falling edge

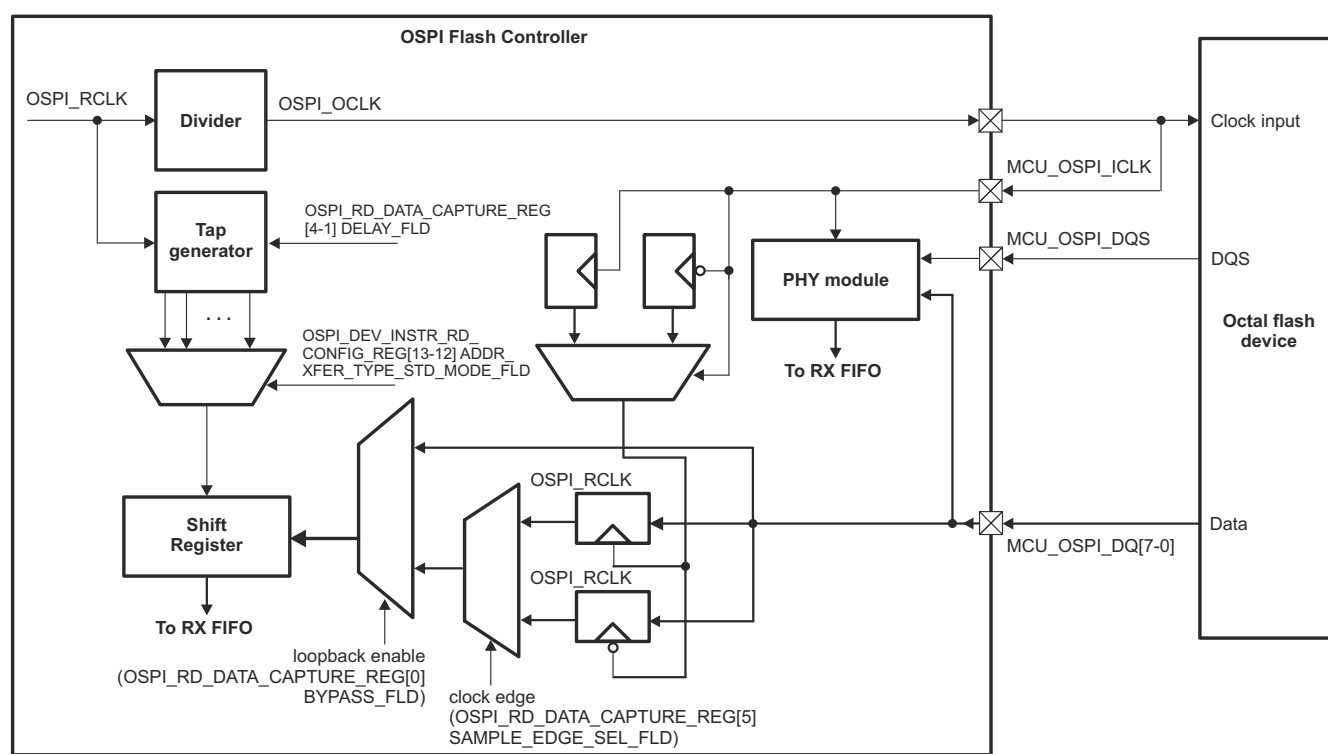

Table 12-213. OSPI Modes (continued)

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
2	1	0	Clock inactive state: high Data launch edge: clock rising edge Data capture edge: clock falling edge
3	1	1	Clock inactive state: high Data launch edge: clock falling edge Data capture edge: clock rising edge

Octal flash devices provide DQS signal which allows source synchronous capture, but for Quad flash devices the OSPI module has a loopback mode. In this loopback mode the clock, looped back at board level, is used for registering the input data, and the edge used is same as the launch edge, thus giving a full cycle path (for more information, see *Read Data Capture*).

12.3.2.3.2.1 Read Data Capture

Figure 12-130 shows the Read Data Capture Logic in the OSPI module.

ospi-005

Figure 12-130. Read Data Capture Logic

The PHY module includes a DLL which allows adjustment of the sampling edge with respect to the incoming data to achieve maximum frequency. There are three sources for the sampling signal:

- The reference clock
- Output SPI clock external loopback
- The DQS (only available in Octal Flash devices)

The loopback mode (only for Quad flash devices) can work in two cases. The first one is when OSPI_CONFIG_REG[2] SEL_CLK_PHASE_FLD=0. When SEL_CLK_PHASE_FLD=1 there aren't enough clock falling edges for the register pipeline to catch the last data driven, thus causing a functional failure. Additionally, since the capture edge is falling edge, it gives a full cycle input path only in SPI mode 0, that is when SEL_CLK_POL_FLD=0 and SEL_CLK_PHASE_FLD=0. Thus SPI mode 0 is the first of two modes that support high MHz operation (greater than 50 MHz). The second mode is when SEL_CLK_PHASE_FLD=1 and

SEL_CLK_PHASE_FLD=1 (SPI mode 3). In this case the missing clock falling edge is compensated inside the OSPI controller when using the incorporated PHY module by inverting the loopback clock.

The loopback mode is enabled by writing 0x0 to OSPI_RD_DATA_CAPTURE_REG[0] BYPASS_FLD. The taps are selected by programming OSPI_RD_DATA_CAPTURE_REG[4-1] DELAY_FLD field. The taps delay the read data capturing logic by the programmed number of OSPI_RCLK cycles.

12.3.2.3.2.1.1 Mechanisms of Data Capturing

There are two mechanisms of data capturing in the OSPI module. They can be combined in some parts to ensure reliable sampling solution independent on the system requirements and the controller configuration. The mechanisms are as follows:

- Data capturing mechanism using taps
- Data capturing mechanism using PHY module.

12.3.2.3.2.1.2 Data Capturing Mechanism Using Taps

This section describes the data capturing mechanism where sampling point is adjusted for one of the reference clock edges inside divided OSPI clock.

After POR, the adapted loopback clock circuit and the OSPI_RCLK delay register line both wake in a disabled state. The OSPI_RD_DATA_CAPTURE_REG register provides the control for the mechanism using taps.

OSPI_RD_DATA_CAPTURE_REG[5] SAMPLE_EDGE_SEL_FLD bit selects the edge of the reference clock, on which data outputs from flash memory are sampled.

OSPI_RD_DATA_CAPTURE_REG[4-1] DELAY_FLD bit field controls the additional number of read data capture cycles (this is the fast reference clock, running at least x4 of the device clock) that should be applied to the internal read data capture circuit. The large clock-to-out delay of the flash memory together with trace delays as well as other device delays may impose a maximum flash clock frequency which is less than the flash memory device itself can operate at. To compensate, software shall set this register to a value that guarantees robust data captures.

12.3.2.3.2.1.3 Data Capturing Mechanism Using PHY Module

PHY module is responsible for data capturing. More detailed description of all internal PHY sampling mechanisms is included in [Section 12.3.2.3.16.2, Read Data Capturing by the PHY Module](#).

12.3.2.3.2.2 External Pull Down on DQS

Per the OSPI protocol, the FLASH device drives DQS while CS is asserted. When CS is not asserted the FLASH device presents HiZ on DQS. When configured to use DQS, the controller uses the DQS as a clock, which samples the incoming data into a FIFO. Noise on the DQS when it is HiZ can cause spurious false triggering of the FIFO and filling it with invalid data. There is no way to clear this data except to reset the OSPI module.

To avoid this issue, it is recommended to add a pull down on the DQS line.

During device wakeup, before the IO ring is configured properly, the CS to the FLASH device is HiZ. Depending on the actual level of the CS line the FLASH device might drive the DQS High, Low or HiZ. A pull down on DQS forces the DQS input to Low, but the DQS might still be High or in the presence of noise there might be transitions between Low and High. This again can cause the same issue of capturing garbage data in the Controller FIFO.

To avoid this issue it is recommended to release the OSPI from reset only after the IO ring is configured properly.

12.3.2.3.3 OSPI Power Management

Note

The OSPI module does not provide any hardware signal for busy or idle status. Software need to ensure that the OSPI module is idle before clocks can be shut off by reading the OSPI_CONFIG_REG[31] IDLE_FLD bit.

OSPI_PCLK and OSPI_HCLK share the same clock stop request/acknowledge and clock enable/acknowledge interface.

12.3.2.3.4 Auto HW Polling

The OSPI controller is capable of automatically testing the Flash device busy bit to guarantee no reads or writes are ignored by the flash when it is busy burning in programmed data.

At the end of a programming transaction, the Flash device goes into a burn-in state and becomes busy.

When Auto HW Polling is enabled, the OSPI controller keeps track of programming transactions and will initiate a Flash status read polling transactions automatically, until Flash indicates it is not busy, before any additional data read or programming operations are sent to the flash device. See OSPI_WRITE_COMPLETION_CTRL_REG register and the associated registers.

The OSPI controller requires that the OSPI_WRITE_COMPLETION_CTRL_REG[23-16] POLL_COUNT_FLD field should always be set with values greater or equal to 3 (≥ 3).

12.3.2.3.5 Flash Reset

OSPI provides Flash reset out ports. These ports are active low and controlled thru OSPI_CONFIG_REG register.

12.3.2.3.6 OSPI Memory Regions

Table 12-214 shows the OSPI memory map in MCU domain.

Table 12-214. OSPI Memory Map

Address Range		Size	Description
MCU_FSS0_OSPI0	MCU_FSS0_OSPI1		
0x00 4704 0000 to 0x00 4704 0100	0x00 4705 0000 to 0x00 4705 0100	256 B	Configuration registers space
0x00 4704 4000 to 0x00 4704 4200	0x00 4705 4000 to 0x00 4705 4200	512 B	Global control registers space
0x00 4706 8000 to 0x00 4706 8400	0x00 4706 4000 to 0x00 4706 4400	1 KB	OSPI_ECC_AGGR registers space

Note

For more information about the memory space, see [Section 12.3.1.3.5, FSS Memory Regions](#).

12.3.2.3.7 OSPI Interrupt Requests

The OSPI module generates three interrupts per instance. The ECC interrupts (MCU_FSS0_OSPI_0_OSPI_ECC_CORR_LVL_INTR_0 and MCU_FSS0_OSPI_0_OSPI_ECC_UNCORR_LVL_INTR_0 for MCU_FSS0_OSPI0; MCU_FSS0_OSPI_1_OSPI_ECC_CORR_LVL_INTR_0 and MCU_FSS0_OSPI_1_OSPI_ECC_UNCORR_LVL_INTR_0 for MCU_FSS0_OSPI1) are generated by the ECC aggregator.

The other interrupts (MCU_FSS0_OSPI0_LVL_INTR_0 for MCU_FSS0_OSPI0 and MCU_FSS0_OSPI1_LVL_INTR_0 for MCU_FSS0_OSPI1) are generated by the OSPI module.

Table 12-215 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 12-215. OSPI Events

Event Flag	Event Mask	Description
OSPI_IRQ_STATUS_REG[0] MODE_M_FAIL_FLD	OSPI_IRQ_MASK_REG[0] MODE_M_FAIL_MASK_FLD	Event Flag and Event Mask for the OSPI Interrupts.

12.3.2.3.8 OSPI Data Interface

12.3.2.3.8.1 Data Interface Address Remapping

The incoming data interface address, by default, maps directly to the address sent serially to the FLASH device. If the FLASH device has a 24-bit address, then the 24 LSB's of the data address is forwarded. A remap feature is available to remap all incoming data addresses to ADDRESS + N, where N is the value stored in the OSPI_REMAP_ADDR_REG[31-0] VALUE_FLD bit field. It is enabled via the OSPI_CONFIG_REG[16] ENB_AHB_ADDR_REMAP_FLD bit. This feature could be used when software needs to move boot code to another FLASH region.

12.3.2.3.8.2 Write Protection

In order to protect the FLASH device, a software controlled write protection feature is supported. Any data write detected (by using DAC), pointing to an area of the FLASH that is protected, is not permitted.

A programmable region of the FLASH device, defined as a number of FLASH 'blocks' starting from a particular block number can be protected. Three programmable registers are provided. The first OSPI_LOWER_WR_PROT_REG register defines the FLASH block that is located at the bottom of the region to be protected. The second OSPI_UPPER_WR_PROT_REG register defines the FLASH block that is located at the top of the region to be protected. The third OSPI_WR_PROT_CTRL_REG register is a control register consisting of 2 bits. The OSPI_WR_PROT_CTRL_REG[0] INV_FLD bit allows software to invert the region that is being protected, causing the programmed region to become the only areas of FLASH memory that is not protected from writes. The OSPI_WR_PROT_CTRL_REG[1] ENB_FLD bit is the write protection enable bit. When this bit is set to 0, the FLASH device is unprotected.

For implementation, the data interface must map the incoming address into its associated FLASH block. A block can be between 1 and 65 KB, programmed via the OSPI_DEV_SIZE_CONFIG_REG register.

12.3.2.3.8.3 Access Forwarding

For legal accesses, the data interface will forward all accesses to one of two access controllers - the direct access and the indirect access controllers. Assuming DAC has been enabled via the OSPI_CONFIG_REG[7] ENB_DIR_ACC_CTRL_FLD bit, then by default all accesses will be forwarded to this controller. Before any accesses can be forwarded to INDAC, it must first be configured by software. This process is fully explained in [Section 12.3.2.3.10, Indirect Controller \(INDAC\)](#). If DAC is disabled, any incoming access that cannot be forwarded to INDAC will be completed immediately with an error. If DAC is enabled, the same access will be forwarded and serviced by DAC.

12.3.2.3.9 OSPI Direct Access Controller (DAC)

Direct access refers to the operation where data interface accesses directly trigger a read or write to FLASH memory. It is memory mapped and can be used to both access and directly execute code from external FLASH memory. Any incoming access that is not recognized as being within the programmable indirect trigger region is assumed to be a direct access and will be serviced by the DAC. Note that accesses that use DAC do not use the embedded SRAM. The data transfer stops when read or write burst is carried out. The amount of wait states applied will be dependent on the latency through the controller. Latency is kept to a minimum when the use of XIP read instructions are enabled (see OSPI_CONFIG_REG[18] ENTER_XIP_MODE_IMM_FLD and OSPI_CONFIG_REG[17] ENTER_XIP_MODE_FLD bits).

12.3.2.3.10 OSPI Indirect Access Controller (INDAC)

12.3.2.3.10.1 Indirect Read Controller

The aim of the indirect mode of operation is to read significant numbers of bytes from FLASH memory without requiring a data interface access to trigger it. Instead indirect operations are controlled and triggered by software via specific control/configuration Indirect Read Transfer registers (OSPI_INDIRECT_READ_XFER_CTRL_REG, OSPI_INDIRECT_READ_XFER_WATERMARK_REG, OSPI_INDIRECT_READ_XFER_START_REG, and OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG). This block will communicate with an embedded low level SPI protocol state machine module to perform an efficient and optimized FLASH read burst, placing the read data into the local SRAM module ready for fast and low latency delivery to any external master.

By default, the Indirect Read controller is disabled. Before enabling it, software must configure how much data is required and the start address. The start address and total number of bytes to be fetched is defined in OSPI_INDIRECT_READ_XFER_START_REG and OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. For more information refer to [Section 12.3.2.3.10.3, Indirect Access Queuing](#).

The total number of bytes to read in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the size of requests. In the case of SRAM overrun, the controller will back pressure FLASH reads until space becomes available in the SRAM. Back pressuring the reads on the SPI interface is handled by completing any current read burst, waiting until space in the SRAM becomes available and then issuing a new read burst at the address where the previous terminated burst ended.

An external master will be able to fetch the data that the controller has read from external FLASH memory by issuing data interface reads to the OSPI module. The address of the incoming read access must be in the range of indirect trigger address programmed via the OSPI_IND_AHB_ADDR_TRIGGER_REG register to indirect trigger address + $2^{**}(\text{indirect trigger address range}) - 1$. Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the indirect range to grant SRAM as source. Each valid Indirect Read will cause the internal SRAM to be popped, thereby decoupling the incoming read access address from the FLASH address – that is not direct mapped. Therefore the indirect trigger address does not have any relationship with the FLASH address. It is just to indicate that data should take the SRAM as source instead of the FLASH memory array after triggering of any valid Indirect Read. The FLASH address for Indirect Read is taken from the OSPI_INDIRECT_READ_XFER_START_REG register. Assuming the requested data is present in the SRAM at the point the data interface access is received by the OSPI module, then the data will be fetched from the SRAM and the response to the read burst will be achieved with minimum latency. Once the data has been read from the SRAM, the OSPI module will free up the associated resource in the SRAM.

If a read access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a read access is received whose address is within the range described above but the requested data is not immediately present in the SRAM then wait states will be applied until the data has been read from FLASH and pushed to the SRAM.

If a read burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external master is only permitted to issue 32-bit data interface reads until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final read, the external master may issue a 16-bit (Halfword) or byte access to complete the transfer. It is also permitted for the external master to always issue a 32-bit Word read on the last indirect access. The controller will pad the upper bits of the response with zero. The current expectation is that the SRAM will be kept fairly full while the read operation is carried out. The fill level of the SRAM is directly readable by software reading the OSPI_SRAM_FILL_REG register.

An indirect operation may be cancelled at any time by setting 1 to OSPI_INDIRECT_READ_XFER_CTRL_REG[1] CANCEL_FLD bit.

Any bus master should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via configuration registers and then decide for itself when the data should be fetched from the local SRAM. The fill level watermark register (see OSPI_INDIRECT_READ_XFER_WATERMARK_REG register) is provided. When the SRAM fill level passes this watermark, an interrupt is generated. If the watermark value is > 0, the watermark interrupt is also generated when the final byte of data has been read by the OSPI module and placed in the SRAM, even if the actual SRAM fill level has not risen above the watermark. This last feature is useful to avoid software tracking how much data has been read and resetting the watermark value for the last few bytes of an indirect read transfer.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an Indirect Read operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD bit starts an indirect read operation. OSPI_INDIRECT_READ_XFER_CTRL_REG[2] RD_STATUS_FLD bit is available to check the status.

12.3.2.3.10.1 Indirect Read Transfer Process

The following sequence can be followed:

1. Setup OSPI_CONFIG_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI_INDIRECT_READ_XFER_START_REG register.
3. Setup the number of bytes to be transferred in the OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG register.
4. Setup the indirect transfer's trigger address in the OSPI_IND_AHB_ADDR_TRIGGER_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI_INDIRECT_TRIGGER_ADDR_RANGE_REG register.
6. If the watermark interrupt feature is to be used, set the OSPI_INDIRECT_READ_XFER_WATERMARK_REG register which will cause an interrupt to be generated when the fill level increases beyond the watermark level. Setting the watermark can be useful indication to software when to read the next part of the indirect read transfer. Note that if the watermark is set to a value other than zero, the watermark interrupt will always trigger once the final byte of indirect transfer has been fetched and placed in the embedded SRAM, even if the watermark value is higher than the actual completed fill level.
7. Trigger Indirect Read access by setting the OSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD bit to 1.
8. If the watermark interrupt feature is to be used, wait for watermark interrupt. Else poll the SRAM fill level via the OSPI_SRAM_FILL_REG register to decide when sufficient data is in the SRAM to trigger data fetches.
9. Read the expected amount of data from SRAM. If there is still more data to fetch in order to complete the indirect read transfer, then loop back to step 8. Otherwise continue to step 10.
10. The completion status of the Indirect Read operation can be polled via the OSPI_INDIRECT_READ_XFER_CTRL_REG[5] IND_OPS_DONE_STATUS_FLD bit.
11. An Indirect Complete interrupt will be generated when the Indirect read operation has completed.

12.3.2.3.10.2 Indirect Write Controller

The aim of the indirect mode of operation is to perform bulk transfer of data from the processor into a FLASH memory in the most efficient manner. The fewest possible write cycles inside the FLASH device will be carried out for the indirect transfer, thus maximizing the life of the device. Indirect write operation can be thought of from a software perspective as the inverse of the indirect read. It is controlled and triggered by software via specific control/configuration Indirect Write Transfer registers (for more information see the following registers: OSPI_INDIRECT_WRITE_XFER_CTRL_REG, OSPI_INDIRECT_WRITE_XFER_WATERMARK_REG, OSPI_INDIRECT_WRITE_XFER_START_REG, and OSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG). This block will await delivery of the write data via the external data interface master, placing it in the local SRAM before communicating with the existing legacy SPI core to perform an efficient and optimized FLASH write burst.

By default, the indirect write controller is disabled. Before enabling it, the software must configure how much data is required and the start address. The start address and total number of bytes to be written is defined in OSPI_INDIRECT_WRITE_XFER_START_REG and OSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. The Indirect write queuing is very similar to indirect read queuing. For more information refer to [Section 12.3.2.3.10.3, Indirect Access Queuing](#).

The total number of bytes to write in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the amount of data that can be accepted from the external master. In the case of an SRAM overrun, the controller will back pressure the data interface with wait states. Note the fill level of the SRAM is readable via programmable OSPI_SRAM_FILL_REG register and this can be used to avoid this situation.

An external master will provide the write data and will transfer this to the OSPI module by issuing data interface writes. The address of the incoming write access must be in the range of Indirect trigger address programmed via the OSPI_IND_AHB_ADDR_TRIGGER_REG register to Indirect trigger address + $2^{**}(\text{Indirect trigger address range}) - 1$. Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the Indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the Indirect Range to grant SRAM as source. Each write will cause the internal SRAM to be pushed, thereby decoupling the incoming write access address from the FLASH address – that is not direct mapped. Therefore Indirect trigger address does not have any relationship with FLASH address. It is just to indicate that data should take SRAM as source instead of FLASH Memory array after triggering of any valid Indirect Write. The FLASH address for Indirect Write is taken from the OSPI_INDIRECT_WRITE_XFER_START_REG register. Assuming the SRAM is not full at the point the data interface access is received by the OSPI module, then the data will be pushed to the SRAM with minimum latency.

If a write access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a write access is received whose address is within the range described above but the SRAM is full then wait states will be applied until some or all of the data has been pushed from the SRAM to the FLASH.

If a write burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller, and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external master is only permitted to issue 32-bit data interface writes until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final write, the external master may issue a 32-bit word, 16-bit (halfword) or a byte access to complete the transfer. If the number of bytes to write is less than 4 on the last transfer, the master is still permitted to issue a 32-bit transfer. In these cases, the extra bytes are discarded by the controller.

When the SRAM holds a number of bytes equal to or greater than the size of a FLASH page (which itself is programmed into the OSPI module, with a default of 256 bytes) or when the SRAM holds all remaining bytes of the currently executing indirect transfer, the OSPI module will initiate a write burst to the flash command generator.

An indirect operation may be cancelled at any time by setting 1 to the OSPI_INDIRECT_WRITE_XFER_CTRL_REG[1] CANCEL_FLD bit.

Any bus master should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via the configuration registers and then decide for itself when the data should be written to the local SRAM. The fill level watermark register (see OSPI_INDIRECT_WRITE_XFER_WATERMARK_REG register) is provided. When the SRAM fill level falls below this watermark, an interrupt is generated.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an indirect write operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD bit starts an indirect write operation. The OSPI_INDIRECT_WRITE_XFER_CTRL_REG[2] WR_STATUS_FLD bit is available to check the status.

12.3.2.3.10.2.1 Indirect Write Transfer Process

The following sequence can be followed:

1. Setup OSPI_CONFIG_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI_INDIRECT_WRITE_XFER_START_REG register.
3. Setup the number of bytes to be transferred in the OSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG register.
4. Setup the indirect transfer's trigger address in the OSPI_IND_AHB_ADDR_TRIGGER_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI_INDIRECT_TRIGGER_ADDR_RANGE_REG register.
6. It is functionally valid for software to simply write all the data to the SRAM in one block transfer. However, if the total number of bytes to write is greater than the size of the partitioned SRAM, then it is quite likely the SRAM will become full causing the OSPI to back-pressure the system data bus for a considerable time. This time is based on the FLASH data-rate and the page-write time of the device. To avoid sending all the write data in one block transfer, software can make use of the watermark interrupt to identify a convenient time to send data a page at a time to the SRAM module. Alternatively, software can poll the SRAM fill level register directly to identify how empty the SRAM is at any one time in order to make a judgment as to when the most practical time to send the next part of the transfer.
7. If the watermark interrupt feature is to be used, set the OSPI_INDIRECT_WRITE_XFER_WATERMARK_REG register which will cause an interrupt to be generated when the fill level falls below the watermark. The watermark should be set to a number between zero and a page size. That is if the page size is 256 bytes, then setting the watermark to a value between 10 and 250 is reasonable and will cause the interrupt to trigger when the fill level drops below the programmed number. Setting the watermark can be useful to provide an indication to software when to write the next page of data to the SRAM.
8. Trigger Indirect Write access by setting OSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD bit.
9. If the remaining number of bytes still to be transferred into the SRAM for the current indirect transfer is greater than a FLASH page, then write 1 FLASH page worth of data to the SRAM. Otherwise send the remaining data from the indirect transfer to SRAM.
10. If all the data in the indirect transfer has now been sent to the SRAM, then go to 12 and await indirect complete status. Otherwise if there is more data still to be transferred then either:
 - If the watermark interrupt feature is being used, then wait for watermark interrupt.
 - Alternatively the SRAM fill level can be interrogated to identify a convenient time to send more data.
11. Loop back to 9.
12. Optional: The completion status of the Indirect write operation can be polled via OSPI_INDIRECT_WRITE_XFER_CTRL_REG[5] IND_OPS_DONE_STATUS_FLD.
13. An Indirect Complete interrupt will be generated when the Indirect write operation has completed.

12.3.2.3.10.3 Indirect Access Queuing

Software is permitted to queue up to two indirect transfers for both the indirect write controller and the indirect read controller. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. Any attempt to queue more than two operations will cause an interrupt to be generated. To take advantage of this feature, software should attempt to keep both indirect programming slots full at all times.

From the software perspective, indirect access queuing is achieved by triggering bit 0 of the indirect transfer control register (OSPI_INDIRECT_READ_XFER_CTRL_REG[0] START_FLD bit or OSPI_INDIRECT_WRITE_XFER_CTRL_REG[0] START_FLD bit) twice in short succession. The indirect number of bytes register (OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG or OSPI_INDIRECT_WRITE_XFER_NUM_BYTES_REG register) and the indirect FLASH start address register (OSPI_INDIRECT_READ_XFER_START_REG or OSPI_INDIRECT_WRITE_XFER_START_REG register) must be setup with the relevant transfer data before START_FLD bit can be triggered for each transfer. Since these registers will change regularly, the hardware must keep sampled versions of these registers for the duration of the indirect transfer.

The internal register block will only issue an indirect start trigger to the key underlying datapath blocks one at a time. There are 2 independent datapath blocks in the indirect access controller that will receive and independently sample this information. The first is the datapath block on the data bus side of the SRAM. For indirect reads, this is a read interface, for indirect writes, it is a write interface. The second is the datapath block on the FLASH side of the SRAM. For indirect reads, this is a write interface, for indirect writes, it is a read interface. Both blocks will process the indirect transfers at different times. For example, for an indirect read operation, the datapath block on the FLASH side of the SRAM will be able to start processing the second queued transfer as soon as the last byte of the first transfer has been written to the SRAM. Before commencing the second transfer, this block must resample the OSPI_INDIRECT_READ_XFER_NUM_BYTES_REG and OSPI_INDIRECT_READ_XFER_START_REG registers. Similarly, the datapath block on the bus side will resample the same registers locally when it has forwarded all the FLASH data associated with the first indirect transfer from the SRAM onto the data bus.

12.3.2.3.10.4 Consecutive Writes and Reads Using Indirect Transfers

It is permitted for software to trigger an indirect read operation while an indirect write operation is in progress. Similarly it is permitted to trigger an indirect write while an indirect read operation is in progress. Indirect write operations will take overall precedence.

12.3.2.3.10.5 Accessing the SRAM

The SRAM depth is separated in two segments. The lower segment is reserved for indirect read use. The upper segment is for indirect write use only. The size of each segment is programmable via the OSPI_SRAM_PARTITION_CFG_REG register. This feature allows to allocate how many bits of the SRAM address bus are allocated to indirect read. By default, this is set so that exactly half of the SRAM is portioned for use by the indirect read controller. To ensure the read data bus is not directly fed by the SRAM read data through combinatorial logic, an extra bank of holding registers is included in the indirect read data path. These registers act as an extra location to be added to the allocated number of SRAM locations for indirect read.

To illustrate how the SRAM (and the extra bank of holding registers) can be allocated between indirect read and write, the following example is provided. The depth of the SRAM in this example is configured to be 8 bits. This is equal to 256 locations.

- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0x00, then 256 locations are allocated to indirect writes and 1 location to indirect reads.
- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0x01, then 255 locations are allocated to indirect writes and 2 locations to indirect reads.
- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0x02, then 254 locations are allocated to indirect writes and 3 locations to indirect reads.
- And so on until.
- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0xFD, then 3 locations are allocated to indirect writes and 254 locations to indirect reads.

- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0xFE, then 2 locations are allocated to indirect writes and 255 locations to indirect reads.
- If the OSPI_SRAM_PARTITION_CFG_REG[7-0] ADDR_FLD field is set to 0xFF, then 1 location is allocated to indirect writes and 256 locations to indirect reads.

Note

A value of 0xFF or 0x00 in the OSPI_SRAM_PARTITION_CFG_REG register should be avoided by software, as only the bottom 8 bits of the SRAM fill level are accessible through software (up to 255 limit) via the OSPI_SRAM_FILL_REG register. If the fill level reaches 256 on either the indirect read or write side, it will appear when reading the Fill Level to be 0.

There are four SRAM sources that are arbitrated and muxed onto the single SRAM port. Up to three sources can access this port at any one time. The sources are described as follows:

- Indirect Write, Write source. This is located on the data bus side of the SRAM.
- Indirect Write, Read source. This is located on the FLASH side of the SRAM.
- Indirect Read, Write source. This is located on the FLASH side of the SRAM.
- Indirect Read, Read source. This is located on the data bus side of the SRAM.

A fixed priority arbitration scheme is implemented. [Table 12-216](#) shows priority allocated to these sources.

Table 12-216. SRAM Access Priority

SRAM Access Priority		
Indirect Write	Write to SRAM (from System Data Bus)	3rd (exclusive with Data Bus Read Request)
	Read from SRAM (from OSPI Module)	2nd
Indirect Read	Write to SRAM (from OSPI Module)	1st
	Read from SRAM (from System Data Bus)	3rd (exclusive with Data Bus Write Request)

Note

With the exception of the write port during an Indirect Read operation (on the FLASH side of the SRAM), the logic driving all four sources must not assume single cycle completion. Writes to the SRAM during an indirect read must be allowed to complete immediately to avoid data loss. Therefore this port is given maximum priority.

12.3.2.3.11 OSPI Software-Triggered Instruction Generator (STIG)

The DAC and INDAC are used to transfer data. In order to access the volatile and non-volatile configuration registers, the legacy SPI Status register, other status/protection registers as well as to perform ERASE functions, a separate software controller is required. The software triggered instruction generator (STIG) is controlled using the OSPI_FLASH_CMD_CTRL_REG register by setting up the command to issue to the FLASH device. This is a generic controller and can be used to perform any instruction that the FLASH device supports from the extended SPI protocol. Configuring of instructions which are not compliant with the specification of the FLASH devices could cause unpredicted behavior of the controller. OSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD bits should be set different than OSPI_DEV_INSTR_RD_CONFIG_REG[7-0] RD_OPCODE_NON_XIP_FLD and OSPI_DEV_INSTR_WR_CONFIG_REG[7-0] WR_OPCODE_FLD. The OSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit is used to trigger the command. The OSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit is used by software to poll the status of the command execution. For reads, when the command has been serviced (OSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit toggles from '1' to '0'), up to 8 bytes of read data will be placed in the OSPI_FLASH_RD_DATA_LOWER_REG and OSPI_FLASH_RD_DATA_UPPER_REG registers. For writes, the write data should be placed in the OSPI_FLASH_WR_DATA_LOWER_REG and OSPI_FLASH_WR_DATA_UPPER_REG registers.

The completion of the STIG request could be also checked by the corresponding interrupt. The occurrence of the interrupt indicates that the controller is ready for accepting a new STIG request. It is important to notice that completion of the STIG request is not equivalent to completion it on SPI side. For example, if STIG is configured

to the command composed of data to transmit only, the data is taken from the corresponding STIG register fields and put into TX FIFO. Since all bytes to write are known, another STIG can be queued before serialization of the current one is completed.

There are some commands which require more data to read than 8 bytes (for example READ ID command). The additional STIG Memory Bank is implemented in order to accommodate these data if needed. The STIG Memory Bank (internal component of the controller) is controlled by the OSPI_FLASH_CMD_CTRL_REG[2] STIG_MEM_BANK_EN_FLD bit. If enabled, the number of bytes to read in the STIG is extended to the value ranging from 16 to 512 as defined in OSPI_FLASH_COMMAND_CTRL_MEM_REG[18-16] NB_OF_STIG_READ_BYTES_FLD bit field. It should be noticed that there are very few commands (excluding Read Array ones which are not intended to handle effectively in STIG Mode but in Direct/Indirect Modes) which return more than 8 bytes to the controller. If the maximum number of bytes to Read using STIG in target application is less than 512, the depth of the STIG Memory Bank can be set smaller what will result in saving noticeable part of the area.

If number of bytes to Read in the STIG as defined in OSPI_FLASH_COMMAND_CTRL_MEM_REG[18-16] NB_OF_STIG_READ_BYTES_FLD bit field exceeds the Memory Bank Depth, remaining data will overwrite the STIG Memory Bank locations starting from its first address. OSPI_FLASH_RD_DATA_LOWER_REG and OSPI_FLASH_RD_DATA_UPPER_REG keep the last 8 bytes read from the Flash Device by STIG when Memory Bank is enabled. Therefore, for example if the user wants to get just a single byte from the last eight bytes from long continuous read SPI data chain, there is no need to access the STIG Memory Bank since data can be taken from suitable Flash Command Read Data register. In order to access more data, STIG Memory Bank data request should be triggered. It is controlled by the OSPI_FLASH_COMMAND_CTRL_MEM_REG and works analogously for triggering STIG from the functional standpoint.

OSPI_FLASH_COMMAND_CTRL_MEM_REG[0] TRIGGER_MEM_BANK_REQ_FLD bit is used to trigger the command, bit OSPI_FLASH_COMMAND_CTRL_MEM_REG[1] MEM_BANK_REQ_IN_PROGRESS_FLD is used by software to poll the status of the command execution. When MEM_BANK_REQ_IN_PROGRESS_FLD bit toggles from "1" to "0", the byte of data (OSPI_FLASH_COMMAND_CTRL_MEM_REG[15-8] MEM_BANK_READ_DATA_FLD) from corresponding address (OSPI_FLASH_COMMAND_CTRL_MEM_REG[28-20] MEM_BANK_ADDR_FLD bit field) is valid. The address should be set before triggering the STIG Memory Bank access. Each consecutive STIG access overwrites the previous one so that the data in the Bank always fit into byte index fetched by the last STIG access configured to use the Memory Bank (first incoming byte equals first address of the Memory Bank, second one equals the second address and so on).

12.3.2.3.11.1 Servicing a STIG Request

A STIG request will cause the OSPI Flash controller to interrogate the OSPI_FLASH_CMD_CTRL_REG register to determine what and how many bytes it should send to the FLASH device. The OSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD field of this register indicate the instruction to be sent and is always pushed first. If there is an address to send, then the address (the size of which is also programmed in the same register) is sent next. The address itself is stored in the OSPI_FLASH_CMD_ADDR_REG register. If Mode bits are enabled by OSPI_FLASH_CMD_CTRL_REG[18] ENB_MODE_BIT_FLD bit. OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD bit field are being sent right after address. If OSPI_FLASH_CMD_CTRL_REG[18] ENB_MODE_BIT_FLD and OSPI_CONFIG_REG[29] CRC_ENABLE_FLD are both enabled, STIG will replace XIP Mode bits (not applicable for CRC aware SPI interface) for automatically calculated address CRC byte. Therefore, to execute CRC aware STIGs (meaning the commands requiring sending address CRC byte), ENB_MODE_BIT_FLD bit should always be set. If there are any dummy cycles to send (the size of which is also programmed in OSPI_FLASH_CMD_CTRL_REG register) then those are sent next. If there is data to write or read (the size of which is also programmed in OSPI_FLASH_CMD_CTRL_REG register) then for the case of writes, up to 8 bytes can be sent (as stored in the Flash Command Write Data registers, OSPI_FLASH_WR_DATA_LOWER_REG and OSPI_FLASH_WR_DATA_UPPER_REG registers) next. In the read case, when the read data has been collected from the FLASH device, the OSPI Flash Controller stores that in the Flash Command Read Data Registers (OSPI_FLASH_RD_DATA_LOWER_REG and OSPI_FLASH_RD_DATA_UPPER_REG registers). Up to 8 bytes can be get if OSPI_FLASH_CMD_CTRL_REG[2] STIG_MEM_BANK_EN_FLD bit is disabled or up to 512 when enabled. When the OSPI Flash controller starts to service a STIG request, it sets the

OSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit to indicate a command execution is in progress. When the OSPI Flash controller is in the auto-polling state, servicing a STIG request is slightly different. Most of devices are largely inaccessible after a program operation until the device has completed that write. Some group of them has a possibility to suspend programming page. It can be controlled by the OSPI_POLLING_FLASH_STATUS_REG[8] DEVICE_STATUS_VALID_FLD bit, which indicate active auto-polling phase. After requesting a STIG, the OSPI Flash Controller immediately issues appropriate OPCODE to Memory. During servicing a STIG (in auto-polling phase) the status bit of command execution remains steady and other parts of transfer such as ADDRESS or DUMMY BITS, and so forth, are disabled (to issued Program Suspend Command is needed OPCODE only). There is a programmable option to add delay between every repetitive poll operation (delay is defined by OSPI_WRITE_COMPLETION_CTRL_REG[31-24] POLL_REP_DELAY_FLD bit field). This feature is implemented to free up SPI bandwidth if needed.

Note

The OSPI data is sent LSB first, while address is sent MSB first.

Note

The STIG complete status bit gets cleared before the actual flash access completes. Software should wait for about 700 ns if there is any dependency on actual access completion.

12.3.2.3.12 OSPI Arbitration Between Direct / Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a simple fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

- The Indirect Access Write
- The Direct Access Write
- The STIG
- The Direct Access Read
- The Indirect Access Read

12.3.2.3.13 OSPI Command Translation

Requests issued by the direct access controller, the indirect access controller or the STIG will be translated into a sequence of byte transfers to send downstream (before serialization to the FLASH device). These sequences depend on the requested transfer but an example of a typical 1-byte non sequential READ is shown below:

INSTRUCTION OPCODE -> ADDRESS -> Mode Byte -> Dummy Bytes -> 1 byte of don't care

For sequential accesses, an extra byte of data per read is pushed to the FLASH device on the back of the above sequence assuming it can be done so with no gap between each transferred byte.

When PHY mode is enabled and consequently no clock divider is configured, latency caused by multi domain synchronization may make an extra byte insufficient to avoid the transfer gap. To ensure the sequential access non-interrupted and keep the maximum performance of the controller, PHY Pipeline Mode is implemented. When enabled, number of don't care bytes is calculated based on the configuration.

The actual sequence sent to the FLASH device depends on the requested transfers, whether the transfer is non-sequential or sequential, whether the device has been configured in XIP mode and the state of the main Device Instruction Type programmable registers (OSPI_DEV_INSTR_RD_CONFIG_REG and OSPI_DEV_INSTR_WR_CONFIG_REG).

For writes, the write enable latch (or WEL) within the FLASH device itself must be high before a write sequence can be issued. The OSPI Flash Controller will automatically issue the write enable latch command before triggering a write command via the direct or indirect access controllers (DAC/INDAC) – that is the user does not need to perform this operation. For increasing flexibility and performance user can turn off this feature by setting the OSPI_DEV_INSTR_WR_CONFIG_REG[8] WEL_DIS_FLD bit. The opcode for WREN is typically 0x06 and is common between devices.

When write requests from the direct or indirect access controllers are no longer being received and all outstanding requests have been sent, the FLASH device will automatically start the page program write cycle. Any incoming request at this time will be held in wait states until the cycle has completed. The OSPI Flash Controller will automatically poll the FLASH device legacy SPI status register to identify when the write cycle has completed. This is achieved by sending the RDSR opcode to the FLASH device and waiting until the device itself has indicated the write cycle has completed (until the Write in Progress bit has cleared to zero and the write enable latch bit has also cleared to zero or device is ready bit has set to one). The WREN and the RDSR device instructions are the only ones that are sent by the controller under the hood. For any other specific instruction that the user determines should be sent to the device (for example if the device needs to be unprotected before a write command is issued), these should be handled separately by issuing FLASH commands via the STIG.

There is an option to trigger HOLD or RESET feature on I/Os of the Flash Device. The HOLD one is generally common across the devices and takes an alternative function of DQ3 pin (applicable when device operates neither in Quad SPI mode nor DDR). The transfer can be hold and then resumed by dedicated software trigger field (OSPI_CONFIG_REG[4] HOLD_PIN_FLD). The devices which have the HOLD feature on DQ3 usually need another dedicated pin for hardware reset and ones without HOLD feature usually have alternative reset on DQ3 what makes the additional reset pin being redundant. The controller supports both variants and reset selection register field (OSPI_CONFIG_REG[6] RESET_CFG_FLD) allows the user to configure which hardware reset solution is implemented in the device under usage.

After configuration is done, it is possible to trigger HOLD or RESET features using I/Os (OSPI_CONFIG_REG[4] HOLD_PIN_FLD or OSPI_CONFIG_REG[5] RESET_PIN_FLD bits). After HOLD activation the controller is introduced into waiting state and any other operations should not be requested before de-asserting of HOLD configuration bit. The HOLD feature is useful when any SPI transaction needs to be prolonged in order to adjust it into specific point in time. Note that any HOLD trigger issued during active SPI transaction may be synchronized into reference clock domain at the time the SPI transfer turns to be finished. In this case, there is nothing to hold so the low level SPI logic will not activate HOLD on DQ3. To check if HOLD request suspended the transfer OSPI_CONFIG_REG[31] IDLE_FLD bit can be polled for. If SPI is not in the IDLE state, the transfer was successfully suspended. It is important for the software to take care of resetting OSPI_CONFIG_REG[4] HOLD_PIN_FLD bit before newly triggered SPI transaction. In case HOLD request is set before the beginning of the transfer it will be HOLD right after it starts what may not always be a goal. The hardware RESET needs to be activated when CS is high (no valid transaction is present on SPI bus). It can be checked by polling of OSPI_CONFIG_REG[31]. If the controller is in the IDLE state and no other transfer requests are queued to perform, the hardware RESET can be triggered. The RESET feature is useful when any write, program or erase operation needs to be cancelled. No transfer request is permitted before driving the reset back to being inactive. Triggering HOLD or RESET on DQ3 at the time the device is configured to work in Quad SPI mode or DDR will overwrite transfer data on DQ3 with '0'. This behavior is considered as a software error so it is advisable for the system to make sure that the flash device was introduced to suitable SPI mode (that is by polling its configuration register) before triggering alternative DQ3 function. There are four independent reset outputs implemented to separate between multiple devices connected to the controller (up to 4 are supported). The decision which reset output is to be activated after triggering OSPI_CONFIG_REG[5] RESET_PIN_FLD bit is made based on OSPI_CONFIG_REG[9] PERIPH_SEL_DEC_FLD and OSPI_CONFIG_REG[13-10] PERIPH_CS_LINES_FLD bits. Reset output OSPI_ECC_VECTOR is to be directly driven into corresponding dedicated RESET pins of the devices with separated RESET pin and alternatively, Reset output OSPI_ECC_VECTOR is to be control OSPI_ECC_VECTOR of the DQ3 RESET devices enabling separating of DQ3 Master Outputs on SoC integration level.

The controller supports all combinations of CPHA and CPOL for Serial Clock. It allows the controller to support any SPI slave devices not limited to Flash Memories. Multiple-SPI flash devices use just a subset of these combinations depending on the Transfer Mode as defined in [Table 12-217](#).

Table 12-217. Flash SPI Modes

(SEL_CLK_POL_FLD, SEL_CLK_PHASE_FLD)	Edge Mode	Support
0x00 (SPI MODE 0)	SDR	Yes
0x01 (SPI MODE 1)	SDR	No
0x10 (SPI MODE 2)	SDR	No

Table 12-217. Flash SPI Modes (continued)

0x11 (SPI MODE 3)	SDR	No
0x00 (SPI MODE 0)	DDR	Yes
0x01 (SPI MODE 1)	DDR	No
0x10 (SPI MODE 2)	DDR	No
0x11 (SPI MODE 3)	DDR	No

12.3.2.3.14 Selecting the Flash Instruction Type

In order to send the correct READ and WRITE opcodes, software should initialize the OSPI_DEV_INSTR_RD_CONFIG_REG and the OSPI_DEV_INSTR_WR_CONFIG_REG registers. These registers include fields to setup the required instruction opcodes that is intended to be used to access the FLASH (default is basic READ and basic page program) as well as the instruction type, edge mode (DDR or SDR) and whether the instruction uses single, dual, quad or octal pins for address and data transfer. Providing this level of control to the user provides a future proofed generic solution. To ensure the controller can operate from a reset state, the registers will be reset to an opcode compatible with SIO devices what can be modified using BOOT feature.

Despite being applicable for both READs and WRITES, the OSPI_DEV_INSTR_RD_CONFIG_REG[9-8] INSTR_TYPE_FLD field only appears once – it is not included in the OSPI_DEV_INSTR_WR_CONFIG_REG register. If software sets this to anything other than '0', then the address transfer type and the data transfer type bits of both OSPI_DEV_INSTR_RD_CONFIG_REG and OSPI_DEV_INSTR_WR_CONFIG_REG registers become don't care. It is made available to allow software to support the less common FLASH instructions where the opcode, address and data are sent on 2 or 4 lanes (the opcode from most instructions are sent serially to the FLASH device, even for dual/quad instructions).

There are devices capable to handling Read Operations in Dual Data Rate Mode (DDR) (it is also called Dual Transfer Rate Mode (DTR)). That means they can issue and capture the data on both rising and falling edges during working with dedicated command type. This enables the controller to maintain throughput at twice lower frequency of OSPI clock. The Device Read Instruction Register has DDR enable bit which informs Octal-SPI Flash Controller that opcode written into Read Opcode field is capable with DDR command type. The other field defined in OSPI_RD_DATA_CAPTURE_REG[19-16] DDR_READ_DELAY_FLD which enables the controller to shift the transmitted data in DDR mode. By default, data are shifted by 1 clock cycle to ensure hold timing greater than 0 during DDR transactions. It may not be sufficient for high reference clock frequency in accordance with the high dividers.

Table 12-218 shows how software should configure the OSPI module for selected specific READ and WRITE instruction supported by the abovementioned device.

Table 12-218. READ and WRITE Instruction Configuration

READ							
OPCODE	OPCODE sent over how many lanes / edge mode?	ADDRESS / DUMMY / MODE sent over how many lanes / edge mode?	DATA bytes sent over how many lanes / edge mode?	Instruction Type (OSPI_DEV_INSTR_RD_CONFIG_REG[9-8] INSTR_TYPE_FLD)	Address transfer type (OSPI_DEV_INSTR_RD_CONFIG_REG[13-12] ADDR_XFER_TYPE_STD_MODE_FLD)	Data transfer type (OSPI_DEV_INSTR_RD_CONFIG_REG[17-16] DATA_XFER_TYPE_EXT_MODE_FLD)	DDR bit enable (OSPI_DEV_INSTR_RD_CONFIG_REG[10] DDR_EN_FLD)
READ	1/SDR	1/SDR	1/SDR	0	0	0	0
FAST_READ	1/SDR	1/SDR	1/SDR	0	0	0	0
DTR_FAST_READ	1/SDR	1/DDR	1/DDR	0	0	0	1
DOFR (Dual O/p Fast Read)	1/SDR	1/SDR	2/SDR	0	0	1	0
DIOFR (Dual I/O Fast Read)	1/SDR	2/SDR	2/SDR	0	1	1	0

Table 12-218. READ and WRITE Instruction Configuration (continued)

DDIOFR (DTR Dual I/ O Fast Read)	1/SDR	2/DDR	2/DDR	0	1	1	1
QOFR (Quad O/p Fast Read)	1/SDR	1/SDR	4/SDR	0	0	2	0
QIOFR (Quad I/O Fast Read)	1/SDR	4/SRD	4/SDR	0	2	2	0
DQIOFR (DTR Quad I/ O Fast Read)	1/SDR	4/DDR	4/DDR	0	2	2	1
OOFR (Octal O/p Fast Read)	1/SDR	1/SDR	8/SDR	0	0	3	0
OIOFR (Octal I/O Fast Read)	1/SDR	8/SDR	8/SDR	0	3	3	0
DOIOFR (DTR Octal O/p Fast Read)	1/SDR	1/DDR	8/DDR	0	0	3	1
4DOIOFR (4-byte DTR Octal I/O Fast Read)	1/SDR	8/DDR	8/DDR	0	3	3	1
DCFR (Dual Command Fast Read)	2/SDR	2/SDR	2/SDR	1	Don't care	Don't care	0
DDCFR (DTR Dual Command Fast Read)	2/SDR	2/DDR	2/DDR	1	Don't care	Don't care	1
QCFR (Quad Command Fast Read)	4/SDR	4/SRD	4/SDR	2	Don't care	Don't care	0
DQCFR (DTR Quad Command Fast Read)	4/SDR	4/DDR	4/DDR	2	Don't care	Don't care	1
OCFR (Octal Command Fast Read)	8/SDR	8/SDR	8/SDR	3	Don't care	Don't care	0
4DOCFR (4-byte DTR Octal Command Fast Read)	8/SDR	8/DDR	8/DDR	3	Don't care	Don't care	1

WRITE

OPCODE	OPCODE sent over how many lanes?	ADDRESS / DUMMY / MODE sent over how many lanes?	DATA bytes sent over how many lanes?	Instruction Type (OSPI_DEV_INSTR_RD_CONFIG_REG[9-8] INSTR_TYPE_FLD)	Address transfer type (OSPI_DEV_INSTR_WR_CONFIG_REG[13-12] ADDR_XFER_TYPE_STD_MODE_FLD)	Data transfer type (OSPI_DEV_INSTR_WR_CONFIG_REG[17-16] DATA_XFER_TYPE_EXT_MODE_FLD)
PP	1	1	1	0	0	0

Table 12-218. READ and WRITE Instruction Configuration (continued)

OIFP (Octal Input Fast Program)	1	1	8	0	0	3
OIEFP (Octal Input Extended Fast Program)	1	8	8	0	3	3
DCPP (Dual Command Fast Program)	2	2	2	1	Don't care	Don't care
QCPP (Quad Command Fast Program)	4	4	4	2	Don't care	Don't care
OCPP (Octal Command Fast Program)	8	8	8	3	Don't care	Don't care

Note

This data are applicable for both 3-byte or 4-byte address variants of the commands if did not indicate otherwise.

Note

In DTR protocol all transfer phases (including opcode) take DDR edge mode independently on the command under execution. DTR protocol is to be enabled by OSPI_CONFIG_REG[24] ENABLE_DTR_PROTOCOL_FLD bit. It has higher priority than DDR Mode enable bit from OSPI_DEV_INSTR_RD_CONFIG_REG[10] DDR_EN_FLD.

12.3.2.3.15 OSPI Data Integrity

The CRC aware SPI transfer can be performed when both controller and device are configured to work in the Octal DDR Protocol.

For write transactions (the controller transmits data throughout all transfer), the controller is responsible for sending address CRC byte (XOR of all address bytes) following address bytes and TX data CRC byte (XOR of all data bytes to write) following data chunk with size as defined in OSPI_MODE_BIT_CONFIG_REG[10-8] CHUNK_SIZE_FLD bit field. All CRC data are being calculated and sent automatically by the controller and the external device is responsible for reacting accordingly on any possible interpolation on the Flash interface. For read transactions, the controller is also responsible for sending address CRC byte (like for write) and for getting and progressing RX data CRC byte returning by the Flash Device after each chunk with size as defined in OSPI_MODE_BIT_CONFIG_REG[10-8] CHUNK_SIZE_FLD bit field. At the time when the Flash Device is returning data back to the controller, the controller dynamically calculates checksum byte by byte. Once the chunk is completed, CRC returned from Flash Device should fit to dynamically calculated CRC by the controller. In case of any deviation, controller reports CRC error to the system by corresponding interrupt (CRC error interrupt). The controller also provides the last captured CRC data in RX data chunk (defined in OSPI_MODE_BIT_CONFIG_REG[31-24] RX_CRC_DATA_LOW_FLD and OSPI_MODE_BIT_CONFIG_REG[23-16] RX_CRC_DATA_UP_FLD bit fields) to give the software driver the opportunity to further detecting any data corruption on system interfaces. The CRC data valid interrupt informs the system about the accessibility of the new RX CRC data in the registers. Once the system gets the full data word, it can calculate CRC by itself. At the time it collects all data words in chunk and then gets the CRC data valid interrupt, it can compare these data and react accordingly.

Some devices also have embedded ECC mechanism allowing them to report data abnormal conditions on their ECC Correction Signal output. At the time this output turns low, the device expect the OSPI controller to read status register of the device in order to get more details about the source of detected abnormal situation. The OSPI controller investigates ECC status on its ECC_FAIL input and generates an interrupt when detecting this signal being low.

12.3.2.3.16 OSPI PHY Module

OSPI module fully integrates PHY module dedicated to more flexible and power efficient transfers.

The PHY module communicates with the OSPI Flash controller via the aforementioned PHY Interface and handles data transfer on low-level stage of design hierarchy. However, when the OSPI_RCLK is configured to be equal to the SPI clock instead of alternative approach using clock divider, there is just one OSPI_RCLK cycle (not 4 or more) within single SPI period or half period for DDR Mode (SPI Control Module works on reference clock). Given that OSPI_RCLK is the input clock for RX FIFO and the output one for TX FIFO, the PHY solution incurs more restrictive requirement for value of system clock in order to synchronize data without SPI transfer interruption. For example, when the controller operates in DDR 1× octal Mode, 2 bytes of data (equivalent to one RX FIFO location) is gathered within just single OSPI_RCLK cycle. The controller cannot predict next data access while operating in the Direct Mode (meaning its size or whether it is sequential to the previous one or not). As a result, if the OSPI_HCLK is not significantly greater than OSPI_RCLK, the SPI transfer has to be suspended until the Flash Command Generator forwards new data to TX FIFO.

An optional PHY Pipeline Mode is implemented to avoid the necessity of stable clocking of the system clock for the Direct Mode when the PHY mode is enabled and to keep maximum performance while ensuring correct operation of the OSPI controller with the PHY using low frequencies from all its domains. This mode is a trade-off between large software overhead when operating in the Indirect Mode and the described limitations present in the Direct Mode. For more information about PHY Pipeline Mode, see [Section 12.3.2.3.16.1, PHY Pipeline Mode](#).

When DDR 2× Mode is granted based on configuration – SPI transfer is automatically performed using the PHY module even if the OSPI_CONFIG_REG[3] PHY_MODE_ENABLE_FLD is de-asserted. SDR 2× commands are handled with PHY module paths being bypassed. Nevertheless, dividers of 2, 4 or 6 for DDR and divider of 2 for SDR should not be configured based on controller requirements and these configurations are perceived as a software error.

The following steps are an example of software algorithm of adapting the OSPI controller with the PHY module incorporated to work in octal 1× clock DDR Protocol. Note that all necessary configuration steps described in [Section 12.3.2.4.2, Configuring the OSPI Controller for Optimal Use](#) shall be completed before the algorithm.

1. Set PHY mode enable (OSPI_CONFIG_REG[3] PHY_MODE_ENABLE_FLD bit) and DDR protocol (OSPI_CONFIG_REG[24] ENABLE_DTR_PROTOCOL_FLD bit). It is assumed that device is configured to work in DDR Protocol.
2. Before setting the DLL parameters, software calibration could be needed.
OSPI_PHY_MASTER_CONTROL_REG[23] PHY_MASTER_BYPASS_MODE_FLD bit controls the bypass mode of the master and slave DLLs. If this bit is set, the DLL bypass mode is enabled. This mode is intended to be used only for debug. When set to 0, a Master operational mode is selected, when set to 1 the Bypass mode is selected.

DLL works in normal mode of operation where the slave delay line settings are used as fractional delay of the master delay line encoder reading of the number of delays in one cycle.

Master DLL is disabled with only 1 delay element in its delay line. The slave delay lines decode delays in absolute delay elements rather than as fractional delays.

- DLL Bypass Mode (follow only if operating in this mode):
 - Depending on frequency of reference clock, calculate how many delay elements should be used to shift this clock by 25% of its period (best case for DDR transfers from setup/hold timings standpoint). Note that delay could be slightly different in a real design. TX Delay is configured in OSPI_PHY_CONFIGURATION_REG[22-16] PHY_CONFIG_TX_DLL_DELAY_FLD bit field.
 - Re-synchronize DLLs by asserting OSPI_PHY_CONFIGURATION_REG[31] PHY_CONFIG_RESYNC_FLD bit (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set PHY bypass mode enable through OSPI_PHY_MASTER_CONTROL_REG[23] PHY_MASTER_BYPASS_MODE_FLD bit.
- DLL Master Mode (follow only if operating in this mode):
 - Drive DLL reset bit OSPI_PHY_CONFIGURATION_REG[30] PHY_CONFIG_RESET_FLD into low.

- Calculate initial delay value for the Master DLL according to the OSPI_PHY_MASTER_CONTROL_REG[6-0] PHY_MASTER_INITIAL_DELAY_FLD bit field.
- Depending on frequency of reference clock, calculate how many delay elements should be used to shift this clock by 25% of its period (best case for DDR transfers from setup/hold timings standpoint). Note that delay could be slightly different in a real design. TX Delay is configured in OSPI_PHY_CONFIGURATION_REG[22-16] PHY_CONFIG_TX_DLL_DELAY_FLD bit field.
- Re-synchronize DLLs by asserting OSPI_PHY_CONFIGURATION_REG[31] PHY_CONFIG_RESYNC_FLD (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set DLL reset bit back to high (since both bits are within the same register, it is acceptable to set both bits simultaneously).
- Poll OSPI_DLL_OBSERVABLE_LOWER_REG[15] DLL_OBSERVABLE_LOWER_LOOPBACK_LOCK_FLD bit. When set – lock is done.
- Re-synchronize Slave DLLs by asserting OSPI_PHY_CONFIGURATION_REG[31] PHY_CONFIG_RESYNC_FLD bit (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set TX DLL Delay (OSPI_PHY_CONFIGURATION_REG[22-16] PHY_CONFIG_TX_DLL_DELAY_FLD) and RX DLL Delay (OSPI_PHY_CONFIGURATION_REG[6-0] PHY_CONFIG_RX_DLL_DELAY_FLD) fields which are equivalent to percentage clock offsets now. It is recommended to wait for the new configuration being propagated by 20 reference clock cycles before triggering the next SPI transfer.
- Consider Read Data from location where its value is predictable. This step can be performed in different ways, depending on the device. Parameter Page, ID, Status, Data from OTP region or Data from location of Flash Array the value of which is known can act as the pattern.
- Trigger Read request chosen from above options.
- Check correctness of data and store that information:
 - Increment value of RX clock delay – it is configurable in the OSPI_PHY_CONFIGURATION_REG[6-0] PHY_CONFIG_RX_DLL_DELAY_FLD bit field.
 - Re-synchronize DLLs.
 - Trigger valid Read request.
 - Check correctness of data and store information.
 - If range boundary of RX clock delay is achieved, go to step 3. Otherwise go back to step "Increment value of RX clock delay".
- 3. Set RX clock delay value for one from the middle of valid range based on information in storage.
- 4. Re-synchronize DLLs.
- 5. Set OSPI_DEV_INSTR_RD_CONFIG_REG for Octal Read DDR Configuration (each transfer phase should be configured to work in Octal mode, Number of Dummy cycles should be set as specified in the documentation of the device or more when because of additional read paths delays of actual systems data is predicted to be flopped by PHY module with delay excesses actual cycle of SPI clock generated by the controller).
- 6. Enable Pipeline mode in the OSPI_CONFIG_REG[25] PIPELINE_PHY_FLD bit.
- 7. Perform Sequential Read of Data consistent with conditions indicated within [Section 12.3.2.3.16.1, PHY Pipeline Mode](#).
- 8. After de-asserting the data slave select signal by software – poll OSPI_CONFIG_REG[31] IDLE_FLD bit.
- 9. When it is asserted to high – next transfer request can be triggered.

12.3.2.3.16.1 PHY Pipeline Mode

This mode is used for Direct Read Mode of operation. If any other operations are intended to be executed, it is recommended to disable PHY Pipeline Mode and re-enable for subsequent Direct Reads in PHY mode. Since there is comprehensive software mechanism controlling Read data transfers in Indirect Mode, pipeline of data interface accesses is not effective for this mode. Enable PHY Pipeline feature when at least four 4-byte-sized data words are predicted to be read in sequentially. The Flash Command Generator pipelines and puts them into TX FIFO which causes CS to remain active because low level SPI protocol controller controls TX FIFO fill level. In order to correctly trigger Direct Read in Pipeline Mode TX FIFO must be empty. Therefore first polling of OSPI_CONFIG_REG[31] IDLE_FLD bit needs to be done. The sequential data transfer will be interrupted when the data slave select signal of the data interface is asserted to low. This information is also detected by

Data Slave Module which informs the Flash Command Generator that the next access is invalid and a TX FIFO locations can be flushed transparently for the system.

In PHY Pipeline Mode it is recommended for Data Master not to introduce wait states in between consecutive occurrences of the data interface signal that indicates transfer has finished. It will ensure regular transfer rate on data side. Introducing wait states gradually slows data transfer rate down and may finally cause SPI transfer interruption because of TX FIFO data starvation. The system, however, may need to introduce some number of wait states after completion of sequential transfer (composed of 4-byte sized data words) for progressing the data. The dedicated buffer is implemented in Data Slave Controller which collects all incoming data during wait states injection. In order to keep SPI transfer uninterrupted, number of wait states should be as little as possible. The higher the OSPI_HCLK/ OSPI_RCLK ratio the more wait states can be introduced without SPI transfer interruption. In case the system is able to launch a new transfer before wait states overflow, buffered data transfer to the host will continue. It compensates slowed down transfer by introducing wait states. In case the system is not able to launch a new transfer before wait states overflow, next incoming transfer is considered non-sequential and is executed after all pipelined data is flushed.

This mode can be enabled when following conditions are met:

- OSPI_HCLK > OSPI_RCLK (Comparing the slow data clock with the fast reference one makes Pipeline Mode ineffective – Suspend of SPI Transfer would be possible. Consequently, this condition has to be met to operate in this mode.)
- Only 4-byte sized Data Words are permitted (This ensures more data clock cycles for synchronization of FIFOs between consecutive pulses of the signal indicating transfer has finished.)
- The transfer with introduced wait states or non-sequential transfers can only be triggered in between at least four 4-byte sized Data Bursts sequential accesses (16 Bytes) to be sure that Data Master can trust buffered incoming data during wait states injection.
- Do not use Pipeline Mode along with Continuous Mode (XIP). Benefit of XIP is limited for bulk data transfers intended to execute in Pipeline Mode.

12.3.2.3.16.2 Read Data Capturing by the PHY Module

Read Data Capturing by the PHY module is useful, as the user is not responsible for the design dedicated DLL being compatible with the Octal-SPI Flash Controller. Another benefit is an option to adjust both SPI clock and sampling clock in a very wide range to fit them into individual requirements of any system. If loopback clock (OSPI_RD_DATA_CAPTURE_REG[0] BYPASS_FLD) and PHY mode (OSPI_CONFIG_REG[3] PHY_MODE_ENABLE_FLD) are both enabled, the loopback clock is driven into RX DLL instead of gated reference clock. Because of the architecture of DLL, loopback clock needs to be provided in SPI Mode 0. If DQS (OSPI_RD_DATA_CAPTURE_REG[8] DQS_ENABLE_FLD) and PHY mode (OSPI_CONFIG_REG[3] PHY_MODE_ENABLE_FLD) are both enabled, the DQS is driven into RX DLL instead of gated reference clock.

12.3.2.4 OSPI Programming Guide

12.3.2.4.1 Configuring the OSPI Controller for Use After Reset

The OSPI controller has been designed to wake up in a state that is suitable for performing basic reads and writes using the direct access controller. The BASIC read (opcode 0x03) and BASIC write (opcode 0x02) instructions are operations supported by all target devices. The controller also wakes up with a baud rate divider setting of divide-by-32. Assuming the reference clock is operating at 400 MHz after reset, then this means the effective SPI clock is just 12.5 MHz. This should be slow enough to meet all timing requirements of all target devices without any further device programming.

If the target device does not use 3 address bytes, the device size configuration register must be modified to the appropriate size.

If software plans to write to the device, and the number of bytes per device page is not equal to 256, then the device size configuration register must also be modified.

While not a requirement, it is prudent for software to enable the write protect feature prior to enabling the OSPI controller. This will block any data writes from taking effect. To do so, the protection registers (OSPI_LOWER_WR_PROT_REG, OSPI_UPPER_WR_PROT_REG and OSPI_WR_PROT_CTRL_REG) should be setup and the number of bytes per device block in the device size configuration register should also be setup.

After Power-on Reset (POR), software can read from and write to the FLASH device (albeit slowly). Enabling/Disabling the controller and DAC is achieved with just one write to corresponding fields of the OSPI_CONFIG_REG register. User shall take note to maintain the default values of the baud rate divisor and the default state of SEL_CLK_POL_FLD/ SEL_CLK_PHASE_FLD bits of this register. A write data value of 0x00780081 is recommended.

12.3.2.4.2 Configuring the OSPI Controller for Optimal Use

Note

When using the OSPI Controller, the opcodes in OSPI_DEV_INSTR_RD_CONFIG_REG[7-0] RD_OPCODE_NON_XIP_FLD, OSPI_DEV_INSTR_WR_CONFIG_REG[7-0] WR_OPCODE_FLD and OSPI_WRITE_COMPLETION_CTRL_REG[7-0] OPCODE_FLD bit fields shall not match the opcode in the OSPI_FLASH_CMD_CTRL_REG[31-24] CMD_OPCODE_FLD bit field.

For high speed transfers PHY mode can be enabled and for optimal configuration PHY Pipeline mode is recommended. For more information, see [Section 12.3.2.3.16.1, PHY Pipeline Mode](#).

To access the flash optimally, software must configure the controller accurately:

1. Wait until any pending STIG or INDAC operation has completed or poll OSPI_CONFIG_REG[31] IDLE_FLD bit.
2. Disable the DAC through OSPI_CONFIG_REG[7] ENB_DIR_ACC_CTLR_FLD bit. It is permitted, but not necessary to also disable the OSPI controller completely via OSPI_CONFIG_REG[0] ENB_SPI_FLD bit.
3. Update the OSPI_DEV_INSTR_RD_CONFIG_REG and OSPI_DEV_INSTR_WR_CONFIG_REG registers for the instruction type you wish to use for indirect and direct writes and reads.
4. Update the OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD bit field if mode bits have been enabled in the OSPI_DEV_INSTR_RD_CONFIG_REG[20] MODE_BIT_ENABLE_FLD bit.
5. Update the OSPI_DEV_SIZE_CONFIG_REG if the contents are incorrect. Note parts or all of this register may have been updated after initialization. The number of address bytes is a key configuration setting required for performing reads and writes. The number of bytes per page is required for performing any write. The number of bytes per device block is only required if the write protect feature is used. If the default values are correct for the target device, or if some of the values (not including the number address bytes) were incorrect but device writes were not permitted.
6. Update the OSPI_DEV_DELAY_REG. This register allows the user to tweak how the chip select is driven after each FLASH access. This is required as each device may have different timing requirements. As the serial clock frequency is increased, these timing requirements become more important. Note the numbers programmed in this register are based on the period of reference clock. Example: A device

needs 50ns minimum time before CS can be re-asserted after it has been de-asserted. By default, the controller will only provide a minimum of 1 SCLK period. When the device is operating at 100 MHz, the SCLK period is only 10ns, so 40ns extra is required. Since the register defines the number of reference clock cycles to add, and reference clock is running at 400 MHz (2.5ns period), then the user should program a value of at least 16 to the OSPI_DEV_DELAY_REG[31-24] D_NSS_FLD. This delay can be extended during auto-polling phase. There is possibility to define the polling repetition delay in the OSPI_WRITE_COMPLETION_CTRL_REG[31-24] POLL_REP_DELAY_FLD bit field.

7. Update the OSPI_REMAP_ADDR_REG register, if required. Affects DAC path only.
8. Setup and enable write protection registers (OSPI_LOWER_WR_PROT_REG, OSPI_UPPER_WR_PROT_REG and OSPI_WR_PROT_CTRL_REG) if they are required and if they have not already been setup from post initialization.
9. Enable required interrupts via the OSPI_IRQ_MASK_REG register.
10. Setup the baud rate divisor in the OSPI_CONFIG_REG[22-19] MSTR_BAUD_DIV_FLD to define the required clock frequency of the target device.
11. Update the OSPI_RD_DATA_CAPTURE_REG register. This register will delay when the read data is captured and can help when the read data path from the device to the controller is long and the device clock frequency is high. An update to this register may not be necessary.
12. Enable the OSPI controller and the DAC via the OSPI_CONFIG_REG.

12.3.2.4.3 Using the Flash Command Control Register (STIG Operation)

The OSPI_FLASH_CMD_CTRL_REG register provides software means to access the FLASH device in a flexible and programmable manner. This is known as a STIG operation (Software Triggered Instruction Generator). The instruction opcode, number of address bytes (if any), the address itself, number of dummy cycles (if any), number of write data bytes (if any), the write data itself and the number of read data bytes (if any) can be programmed. Once these have been programmed, software can trigger the command via OSPI_FLASH_CMD_CTRL_REG[0] CMD_EXEC_FLD bit and wait for its acceptance by polling OSPI_FLASH_CMD_CTRL_REG[1] CMD_EXEC_STATUS_FLD bit. When CMD_EXEC_STATUS_FLD bit turns de-asserted, another STIG can be triggered. This method of accessing the FLASH is the typical mechanism that software would use to access the FLASH device's registers, as well as for performing ERASE operations. It can also be used to access the FLASH array itself, although the maximum of 8 data bytes may be read or written at any one time, defined in the Flash Command Write and Read Data registers (OSPI_FLASH_RD_DATA_LOWER_REG, OSPI_FLASH_RD_DATA_UPPER_REG, OSPI_FLASH_WR_DATA_LOWER_REG and OSPI_FLASH_WR_DATA_UPPER_REG). This number of bytes can be extended for Read Data commands using additional STIG Memory Bank controlled by OSPI_FLASH_CMD_CTRL_REG[2] STIG_MEM_BANK_EN_FLD and OSPI_FLASH_COMMAND_CTRL_MEM_REG.

Commands issued using this interface have a higher priority than all other READ accesses coming from data interface, and will therefore interrupt any READ commands being requested by the indirect or direct controllers.

12.3.2.4.4 Using SPI Legacy Mode

SPI legacy mode allows software to access the internal TX-FIFO and RX-FIFO directly, thus bypassing the direct, indirect and STIG controllers.

Legacy mode allows the user to issue any FLASH instruction to the device, but does place a heavy software overhead in order to manage the fill levels of the FIFO's effectively. This is because the legacy SPI core is bi-directional in nature, with data continuously being transferred in either direction while the chip select is enabled. Even if the driver only wishes to read data from the FLASH device, dummy data must be written out to ensure the chip select stays active, and vice versa for write transactions.

Since the TX-FIFO and RX-FIFO are of limited depth, software has a responsibility to maintain the FIFO levels to ensure the TX-FIFO does not become exhausted during the instruction execution and the RX-FIFO doesn't overflow. This can place a lot of overhead on software. Interrupts are provided to indicate when the fill levels pass programmable watermarks, which are themselves programmable registers OSPI_TX_THRESH_REG and OSPI_RX_THRESH_REG.

The limited depth may impose the limitation over execution of some specific SPI commands in legacy mode. Note that the controller interprets all transmitted bytes as valid. For example, if the Flash Device was configured

to return valid data after many dummy cycles, the TX FIFO could become full before the controller sends all of dummy data.

12.3.2.4.5 Entering XIP Mode from POR

XIP is a mode that can be entered in a non-volatile way if the device has XIP enabled as a non-volatile configuration setting. Software will not be able to discover the state of XIP from POR via FLASH status register reads as the only operation a FLASH device will recognize when XIP mode is enabled is an XIP read operation.

If it is already known that the device will enter XIP from POR, then the OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD and OSPI_CONFIG_REG[18] ENTER_XIP_MODE_IMM_FLD bits should be set in initial boot.

If it is not already known that the device will enter XIP from POR, and XIP from POR may be supported by the attached FLASH device, then software can attempt to exit XIP mode by issuing an XIP exit command using a STIG command (via the OSPI_FLASH_CMD_CTRL_REG register). To do this, software must be aware of the mode bit requirements of that device, as XIP entry and exit changes per device.

12.3.2.4.6 Entering XIP Mode Otherwise

XIP mode is supported in most FLASH devices. Some of them use signature bits that are sent to the device immediately following the address bytes, other use signature bits and also require a FLASH device configuration register write to enable XIP. For the FLASH devices that must be compliant to the OSPI controller, the following steps can be taken by software to enter XIP mode:

1. Disable the DAC and INDAC (OSPI_CONFIG_REG[7] ENB_DIR_ACC_CTRL_FLD) to ensure no new data read accesses will be sent to the FLASH device.
2. (Optional) Configure the OSPI_FLASH_CMD_CTRL_REG to issue a VCR write to FLASH memory, because XIP mode must first be enabled for some devices.
3. Configure the XIP mode bits in the OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD bit field.
4. Enable the local controllers XIP mode by setting OSPI_CONFIG_REG[17] ENTER_XIP_MODE_FLD bit.
5. Re-enable the DAC and, if required, the INDAC.

12.3.2.4.7 Exiting XIP Mode

To exit XIP mode, software should first disable the DAC and INDAC to ensure no new data read accesses will be sent to the FLASH device. It should then set mode bits to other than the established in the corresponding Flash Device specifications. These are dependent on the FLASH device and manufacturer. Software should then reset OSPI_CONFIG_REG[17] ENTER_XIP_MODE_FLD.

Note the FLASH device must see a READ instruction before it can disable its internal XIP mode state, so this means XIP mode will internally stay active until the next READ instruction is serviced. User must take care to ensure that XIP mode is disabled before the end of any READ sequence.

12.3.3 HyperBus Interface

This section describes the HyperBus module in the device.

12.3.3.1 HyperBus Overview

The HyperBus module is a part of the device Flash Subsystem (FSS). For more information about FSS, see *Flash Subsystem (FSS)*.

The HyperBus module is a low pin count memory interface that provides high read/write performance. The HyperBus module connects to HyperBus memory (HyperFlash or HyperRAM) and uses simple HyperBus protocol for read and write transactions.

There is one HyperBus™ module inside the device. The HyperBus module includes one HyperBus Memory Controller (HBMC).

12.3.3.1.1 HyperBus Features

- Support for Cypress® HyperFlash and HyperRAM
 - Up to 166 MHz maximum memory bus operation for reads
 - Supports up to 166 MHz dual data rate (333 MBps) flash devices for system requiring rapid boot or instant-on displays
 - Supports up to 333 MBps external pseudo-RAM (HyperRAM) for systems
- Note:** For more information, see section Timing and Switching Characteristics in the device-specific Datasheet.
- Low pin count interface with LVCMOS I/O pins (can be muxed with other FSS interfaces (OSPIs))
 - Two memory chip selects
 - Linear incrementing mode for reads and writes
 - Up to 16 outstanding read transactions (see [Section 12.3.3.3.5, HyperBus True Continuous Read \(TCR\) Mode](#))
 - Asynchronous bus clock

12.3.3.1.2 Hyperbus Ports

Table 12-219. MCU_FSS0_HPBO Clocks and Resets

Clocks	
Module Clock Input	Description
MCU_FSS0_HPBO_ICLK	Interface Clock
MCU_FSS0_HPBO_CLKX1	Functional Clock 1 (main functional clock)
MCU_FSS0_HPBO_CLKX1_INV	Functional Clock 2 (inverted Functional Clock 1 to create 180 degree phase shift)
MCU_FSS0_HPBO_CLKX2	Functional Clock 3 (2 × Functional Clock 1 for DDR data and command)
MCU_FSS0_HPBO_CLKX2_INV	Functional Clock 4 (inverted Functional Clock 3 to create 180 degree phase shift)
Resets	
Module Reset Input	Description
MCU_FSS0_HPBO_RST	HyperBus Reset

Table 12-220. MCU_FSS0_HPBO Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
MCU_HYPFLSH_INT	HyperBus Interrupt Request	Level
MCU_HYPFLSH_SEC_INT	HyperBus ECC SEC Error Interrupt Request	Level
MCU_HYPFLSH_DED_INT	HyperBus ECC DED Error Interrupt Request	Level

12.3.3.2 HyperBus Environment

This section describes the HyperBus external connections (environment).

[Table 12-221](#) describes the HyperBus I/O signals.

Table 12-221. HyperBus I/O Signals

Module Pin	I/O ⁽¹⁾	Description
CK	O	HyperBus Clock Output (differential)
CK _n	O	HyperBus Inverted Clock Output (differential)
RWDS	I/O/HiZ	HyperBus Read/Write Data Strobe
DQ[7:0]	I/O/HiZ	HyperBus Data
CS _{n0}	O	HyperBus Chip Select 0
CS _{n1}	O	HyperBus Chip Select 1
RESET _n	O	HyperBus Reset Output
RESET _{On}	I	Reset State Indicator (output from HyperBus memory)
INT _n	I	Memory Interrupt (output from HyperBus memory)
WP _n ⁽²⁾	O	HyperBus Write Protect (output to HyperBus memory)

(1) I = Input; O = Output; HiZ = High Impedance

(2) WP_n pin is not used on Cypress flash devices.

12.3.3.3 HyperBus Functional Description

The HyperBus module is a high throughput memory interface. It is a part of the device FSS and provides execute in place (XIP) operation and block copy access to HyperBus memory devices (HyperRAM and HyperFlash). The FSS enables in-line ECC protection and authentication features for the HyperBus module.

For more information about FSS, see *Flash Subsystem (FSS)*.

The HyperBus module is compliant to the *Cypress HyperBus™ Specification v1.2*.

Figure 12-131 shows the HyperBus module block diagram.

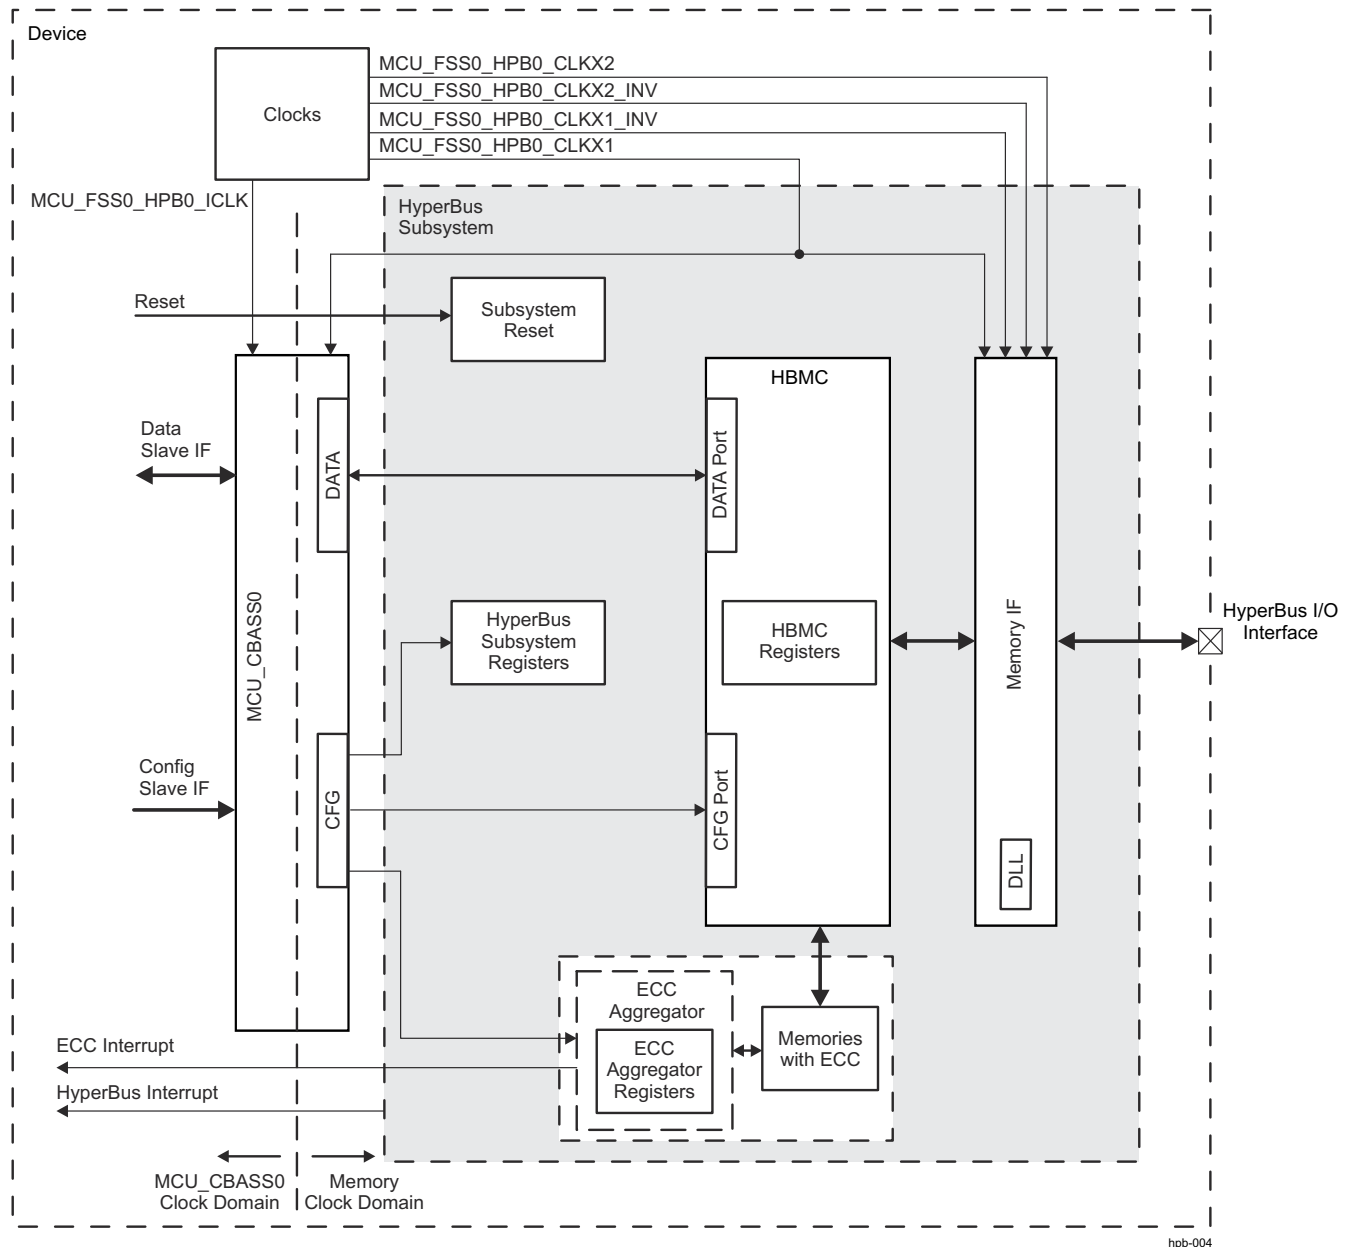

Figure 12-131. HyperBus Module Block Diagram

Basic Blocks:

- **HBMC:** The HyperBus Memory Controller (HBMC) is the main part (the core) of the HyperBus Subsystem and provides accessibility to external HyperBus memory (HyperFlash or HyperRAM) using simple HyperBus protocol for data read and write transfers.

- The Data Port on the HBMC is used for CBASS data slave interface to access the external HyperBus memory.
- The CFG Port on the HBMC is used for configuration of the HBMC registers.
- HyperBus I/O Interface: The HyperBus I/O Interface includes all used interface pins (for more information, see *HyperBus I/O Signals*).
- Memory IF: The Memory IF block implements the following functionality:
 - Convert single-rate command and data output from the HBMC to double-rate (DDR)
 - Use DLL to delay the incoming read data strobe from the memory
- FIFO Memories with ECC: There are internal HyperBus FIFOs implemented with memories that are used during read and write transactions. These FIFO memories are ECC protected (for more information about the FIFOs, see [Section 12.3.3.3.3, HyperBus Internal FIFOs](#)).
- ECC Aggregator: The ECC Aggregator facilitates aggregating and reporting internal HyperBus FIFO memory errors (for more information, see [Section 12.3.3.3.2, HyperBus ECC Support](#)).
- HBMC Registers: This block includes set of all used HBMC registers.
- HyperBus Subsystem Registers: This block implements memory-mapped registers at the HyperBus Subsystem level.
- ECC Aggregator Registers: This block includes all used ECC Aggregator registers.

For more information about all HyperBus registers, see *HyperBus Registers*.

- MCU_CBASS0: The MCU_CBASS0 interconnect implements the clock domain crossing bridges needed to separate the two main clock domains: MCU_CBASS0 clock domain and Memory clock domain.
- Data Slave IF: The Data Slave IF on the interconnect is a 32-bit wide interface and is used to access an external HyperBus memory via the Data Port on the HBMC. The data interface supports linear incrementing addresses only. Cache-line wrap and fixed addressing modes are not supported.
- Config Slave IF: The Config Slave IF on the interconnect is a 32-bit wide interface and is used to access the HBMC registers (via the CFG Port on the HBMC), HyperBus Subsystem registers, and ECC Aggregator registers. The config interface also supports linear incrementing address mode only.

For more information about supported and not supported HyperBus features, see *HyperBus Overview*.

- Clocks: For more information about HyperBus Clocks, see *MCU_FSS0_HBP0 Clocks and Resets*.
- Subsystem Reset: The reset signal to the Subsystem Reset block provides reset to the all HyperBus Subsystem parts (for more information about HyperBus Resets, see *MCU_FSS0_HBP0 Clocks and Resets*).
- Interrupts: For more information, see *MCU_FSS0_HBP0 Clocks and Resets* and *HyperBus Interrupts*.

12.3.3.3.1 HyperBus Interrupts

The HyperBus module sources one active high level HyperBus interrupt and two active high level ECC Aggregator interrupts (see *MCU_FSS0_HBP0 Hardware Requests*).

The HyperBus interrupt is generated based on the HyperBus memory's active low level interrupt. In the HyperBus Subsystem this active low level interrupt is converted to active high level HyperBus interrupt (see RESETOn pin in *Hyperbus I/O Signals*).

The ECC Aggregator interrupts are generated based on the ECC errors (single (correctable) and double (uncorrectable) bit errors) in the embedded HyperBus memories (for more information, see *HyperBus ECC Support*).

12.3.3.3.2 HyperBus ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

The SEC logic detects and corrects a single bit error (single bit error per ECC word or per ECC data segment). The DED logic only detects (does not correct) double errors (double bit errors per ECC word or per ECC data segment).

The embedded HyperBus memories are ECC protected.

12.3.3.3.2.1 ECC Aggregator

Note

For more information about ECC Aggregator, refer to [Section 12.10.6, ECC Aggregator](#).

For more information about ECC Aggregator Registers, refer to *HyperBus Registers*.

12.3.3.3.3 HyperBus Internal FIFOs

There are 10 FIFO buffers in the module that help improve performance. [Table 12-222](#) shows the HyperBus FIFOs details.

Table 12-222. HyperBus FIFOs

Buffer Name	Size (Width x Depth)
Address (ADR) FIFO	Two port RAM – 16 x 46-bit
Write data (WDAT) FIFO	Two port RAM – 256 x 40-bit
Write status (BDAT) FIFO	Two port RAM – 16 x 2-bit
Read data (RDAT) FIFO	Two port RAM – 128 x 40-bit
Receive (RX) FIFO	Two port RAM – 256 x 20-bit
Address write (AW) FIFO	Two port RAM – 16 x 44-bit
Write ID (WID) FIFO	Two port RAM – 16 x 2-bit
Address write ID (AWID) FIFO	Two port RAM – 16 x 14-bit
Address read (AR) FIFO	Two port RAM – 16 x 44-bit
Address read ID (ARID) FIFO	Two port RAM – 16 x 18-bit

12.3.3.3.4 HyperBus Data Regions

For more information about HyperBus data regions, refer to [Section 12.3.1.3.5, FSS Memory Regions](#).

12.3.3.3.5 HyperBus True Continuous Read (TCR) Mode

The HBMC supports True Continuous Read (TCR) operation for HyperFlash. This feature is able to improve HyperFlash read performance.

When this feature is enabled, the HBMC can merge multiple up to 16 max burst read commands that are present in its command FIFO into a single memory read transaction to the HyperFlash memory. As a result, the command input and initial latency for the latter burst read commands are saved, which leads to improved throughput.

12.3.3.4 HyperBus Programming Guide

12.3.3.4.1 HyperBus Initialization Sequence

The HBMC provides two sets of Memory Base Address, Memory Configuration and Memory Timing registers to access devices connected to the two external chip selects. The following programming guidelines need to use the correct set of registers depending on which chip select is accessed.

The HBMC compares the input address bits [31-24] to the value programmed in the MCU_FSS0_HPBO_MC_MBAR_y registers to determine the external chip select that is accessed.

12.3.3.4.1.1 HyperFlash Access

Table 12-223. HyperFlash Access Sequence

Step	Description
1.	Ensure that the FIFO RAM auto-initialization is complete by reading the MCU_FSS0_HPBO_SS_RAM_STAT_REG[0] INIT_DONE bit .
2.	<p>Lock MDLL:</p> <ul style="list-style-type: none"> - To ensure that the MDLL in the HyperBus is locked, the reset to the HyperBus module should be de-asserted only after all the clock inputs are stable at the desired operating frequency (see <i>MCU_FSS0_HPBO Clocks and Resets</i>). The MDLL can lose the lock if the frequencies of the clock inputs to the HyperBus module are changed during operation. - To ensure that the MDLL is stabilized, the following sequence is required. Boot code should attempt to read 64 bytes of Flash data, for 16 iterations, and if the data is the same in 4 successive iterations, the DLL can be considered to be stabilized and the software proceed with normal Flash access . - The MCU_FSS0_HPBO_SS_DLL_STAT_REG[0] MDLL_LOCK and MCU_FSS0_HPBO_SS_DLL_STAT_REG[1] SDL_LOCK bits can be used to determine if the master delay line and slave delay line have locked, respectively .
3.	<p>Initialize Memory Configuration register (MCU_FSS0_HPBO_MC_MCR_y):</p> <ul style="list-style-type: none"> - MCU_FSS0_HPBO_MC_MCR_y[31] MAXEN bit and MCU_FSS0_HPBO_MC_MCR_y[26-18] MAXLEN bit field based on burst transaction length to memory. - MCU_FSS0_HPBO_MC_MCR_y[17] TCMO = 1h, to enable HBMC to merge multiple accesses with sequential addresses into a single memory access. This will improve memory throughput. - MCU_FSS0_HPBO_MC_MCR_y[16] ACS = 0h, to set 'No asymmetry cache system support'. - MCU_FSS0_HPBO_MC_MCR_y[5] CRT = 0h, to set 'Memory space' instead 'CR space'. - MCU_FSS0_HPBO_MC_MCR_y[4] DEVTYPE = 0h, to set 'HyperFlash' instead 'HyperRAM'. - MCU_FSS0_HPBO_MC_MCR_y[1-0] WRAPSIZE = 00h, since the HBMC does not support wrap bursts.
4.	Initialize Memory Timing register (MCU_FSS0_HPBO_MC_MTR_y) based on timing of the memory device being used.
5.	<p>Initialize Memory Base Address register (MCU_FSS0_HPBO_MC_MBAR_y):</p> <ul style="list-style-type: none"> - MCU_FSS0_HPBO_MC_MBAR_y[31-24] A_MSB = 8 MSB bits of memory address space. This will define the start of the 16 MB address region in the system memory where the HyperFlash can be accessed. The HBMC will initiate HyperFlash access to any memory mapped access in this range.
6.	Check the MCU_FSS0_HPBO_MC_CSR[10] RRSTOERR bit in Controller Status register to ensure that the HyperFlash is out of reset.
7.	Normal HyperFlash access can be performed after this.
8.	The HyperFlash device registers and CFI (Common Flash Interface) region can be accessed by read/write transactions to the offset from the base address as specified in the device command summary table.
9.	The HyperFlash memory data array can be read as memory mapped access.
10.	The HyperFlash write sequence needs to be followed to update contents of the memory array.

12.3.3.4.1.2 HyperRAM Access

Table 12-224. HyperRAM Access Sequence

Step	Description
1.	Wait 150 μ s for RAM to power up after reset. The HyperRAM does not provide any feedback on reset/ready state to the HBMC.
2.	Ensure that the FIFO RAM auto-initialization is complete by reading the MCU_FSS0_HPB0_SS_RAM_STAT_REG[0] INIT_DONE bit.
3.	Lock MDLL: <ul style="list-style-type: none"> - To ensure that the MDLL in the HyperBus is locked, the reset to the HyperBus module should be de-asserted only after all the clock inputs are stable at the desired operating frequency (see <i>MCU_FSS0_HPB0 Clocks and Resets</i>). The MDLL can lose the lock if the frequencies of the clock inputs to the HyperBus module are changed during operation. - To ensure that the MDLL is stabilized, the following sequence is required. Boot code should attempt to read 64 bytes of RAM data, for 16 iterations, and if the data is the same in 4 successive iterations, the DLL can be considered to be stabilized and the software proceed with normal RAM access. - The MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK and MCU_FSS0_HPB0_SS_DLL_STAT_REG[1] SDL_LOCK bits can be used to determine if the master delay line and slave delay line have locked, respectively.
4.	Initialize Memory Configuration register (MCU_FSS0_HPB0_MC_MCR_y): <ul style="list-style-type: none"> - MCU_FSS0_HPB0_MC_MCR_y[31] MAXEN bit and MCU_FSS0_HPB0_MC_MCR_y[26-18] MAXLEN bit field based on burst transaction length to memory. - MCU_FSS0_HPB0_MC_MCR_y[17] TCMO = 0h, since HBMC does not support command merging for HyperRAM accesses. - MCU_FSS0_HPB0_MC_MCR_y[16] ACS = 0h, to set 'No asymmetry cache system support'. - MCU_FSS0_HPB0_MC_MCR_y[5] CRT = 0h or 1h, depending on what needs to be accessed (memory or register space). - MCU_FSS0_HPB0_MC_MCR_y[4] DEVTYPE = 1h, to set 'HyperRAM' instead 'HyperFlash'. - MCU_FSS0_HPB0_MC_MCR_y[1-0] WRAPSIZE = 00h, since the HBMC does not support wrap bursts.
5.	Initialize MCU_FSS0_HPB0_MC_MTR_y register based on timing of the memory device being used.
6.	Initialize MCU_FSS0_HPB0_MC_MCR_y register: <ul style="list-style-type: none"> - MCU_FSS0_HPB0_MC_MCR_y[31-24] A_MSB = 8 MSB bits of memory address space. This will define the start of the 16 MB address region in the system memory where the HyperRAM can be accessed. The controller will initiate HyperRAM access to any memory mapped access in this range.
7.	Check the MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK bit to ensure the Master DLL is locked.
8.	Normal HyperRAM access can be performed after this.
9.	The HyperRAM device registers can be accessed by read/write transactions to the offset from the base address as specified in the device command summary table with MCU_FSS0_HPB0_MC_MCR_y[5] CRT bit set to register space.
10.	The HyperRAM memory data array can be read/written to as memory mapped access with MCU_FSS0_HPB0_MC_MCR_y[5] CRT bit set to memory space.

Note

HyperRAM devices have a 150 μ s startup time. Software needs to wait this duration after reset to initiate transactions to a HyperRAM device.

12.3.3.4.2 HyperBus Real-time Operating Requirements

The HBMC may assert the memory interrupt based on the status of the memory transaction. Software needs to handle this interrupt using the MCU_FSS0_HPB0_MC_ISR register. The MCU_FSS0_HPB0_MC_ISR register can provide the status information to determine the cause of the interrupt.

12.3.3.4.3 HyperBus Power Up/Down Sequence

Software needs to ensure that there are no pending transactions before stopping clock and/or power to the HBMC.

12.3.4 General-Purpose Memory Controller (GPMC)

This section describes the General-Purpose Memory Controller (GPMC) for the device.

12.3.4.1 GPMC Overview

The General-Purpose Memory Controller is a unified memory controller dedicated for interfacing with external memory devices like:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in non-multiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

12.3.4.1.1 GPMC Features

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to 4 chip select regions of programmable size and programmable base addresses in a total address space of 1GB
- Supports on-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) ($t = 4, 8, \text{ or } 16$) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth usage
- The clock to the external memory is provided from GPMC_FCLK divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters with a timing granularity of one GPMC_FCLK clock cycle.
- Flexible internal access time control (wait state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write-posting engine associated with DMA controller at system level to achieve full performance from the NAND device with minimum effect on NOR/SRAM concurrent access
- 32-bit interconnect slave interface which supports non-wrapping and wrapping burst of up to 16x32 bits.

The GPMC supports the following various access types:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8 and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8 and 16 Word16)
- Address-data-multiplexed (AD) access
- Address-address-data (AAD) multiplexed access
- Little-endian access only

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit non-multiplexed NOR flash device
- External 16-bit address and data multiplexed NOR Flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

Note

Page mode is available only in non-multiplexed mode.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.3.4.2 GPMC Environment

This section describes the GPMC0 external connections (environment).

[Table 12-227](#) lists the GPMC subsystem input/output (I/O) pins.

Table 12-227. GPMC I/O Signals (Master Mode)

Module Pin	I/O ⁽¹⁾	Description
A[27-0]	O	28-bit output address bus
A[16-1]/D[15-0]	I/O	Multiplexed address/data
nCS[3-0]	O	Chip-selects (active low)
CLK	O	Clock generated for the external memory or device. For more information, see <i>GPMC Integration</i> .
RET_CLK		
N/A	O	Free running clock. GPMC functional clock (GPMC0_FCLK) propagated on a device pad. For more information on the GPMC0_FCLK_MUX integration, see <i>GPMC Integration</i> .
nADV/ALE	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	O	Write enable (active low)
nBE0/CLE	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	O	Upper-byte enable (active low)
WAIT[3-0]	I	External wait signal for NOR and NAND protocol memories. Can be mapped on any of the chip-selects.
nWP	O	Write protect (active low)
DIR	O	This signal can be used to control an external buffer direction. Also controls the signal direction of D[15-0]. Low during transmit (for write access: data OUT from GPMC0 to memory). High during receive (for read access: data IN from memory to GPMC0).

(1) I = Input; O = Output; I/O - Bidirectional

12.3.4.3 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the four configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external WAIT pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

12.3.4.3.1 GPMC Block Diagram

Figure 12-132 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

gpmc-005

Figure 12-132. GPMC Block Diagram

The GPMC can access various external devices. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

12.3.4.3.2 GPMC Clock Configuration

Table 12-228 describes the GPMC clocks.

Table 12-228. GPMC Clocks

Signal	I/O ⁽¹⁾	Description
GPMC_FCLK	I	Functional clock

Table 12-228. GPMC Clocks (continued)

Signal	I/O ⁽¹⁾	Description
GPMC_ICLK	I	Interface clock
CLK (GPMC_CLKOUT pin)	O	External clock provided to synchronous external memory devices.

(1) I = Input; O = Output; I/O - Bidirectional

The GPMC output clock (CLK) is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in *GPMC0 Clocks and Resets*. The GPMC output clock is configured using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), as shown in [Table 12-229](#).

Table 12-229. GPMC Output Clock Configuration

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC Output Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

When using synchronous interface protocols, the GPMC output clock (CLK), toggles only during the read or write access cycle. In some applications, it may be desirable to have a continuous clock running at the GPMC interface clock frequency for clocking attached devices. This option is enabled by an optional clock path from the GPMC functional clock input (GPMC_FCLK) to the GPMC_FCLK_MUX pin. This output clock, to GPMC_FCLK_MUX pin, can be selected through the standard MUXMODE selection of the GPMC_FCLK_MUX pin PADCONFIG control register.

Note that when using such synchronous interface protocols with the continuous clock option, user should ensure that the GPMC outputs are timed to the same frequency (GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0).

12.3.4.3.3 GPMC Power Management

[Table 12-230](#) describes the local power-management features available for the GPMC module.

Table 12-230. GPMC Local Power-Management Features

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_ICLK clock upon the internal activity.
Slave idle modes	GPMC_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle and smart-idle modes are available.

12.3.4.3.4 GPMC Interrupt Requests

The GPMC generates one interrupt request (see *GPMC0 Hardware Requests*).

[Table 12-231](#) lists the event flags, and their mask, that can cause module interrupts.

Table 12-231. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[11] WAIT3EDGE DETECTIONSTATUS	GPMC_IRQENABLE[11] WAIT3EDGE DETECTIONENABLE	Edge	Wait3 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT3 signal. The rising or falling edge detection of Wait3 is selected through the GPMC_CONFIG[11] WAIT3PINPOLARITY bit.
GPMC_IRQSTATUS[10] WAIT2EDGE DETECTIONSTATUS	GPMC_IRQENABLE[10] WAIT2EDGE DETECTIONENABLE	Edge	Wait2 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT2 signal. The rising or falling edge detection of Wait2 is selected through the GPMC_CONFIG[10] WAIT2PINPOLARITY bit.

Table 12-231. GPMC Interrupt Events (continued)

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

12.3.4.3.5 GPMC Interconnect Port Interface

Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The GPMC interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the GPMC_CONFIG1_i[31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

12.3.4.3.6 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-non-multiplexed memories or devices is supported with an address range of 256MB.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit-wide NOR devices do not use GPMC I/O: GPMC_AD[15-8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: .
- 8-bit-wide NAND devices do not use GPMC I/O: and GPMC I/O: GPMC_AD[15-8].

12.3.4.3.6.1 GPMC I/O Configuration Setting

Note

In this section and the following sections, the *i* in GPMC_CONFIGx_i stands for the GPMC chip-select *i*, where *i* = 0 to 3.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b10
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b01

To select an address/data-non-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9-8] MUXADDDATA = 0b00

12.3.4.3.7 GPMC Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and four sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

12.3.4.3.7.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 128MB address space. For more information, see *Memory Map*.

Note

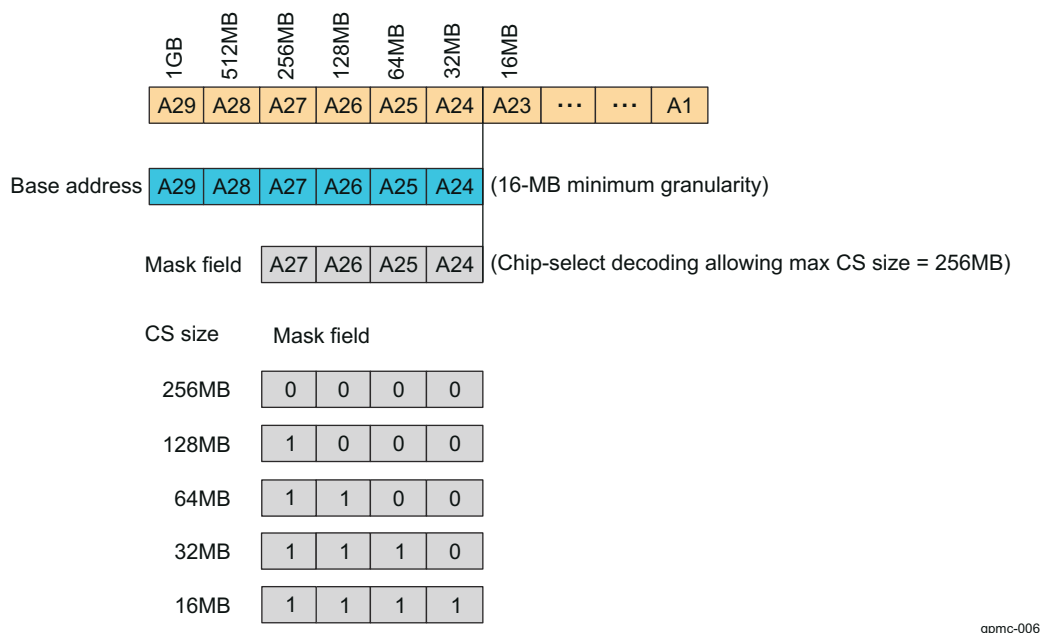

Even though GPMC supports total address space of 1GB, only 128MB are physically available in this device.

The GPMC 128MB address space can be divided into a maximum of four chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16MB to 256MB

(must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in [Figure 12-133](#) (with A0 as the device system byte-address line). The base address is programmed through the GPMC_CONFIG7_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11-8] MASKADDRESS bit field.

gpmc-006

Figure 12-133. Chip-Select Address Mapping and Decoding Mask

For example, to map the 128MB address space (from 2000 0000h to 27FF FFFFh), the GPMC_CONFIG7_i[5-0] BASEADDRESS bit field should be set to 20h.

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (where i stands for the GPMC chip-select i, where i = 0 to 3). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

CAUTION

Although the GPMC interface can drive up to four chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines at the value specified in the device-specific Datasheet.

12.3.4.3.7.2 Access Protocol

12.3.4.3.7.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11-10] DEVICETYPE parameter (where i = 0 to 3) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM
- NAND flash asynchronous devices

Note

For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 12.3.4.3.11, GPMC NAND Device Basic Programming Model](#), and [Section 12.3.4.3.11.1, NAND Memory Device in Byte or Word16 Stream Mode](#).

12.3.4.3.7.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13-12] DEVICESIZE bit field (where i = 0 to 3) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

12.3.4.3.7.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[9-8] MUXADDDATA bit field (where i = 0 to 3). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See *GPMC Integration*.

Note

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See [Section 12.3.4.3.11, NAND Device Basic Programming Model](#).

12.3.4.3.7.3 External Signals

12.3.4.3.7.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external GPMC_WAIT pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features four input WAIT pins: GPMC_WAIT0 through GPMC_WAIT3. These pins allow control of external devices with different WAIT pin polarity. They also allow the overlap of WAIT pin assertion from different devices without affecting access to devices for which the WAIT pin is not asserted.

- The GPMC_CONFIG1_i[17-16] WAITPINSELECT bit field (where i = 0 to 3) selects which input GPMC_WAIT pin is used for the device attached to the corresponding chip-select.
- The polarity of the WAIT pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A WAIT pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a WAIT pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the WAIT pin of the external memory device, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether or not the WAIT pin must be monitored during read accesses.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether or not the WAIT pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the WAIT pin of the external memory device asynchronously or synchronously with the GPMC output clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

12.3.4.3.7.3.1.1 Wait Monitoring During Asynchronous Read Access

When WAIT pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with WAIT pin monitoring enabled, the WAIT pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through WAIT pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the WAIT pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and no GPMC output clock is provided to the external device. Still, because GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 12-134 shows wait behavior during an asynchronous single read access.

Figure 12-134. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

Note

The WAIT signal is active low. GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0b00, or 0b01.

12.3.4.3.7.3.1.2 Wait Monitoring During Asynchronous Write Access

When WAIT pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the WAIT pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

12.3.4.3.7.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with WAIT pin monitoring enabled, the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC output clock cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3), and is expressed as a number of GPMC output clock cycles.

In synchronous mode, when WAIT pin monitoring is enabled (the GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the WAIT pin must be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access

time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.

- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 12-135 shows wait behavior during a synchronous read burst access.

Figure 12-135. Wait Behavior During a Synchronous Read Burst Access

Note

The WAIT signal is active low. WAITMONITORINGTIME = 0b00, 0b01.

12.3.4.3.7.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with WAIT pin monitoring enabled (the GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit), the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

If enabled, external WAIT pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC output clock capture edge of the effective memory device.

WAIT-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Note

WAIT monitoring is supported for all configurations except GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0x0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 (the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field is equal to 0x0 or 0x1, respectively).

12.3.4.3.7.3.1.5 Wait With NAND Device

For information about the use of the WAIT pin for communication with a NAND flash external device, see [Section 12.3.4.3.11.2, NAND Device-Ready Pin](#).

12.3.4.3.7.3.1.6 Idle Cycle Control Between Successive Accesses

12.3.4.3.7.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3-0] BUSTURNAROUND bit field (where i = 0 to 3).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

Note

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3-0] CYCLE2CYCLEDELAY bit field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see the following figures).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

Figure 12-136. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)

12.3.4.3.7.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSSEN bit (where i = 0 to 3) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRD OFFTIME/ CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC output clock (CLK)) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC output clock at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

12.3.4.3.7.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

Note

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the GPMC_CONFIG6_i registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see [Section 3.4.3.7.3.1.6.1, Bus Turnaround \(BUSTURNAROUND\)](#).

Table 12-232 describes the configuration required for idle cycle insertion.

Table 12-232. Idle Cycle Insertion Configuration

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.

Table 12-232. Idle Cycle Insertion Configuration (continued)

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

12.3.4.3.7.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select i, where i = 0 to 3). Increasing all access timing parameters allows support of slow devices.

12.3.4.3.7.3.2 DIR Pin

The DIR pin is used to control I/O direction on the GPMC data bus GPMC_D[15-0]. Depending on pad multiplexing, this signal can be output and used externally to the device, if required. The DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the DIR pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled
 - The DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
 - After an asynchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
 - After a synchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the DIR pin is OUT (see [Section 12.3.4.3.8.10, Bus Keeping Support](#)). In non-multiplexed devices, the DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

12.3.4.3.7.3.3 Reset

No reset signal is sent to the external memory device by the GPMC.

GPMC_RST is the reset signal for the GPMC module. It is connected and controlled by LPSC8 in VD_CORE. That reset signal initializes the internal state-machine and the internal configuration registers.

12.3.4.3.7.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The nWP output pin value is controlled through the GPMC_CONFIG[4] WRITEPROTECT bit which is common for all chip selects.

12.3.4.3.7.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

12.3.4.3.7.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. An interrupt generation is handled at interconnect level.

12.3.4.3.8 GPMC Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about GPMC_CLKOUT and GPMC_FCLK, see *GPMC_CLKOUT*.

Note

In the following sections, the start access time refers to the time at which the access begins.

12.3.4.3.8.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4-0] RDCYCLETIME and GPMC_CONFIG5_i[12-8] WRCYCLETIME bit fields (where $i = 0$ to 3) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC output clock between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC output clock cycle. The RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

When RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

Note

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC output clock) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC output clock at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC_FCLK cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, CYCLE2CYCLESAMECSSEN = 1 or CYCLE2CYCLEDIFFCSSEN = 1), the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

12.3.4.3.8.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3-0] CSONTIME bit field (where i = 0 to 3) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12-8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20-16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. CSEXTRADELAY is especially useful in configurations where GPMC output clock and GPMC_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

12.3.4.3.8.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3-0] ADVONTIME field (where i = 0 to 3) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12-8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20-16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC output clock and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see [Section 12.3.4.3.11](#), *GPMC NAND Access Description*.

12.3.4.3.8.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3-0] OEONTIME bit field (where i = 0 to 3) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC_CONFIG4_i[12-8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user must ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Note

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

12.3.4.3.8.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19-16] WEONTIME bit field (where i = 0 to 3) defines the nWE signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28-24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

12.3.4.3.8.6 GPMC_CLKOUT

The GPMC output clock generated for external synchronous memory or device is GPMC_CLKOUT.

- The GPMC_CLKOUT clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device-specific Datasheet.
- The GPMC_CLKOUT clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLKOUT activation.
- The GPMC_CLKOUT clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLKOUT clock is kept low when access is defined as asynchronous.

CAUTION

When the cycle time completes, the GPMC_CLKOUT may be high because of the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLKOUT clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

Note

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

12.3.4.3.8.7 GPMC Output Clock and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC output clock edge can be controlled in the following ways:

- For the GPMC output clock signal, the GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC output clock allows setup and hold control of the control-signal assertion and deassertion times.
- When the GPMC output clock runs at the GPMC_FCLK frequency so that GPMC output clock edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by a half-GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter.

This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

12.3.4.3.8.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC_CONFIG5_i[20-16] RDACCESSTIME and GPMC_CONFIG6_i[28-24] WRACCESSTIME bit fields (where i = 0 to 3). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

12.3.4.3.8.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field (where i = 0 to 3) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_FCLK rising edge corresponding to the GPMC output clock rising edge used for the first data capture.

GPMC output clock, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC_CONFIG5_i[4-0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC output clock.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

12.3.4.3.8.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the GPMC_WAIT pin is at a valid state two GPMC output clock cycles before WRACCESSTIME completes. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC output clock rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC output clock edge for a synchronous write access. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

12.3.4.3.8.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field (where i = 0 to 3) can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

12.3.4.3.8.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

12.3.4.3.8.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC output clock edge in synchronous write mode. For more information about wait monitoring, see [Section 12.3.4.3.7.3.1, WAIT Pin Monitoring Control](#).

12.3.4.3.8.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

12.3.4.3.9 GPMC NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (where i = 0 to 3). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit where (i = 0 to 3).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC output clock (CLK), RdAccessTime, WrAccessTime, and WAIT pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

Note

The address bus and nBE[1-0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

12.3.4.3.9.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC output clock is not provided outside the GPMC and is kept low.

12.3.4.3.9.1.1 Access on Address/Data Multiplexed Devices

12.3.4.3.9.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-272](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.4.3.7.2.3, Address/Data-Multiplexing Interface](#).

Address bits (A[16-1] from a GPMC perspective, A[15-0] from an external device perspective) are placed on the address/data bus, and the remaining address bits are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit field. It controls the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
 - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
 - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see [Section 12.3.4.3.9.5, System Burst Versus External Device Burst Support](#).

Between two successive accesses, if an nCS pulse is needed:

- The GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

12.3.4.3.9.1.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-272](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see [Section 12.3.4.3.7.2.3, Address/Data-Multiplexing Interface](#).

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
 - nWE assertion indicates a write cycle.
 - nWE assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME bit field.
 - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12-8] WRCYCLETIME parameter.

Address bits A[16-1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS time.

Note

Multiple write access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 12.3.4.3.8.10, Bus Keeping Support](#).

12.3.4.3.9.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 12.3.4.3.9.3, Asynchronous and Synchronous Accesses in non-multiplexed Mode](#).

12.3.4.3.9.1.2 Access on Address/Address/Data-Multiplexed Devices

12.3.4.3.9.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-272](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
 - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME bit field.
 - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
 - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
 - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME bit field.
 - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
 - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

12.3.4.3.9.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-272](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See [Table 12-263, NAND Memory Type](#).

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
 - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
 - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME bit field.
 - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
 - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
 - nOE assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
 - nOE deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS parameter.

12.3.4.3.9.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 12.3.4.3.9.3, Asynchronous and Synchronous Accessed in non-multiplexed Mode](#).

12.3.4.3.9.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (non-multiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on non-multiplexed devices, see [Section 12.3.4.3.9.3, Asynchronous and Synchronous Accessed in non-multiplexed Mode](#).

In synchronous operations:

- The GPMC_CLKOUT clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLKOUT clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field. In the following section *i* stands for the chip-select number, *i* = 0 to 3.
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME bit field specifies that the GPMC_CLKOUT is provided outside the GPMC for 0 to 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

12.3.4.3.9.2.1 Synchronous Single Read

For formulas to calculate timing parameters, see [Section 12.3.4.4.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-272](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.4.3.7.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
 - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
 - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC_CONFIG5_i[4-0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

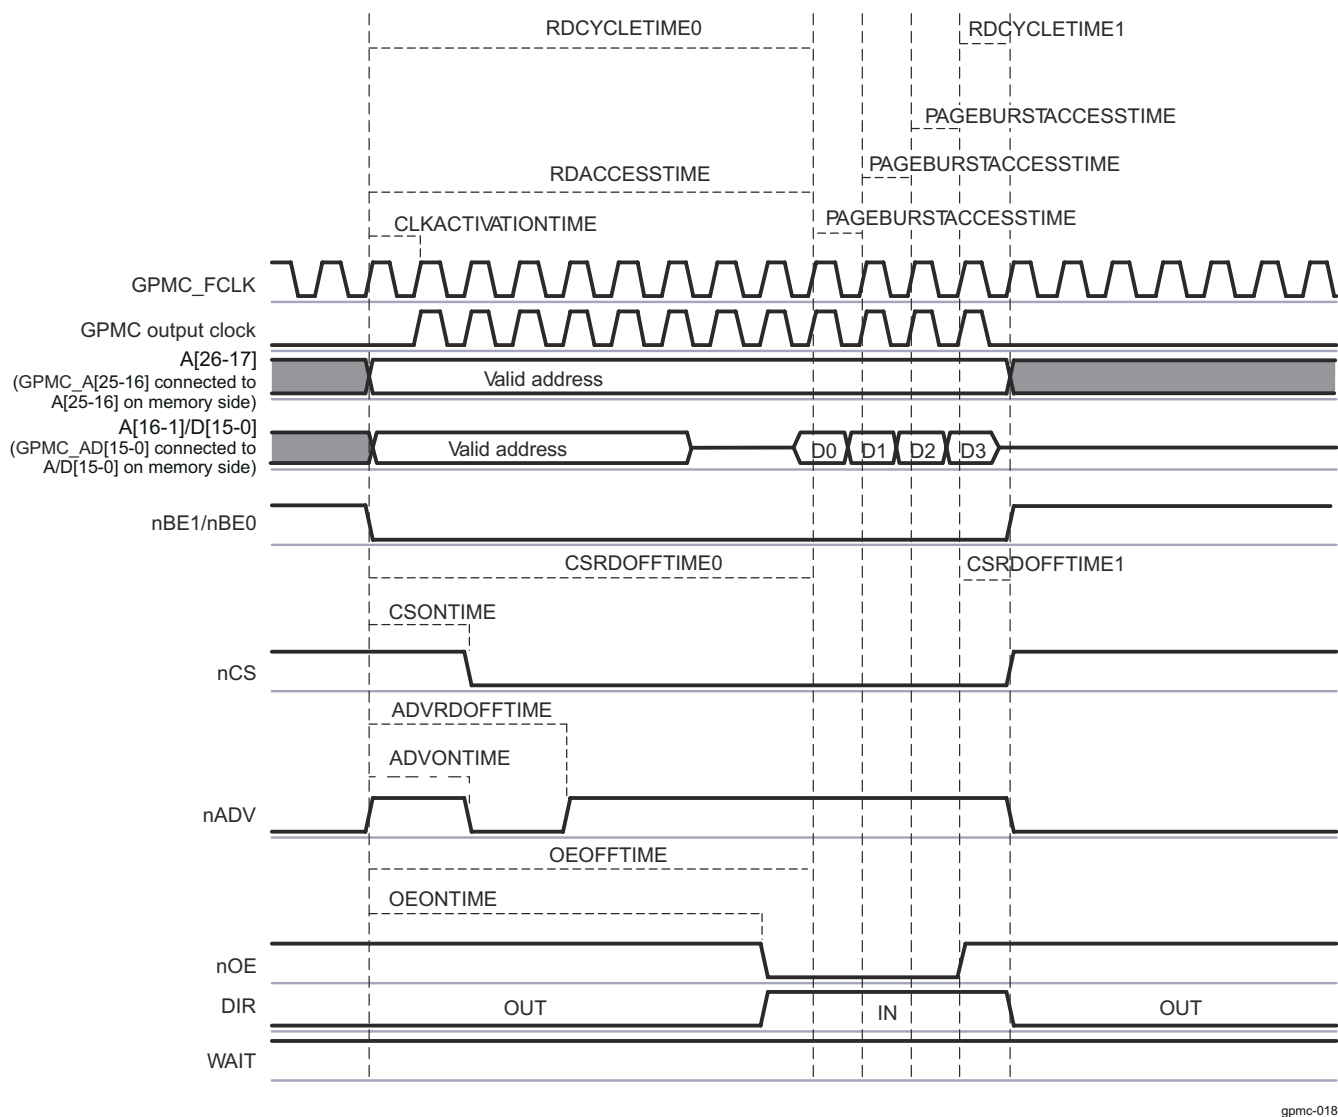

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.

- nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME bit field.
- nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
- nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
 - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME bit field.
 - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
 - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 12.3.4.3.8.10, Bus Keeping Support](#).

12.3.4.3.9.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

[Figure 12-137](#) and [Figure 12-138](#) show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

gpmc-018

Figure 12-137. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

gpmc-019

Figure 12-138. Synchronous Multiple (Burst) Read (GPMCCLKDIVIDER = 1)

When the GPMC_CONFIG5_i[20-16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See [Table 12-258, NOR Memory Type](#).

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC_CLKOUT cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC_CONFIG1_i[1-0] GPMCCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In [Figure 12-138](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 12.3.4.3.8.10, Bus Keeping Support](#).

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word linear burst access to wrap within its burst-length boundary through the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field.

12.3.4.3.9.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16-1]) until the GPMC_CONFIG6_I[19-16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

12.3.4.3.9.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 12-139 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 12-139. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

Figure 12-140 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

Figure 12-140. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

The first data of the burst is driven on the A/D bus at the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS bit field.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.4.3.7.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME bit field (where i = 0 to 3) and ensures address setup time to nCS assertion.
 - nCS deassertion time controlled by the GPMC_CONFIG2_i[20-16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
 - nADV deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME bit field.
- Write enable signal nWE:

- nWE assertion indicates a read cycle.
- nWE assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME bit field.
- nWE deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME bit field.

Note

The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME bit field.
 - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME bit field.
 - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME bit field.
 - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME bit field.
 - nOE first deassertion time is controlled by the GPMC_CONFIG4_i[15-13] OEAADMUXOFFTIME bit field.
 - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME bit field.
 - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28-24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In [Figure 12-139](#), the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 12.3.4.3.8.10, Bus Keeping Support](#).

12.3.4.3.9.3 Asynchronous and Synchronous Accesses in non-multiplexed Mode

Page mode is available only in non-multiplexed mode.

- Asynchronous single-read operation on a non-multiplexed device
- Asynchronous single-write operation on a non-multiplexed device
- Asynchronous multiple- (page mode) read operation on a non-multiplexed device
- Synchronous operations on a non-multiplexed device

12.3.4.3.9.3.1 Asynchronous Single-Read Operation on non-multiplexed Device

The address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus and the 16-bit data is driven onto the data bus D[15-0].

Read data is latched at GPMC_CONFIG1_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4-0] RDCYCLETIME parameter.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 12-263](#), *NAND Memory Type*).

12.3.4.3.9.3.2 Asynchronous Single-Write Operation on non-multiplexed Device

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 12-263](#)).

12.3.4.3.9.3.3 Asynchronous Multiple (Page Mode) Read Operation on non-multiplexed Device

[Figure 12-141](#) shows an asynchronous multiple-read operation on a non-multiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

gpmc-014

Figure 12-141. Asynchronous Multiple (Page Mode) Read

Note

The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 12-263](#)).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20-16] RDACCESSTIME completion time (where i = 0 to 3). The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4-0] RDCYCLETIME bit field.
- In [Figure 12-141](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

12.3.4.3.9.3.4 Synchronous Operations on a non-multiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 12.3.4.4.3, GPMC Configuration in NOR Mode](#).

12.3.4.3.9.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITEMULTIPLE bits (where i = 0 to 3) are associated with the READTYPE and WRITETYPE parameters.

Note

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

12.3.4.3.9.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 3). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (where i = 0 to 3) must be set to 1. Similarly

DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), WAIT pin monitoring must be enabled to dynamically control data access completion within the burst.

Note

When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

12.3.4.3.10 GPMC pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[11-10] DEVICETYPE bit field (where i = 0 to 3) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

12.3.4.3.11 GPMC NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

12.3.4.3.11.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model depends on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

12.3.4.3.11.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 3) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in [Table 12-233](#). Failure to comply with these settings corrupts the NAND interface protocol.

Table 12-233. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] ⁽¹⁾	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26-25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24-23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19-18]	Don't care	Wait not monitored by GPMC access engine

Table 12-233. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
WAITPINSELECT	GPMC_CONFIG1_i[17-16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13-12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11-10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9-8]	0b00	non-multiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1-0]	Don't care	Asynchronous mode

(1) $i = 0$ to 3

The GPMC_CONFIG1_i to GPMC_CONFIG4_i registers (where $i = 0$ to 3) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

12.3.4.3.11.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (where $i = 0$ to 3) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations must be posted for faster operations (where $i = 0$ to 3). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers (where $i = 0$ to 3) are 32-bit word locations, which means any 32- or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC_NAND_COMMAND_i and a GPMC_NAND_ADDRESS_i (where $i = 0$ to 3) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

12.3.4.3.11.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i location (where i = 0 to 3) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 12-142 shows the NAND command latch cycle.

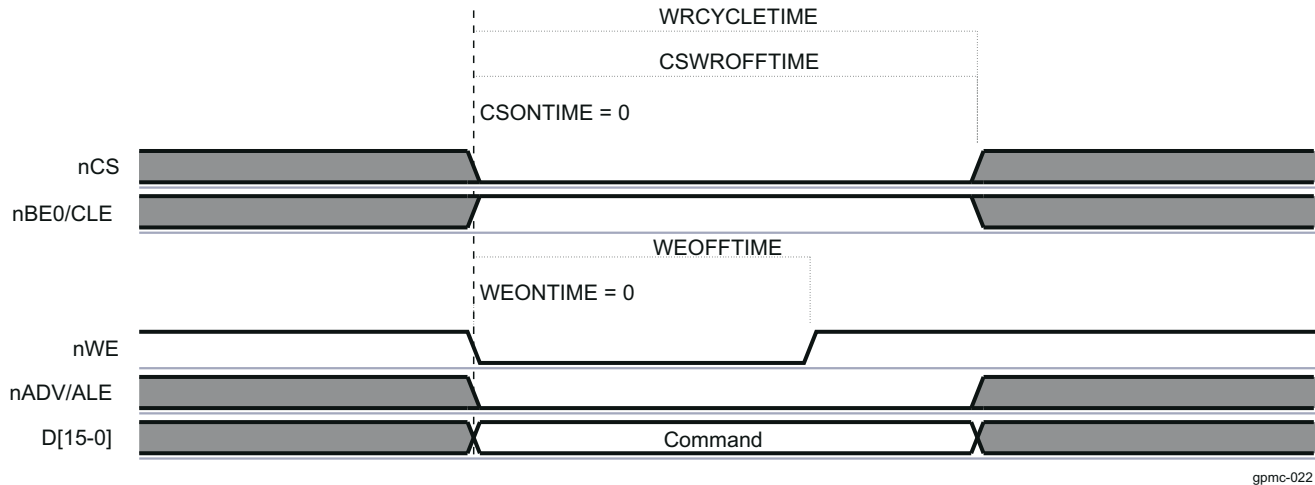

Figure 12-142. NAND Command Latch Cycle

Note

CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

12.3.4.3.11.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (where i = 0 to 3) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 12-143 shows the NAND address latch cycle.

Figure 12-143. NAND Address Latch Cycle

Note

ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

12.3.4.3.11.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (where $i = 0$ to 3) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 12-144 shows the NAND data read cycle.

Figure 12-144. NAND Data Read Cycle

Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CS ONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WE ONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 12-145 shows the NAND data write cycle.

Figure 12-145. NAND Data Write Cycle

12.3.4.3.11.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see [Section 12.3.4.3.11.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMEECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

12.3.4.3.11.1.7 Read and Write Access Size Adaptation

12.3.4.3.11.1.7.1 8-Bit-Wide NAND Device

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

12.3.4.3.11.1.7.2 16-Bit-Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

12.3.4.3.11.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

Note

If a read access to a NAND flash is done using WAIT monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the WAIT pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where i = 0 to 3), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 3) of the GPMC_STATUS.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE register bits[11-8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

12.3.4.3.11.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (where x = 0 to 3). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

12.3.4.3.11.2.2 Ready Pin Monitored by Hardware Interrupt

Each GPMC_WAIT input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (where x = 0 to 3) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 3) of the GPMC_IRQSTATUS register according to the GPMC_WAIT pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the GPMC_WAIT pin used for NAND device ready signal monitoring.

12.3.4.3.11.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhuri-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3-1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

12.3.4.3.11.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

12.3.4.3.11.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3-0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC_ECCj_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZe bits (where j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZe bits are set to 0, and the ECC9RESULTSIZe bit is set to 1.

12.3.4.3.11.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3-1] ECCCS bit field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZe (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

[Table 12-234](#) describes the ECC enable settings.

Table 12-234. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZe (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

12.3.4.3.11.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 12-146 and Figure 12-147. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

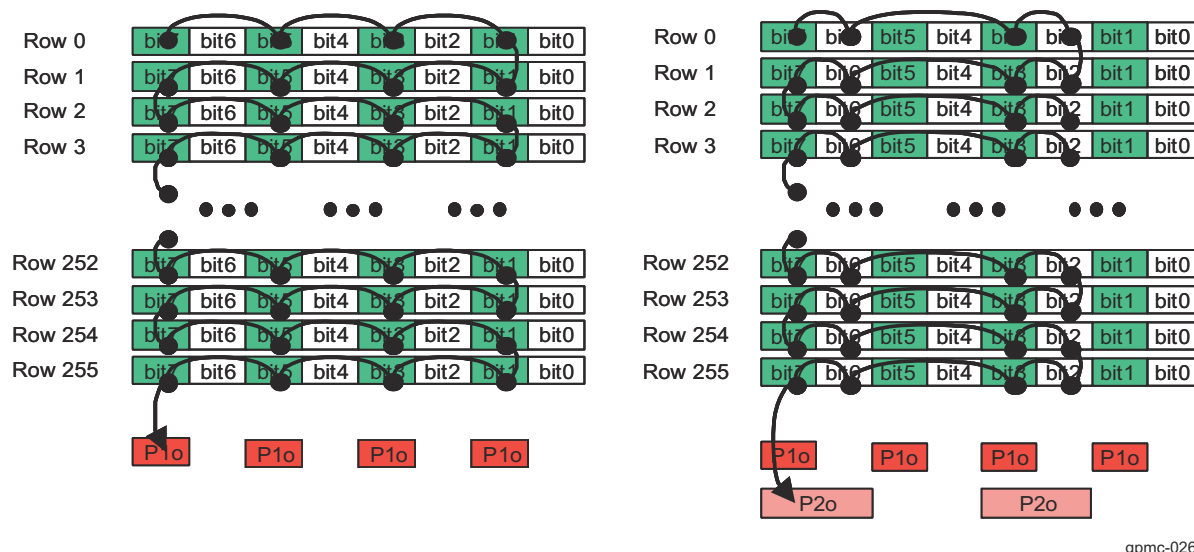

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

gpmc-026

Figure 12-146. Hamming Code Accumulation Algorithm (1/2)

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

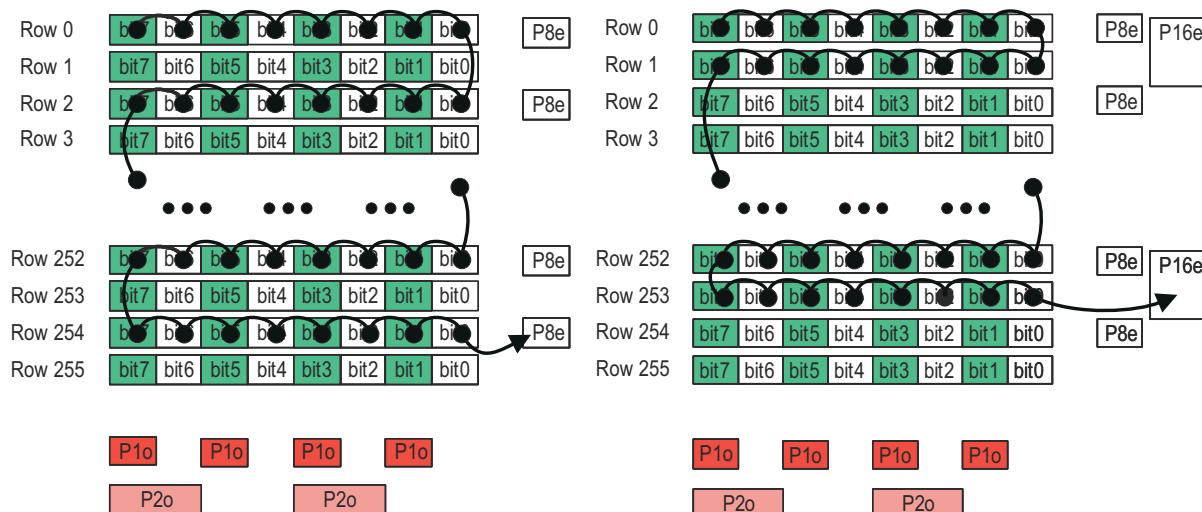

Figure 12-147. Hamming Code Accumulation Algorithm (2/2)

Unused parity bits in the result registers are set to 0.

Figure 12-148 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 12-148. ECC Computation for a 256-Byte Data Stream (Read or Write)

Figure 12-149 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

For a 2-KB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (where j = 1 to 9).

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- #### 12.3.4.3.11.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. [Figure 12-150](#) and [Figure 12-151](#) show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

Figure 12-150. 128 Word16 ECC Computation

Figure 12-151. 256 Word16 ECC Computation

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.

- Typical page write sequence:
 - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy accesses.
 - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
 - NAND writes its cache line (page) to the array.

- Typical page read sequence:
 - Sequential read of a page. ECC is calculated on the fly.
 - The status of the ECC module buffers determines the presence of errors.
- 2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
- 3. Each page can hold up to 4KB of data, spare bytes not included. This means up to 8×512 -byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- 4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
- 5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

12.3.4.3.11.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message $M(x)$. In a standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} - 1 = 4095$, with parameters ranging from M_0 to M_{4095} . For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial $R(x)$ of degree 103 (or 51, depending on the selected mode). The complete codeword $C(x)$ is the concatenation of $M(x)$ and $R(x)$, as described in [Table 12-235](#).

Table 12-235. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

Bit Number	Message $M(x)$			ECC $R(x)$		
	M_{4095}	...	M_0	R_{103}	...	R_0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message $M(x)$ of degree $((512 + 3) \times 8) - 1 = 4119$, for a total of $3 + 13 = 16$ spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where $i = 0$ to 3):

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

12.3.4.3.11.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte b_7 - b_0 (with b_0 the LSB) represents a segment of polynomial $b_7 * x^{(7+i)} + b_6 * x^{(6+i)} + \dots + b_0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

Note

The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 12-236 and Table 12-237 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset module 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2¹²–1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

Table 12-236. Aligned Message Byte Mapping in 8-Bit NAND

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

Table 12-237. Aligned Message Byte Mapping in 16-Bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 12-238 through Table 12-243 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

Table 12-238. Aligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble

...
(S + 3) / 2 – 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S + 3) / 2 – 2			Nibble 0 (LSB)	

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

12.3.4.3.11.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.

- The completed line buffer is then written to the NAND array.

12.3.4.3.11.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see [Section 12.3.4.3.11.3.2.3, Supported NAND Page Mappings and ECC Schemes](#).

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for $t = 4$ ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

12.3.4.3.11.3.2.2.3.1 Manual Mode (0x0)

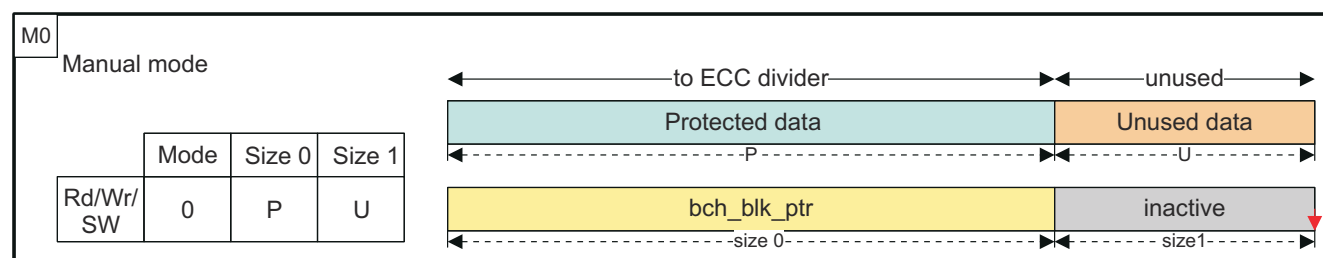

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC_ECC_SIZE_CONFIG[31-22] ECCSIZE1. In the same example, 5 nibbles to process + 3 to discard = 8 nibbles = 2×16 -bit accesses. Software must set:

- GPMC_ECC_SIZE_CONFIG[21-12] ECCSIZE0 = 0x5
- GPMC_ECC_SIZE_CONFIG[31-22] ECCSIZE1 = 0x3

Note

In the following figures, size and size0 are the same parameter.

gpmc-032

Figure 12-152. Manual Mode Sequence and Mapping

Section processing sequence:

- One time with buffer
 - size0 nibbles of data, processing ON
 - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

12.3.4.3.11.3.2.2.3.2 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $S - (\text{size0} + \text{size1})$

12.3.4.3.11.3.2.2.3.3 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - 1 nibble pad spare, processing OFF
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $S - (\text{size0} + 1 + \text{size1})$

12.3.4.3.11.3.2.2.3.4 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $S - (\text{size0} + \text{size1})$

12.3.4.3.11.3.2.2.3.5 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $\text{size0} + (S - \text{size1})$

12.3.4.3.11.3.2.2.3.6 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $\text{size0} + (S - \text{size1})$

12.3.4.3.11.3.2.2.3.7 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

12.3.4.3.11.3.2.2.3.8 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

12.3.4.3.11.3.2.2.3.9 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

12.3.4.3.11.3.2.2.3.10 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF

- size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $S - (\text{size0} + 1 + \text{size1})$

12.3.4.3.11.3.2.2.3.12 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $S - (\text{size0} + \text{size1})$

12.3.4.3.11.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 3.4.3.11.3.2.2.1, Memory Mapping of Data Message](#).

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 12-153](#) through [Figure 12-155](#), the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KB + spares; that is, $S = 2$ sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits; that codeword (higher-order bits) is all-zero and implicit during computations.

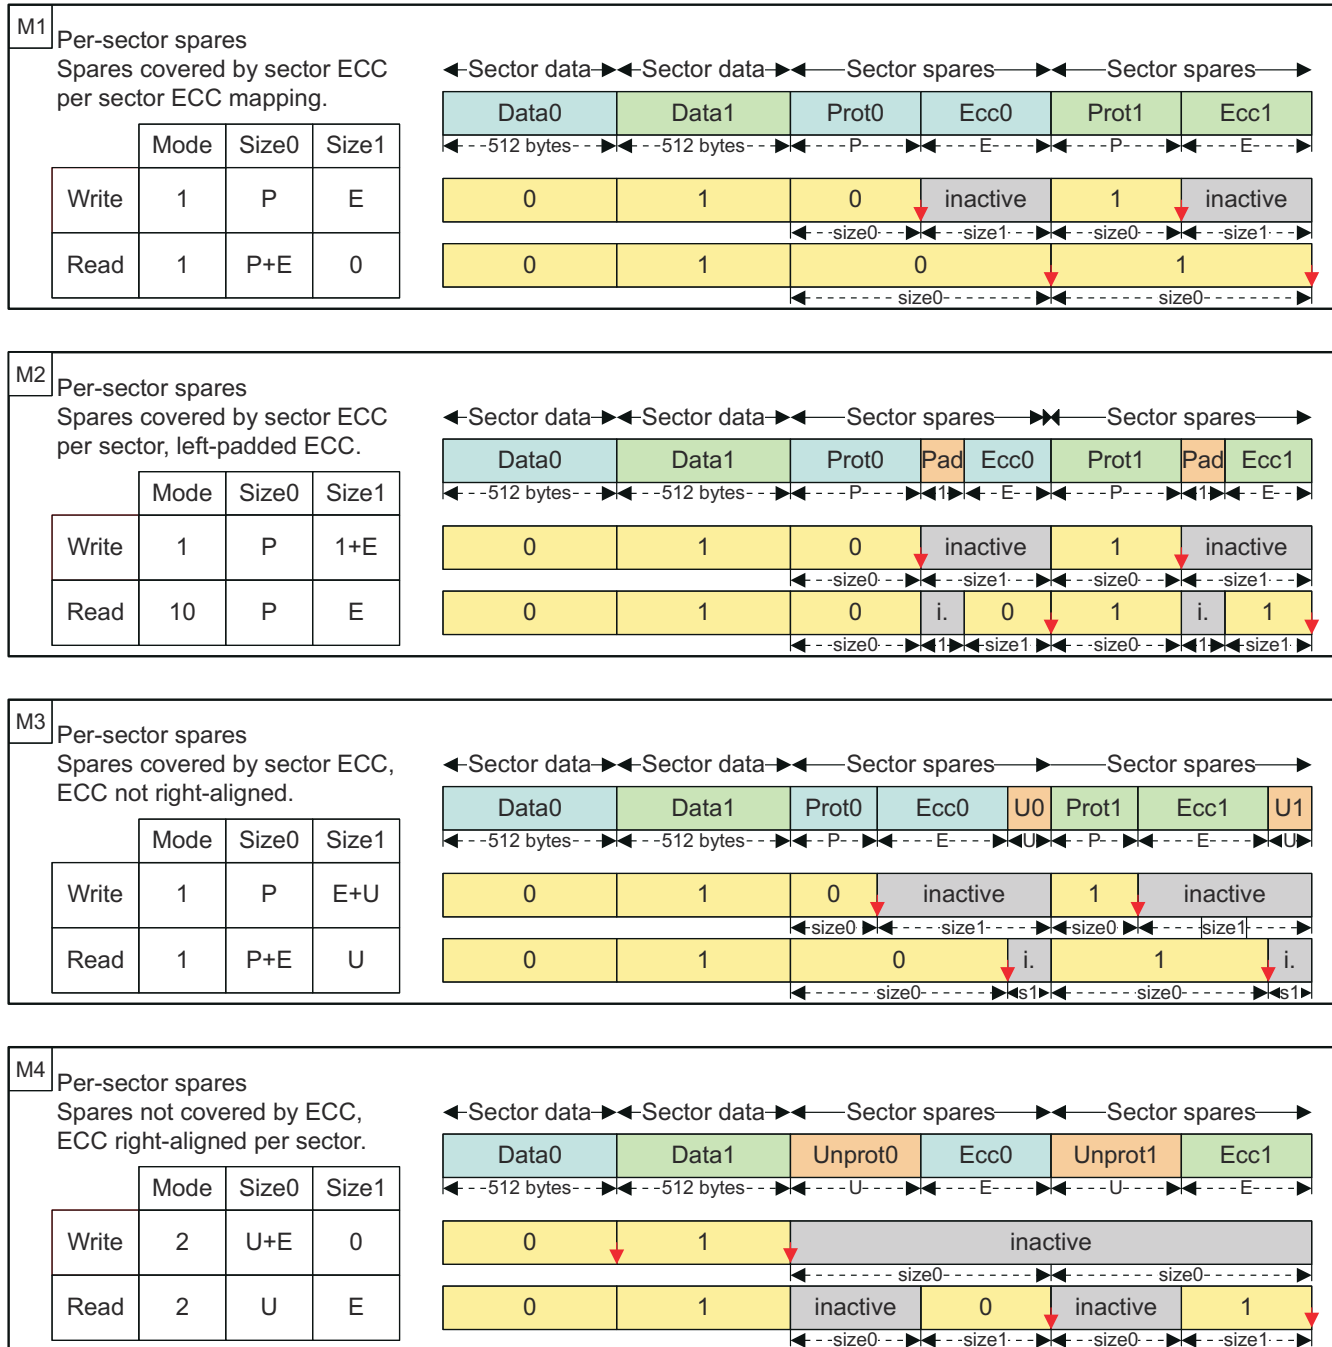

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
 - All sectors: $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
 - Sector 0 codeword: $(512) + P + E$
 - Other sectors: $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
 - All codewords $(512) + E$

12.3.4.3.11.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

gpmc-033

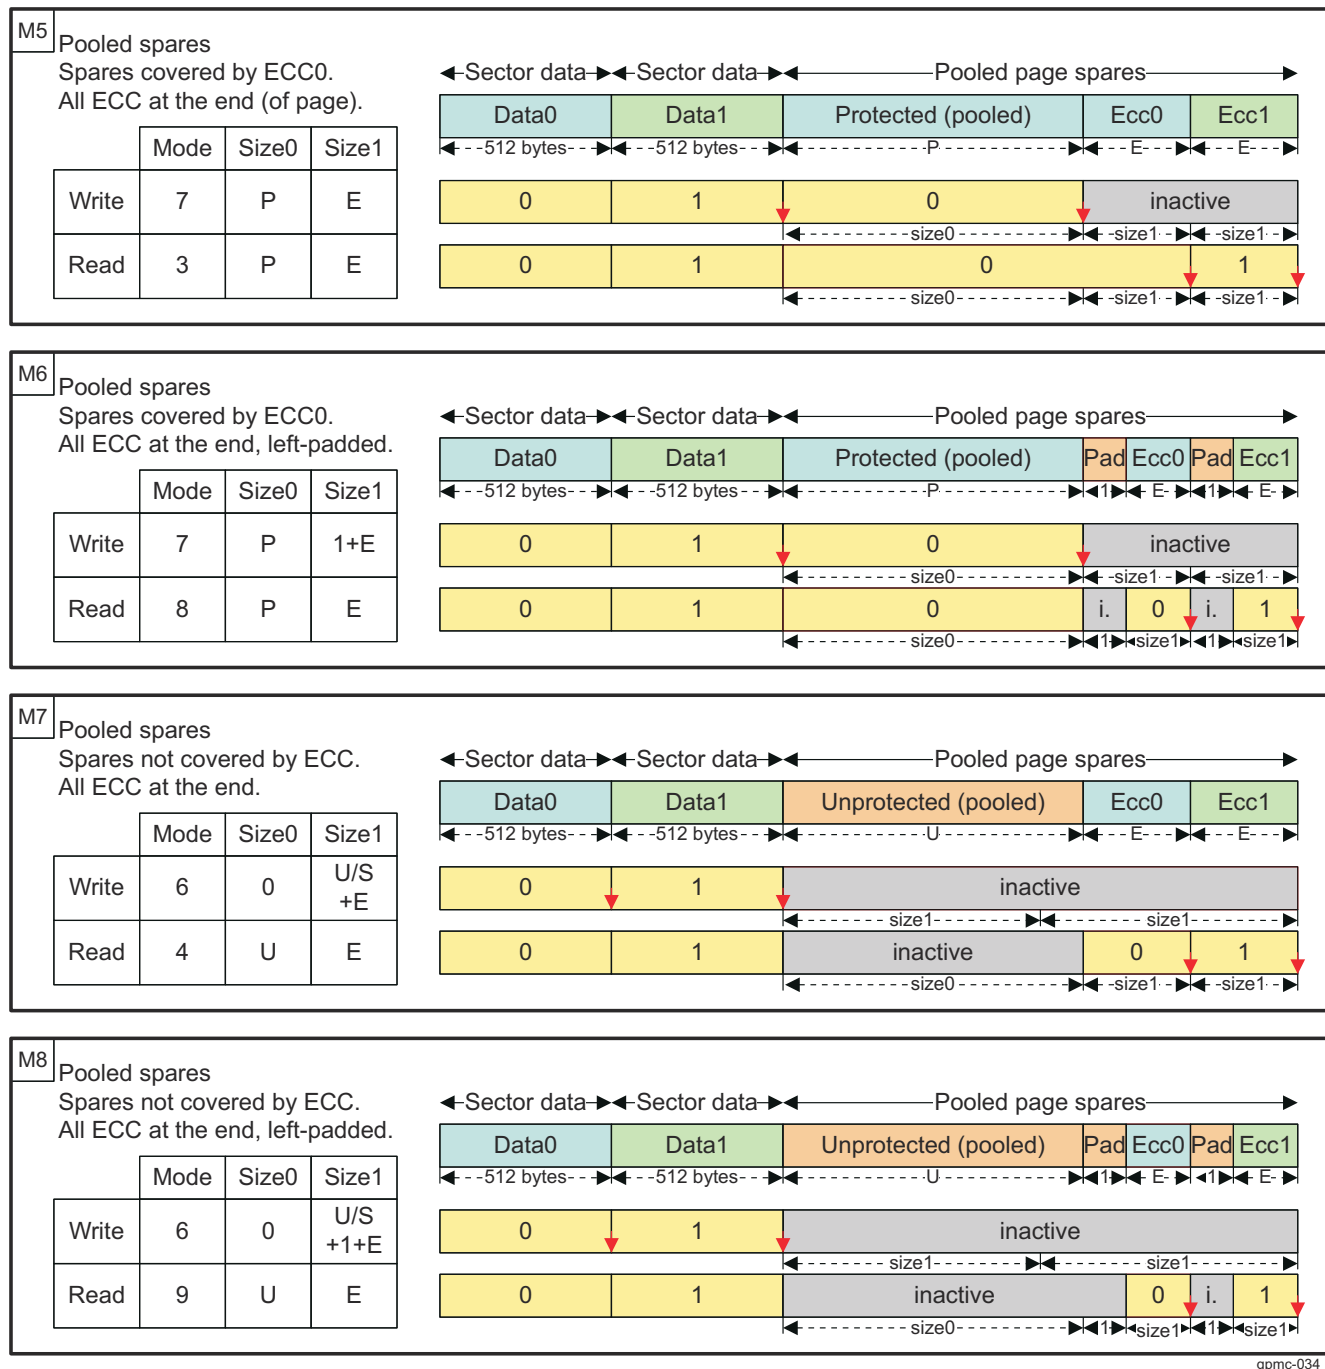

Figure 12-153. NAND Page Mapping and ECC: Per-Sector Schemes

12.3.4.3.11.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.

- The non-ECC spare data may or may not be covered by the ECC of sector 0.

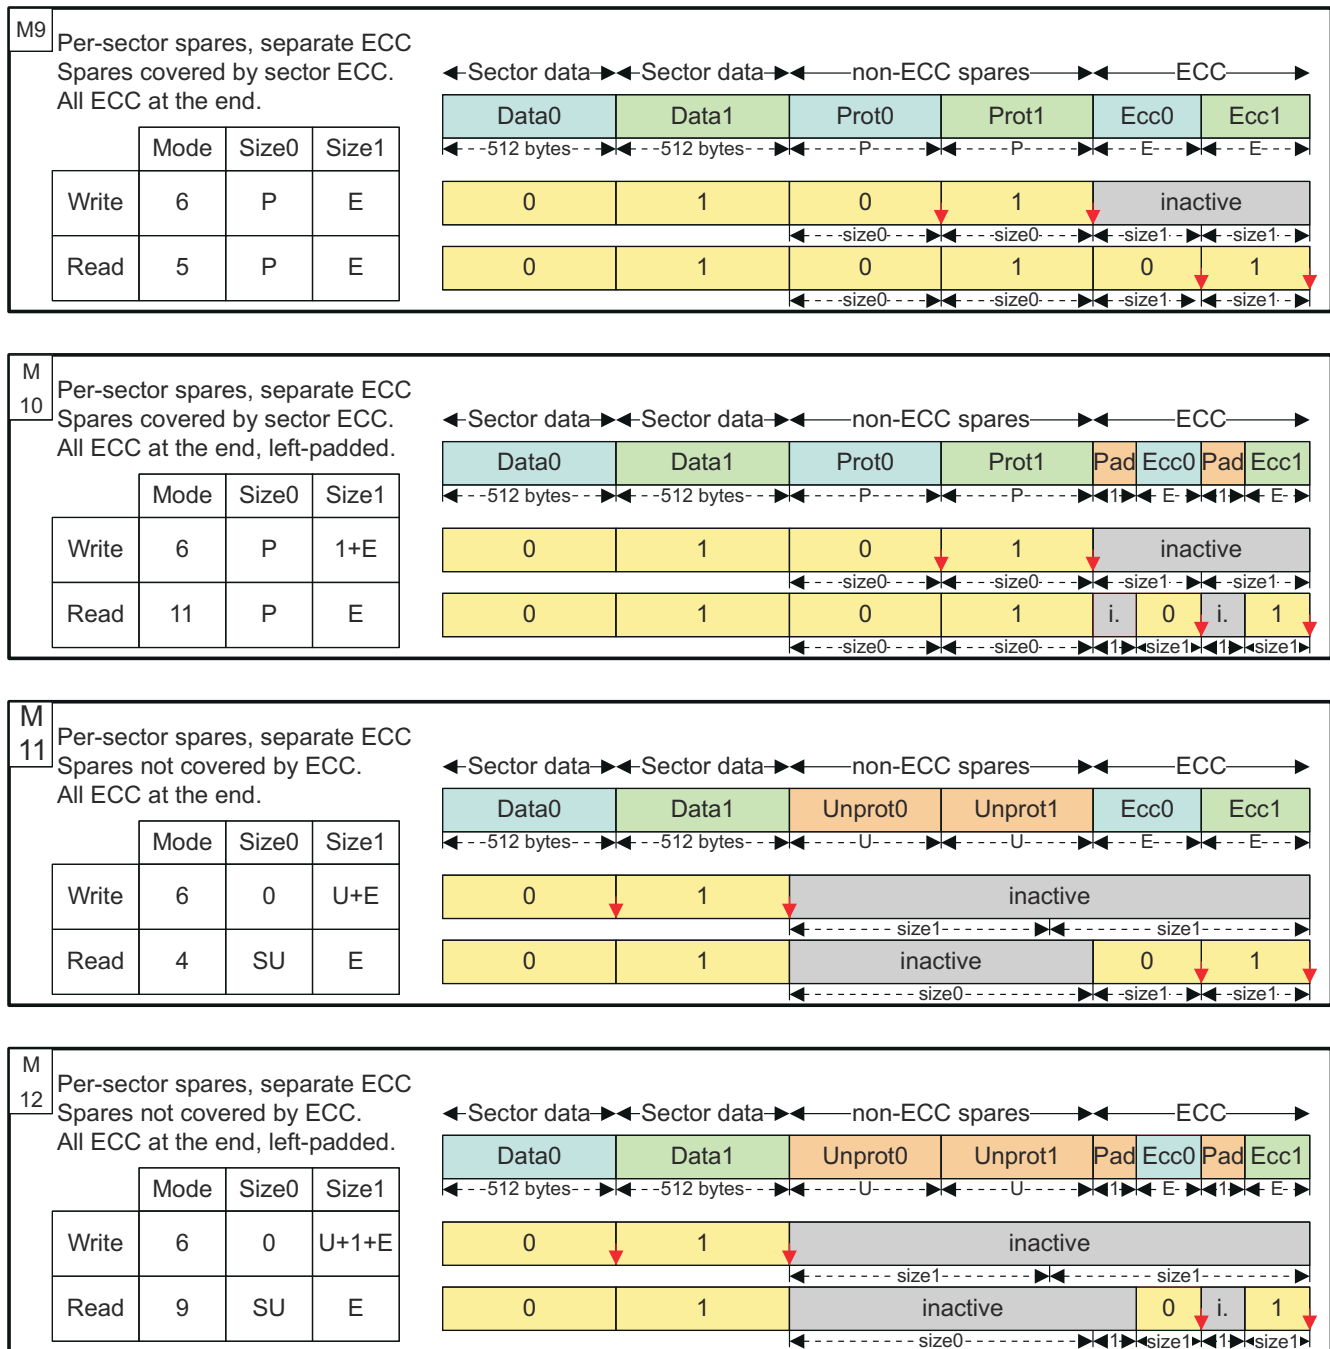

gpmc-034

Figure 12-154. NAND Page Mapping and ECC: Pooled Spare Schemes

12.3.4.3.11.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

12.3.4.3.11.4 Prefetch and Write-Posting Engine

Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

NAND device data access cycles are usually much slower than the CPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system

performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the interconnect interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine depends on the NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write-posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

Note

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

12.3.4.3.11.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 3):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13-0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

12.3.4.3.11.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see [Section 12.3.4.3.11.2.2, Ready Pin Monitored by Hardware Interrupt](#)). The GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR bit field selects which GPMC_WAIT pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT bit field.

[Table 12-244](#) describes the prefetch mode configuration.

Table 12-244. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17-16]	0 to 1	Selects WAIT pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 12.3.4.3.11.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine .
CYCLOOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

12.3.4.3.11.4.3 FIFO Control in Prefetch Mode**Note**

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be drained directly by a device host processor or a DMA module channel.

In draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER bit field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, all the available bytes must be read, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

Note

The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

12.3.4.3.11.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

[Table 12-245](#) describes the write-posting configuration.

Table 12-245. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 12.3.4.3.11.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine .
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

12.3.4.3.11.4.5 FIFO Control in Write-Posting Mode**Note**

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be filled directly by a device host processor or a DMA module channel.

In filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, enough bytes must be written to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

Note

The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, DMA or CPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

12.3.4.3.11.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMEECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i location, where i = 0 to 3) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION bit field defines the number of GPMC_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 12-156 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMEECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION bit field.

Figure 12-156. NAND Read Cycle Optimization Timing Description

12.3.4.3.11.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

12.3.4.3.12 GPMC Use Cases and Tips

12.3.4.3.12.1 How to Set GPMC Timing Parameters for Typical Accesses

12.3.4.3.12.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or non-multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

12.3.4.3.12.1.2 Typical GPMC Setup

Table 12-246 lists some of the I/Os of the GPMC module.

Table 12-246. Typical GPMC Setup Signals

Module Pin	I/O ⁽¹⁾	Description
GPMC0_FCLK	Internal	Functional clock. Acts as the time reference.
GPMC0_ICLK	Internal	Interface clock. Acts as the time reference.
GPMC0_CLKOUT	O	External clock provided to the external device for synchronous operations
	O	Address
GPMC0_AD[15-0]	I/O	Data-multiplexed with addresses A[16-1] on memory side
GPMC0_CSn[3-0]	O	Chip-selects
GPMC0_ADVn_ALE	O	Address valid enable
GPMC0_OEn_REn	O	Output enable (read access only)
GPMC0_WEn	O	Write enable (write access only)
GPMC0_WAIT[3-0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

(1) I = Input; O = Output

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

12.3.4.3.12.1.2.1 GPMC Configuration for Synchronous Burst Read Access

Note

The examples in Section 12.3.4.3.12.1.2.1 through Section 12.3.4.3.12.1.2.3 are based on a clock rate of 104 MHz. See the device-specific Datasheet for the maximum frequency appropriate for this device and the memory datasheet for the maximum frequency for the particular memory device.

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9.615 \text{ ns}$).

Table 12-247 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 12-248 shows how to calculate timings for the GPMC using the memory parameters.

Figure 12-157 shows the synchronous burst read access.

Table 12-247. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3

Table 12-247. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5.2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ($T = 9.615$ ns). The read access time between two bursts of data is $tBACC = 5.2$ ns. Therefore, data setup time is a clock period – $tBACC = 4.415$ ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 12-248. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	$\min(tCES, tACS)$	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	$\text{roundmax}(\text{ClkActivationTime} + tIACC + \text{DataSetupTime})$	94.03: (9.615 + 80 + 4.415)	10: $\text{roundmax}(94.03 / 9.615)$	RDACCESSTIME = 0xA
PageBurst RdAccessTime	$\text{roundmax}(tBACC)$	$\text{roundmax}(5.2)$	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	$\text{RdAccess time} + \max(tCEZ, tOEZ)$	101.03: (94.03 + 7)	11	RDCYCLETIME = 0xB
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	–	11	CSRDOFFTIME = 0xB
AdvOnTime	tAVC ⁽¹⁾	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC ⁽²⁾	12	2	ADVRDOFFTIME = 0x2
OeOnTime ⁽³⁾	$(\text{ClkActivationTime} + tACH) < \text{OeOnTime}(\text{ClkActivationTime} + tIACC)$	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0xB

(1) The external clock provided to the NOR flash is not yet available.

(2) $\text{AdvRdOffTime} - \text{AdvOnTime} = tAVD$; thus, $\text{AdvRdOffTime} = tAVD + \text{AdvOnTime} = tAVD + tAVC$.

(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

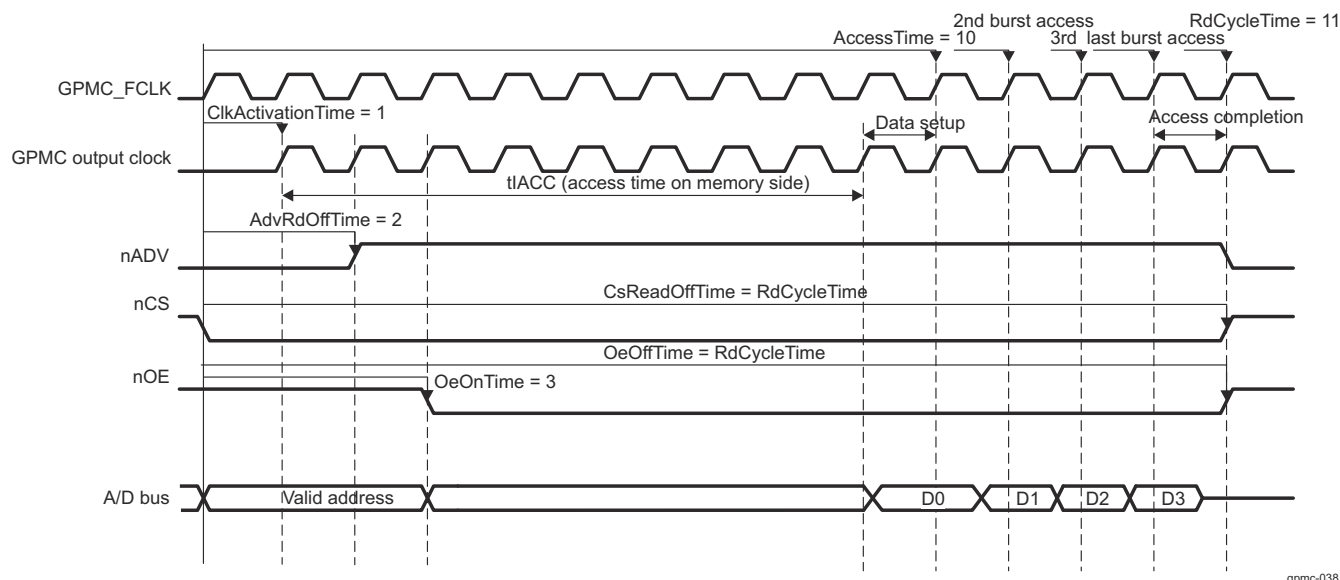

Figure 12-157. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

12.3.4.3.12.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9.615 \text{ ns}$).

Table 12-249 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 12-250 shows how to calculate timings for the GPMC using the memory parameters.

Figure 12-158 shows the asynchronous read access.

Table 12-249. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

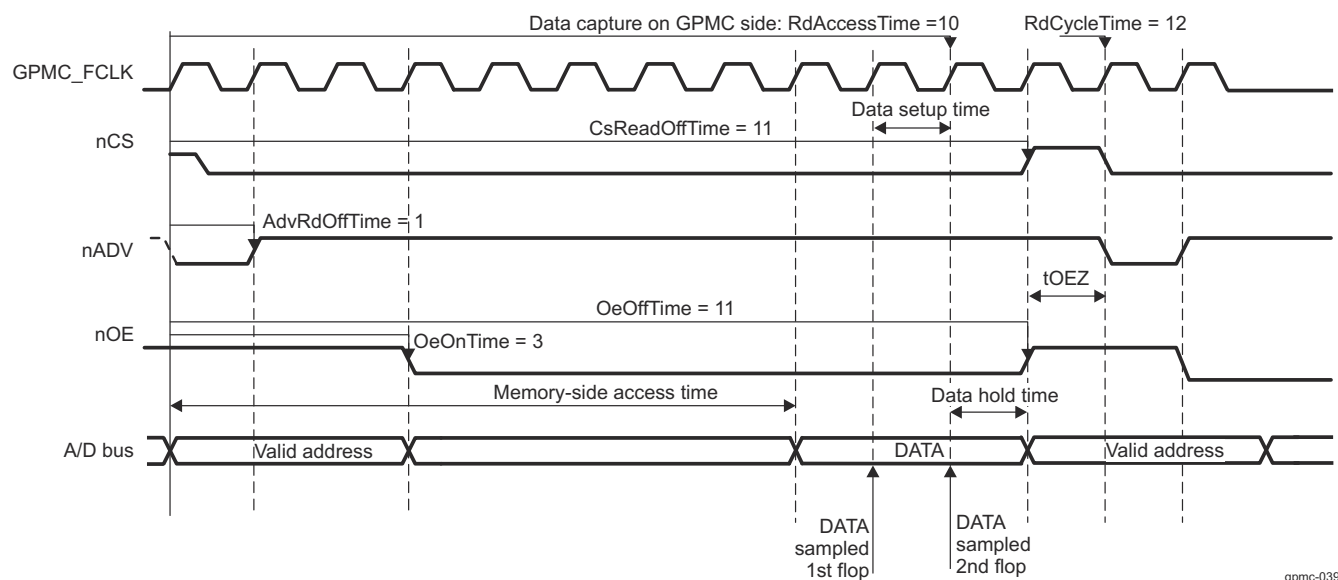

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 12-249: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).
4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.
5. Addresses can now be relatched and a new read cycle begun.

Table 12-250. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = 0xA
PageBurstAccessTime	N/A (single access)			
RdCycleTime	RdAccessTime + 1cycle + tOEZ	96.615	12	RDCYCLETIME = 0xC
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	RdAccessTime + 1 cycle	89.615	11	CSRDOFFTIME = 0xB
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x1
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	RdAccessTime + 1cycle	89.615	11	OEOFFTIME = 0xB

**Figure 12-158. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)****12.3.4.3.12.1.2.3 GPMC Configuration for Asynchronous Single Write Access**

The clock runs at 104 MHz: (f = 104 MHz; T = 9.615 ns).

Table 12-252 shows how to calculate timings for the GPMC using the memory parameters.

Table 12-251 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 12-159 shows the synchronous burst write access.

Table 12-251. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0

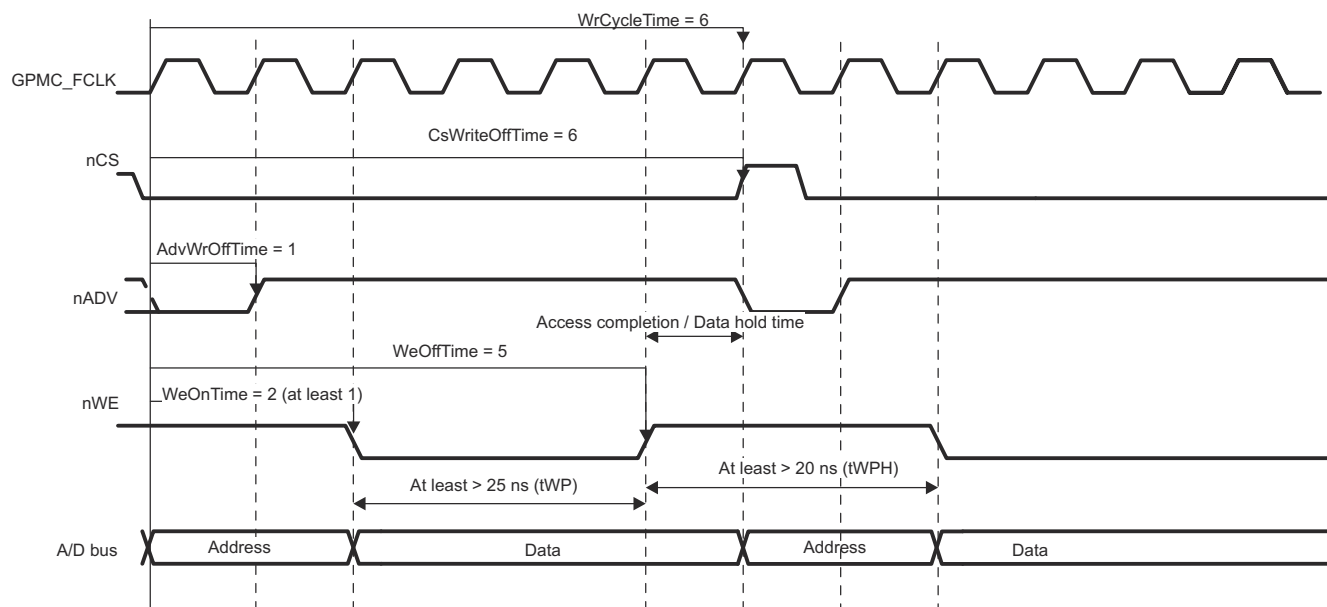

Table 12-251. AC Characteristics for Asynchronous Single Write (Memory Side) (continued)

AC Characteristics on the Memory Side	Description	Duration (ns)
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$. For the AccessCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device-specific Datasheet.

Table 12-252. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		N/A (asynchronous mode)		
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		N/A (single access)		
WrCycleTime	WeOffTime + AccessCompletion	57.615	6	WRCYCLETIME = 0x6
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57.615	6	CSWROFFTIME = 0x6
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x1
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x5

Figure 12-159. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)

12.3.4.3.12.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

12.3.4.3.12.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, and so on)
- 8- and 16-bit NAND flash devices

12.3.4.3.12.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

(1) Addresses seen from the device side. When interfacing to the external device, A1 is connected to the memory A0, A2 to the memory A1, and so on.

12.3.4.3.12.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 12-254 summarizes the NAND interface signals level applied to external device or memories.

Table 12-254. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	nCE	nWE ⁽¹⁾	nRE ⁽¹⁾	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H ⁽²⁾	H ⁽²⁾	H ⁽²⁾	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Standby	x	x	H	x	x	H/L

(1) RE stands for rising edge; FE stands for falling edge

(2) Can be nCE high, or WE and nRE high.

12.3.4.3.12.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited

to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

[Table 12-255](#) summarizes the level of the NOR interface signals applied to external devices or memories.

Table 12-255. NOR Interface Bus Operations Summary

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15-0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

12.3.4.3.12.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

FPGA (Field-Programmable Gate Array) is a low-power integrated circuit based on an array of programmable logic blocks.

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It has synchronous write capability.

12.3.4.4 GPMC Basic Programming Model

12.3.4.4.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

[Figure 12-160](#) and [Table 12-256](#) through [Table 12-257](#) show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

Figure 12-160. Programming Model Top-Level Diagram
Table 12-256. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 12-258 .
NOR Chip-Select Configuration	See Table 12-259 .

Table 12-256. GPMC Configuration in NOR Mode (continued)

Step	Description
NOR Timings Configuration	See Table 12-260 .
WAIT Pin Configuration	See Table 12-268 .
Enable Chip-Select	See Table 12-269 .

Table 12-257. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 12-263 .
NAND Chip-Select Configuration	See Table 12-264 .
Write Operations (Asynchronous)	See Table 12-265 .
Read Operations (Asynchronous)	See Table 12-265 .
ECC Engine	See Table 12-266 .
Prefetch and Write-Posting Engine	See Table 12-267 .
WAIT Pin Configuration	See Table 12-268 .
Enable Chip-Select	See Table 12-269 .

12.3.4.4.2 GPMC Initialization

GPMC can be reset via software bit in LPSC. For more information, see [Section 5.3, Reset](#).

12.3.4.4.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 12-258. NOR Memory Type

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency ⁽¹⁾ .	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	x
Choose an output clock activation time ⁽¹⁾ .	GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations ⁽¹⁾ .	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

(1) Applies only to synchronous configurations (or non-multiplexed asynchronous for multiple access one)

Table 12-259. NOR Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 12-260. NOR Timings Configuration

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See Section 12.3.4.4.6, GPMC Timing Parameters	

Table 12-261. WAIT Pin Configuration

Subprocess Name	Register/Bit Field	Value
Enable or disable WAIT pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable WAIT pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a WAIT pin monitoring time.	GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME	x
Choose the input WAIT pin for the chip-select.	GPMC_CONFIG1_i[17-16] WAITPINSELECT	x

Table 12-262. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

12.3.4.4.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

Table 12-263. NAND Memory Type

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See Section 12.3.4.4.5 , <i>Set Memory Access</i> .	x

Table 12-264. NAND Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select minimum granularity (16MB).	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 12-265. Asynchronous Read and Write Operations

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 12.3.4.4.6 , <i>GPMC Timing Parameters</i> .	

Table 12-266. ECC Engine

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3-0] ECCPOINTER	x ⁽²⁾
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[21-12] ECCSIZE0 and [31-22] ECCSIZE1	x ⁽¹⁾
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZ where j = 1 to 9	x
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3-1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13-12] ECCBCHTSEL and GPMC_ECC_CONFIG[6-4] ECCTOPSECTOR	x

Table 12-266. ECC Engine (continued)

Subprocess Name	Register/Bit Field	Value
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

- (1) Depends on the size of each sector in the NAND page
(2) This parameter depends on the numbers of sectors in a page.

Table 12-267. Prefetch and Write-Posting Engine

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue an interrupt request.	GPMC_PREFETCH_CONFIG1[14-8] FIFOTHRESHOLD	x
Select interrupt synchronization mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

Table 12-268. WAIT Pin Configuration

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x

Table 12-269. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

12.3.4.4.5 Set Memory Access

Note

Some of the GMPC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

This section describes the bit field to configure to set the GPMC in various memory modes. [Table 12-270](#) and [Table 12-271](#) provide check lists for mode parameters and access type parameters, respectively.

Table 12-270. Mode Parameters Check List

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	Don't care	0x1 ⁽¹⁾	Not Supported	0x0	Don't care	0x1	Don't care

Table 12-270. Mode Parameters Check List (continued)

Register	Bit	Name	Asynchronous				Synchronous			
GPMC_CONFIG1_i	29	READTYPE	0x0	Don't care	0x0 ⁽¹⁾	Not Supported	0x1	Don't care	0x1	Don't care
GPMC_CONFIG1_i	28	WRITEMULTIPLE	Don't care	0x0	- ⁽¹⁾	Not Supported	Don't care	0x0	Don't care	0x1
GPMC_CONFIG1_i	27	WRITETYPE	Don't care	0x0	- ⁽¹⁾	Not Supported	Don't care	0x1	Don't care	0x1

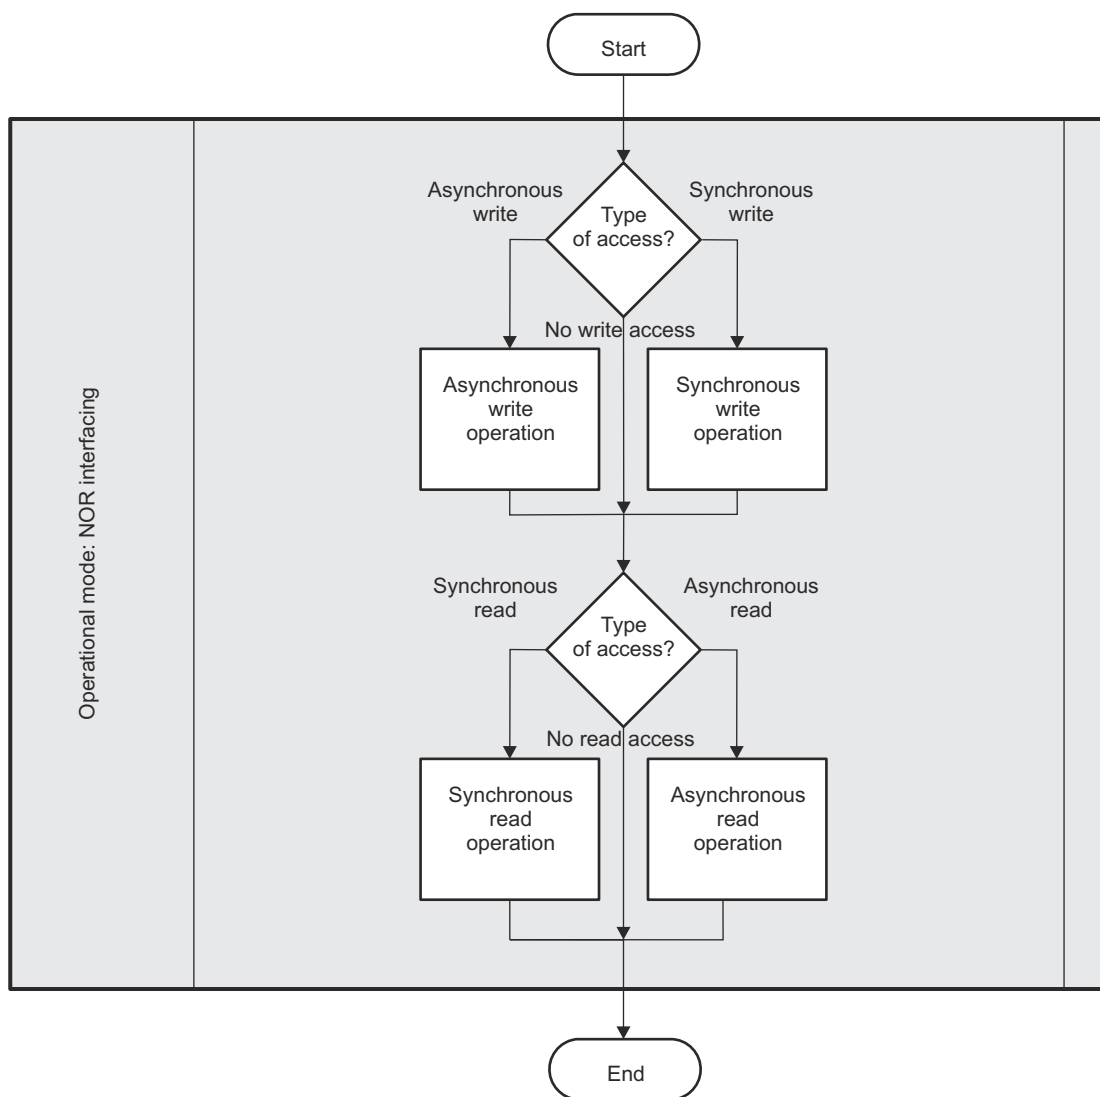

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in non-multiplexed mode.

Table 12-271. Access Type Parameters Check List

Register	Bit	Name	Access Type		
			non-multiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9-8	MUXADDDATA	0x0	0x2	0x1

12.3.4.4.6 GPMC Timing Parameters

Figure 12-161 shows a programming model diagram for the NOR interfacing timing parameters.

12.3.4.4.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device-specific Datasheet.

12.3.4.4.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 0x2. [Table 12-273](#) describes the NAND timing parameters.

Table 12-273. NAND Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – GPMC_WEn valid time
B	ns	Delay time – GPMC_CS valid to GPMC_WEn valid
C	ns	Delay time – GPMC_BE0n_CLE/GPMC_ADVn_ALE high to GPMC_WEn valid
D	ns	Delay time – GPMC_AD[15-0] valid to GPMC_WEn valid
E	ns	Delay time – GPMC_WEn invalid to GPMC_AD[15-0] invalid
F	ns	Delay time – GPMC_WEn invalid to GPMC_BE0n_CLE/GPMC_ADVn_ALE invalid
G	ns	Delay time – GPMC_WEn invalid to GPMC_CS invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – GPMC_CS valid to GPMC_OEn_REn valid
J	ns	Setup time – GPMC_AD[15-0] valid to GPMC_OEn_REn invalid
K	ns	Pulse duration – GPMC_OEn_REn valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – GPMC_OEn_REn invalid to GPMC_CS invalid

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

$$A = (WEOffTime - WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK \text{ period}$$

$$B = ((WEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - CSEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$C = ((WEOnTime - ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - ADVExtraDelay)) * GPMC_FCLK \text{ period}$$

$$D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEEExtraDelay) * GPMC_FCLK \text{ period}$$

$E = (WrCycleTime - WEOffTime * (TimeParaGranularity + 1) - 0.5 * WEEExtraDelay) * GPMC_FCLK \text{ period}$
 $F = (ADVWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay - WEEExtraDelay) * GPMC_FCLK \text{ period}$
 $G = (CSWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSEExtraDelay - WEEExtraDelay) * GPMC_FCLK \text{ period}$
 $H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$
 $I = ((OEOnTime - CSONTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay - CSEExtraDelay)) * GPMC_FCLK \text{ period}$
 $J = ((RdAccessTime - OEOffTime) * (TimeParaGranularity + 1) - 0.5 * OEExtraDelay) * GPMC_FCLK \text{ period}$
 $K = (OEOffTime - OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$
 $L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$
 $M = (CSRdOffTime - OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSEExtraDelay - OEExtraDelay) * GPMC_FCLK \text{ period}$

Figure 12-162 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

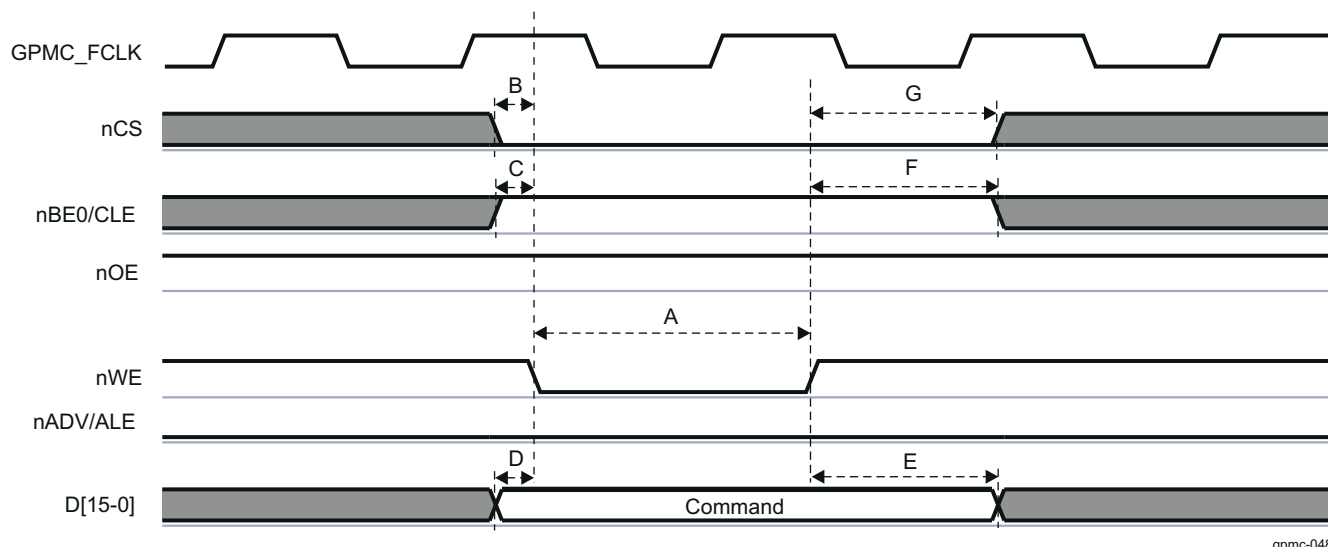

Figure 12-162. NAND Command Latch Cycle Timing Simplified Example

12.3.4.4.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_[11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode. Table 12-274 describes the synchronous NOR formulas.

Table 12-274. Synchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low
B	ns	Delay time – address bus valid to CLK first edge
C	ns	Pulse duration – nBE0 / nBE1 low
D	ns	Delay time – CLK rising edge to nBE0 / nBE1 invalid
E	ns	Delay time – CLK rising edge to nCS invalid
F	ns	Delay time – CLK rising edge to nOE/nRE invalid
G	ns	Delay time – CLK rising edge to nADV/ALE transition
H	ns	Delay time – CLK rising edge to nOE/nRE transition
I	ns	Delay time – CLK rising edge to nWE transition

Table 12-274. Synchronous NOR Formulas Description (continued)

Configuration Parameter	Unit	Description
J	ns	Delay time – CLK rising edge to A[16-1]/D[15-0] data bus transition Delay time – CLK rising edge to nBE0 / nBE1 transition
K	ns	Pulse duration – nADV/ALE low
L	ns	Delay time – WAIT invalid to first data latching CLK edge

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

- For single read accesses:
 $A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
 $C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
 $D = (RDCYCLETIME - RDACCESSTIME) * GPMC_FCLK \text{ period}$
 $E = (CSRDOFFTIME - RDACCESSTIME) * GPMC_FCLK \text{ period}$
- For burst read accesses (where n is the page burst access number):
 $A = (CSRDOFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
 $C = (RDCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
 $D = (RDCYCLETIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK \text{ period}$
 $E = (CSRDOFFTIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK \text{ period}$
- For burst write accesses (where n is the page burst access number):
 $A = (CSWROFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
 $C = (WRCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
 $D = (WRCYCLETIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK \text{ period}$
 $E = (CSWROFFTIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK \text{ period}$
- For all accesses:
 For nCS falling edge (chip-select activated):
 - Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
 $F = 0.5 * CSEXTRADELAY * GPMC_FCLK \text{ period}$
 - Case where GPMCFCLKDIVIDER = 0x1:
 $F = 0.5 * CSEXTRADELAY * GPMC_FCLK \text{ period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)}$
 $F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
 - Case where GPMCFCLKDIVIDER = 0x2:
 $F = 0.5 * CSEXTRADELAY * GPMC_FCLK \text{ period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3}$
 $F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3}$
 $F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3}$
 For nCS rising edge (chip-select deactivated) in reading mode:
 - Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
 $F = 0.5 * CSEXTRADELAY * GPMC_FCLK \text{ period}$
 - Case where GPMCFCLKDIVIDER = 0x1:
 $F = 0.5 * CSEXTRADELAY * GPMC_FCLK \text{ period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)}$
 $F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
 - Case where GPMCFCLKDIVIDER = 0x2:
 $F = 0.5 * CSEXTRADELAY * GPMC_FCLK \text{ period, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3}$

$F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period, when } (CSRDOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period, when } (CSRDOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nCS rising edge (chip-select deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
 $F = 0.5 * CSEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $F = 0.5 * CSEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } CSWROFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } CSWROFFTIME \text{ are even})$
 $F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:
 $F = 0.5 * CSEXTRADELAY * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nADV falling edge (nADV activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
 $G = 0.5 * ADVEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $G = 0.5 * ADVEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVONTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVONTIME \text{ are even})$
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:
 $G = 0.5 * ADVEXTRADELAY * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
 $G = 0.5 * ADVEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $G = 0.5 * ADVEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVRDOFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVRDOFFTIME \text{ are even})$
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:
 $G = 0.5 * ADVEXTRADELAY * GPMC_FCLK \text{ period, when } (ADVRDOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK \text{ period, when } (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK \text{ period, when } (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0:
 $G = 0.5 * ADVEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $G = 0.5 * ADVEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVWROFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVWROFFTIME \text{ are even})$
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:

$G = 0.5 * ADVEXTRADELAY * GPMC_FCLK \text{ period, when } (ADVWROFFTIME - CLKACTIVATIONTIME)$
is a multiple of 3
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK \text{ period, when } (ADVWROFFTIME -$
 $CLKACTIVATIONTIME - 1)$ is a multiple of 3
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK \text{ period, when } (ADVWROFFTIME -$
 $CLKACTIVATIONTIME - 2)$ is a multiple of 3

For nOE falling edge (nOE activated):

- Case where $GPMC_CONFIG1_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where $GPMCFCLKDIVIDER = 0x1$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } OEONTIME \text{ are odd})$ or $(CLKACTIVATIONTIME \text{ and } OEONTIME \text{ are even})$
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where $GPMCFCLKDIVIDER = 0x2$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME)$ is a multiple of 3
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 3
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 3

For nOE rising edge (nOE deactivated):

- Case where $GPMC_CONFIG1_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where $GPMCFCLKDIVIDER = 0x1$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } OEOFFTIME \text{ are odd})$ or $(CLKACTIVATIONTIME \text{ and } OEOFFTIME \text{ are even})$
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where $GPMCFCLKDIVIDER = 0x2$:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME)$ is a multiple of 3
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 3
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 3

For nWE falling edge (nWE activated):

- Case where $GPMC_CONFIG1_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where $GPMCFCLKDIVIDER = 0x1$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } WEONTIME \text{ are odd})$ or $(CLKACTIVATIONTIME \text{ and } WEONTIME \text{ are even})$
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where $GPMCFCLKDIVIDER = 0x2$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME)$ is a multiple of 3
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 3
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 3

For nWE rising edge (nWE deactivated):

- Case where $GPMC_CONFIG1_i[1-0] \text{ GPMCFCLKDIVIDER} = 0x0$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where $GPMCFCLKDIVIDER = 0x1$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } WEOFFTIME \text{ are odd})$ or $(CLKACTIVATIONTIME \text{ and } WEOFFTIME \text{ are even})$

- $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period otherwise.
- Case where $GPMC_FCLKDIVIDER = 0x2$:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME)$ is a multiple of 3
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME - 1)$ is a multiple of 3
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK$ period, when $(WEOFFTIME - CLKACTIVATIONTIME - 2)$ is a multiple of 3

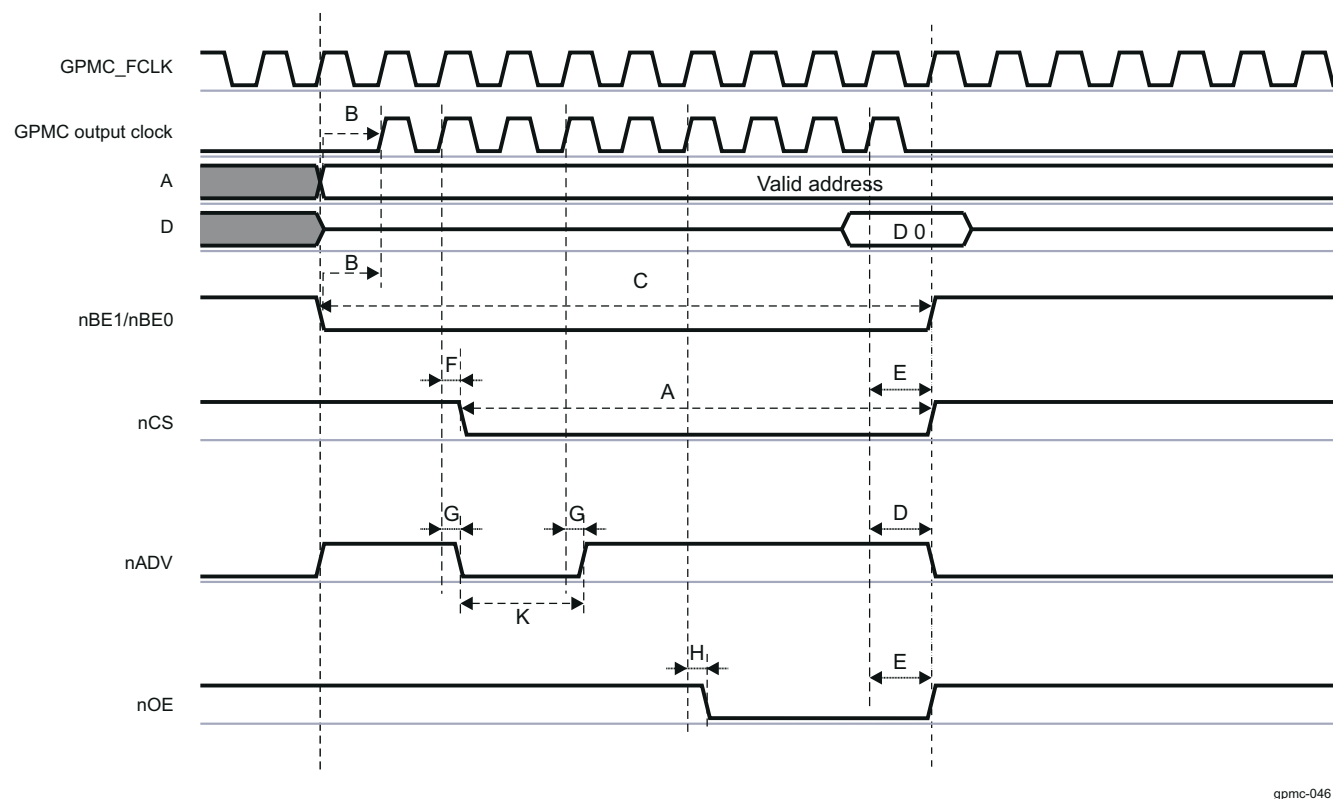

For nADV low pulse duration:

- Read operation:
 $K = (ADVRDOFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK$ period
- Write operation:
 $K = (ADVWROFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK$ period

For WAIT invalid to first data latching GPMC output clock edge:

- $L = WAITMONITORINGTIME * (GPMC_FCLKDIVIDER + 1) * GPMC_FCLK$ period + GPMC output clock period

Figure 12-163 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

gpmc-046

Figure 12-163. Synchronous NOR Single Read Simplified Example

12.3.4.4.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when $GPMC_CONFIG1_i[11-10]$ DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 12-275 describes the asynchronous NOR formulas.

Table 12-275. Asynchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low

Table 12-275. Asynchronous NOR Formulas Description (continued)

Configuration Parameter	Unit	Description
B	ns	Delay time – nCS valid to nADV/ALE invalid
C	ns	Delay time – nCS valid to nOE/nRE invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – nCS valid to nWE valid
F	ns	Delay time – nCS valid to nWE invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before nOE/nRE high
I	ns	Delay time – nCS valid to nOE/nRE invalid (burst read)
J	ns	Delay time – address bus valid to nCS valid Delay time – data bus valid to nCS valid Delay time – nBE0 / nBE1 valid to nCS valid
K	ns	Delay time – nCS valid to nADV/ALE valid
L	ns	Delay time – nCS valid to nOE/nRE valid
M	ns	Delay time – nCS valid to first data latching edge
N	ns	Pulse duration – nBE0 / nBE1 valid time
O	ns	Delay time – nCS valid to nADV/ALE valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device-specific Datasheet.

- nCS low pulse:
For single read: $A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
For burst read: $A = (CSRDOFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$, where N = page burst access number
For single write: $A = (CSWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
For burst write: $A = (CSWROFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$, where N = page burst access number
- nCS valid to nADV/ALE invalid delay:
For reading: $B = ((ADVROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK \text{ period}$
For writing: $B = ((ADVWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK \text{ period}$
- $C = ((OEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK \text{ period}$
- $D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
- $E = ((WEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK \text{ period}$
- $F = ((WEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK \text{ period}$
- $G = CYCLE2CYCLEDELAY * GPMC_FCLK \text{ period}$
- $H = ((OEOFFTIME - RDACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period}$
- $I = ((OEOFFTIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK \text{ period}$, where N = page burst access number
- $J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period}$
- $K = ((ADVONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK \text{ period}$

- $L = ((OEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK \text{ period}$
- $M = ((RDACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) - 0.5 * CSEXTRADELAY) * GPMC_FCLK \text{ period}$
- nBE0 /nBE1 pulse:
For single read: $N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
For burst read: $N = (RDCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$, where N = page burst access number
For burst write: $N = (WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$, where N = page burst access number
- $O = ((WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK \text{ period}$

Figure 12-164 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

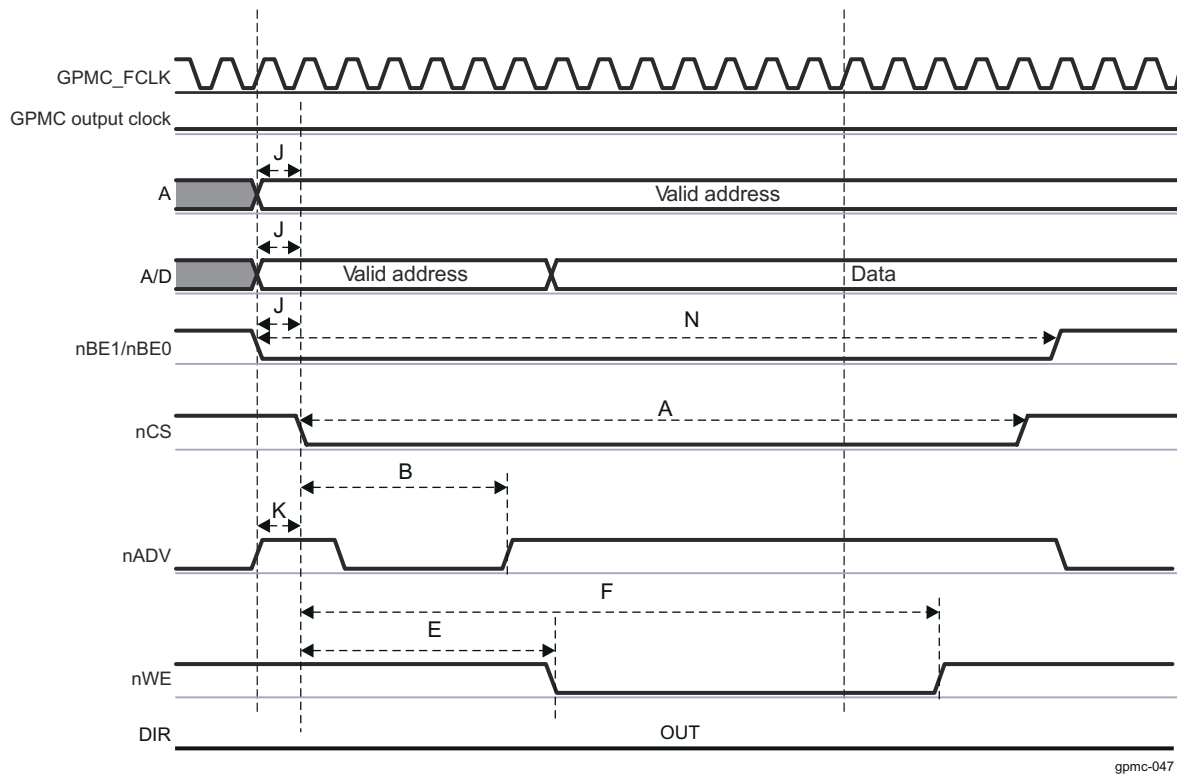

Figure 12-164. Asynchronous NOR Single Write Simplified Example

Note

Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

12.3.5 Error Location Module (ELM)

This section describes the Error Location Module (ELM) for the device.

12.3.5.1 ELM Overview

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. A host processor can then correct the data block by flipping the bits to which the ELM error-location outputs point.

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller. ELM can be also used to support parallel NOR flash or NAND flash.

The General-Purpose Memory Controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The ELM extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM depends on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

12.3.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
 - When the full page has been processed in page mode
 - For each syndrome polynomial in continuous mode.

12.3.5.1.2 ELM Ports

Table 12-276. ELM0 Clocks and Resets

Clocks	
Module Clock Input	Description
ELM_FICLK	ELM functional and interface clock
Resets	
Module Reset Input	Description
ELM_RST	ELM hardware reset

Table 12-277. ELM0 Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
ELM_ELM_POROCPSINTERRUPT_LVL_0	Error-location process complete interrupt	Level

12.3.5.2 ELM Functional Description

The ELM0 module is hereinafter referred to as ELM.

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

12.3.5.2.1 ELM Software Reset

To perform a software reset, set the ELM_SYSCONFIG[1] SOFTRESET bit to 1. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

12.3.5.2.2 ELM Power Management

Note

Some of the ELM features described in this section may not be supported on this family of devices. For more information, see *ELM Not Supported Features*.

Table 12-278 describes the power-management features available to the ELM.

Table 12-278. Local Power-Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FICLK clock upon the interface activity.
Idle modes	ELM_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained.

12.3.5.2.3 ELM Interrupt Requests

Table 12-279 lists the event flags, and their masks, that can cause module interrupts asserting the signal.

Table 12-279. ELM Events

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

12.3.5.2.4 ELM Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL bit field defines the error-correction level used

(4-, 8-, or 16-bit error correction). The ELM_LOCATION_CONFIG[26-16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

12.3.5.2.5 ELM Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION bit field; the second is logged in the ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION bit field, and so on.

Table 12-280 describes the ELM_LOCATION_STATUS_i value decoding.

Table 12-280. ELM_LOCATION_STATUS_i Value Decoding

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

12.3.5.2.6 ELM Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. Software must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, software must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bits. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

Note

Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM_IRQSTATUS bits to check for their status.

12.3.5.3 ELM Basic Programming Model

12.3.5.3.1 ELM Low-Level Programming Model

12.3.5.3.1.1 Processing Initialization

Table 12-281. ELM Processing Initialization

Step	Register/Bit Field/Programming Model	Value
Resets the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management.	ELM_SYSCONFIG[4-3] SIDLEMODE	Set value
Defines the error-correction level used.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length.	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode.	ELM_PAGE_CTRL	Set value
IF continuous mode is used:	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x0
Enable interrupt for syndrome polynomial i.	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
ELSE (page mode is used):	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value
ENDIF		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

12.3.5.3.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 12-282](#) and [Table 12-283](#) describe the processing completion for continuous and page modes, respectively.

Table 12-282. ELM Processing Completion for Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
IF the process fails (too many errors):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
ELSE (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
ENDIF		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 12-283. ELM Processing Completion for Page Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
IF the process fails (too many errors): It is software dependent.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
ELSE (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
ENDIF		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

12.3.5.3.1.3

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

12.3.5.3.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see [Table 12-284](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980.

Table 12-284. Use Case: Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Reset the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	0x2
Define the error-correction level used: 8 bits.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	0x1
Define the maximum buffer length: 528 bytes (2 × 528 = 1056).	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	0x420
Set the ELM in continuous mode.	ELM_PAGE_CTRL	0
Enable interrupt for syndrome polynomial 0.	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0x0000000A
Initiate the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1

Table 12-284. Use Case: Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial 0: is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 12-285](#) are given in decimal format.

Table 12-285. 16-Bit NAND Sector Buffer Address Map

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

12.3.5.3.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for a 16-bit error-correction capability in page mode (see [Table 12-286](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

Table 12-286. Use Case: Page Mode

Step	Register/Bit Field/Programming Model	Value
Reset the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	0x2
Define the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	0x2
Define the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	0x420
Set the ELM in page mode (four blocks in a page)	ELM_PAGE_CTRL[0] SECTOR_0	0x1
	ELM_PAGE_CTRL[1] SECTOR_1	0x1
	ELM_PAGE_CTRL[2] SECTOR_2	0x1
	ELM_PAGE_CTRL[3] SECTOR_3	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	ELM_IRQENABLE	0x100
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xE0B718EF
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xA329AA05

	ELM_SYNDROME_FRAGMENT_5_i (where i = 2)	0xB86ABCD5
	ELM_SYNDROME_FRAGMENT_6_i (where i = 2)	0x69D9

Table 12-286. Use Case: Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Set the input syndrome polynomial 3.	ELM_SYNDROME_FRAGMENT_0_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_1_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_2_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_4_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_5_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_6_i (where i = 3)	0x0
Initiate the computation process for syndrome polynomial 0	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Initiate the computation process for syndrome polynomial 1	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 1)	0x1
Initiate the computation process for syndrome polynomial 2	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 2)	0x1
Initiate the computation process for syndrome polynomial 3	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 3)	0x1
Wait until process is complete for syndrome polynomial 0, 1, 2, and 3: Wait until the interrupt is generated or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Read the process exit status for syndrome polynomial 0: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the process exit status for syndrome polynomial 1: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 1)	0x1
Read the process exit status for syndrome polynomial 2: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 2)	0x1
Read the process exit status for syndrome polynomial 3: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 3)	0x1
Read the number of errors for syndrome polynomial 0: four errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 0)	0x4
Read the number of errors for syndrome polynomial 1: two errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 1)	0x2
Read the number of errors for syndrome polynomial 2: one error detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 2)	0x1
Read the number of errors for syndrome polynomial 3: no errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 3)	0x0
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers:	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1FE
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x617
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x650
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the first two registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x4
	ELM_ERROR_LOCATION_1_i (where i = 1)	0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x3E8
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

12.3.6 Multi-Media Card Secure Digital (MMCSD) Interface

This section describes the MMCSD modules in the device.

12.3.6.1 MMCSD Overview

There are two MMCSD modules inside the device - MMCSD0 and MMCSD1. Each MMCSD module includes one MMCSD Host Controller.

Each controller has the following data bus width:

- MMCSD0 - 8-bit wide data bus
- MMCSD1 - 4-bit wide data bus

The MMCSD Host Controller provides an interface to eMMC 5.1 (embedded Multi-Media Card), SD 4.10 (Secure Digital), and SDIO 4.0 (Secure Digital IO) devices. The MMCSD Host Controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit insertion, and checking for syntactical correctness.

The MMCSD Host Controller provides accessibility to external MMC/SD/SDIO devices using a Programmed IO method or DMA data transfer method. In programmed IO method, the device CPU transfers data using the Buffer Data Port register (MMCSD0_DATA_PORT / MMCSD1_DATA_PORT). In DMA data transfer method, the MMCSD Host Controller can read or write memory without device CPU intervention.

12.3.6.1.1 MMCSD Features

Each MMCSD Host Controller supports:

- Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3 (for more information about ADMA support, see [Section 12.3.6.3.5, Advanced DMA](#))
- System Bus Interface:
 - 64-bit data width (master interface)
 - 64-bit address
 - Clock asynchronous to MMCSD clock (MMCi_CLK)
 - Little endian only
- Configuration Bus Interface:
 - 32-bit data width (slave interface)
 - Linear incrementing addressing mode
 - 32-bit aligned accesses only
 - Little endian only
- Muxing of other LVCMOS interfaces onto the MMCSD interface at the SoC level (MMCSD1 only)

MMCSD0 Host Controller (eMMC interface):

- MultiMedia Card Support:
 - eMMC Electrical Standard 5.1 (JESD84-B51)
 - Backward compatible with earlier eMMC standards
 - Legacy MMC SDR:
 - 1.8 V, 8-bit bus width, 0-25 MHz, 25 MBps
 - 1.8 V, 4-bit bus width, 0-25 MHz, 12.5 MBps
 - 1.8 V, 1-bit bus width, 0-25 MHz, 3.125 MBps
 - High Speed SDR:
 - 1.8 V, 8-bit bus width, 0-50 MHz, 50 MBps
 - 1.8 V, 4-bit bus width, 0-50 MHz, 25 MBps
 - 1.8 V, 1-bit bus width, 0-50 MHz, 6.25 MBps
 - High Speed DDR:
 - 1.8 V, 8-bit bus width, 0-50 MHz, 100 MBps
 - 1.8 V, 4-bit bus width, 0-50 MHz, 50 MBps
 - HS200 SDR:
 - 1.8 V, 0-200 MHz, 8-bit bus width, 200 MBps
 - 1.8 V, 0-200 MHz, 4-bit bus width, 100 MBps
 - HS400 DDR:
 - 1.8 V, 0-200 MHz, 8-bit bus width, 400 MBps

MMCSD1 Host Controller (SD/SDIO interface):

-
- Secure Digital Card Support:
 - Backward compatible with earlier SD card specifications
 - SD Host Controller Standard Specification 4.10 and SD Physical Layer Specification v3.01
 - SDIO Specification v3.00
 - Default Speed mode: 3.3 V signaling, frequency up to 25 MHz, up to 12.5 MBps
 - High Speed mode: 3.3 V signaling, frequency up to 50 MHz, up to 25 MBps
 - SDR12: UHS-I 1.8 V signaling, frequency up to 25 MHz, up to 12.5 MBps
 - SDR25: UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 25 MBps
 - SDR50: UHS-I 1.8 V signaling, frequency up to 100 MHz, up to 50 MBps
 - DDR50: UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 50 MBps
 - SDR104: UHS-I 1.8 V signaling, frequency up to 200 MHz, up to 100 MBps

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.3.6.1.2 MMCSD Ports

Table 12-287. MMCSD Clocks and Resets

Clocks	
Module Clock Input	Description
MMCSD_ICLK	MMCSD Interface Clock
MMCSD_FCLK	MMCSD Functional Clock
Resets	
Module Reset Input	Description
MMCSD_RST	MMCSD Asynchronous Reset

Table 12-288. MMCSD Hardware Requests

Interrupt Requests			
Module Interrupt Signal	Description	Type	
MMCSD_EMMCSS_INTR_0	MMCSD Interrupt Request	Level	
MMCSD_EMMCSS_RXMEM_CORR_ERR_LVL_0	MMCSD Receive ECC Correctable Error Interrupt Request	Level	
MMCSD_EMMCSS_RXMEM_UNCORR_ERR_LVL_0	MMCSD Receive ECC Uncorrectable Error Interrupt Request	Level	
MMCSD_EMMCSS_TXMEM_CORR_ERR_LVL_0	MMCSD Transmit ECC Correctable Error Interrupt Request	Level	
MMCSD_EMMCSS_TXMEM_UNCORR_ERR_LVL_0	MMCSD Transmit ECC Uncorrectable Error Interrupt Request	Level	

12.3.6.2 MMCSD Environment

This section describes the MMCSDi external connections (environment).

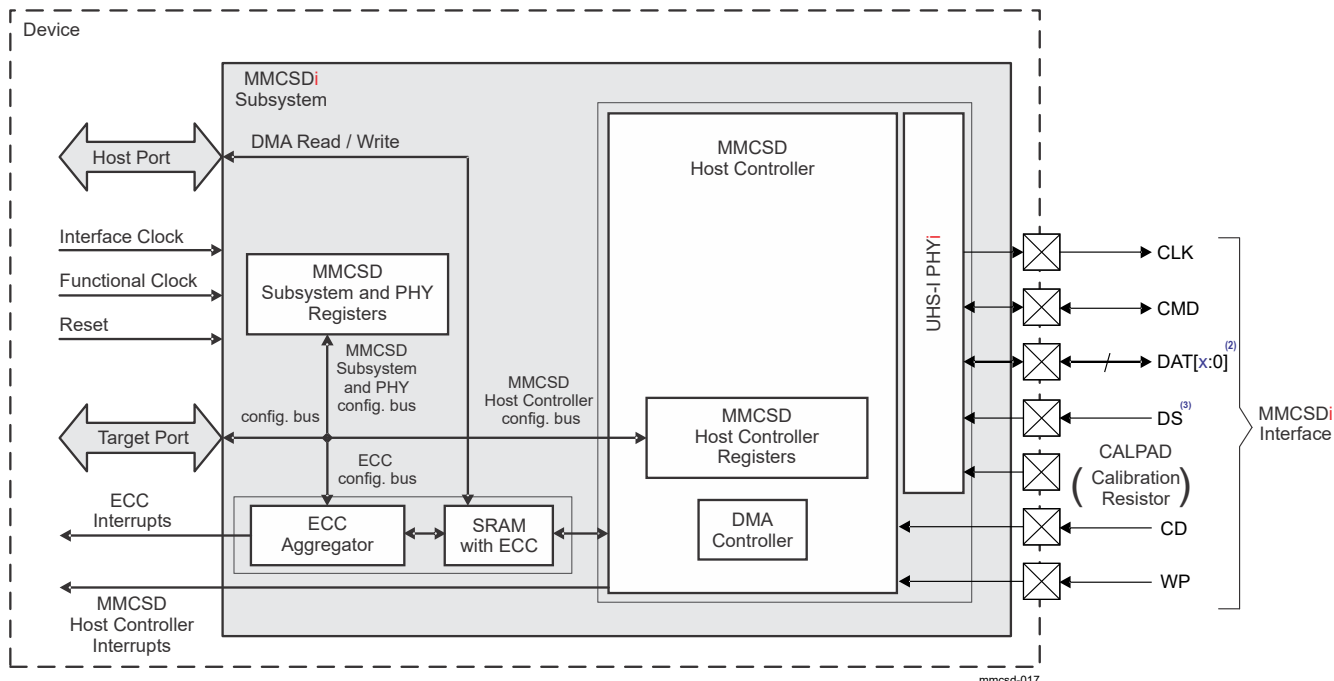

Table 12-289 describes the MMCSDi I/O signals.

Table 12-289. MMCSDi I/O Signals

Module Pin	I/O ⁽¹⁾	Description
DAT[7:0]	I/O	Data Signals
DS	I	Data Strobe
CALPAD	A	PHY Calibration Resistor
CLK	O	External Clock
CMD	I/O	Command Line
DAT[3:0]	I/O	Data Signals
WP	I	SD Card Write Protect
CD	I	SD Card Detect

(1) I = Input; O = Output; HiZ = High Impedance; A = Analog

12.3.6.3.1 Block Diagram

The MMCSD Host Controller can use a Programmed IO method (PIO) or DMA data transfer method to access external MMC/SD/SDIO devices.

The target port is used for device CPU access to the MMCSD Host Controller register set. The MMCSD Host Controller register set provides the communication between the device CPU and the MMCSD Host Controller. In PIO method the device CPU transfers data using the MMCSD0_DATA_PORT / MMCSD1_DATA_PORT register. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the target port, the MMCSD0_DATA_PORT / MMCSD1_DATA_PORT register in the MMCSD Host Controller, and the PHY.

The host port is used for connection to the DMA controller (for more information about ADMA support, see [Section 12.3.6.3.5, Advanced DMA](#) and MMCSD0_CAPABILITIES / MMCSD1_CAPABILITIES register). In DMA data transfer method the DMA controller uses the host port to transfer data between the device memory and the MMCSD Subsystem internal SRAM. The other side of the internal SRAM is connected to the MMCSD Host Controller. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the host port, internal SRAM, MMCSD Host Controller, and the PHY. The DMA controller manages the read/write operations from/to the internal SRAM without device CPU intervention.

12.3.6.3.2 Memory Regions

shows MMCSDi module memory map.

12.3.6.3.3 Interrupt Requests

Each MMCSD instance sources one active high level MMCSD Host Controller interrupt and four active high level ECC Aggregator interrupts (see *MMCSD Hardware Requests*). The MMCSD Host Controller interrupt is generated based on the bit values in the MMCSD0_NORMAL_INTR_STS / MMCSD1_NORMAL_INTR_STS and MMCSD0_NORMAL_INTR_STS_ENA / MMCSD1_NORMAL_INTR_STS_ENA registers. The ECC Aggregator interrupts are generated based on the ECC errors - single and double bit errors (for more information about ECC Aggregator interrupts, see [Section 12.3.6.3.4, ECC Support](#)).

12.3.6.3.4 ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

There are two SRAM memories (transmit SRAM and receive SRAM) within each MMCSD instance. These two memories are ECC protected.

The SEC logic detects and corrects a single bit error (single bit error per ECC word or per ECC data segment). The DED logic only detects (does not correct) double errors (double bit errors per ECC word or per ECC data segment).

12.3.6.3.4.1 ECC Aggregator

There are two SRAMs (each with size 4 KB - 512 words × 64-bit) in each MMCSD Subsystem. One SRAM dedicated for transmit and one SRAM dedicated for receive operations.

[Figure 12-166](#) shows the ECC Aggregator block diagram.

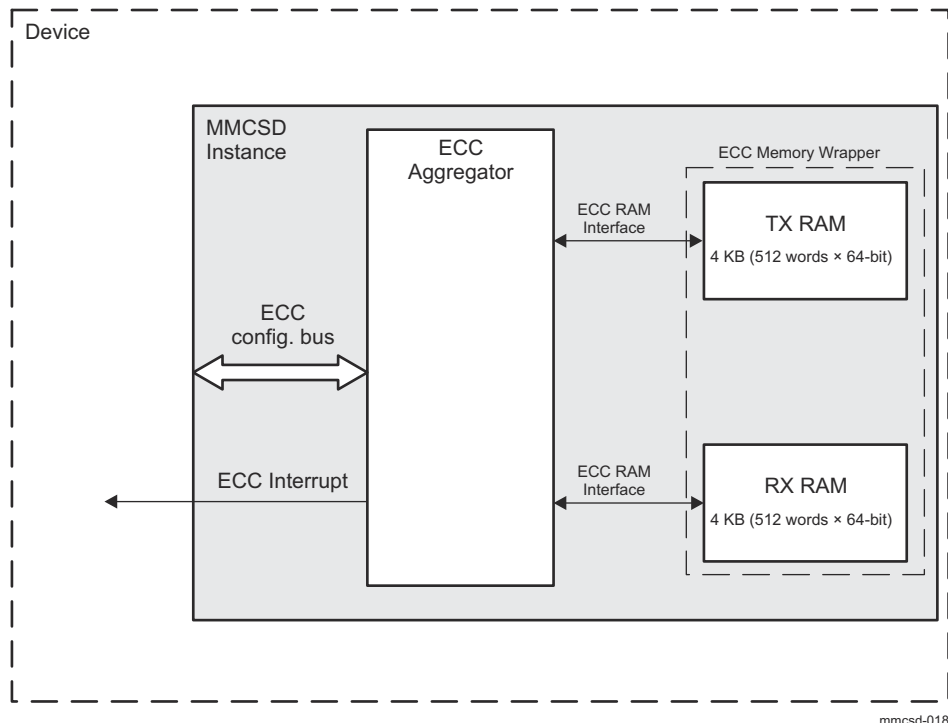

Figure 12-166. ECC Aggregator Block Diagram

Note

For more information about ECC Aggregator Registers, refer to *MMCSd Registers*.

12.3.6.3.5 Advanced DMA

The MMCSd modules support SD Advanced DMA – ADMA2 and ADMA3.

Note

For more information, refer to the SD Association specification titled "*SD Host Controller Simplified Specification, Part A2, Version 4.10*".

12.3.6.3.6 eMMC PHY BIST

12.3.6.3.6.1 BIST Overview

To verify the eMMC5.1 PHY functionality, the BIST function is built on top of the eMMC5.1 PHY that can either be controlled from SOC registers or from special Vendor Registers defined in the TI's eMMC5.1 Host Controller. The functionality of the BIST is to be able to test various functions of the PHY (without using the eMMC protocol/ software stack) and provide the results of the testing to the diagnostic software.

The BIST logic drives a known pattern on the transmit path (into DFE) and is received on the receive path (as the IOs are bidirectional in nature). The received data is captured in the BIST logic (after the DFE) and are compared. The result of the pattern comparison is reported into status register for software to read out.

The fixed pattern is the well-known tuning pattern used in HS200 mode as defined by the JEDEC. This pattern is 128-bytes in length, is preceded by eMMC START Condition on all lanes, and is terminated with END Condition on all lanes. Unlike the normal Tuning command, there is no CRC appended to this pattern.

The 128-byte Test Pattern is as follows:

F	F	0	F	F	F	0	0	F	F	C	C	C	3	C	C	C	3	3	C	C	C	F	F	F	E	F	F	F	E	E	F

Figure 12-167. 128-byte Test Pattern

In non-HS200 Modes, the testing is performed for one time with programmed Tx Phase and Rx Phase values. In HS200 Mode, the testing is performed 32-times and it is expected that some of the iterations will have data mismatch because of the RxPhase Timing. The BIST engine iterates through all 32-phases of Rx Clock and provides the result of data/cmd line compare for each of the phases in a 32-bit status vector.

12.3.6.3.6.2 BIST Modes

The following are the various modes supported by the eMMC5.1 PHY BIST Logic. These modes test both the CMD line and all DATA Lines.

12.3.6.3.6.2.1 DS Mode

This is the Default Speed (DS) mode where the eMMC CLK is set to 25 MHz and the timing of the interface is from negative edge launch to positive edge capture. The DLL and the DLY lines are disabled in this phase.

12.3.6.3.6.2.2 HS Mode with TXDLY using DLL

This is the High Speed (HS) mode where the eMMC CLK is set to 50 MHz. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the TX Clock Phase shift is being performed by using one of the first 16-taps of the DLL TXCLK Phases. The Phase shifting on the RX path is disabled in this mode.

12.3.6.3.6.2.3 HS Mode with TXDLY using Delay Chain

This is the High Speed (HS) mode where the eMMC CLK is set to 50 MHz. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the TX Clock Phase shift is being performed by using one of the first 16-taps of the TX Delay Chain Phases. The Phase shifting on the RX path is disabled in this mode.

The DLL is disabled in this mode.

12.3.6.3.6.2.4 DDR50 Mode with TXDLY using DLL

This is the DDR50 mode where the eMMC CLK is set to 50 MHz. The data is driven on both the edges of the clock. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted TX Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the TX Clock Phase shift is being

performed by using one of the first 16-taps of the DLL TXCLK Phases. The Phase shifting on the RX path is disabled in this mode.

12.3.6.3.6.2.5 DDR50 Mode with TXDLY using Delay Chain

This is the DDR50 mode where the eMMC CLK is set to 50 MHz. The data is driven on both the edges of the clock. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the Tx Clock Phase shift is being performed by using one of the first 16-taps of the Tx Delay Chain Phases. The Phase shifting on the RX path is disabled in this mode. The DLL is disabled in this mode.

12.3.6.3.6.2.6 HS200 Mode with TX/RXDLY using DLL

This is the HS200 mode where the eMMC CLK is set to 200 MHz. To emulate the Interface timing, a small Hold time is inserted on Transmit data lines by using the Phase shifted TX Clock. The amount of phase shift can be from 1 to 16 Taps. The RxClock Phase is adjusted from 1 to 32 Phases to check the data at different phases. In this mode, the TX Phase shift is being performed by using one of the first 16-taps of the DLL TXCLK Phases and the RX Phase shift is being performed by using one of the 32 taps of the DLL RXCLK Phases.

12.3.6.3.6.2.7 HS200 Mode with TX/RXDLY using Delay Chain

This is the HS200 mode where the eMMC CLK is set to 200 MHz. To emulate the Interface timing, a small Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. The Rx Clock Phase is adjusted from 1 to 32 Phases to check the data at different phases. In this mode, the TX Phase shift is being performed by using one of the first 16-taps of the Delay Chain Phases and the RX Phase shift is being performed by using one of the 32 taps of the Delay Chain Phases.

The DLL is disabled in this mode.

12.3.6.3.6.2.8 HS400 Mode

In this mode, the Receive data is captured using the STRB line. To support this mode, the AFE is configured such that the STRB is toggled during the time when the fixed pattern transmission (including the START/END). The Receive STRB line is phase shifted by 90 and 180 degrees by the DLL. As the data is captured using the STRB, there is no need to enable the RX Clock Phases, and these can be disabled. To maintain the timing, the TX Phase can be adjusted accordingly.

12.3.6.3.6.3 BIST Functionality

The BIST engine inside the eMMC PHY leverages the Tuning Pattern to verify the functionality of the PHY (including the IOs and the DLL). The BIST engine is controlled from SOC and the eMMC Host Controller should be disabled during the BIST Mode. The BIST can be run at different modes (Clock Speeds) and the result of the BIST operation is presented to the SOC.

In normal mode, the PHY Transmit Data path operates on the MMCS0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL. This clock is provided by the eMMC Host Controller and the frequency of this clock is varied based on the operating mode. The following are the various frequencies used in various modes.

- Default Speed: 25 MHz
- High Speed: 25 MHz
- DDR52: 50 MHz
- HS200: 200 MHz
- HS400: 200 MHz

This clock is generated by the eMMC Host Controller and under direct control of the software through the Clock Control Register @0x2C of the Host Controller Register Set. The eMMC Host Controller uses the XIN_CLK (the reference clock to the Host Controller, which is usually 200 MHz) and uses the Clock Divider Value and the Clock Enable Control.

The BIST Engine runs on the same MMCS0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL. Though the Host Controller is disabled during the BIST operation, the software should program the Clock Control Register so that the MMCS0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL is generated for the BIST engine.

12.3.6.3.6.4 Signal Interface

The BIST logic is controlled by a set of signals which can be from a set of registers that are software accessible. The following are the signals for BIST Functions.

Table 12-290. BIST Logic Signals

Signal	Direction	Description
MMCSDB0_SS_PHY_CTRL_6_REG[31].BISTENABLE	Input	BIST Enable When set the BIST Controller controls the DFE and overwrites the data path signals from the Host Controller Interface. When this is cleared, the Host Controller signals are connected to the DFE and BIST is disabled.
MMCSDB0_SS_PHY_CTRL_6_REG[27:24].BISTMODE	Input	BIST Mode This selects one of the specified BIST Modes for running the BIST sequence. The following are the encoding for the mode: 4'b0000: HS200 Mode with DLL 4'b0001: HS200 Mode with DLY_CHAIN 4'b0010: HS400 Mode (STROBE Mode) 4'b0011: DDR52 Mode with DLL 4'b0100: DDR52 Mode with DLY_CHAIN 4'b0101: HS Mode with DLL 4'b0110: HS Mode with DLY_CHAIN 4'b0111: DS Mode (with DLY_CHAIN)
MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART	Input	BIST Start The rising edge of this signal is used to start the BIST function on the specified BIST Mode. When the BIST is complete the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE output is asserted. Before setting this signal, the SOC must make sure that the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE is low (deasserted).
MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS	Output	BIST Status This is the status of the BIST Testing. In non HS200 Mode, the Bit[0] indicates whether the BIST Passed or not. In HS200 modes, the 32-bit indicates the Pattern Match at each of the 32-taps on RxClk Path.
MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE	Output	BIST Done This is asserted when the BIST completes its sequence. The result of the test is presented in the MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS output. This is asserted until the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART is deasserted at which point the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE is also cleared.

12.3.6.3.6.5 Programming Flow

For the BIST operation, the OD_EN/REN/PU/OD controls to the CMD/STRB/DAT lines should be programmed as follows:

- OD_EN: 1'b0
- REN: 1'b0
- PU: 1'b1
- OD: 1'b0

12.3.6.3.6.5.1 DS Mode

The following are the various settings required for performing the BIST in Default Speed timing.

12.3.6.3.6.5.1.1 Configuration

- MMCSDB0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL should be set to 25 MHz.
- PHY's DLL should be disabled.
- MMCSDB0_SS_PHY_CTRL_6_REG[27:24].BISTMODE should be set to 4'b0111.
- MMCSDB0_SS_PHY_CTRL_6_REG[31].BISTENABLE should be set to 1'b1.
- MMCSDB0_SS_PHY_CTRL_4_REG[20].OTAPDLYENA to 1'b0.
- MMCSDB0_SS_PHY_CTRL_4_REG[15:12].OTAPDLYSEL to 4'b0000.
- MMCSDB0_SS_PHY_CTRL_4_REG[8].ITAPDLYENA to 1'b0
- MMCSDB0_SS_PHY_CTRL_4_REG[4:0].ITAPDLYSEL to 5'b00000
- MMCSDB0_SS_PHY_CTRL_4_REG[9].ITAPCHGWIN to 1'b0

12.3.6.3.6.5.1.2 BIST Programming

1. Set the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

4. Clear the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b0.

12.3.6.3.6.5.2 HS Mode with DLY_CHAIN

The following are the various settings required for performing the BIST in HS Mode with DLY Chain.

12.3.6.3.6.5.2.1 Configuration

- MMCSDB0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL should be set to 50 MHz.
- PHY's DLL should be disabled.
- MMCSDB0_SS_PHY_CTRL_6_REG[27:24].BISTMODE should be set to 4'b0110.
- MMCSDB0_SS_PHY_CTRL_6_REG[31].BISTENABLE should be set to 1'b1.
- MMCSDB0_SS_PHY_CTRL_4_REG[20].OTAPDLYENA to 1'b1.
- MMCSDB0_SS_PHY_CTRL_4_REG[15:12].OTAPDLYSEL to on of the tap Value based on Timing Closure.
- MMCSDB0_SS_PHY_CTRL_4_REG[8].ITAPDLYENA* to 1'b0.
- MMCSDB0_SS_PHY_CTRL_4_REG[4:0].ITAPDLYSEL* to 5'b00000
- MMCSDB0_SS_PHY_CTRL_4_REG[9].ITAPCHGWIN to 1'b0

* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

12.3.6.3.6.5.2.2 BIST Programming

1. Set the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

4. Clear the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b0.

12.3.6.3.6.5.3 HS Mode with DLL

The following are the various settings required for performing the BIST in HS Mode with DLL.

12.3.6.3.6.5.3.1 Configuration

- MMCSDB0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL should be set to 50 MHz.
- PHY's DLL should be Enabled.
- MMCSDB0_SS_PHY_CTRL_6_REG[27:24].BISTMODE should be set to 4'b0101.
- MMCSDB0_SS_PHY_CTRL_6_REG[31].BISTENABLE should be set to 1'b1.
- MMCSDB0_SS_PHY_CTRL_4_REG[20].OTAPDLYENA to 1'b1.
- MMCSDB0_SS_PHY_CTRL_4_REG[15:12].OTAPDLYSEL to on of the tap Value based on Timing Closure.
- MMCSDB0_SS_PHY_CTRL_4_REG[8].ITAPDLYENA* to 1'b0.
- MMCSDB0_SS_PHY_CTRL_4_REG[4:0].ITAPDLYSEL* to 5'b00000
- MMCSDB0_SS_PHY_CTRL_4_REG[9].ITAPCHGWIN to 1'b0
- MMCSDB0_SS_PHY_CTRL_5_REG[10:8].FRQSEL should be set for 50 MHz Mode.

* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

12.3.6.3.6.5.3.2 BIST Programming

1. Wait for MMCSDB0_SS_PHY_STAT_1_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

5. Clear the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b0.

12.3.6.3.6.5.4 DDR52 Mode with DLY_CHAIN

The following are the various settings required for performing the BIST in DDR52 Mode with DLY Chain.

12.3.6.3.6.5.4.1 Configuration

- MMCSDB0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL should be set to 50 MHz.
- PHY's DLL should be disabled.
- MMCSDB0_SS_PHY_CTRL_6_REG[27:24].BISTMODE should be set to 4'b0100.
- MMCSDB0_SS_PHY_CTRL_6_REG[31].BISTENABLE should be set to 1'b1.
- MMCSDB0_SS_PHY_CTRL_4_REG[20].OTAPDLYENA to 1'b1.
- MMCSDB0_SS_PHY_CTRL_4_REG[15:12].OTAPDLYSEL to on of the tap Value based on Timing Closure.
- MMCSDB0_SS_PHY_CTRL_4_REG[8].ITAPDLYENA* to 1'b0.
- MMCSDB0_SS_PHY_CTRL_4_REG[4:0].ITAPDLYSEL* to 5'b00000
- MMCSDB0_SS_PHY_CTRL_4_REG[9].ITAPCHGWIN to 1'b0

If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

12.3.6.3.6.5.4.2 BIST Programming

1. Set the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

4. Clear the MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b0.

12.3.6.3.6.5.5 DDR52 Mode with DLL

The following are the various settings required for performing the BIST in DDR52 Mode with DLL.

12.3.6.3.6.5.5.1 Configuration

- MMCSD0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL should be set to 50 MHz
- PHY's DLL should be Enabled.
- MMCSD0_SS_PHY_CTRL_6_REG[27:24].BISTMODE should be set to 4'b0011.
- MMCSD0_SS_PHY_CTRL_6_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0_SS_PHY_CTRL_4_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0_SS_PHY_CTRL_4_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0_SS_PHY_CTRL_4_REG[8].ITAPDLYENA* to 1'b0.
- MMCSD0_SS_PHY_CTRL_4_REG[4:0].ITAPDLYSEL* to 5'b00000
- MMCSD0_SS_PHY_CTRL_4_REG[9].ITAPCHGWIN to 1'b0
- MMCSD0_SS_PHY_CTRL_5_REG[10:8].FRQSEL should be set for 50MHz Mode.

If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

12.3.6.3.6.5.5.2 BIST Programming

1. Wait for MMCSD0_SS_PHY_STAT_1_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSD0_SS_PHY_STAT_1_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

5. Clear the MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b0.

12.3.6.3.6.5.6 HS200 Mode with DLY_CHAIN

The following are the various settings required for performing the BIST in HS200 Mode with DLY Chain.

12.3.6.3.6.5.6.1 Configuration

- MMCSD0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL should be set to 200 MHz.
- PHY's DLL should be disabled.
- MMCSD0_SS_PHY_CTRL_6_REG[27:24].BISTMODE should be set to 4'b0001.
- MMCSD0_SS_PHY_CTRL_6_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0_SS_PHY_CTRL_4_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0_SS_PHY_CTRL_4_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0_SS_PHY_CTRL_4_REG[8].ITAPDLYENA to 1'b0
- MMCSD0_SS_PHY_CTRL_4_REG[4:0].ITAPDLYSEL to 5'b00000
- MMCSD0_SS_PHY_CTRL_4_REG[9].ITAPCHGWIN to 1'b0

*In this mode, the BIST Engine cycles thru all the 32 taps, so there is no need of controlling the Input Tap Delay.

12.3.6.3.6.5.6.2 BIST Programming

1. Set the MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSD0_SS_PHY_STAT_1_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS*31:0+ Bit and run the "HS200 Bist Result Check Procedure"

4. Clear the MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b0.

12.3.6.3.6.5.7 HS200 Mode with DLL

The following are the various settings required for performing the BIST in HS200 Mode with DLL.

12.3.6.3.6.5.7.1 Configuration

- MMCSD0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL should be set to 200 MHz.
- PHY's DLL should be disabled.
- MMCSD0_SS_PHY_CTRL_6_REG[27:24].BISTMODE should be set to 4'b0000.
- MMCSD0_SS_PHY_CTRL_6_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0_SS_PHY_CTRL_4_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0_SS_PHY_CTRL_4_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0_SS_PHY_CTRL_4_REG[8].ITAPDLYENA* to 1'b0.
- MMCSD0_SS_PHY_CTRL_4_REG[4:0].ITAPDLYSEL* to 5'b00000
- MMCSD0_SS_PHY_CTRL_4_REG[9].ITAPCHGWIN to 1'b0
- MMCSD0_SS_PHY_CTRL_5_REG[10:8].FRQSEL should be set for 200 MHz Mode.

* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

12.3.6.3.6.5.7.2 BIST Programming

1. Wait for MMCSD0_SS_PHY_STAT_1_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSD0_SS_PHY_STAT_1_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS*31:0+ Bit and run the "HS200 Bist Result Check Procedure".
5. Clear the MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b0.

12.3.6.3.6.5.8 HS400 Mode with DLL

The following are the various settings required for performing the BIST in HS400 Mode with DLL.

12.3.6.3.6.5.8.1 Configuration

- MMCSD0_CLOCK_CONTROL[15:8].SDCLK_FRQSEL should be set to 200 MHz.
- PHY's DLL should be enabled.
- MMCSD0_SS_PHY_CTRL_6_REG[27:24].BISTMODE should be set to 4'b0010.
- MMCSD0_SS_PHY_CTRL_6_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0_SS_PHY_CTRL_4_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0_SS_PHY_CTRL_4_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0_SS_PHY_CTRL_4_REG[8].ITAPDLYENA to 1'b0
- MMCSD0_SS_PHY_CTRL_4_REG[4:0].ITAPDLYSEL to 5'b00000
- MMCSD0_SS_PHY_CTRL_4_REG[9].ITAPCHGWIN to 1'b0
- MMCSD0_SS_PHY_CTRL_5_REG[10:8].FRQSEL should be set for 200 MHz Mode.
- MMCSD0_SS_PHY_CTRL_4_REG[31:24].STRBSEL should be set to appropriate values based on based on STRB timing closure.

* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

12.3.6.3.6.5.8.2 BIST Programming

1. Wait for MMCSD0_SS_PHY_STAT_1_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSD0_SS_PHY_STAT_1_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

5. Clear the MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART to 1'b0.

12.3.6.3.6.6 HS200 BIST Result Check Procedure

In HS200 Mode, the BIST engine in the PHY runs Tuning Pattern test 32 times, with different TAP values selected, for each iteration. The result from the 32 iterations is presented on the MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS output. It is expected that some of the TAP values will have timing issues and results in pattern mismatch when compared with the received pattern for those taps. The PASS/FAIL for the HS200 Mode is based on the following theory.

Of the 32 taps, the Data Capture EYE for certain taps will result in mismatches, but these will be sequential tap values. Thus, in a full 32 iterations, a sequence of taps results in data mismatches. Also, based on the timing closure, the number of taps with pattern mismatch should be approximately 1/4th of the number of taps with pattern match. This 1/4th count is not absolute, as this involves various factors such as the timing closure, PVT variation, and so forth. Anywhere from 4 to 16 invalid sequential taps is normal.

For example, if 8 of the 32 sequential taps have the data mismatches, the following would be the resulting MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS output based which of the 8 sequential taps the mismatches are. The following is the notation used:

- 1: Pattern matched at this tap
- 0: Pattern match failed at this tap

[illegible]

12.3.6.4 MMCSD Programming Guide

12.3.6.4.1 Sequences

This section defines basic sequence flow chart divided into several sub sequences.

Note

This section is applicable for MMCSD0 and MMCSD1 but MMCSD0 registers are used in the content.

Note

UHSII is not supported. For more information, see *Not Supported Features*.

"Wait for interrupts" is used in the flow chart. This means the Host Driver waits until specified interrupts are asserted. If already asserted, then fall through that step in the flow chart. Timeout checking shall be always required to detect no interrupt generated but this is not described in the flow chart.

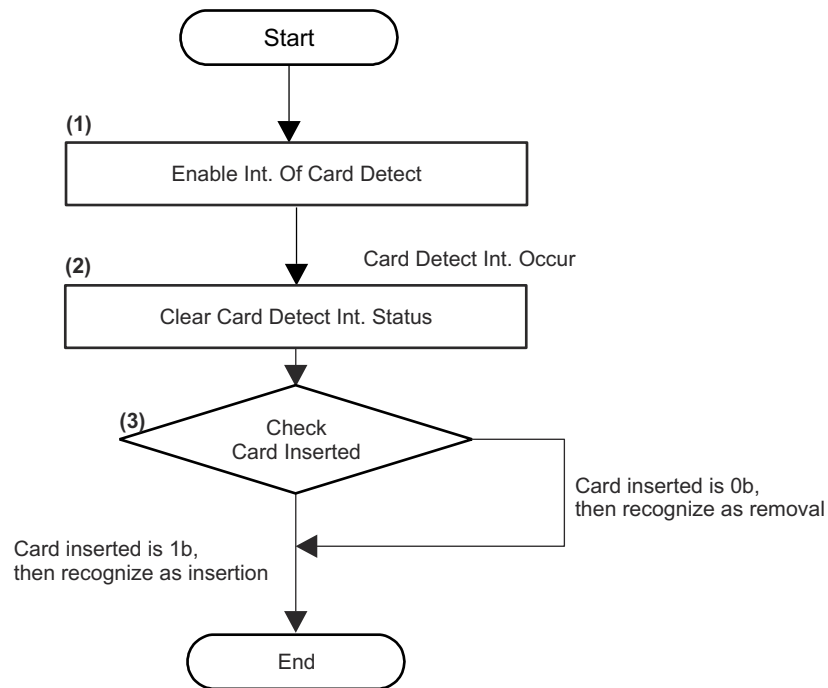

This specification uses the double box like Figure 12-168, (the step (1) in Figure 12-172), it means that the other flows, which already are shown, shall be performed. Therefore, the interrupt may be included in the other flows.

mmcsd-019

Figure 12-168. Double Box Notation

12.3.6.4.1.1 SD Card Detection

mmcsd-020

Figure 12-169. SD Card Detect Sequence

The flow chart for detecting a SD card is shown in Figure 12-169.

Each step is executed as follows:

To enable interrupt for card detection, write 1 to the following bits:

- MMCSD0_NORMAL_INTR_STS_ENA[6] CARD_INSERTION
- MMCSD0_NORMAL_INTR_SIG_ENA[6] CARD_INSERTION
- MMCSD0_NORMAL_INTR_STS_ENA[7] CARD_REMOVAL
- MMCSD0_NORMAL_INTR_SIG_ENA[7] CARD_REMOVAL

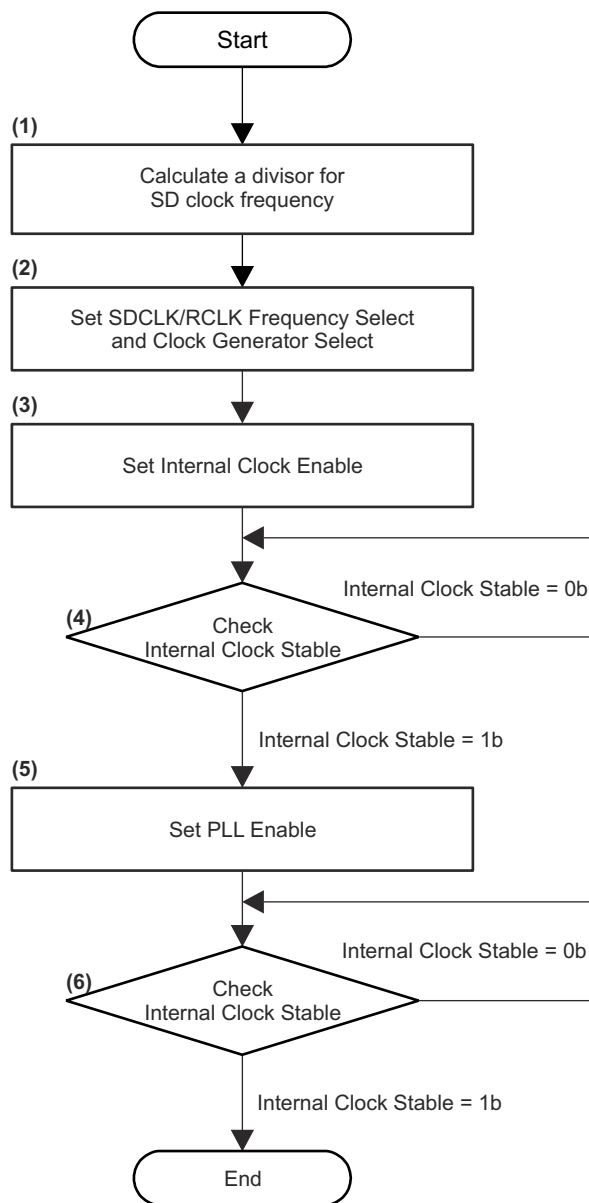

(1) When the Host Driver detects the card insertion or removal, clear its interrupt statuses. If Card Insertion interrupt is generated, write 1 to MMCSD0_NORMAL_INTR_STS_ENA[6] CARD_INSERTION bit. If Card Removal interrupt is generated, write 1 to MMCSD0_NORMAL_INTR_STS_ENA[7] CARD_REMOVAL bit.

(2) Check MMCSD0_PRESENTSTATE[16] CARD_INSERTED bit. In the case where MMCSD0_PRESENTSTATE[16] CARD_INSERTED bit is 1, the Host Driver can supply the power and the clock to the SD card. In the case where MMCSD0_PRESENTSTATE[16] CARD_INSERTED bit is 0, the other executing processes of the Host Driver shall be immediately closed.

If miniSD adaptor is used for standard SD slot and miniSD card is inserted or extracted from the adaptor, card detect interrupt may not be generated. When host does not receive response to any commands, miniSD card is extracted or in idle state, the host should try to re-initialize the card. In this case, all card information shall be re-loaded.

12.3.6.4.1.2 SD Clock Control

12.3.6.4.1.2.1 Internal Clock Setup Sequence

mmscd-021

Figure 12-170. Internal Clock Setup Sequence

The sequence for supplying SD Clock to a SD card is described in [Figure 12-170](#). From Version 4.10, MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is added. This sequence is also applicable to prior versions which do not support MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit.

(1) Calculate a divisor to determine SD Clock frequency for legacy IF or RCLK frequency for UHS-II IF by reading MMCSD0_CAPABILITIES[15-8] BASE_CLK_FREQ and MMCSD0_CAPABILITIES[55-48] CLOCK_MULTIPLIER bit fields. If non-zero value is set to MMCSD0_CAPABILITIES[55-48] CLOCK_MULTIPLIER bit field, Programmable Clock Mode can be used (for more information, see MMCSD0_CLOCK_CONTROL[5] CLKGEN_SEL bit). If MMCSD0_CAPABILITIES[15-8] BASE_CLK_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

(2) Set MMCSD0_CLOCK_CONTROL[15-8] SDCLK_FRQSEL bit field and MMCSD0_CLOCK_CONTROL[5] CLKGEN_SEL bit in accordance with the calculated result of step (1).

If MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit is set, these bits are set by Host Controller automatically as specified in the Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10).

(3) Set MMCSD0_CLOCK_CONTROL[0] INT_CLK_ENA bit.

(4) Check MMCSD0_CLOCK_CONTROL[1] INT_CLK_STABLE bit. Repeat this step until this status is 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

(5) Set MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit. This step does not affect Host Controllers which do not support MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit.

(6) If MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is supported, PLL locked may be checked by this status (if MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is not supported, this status is supposed to indicate 1 by step (3)). Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

12.3.6.4.1.2.2 SD Clock Supply and Stop Sequence

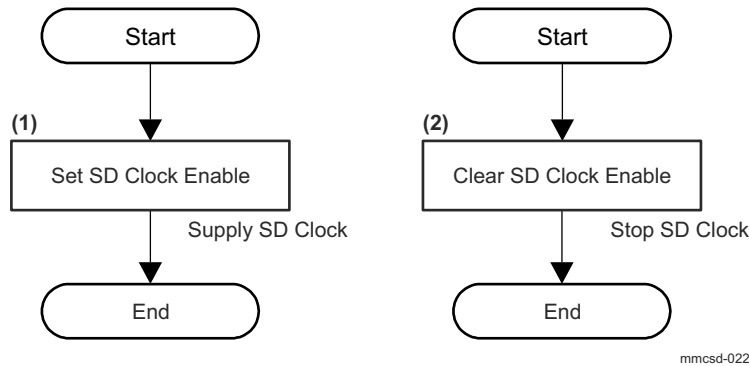

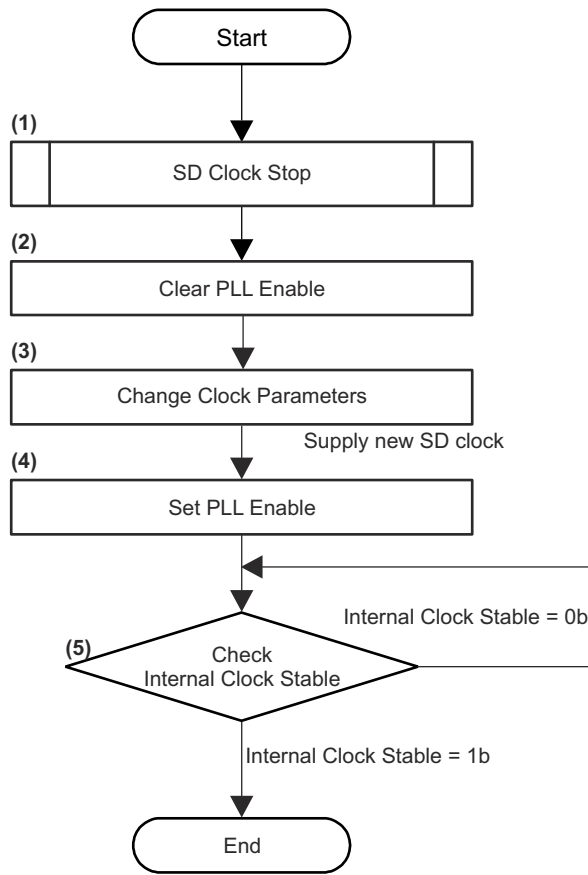

Figure 12-171. SD Clock Supply and Stop Sequence

The flow chart for stopping the SD Clock is shown in [Figure 12-171](#). The Host Driver shall not stop the SD Clock when a SD transaction is occurring on the SD Bus -- namely, when either MMCSD0_PRESENTSTATE[1] INHIBIT_DAT or MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit is set to 1.

(1) Setup Internal Clock (see [Figure 12-170](#)). Then set MMCSD0_CLOCK_CONTROL[2] SD_CLK_ENA bit to 1. Then, the Host Controller starts supplying the SD Clock.

(2) Set MMCSD0_CLOCK_CONTROL[2] SD_CLK_ENA bit to 0. Then, the Host Controller stops supplying the SD Clock. Internal Clock is still oscillating.

12.3.6.4.1.2.3 SD Clock Frequency Change Sequence

mmcscd-023

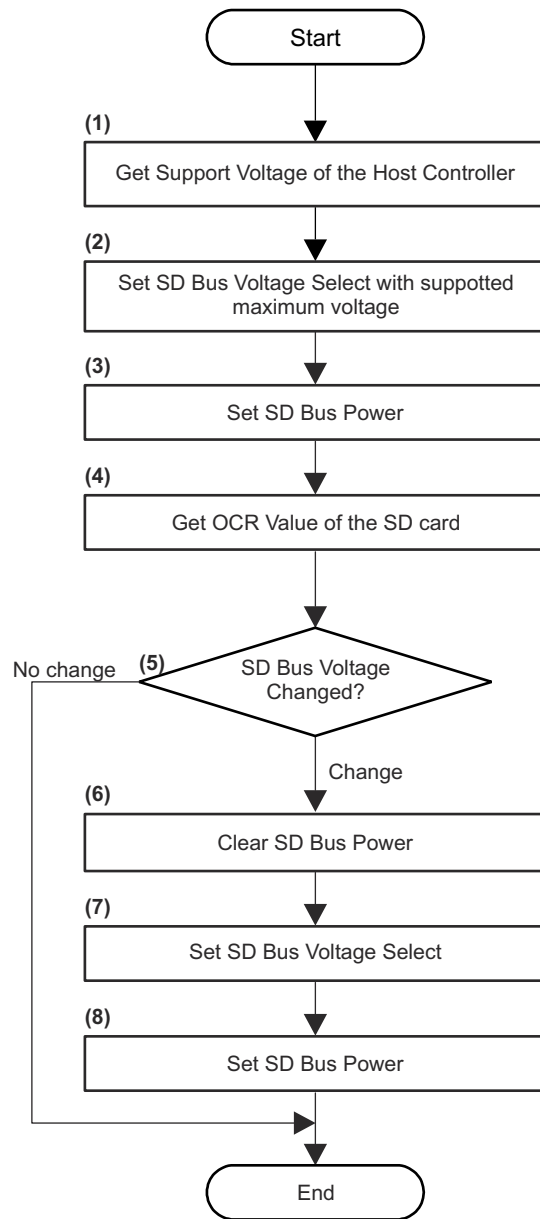

Figure 12-172. SD Clock Change Sequence

The sequence for changing SD Clock frequency is shown in [Figure 12-172](#).

- (1) Execute the SD Clock Stop Sequence (see [Figure 12-171](#)). If SD Clock supply to card is already stopped, skip this step.
- (2) Clear MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit to 0. If MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is not supported, this step has no effect and may be skipped.
- (3) When MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit is set to 0, change clock parameters in the MMCSD0_CLOCK_CONTROL register. When MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit is set to 1, select Bus Speed Mode as described.
- (4) Set MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit to 1. If MMCSD0_CLOCK_CONTROL[3] PLL_ENA bit is not supported, this step has no effect and may be skipped.
- (5) Wait until MMCSD0_CLOCK_CONTROL[1] INT_CLK_STABLE bit is set to 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms. SD Clock Supply Sequence is required to provide clock to device (see [Figure 12-171](#)).

12.3.6.4.1.3 SD Bus Power Control

The sequence for controlling the SD Bus Power is described in [Figure 12-173](#).

mmcsd-024

Figure 12-173. SD Bus Power Control Sequence

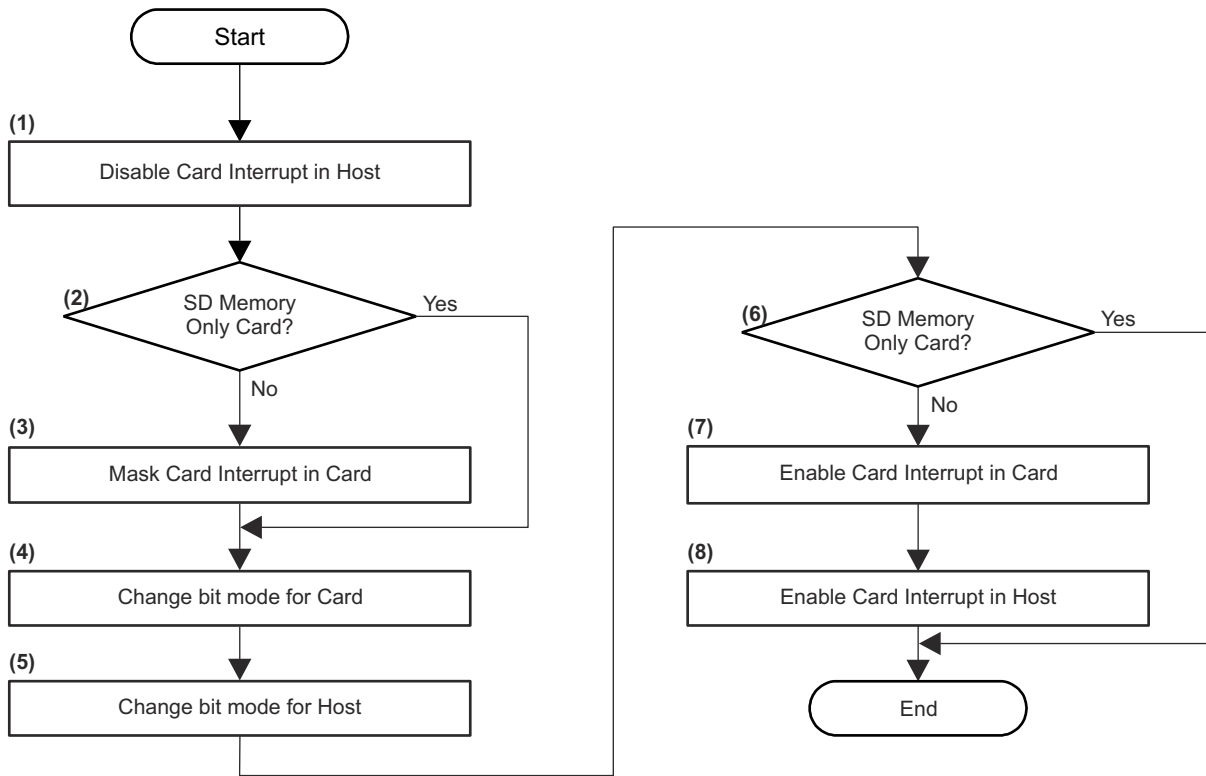

- (1) By reading the MMCSD0_CAPABILITIES register, get the support voltage of the Host Controller.
- (2) Set MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE bit field with maximum voltage that the Host Controller supports.
- (3) Set MMCSD0_POWER_CONTROL[0] SD_BUS_POWER bit to 1.
- (4) Get the OCR value of all function internal of SD card.
- (5) Judge whether SD Bus voltage needs to be changed or not. In case where SD Bus voltage needs to be changed, go to step (6). In case where SD Bus voltage does not need to be changed, go to "End".
- (6) Set MMCSD0_POWER_CONTROL[0] SD_BUS_POWER bit to 0 for clearing this bit. The card requires voltage rising from 0 volt to detect it correctly. The Host Driver shall clear MMCSD0_POWER_CONTROL[0] SD_BUS_POWER bit before changing voltage by setting MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE bit field.

(7) Set MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE bit field.

(8) Set MMCSD0_POWER_CONTROL[0] SD_BUS_POWER to 1.

Note: Step (2) and step (3) can be executed at same time. And also, step (7) and step (8) can be executed at same time.

12.3.6.4.1.4 Changing Bus Width

mmcsd-025

Figure 12-174. Change Bus Width Sequence

The sequence for changing bit mode on SD Bus is shown in [Figure 12-174](#).

(1) Set MMCSD0_NORMAL_INTR_STS_ENA[8] CARD_INTERRUPT bit to 0 for masking incorrect interrupts that may occur while changing the bus width.

(2) In case of SD memory only card, go to step (4). In case of other card, go to step (3).

(3) Set "IENM" of the CCCR in a SDIO or SD combo card to 0 by CMD52.

(4) Change the bus width mode for a SD card. SD Memory Card bus width is changed by ACMD6 and SDIO card bus width is changed by setting Bus Width of Bus Interface Control register in CCCR.

(5) In case of changing to 4-bit mode, set MMCSD0_HOST_CONTROL1[1] DATA_WIDTH bit to 1. In another case (1-bit mode), set this bit to 0.

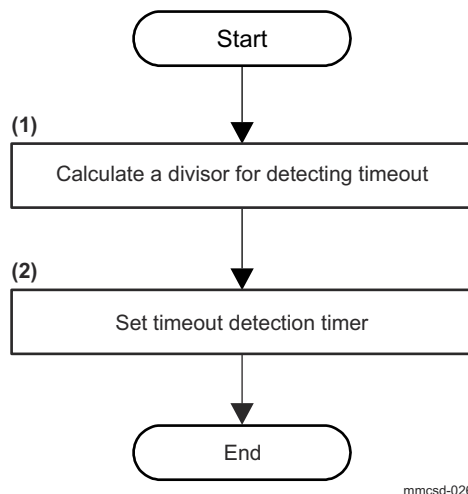

(6) In case of SD memory only card, go to the "End". In case of other card, go to step (7).

(7) Set "IENM" of the CCCR in a SDIO or SD combo card to 1 by CMD52.

(8) Set MMCSD0_NORMAL_INTR_STS_ENA[8] CARD_INTERRUPT bit to 1.

Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

12.3.6.4.1.5 Timeout Setting on DAT Line

mmcsd-026

Figure 12-175. Timeout Setting Sequence

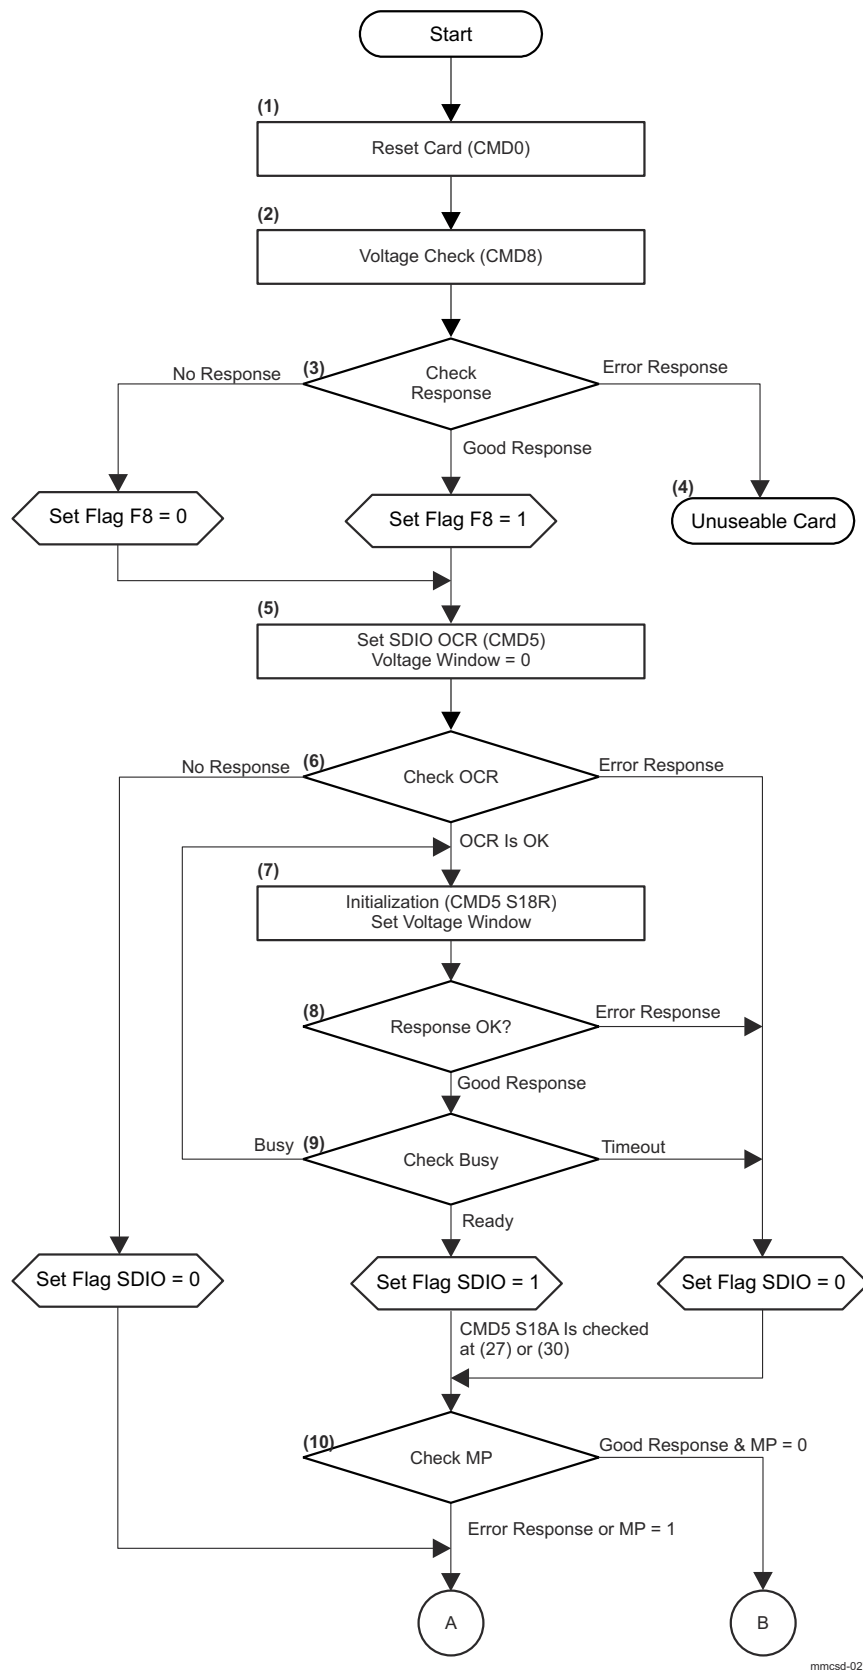

In order to detect timeout errors on DAT line, the Host Driver shall execute the following two steps before any SD transaction. For more information regarding SD transactions:

(1) Calculate a divisor to detect timeout errors by reading MMCSD0_CAPABILITIES[5-0] TIMEOUT_CLK_FREQ bit field and MMCSD0_CAPABILITIES[7] TIMEOUT_CLK_UNIT bit. If MMCSD0_CAPABILITIES[5-0] TIMEOUT_CLK_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

(2) Set MMCSD0_TIMEOUT_CONTROL[3-0] COUNTER_VALUE bit field in accordance with the value from step (1) above.

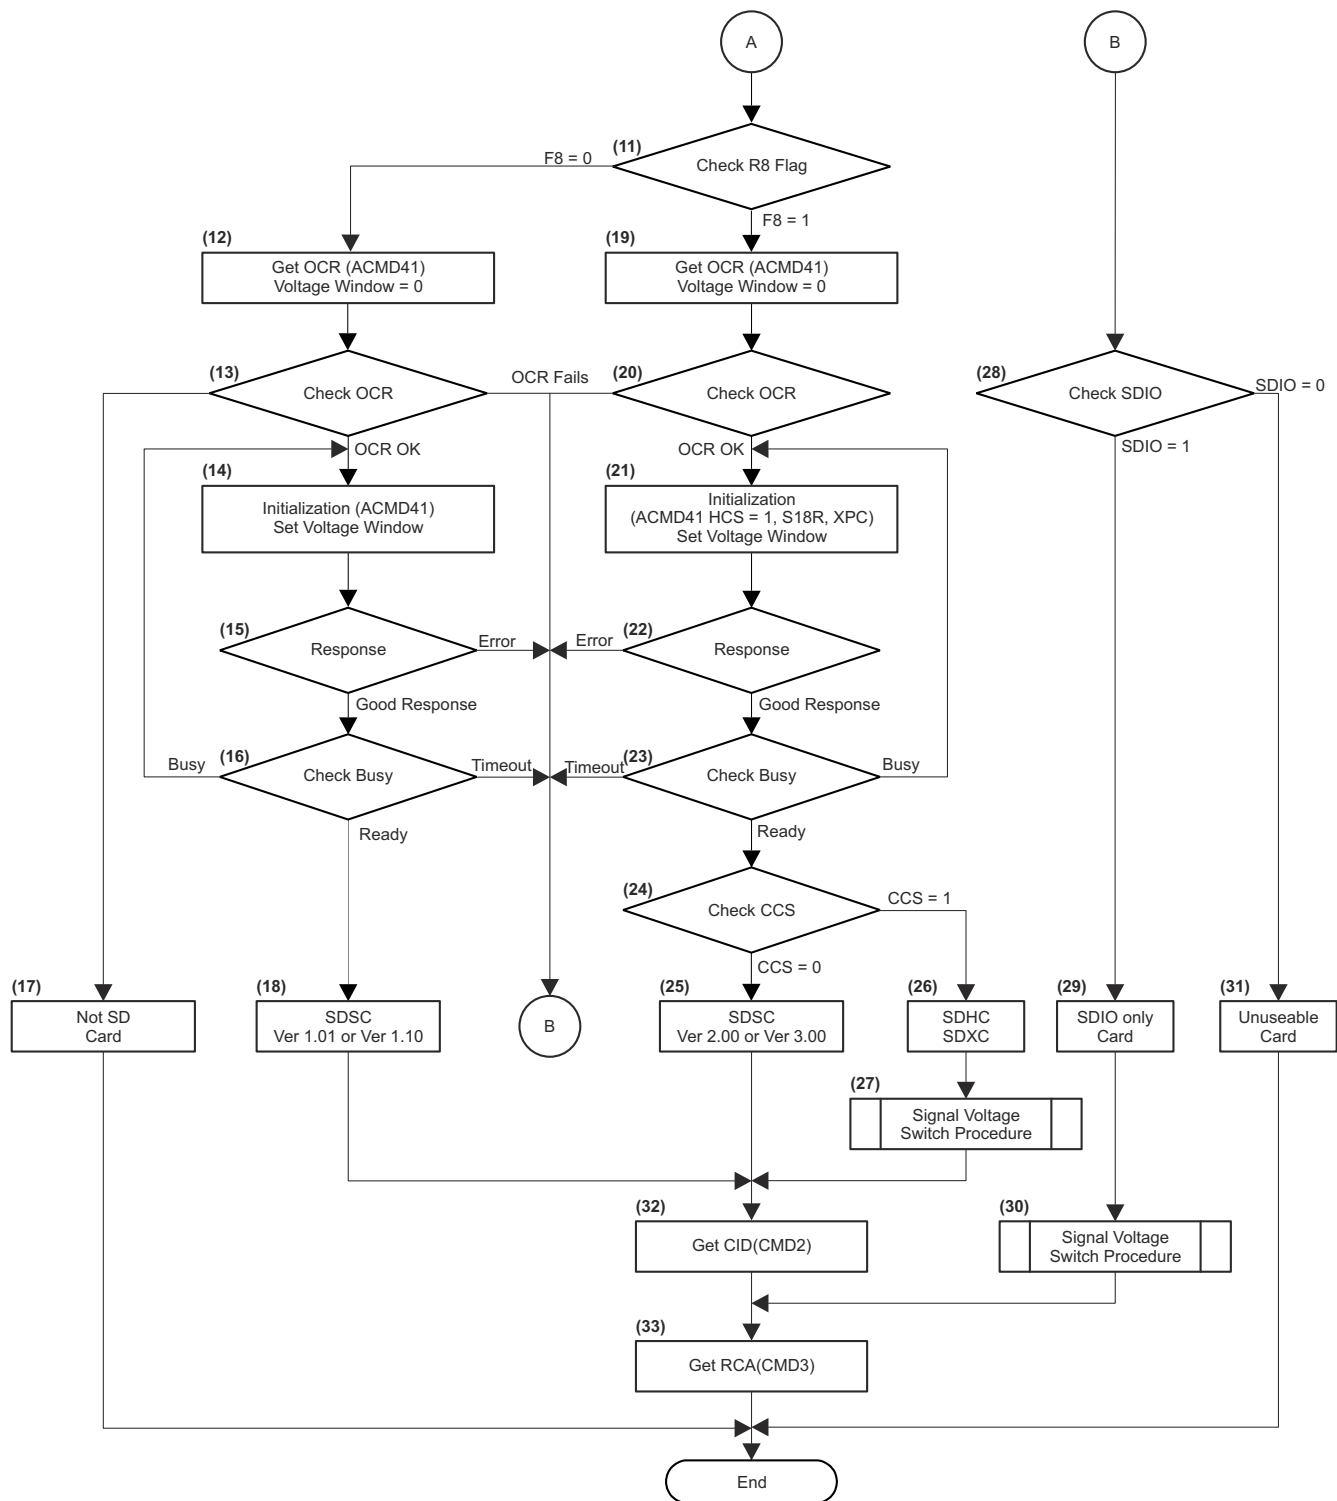

12.3.6.4.1.6 Card Initialization and Identification (for SD I/F)

Figure 12-176 and Figure 12-177 shows initialization and card identification sequence for the Standard Capacity SD Memory Card (SDSC), the High Capacity SD Memory Card (SDHC) and the Extended Capacity SD Memory Card (SDXC) that was based on the Physical Layer Version 3.01. Refer to the latest sequence.

mmcsd-027

Figure 12-176. Card Initialization and Identification (1)

mmcsd-028

Figure 12-177. Card Initialization and Identification (2)

- (1) SD Bus mode is selected by CMD0 (Keep Pin 1 to high during CMD0 execution).
- (2) New CMD8 shall be issued after CMD0 to support High Capacity SD Memory Card.
- (3) Voltage check command enables the Hosts to support future low voltage specification. However, at this time, only one voltage is defined. Legacy cards and Not SD cards do not respond to CMD8. In this case, set F8 to 0 (F8 is CMD8 valid flag used in step (11)) and go to Step (5). Only Version 2.00 or higher cards can respond to

CMD8. The host needs to check whether CRC of the response is valid and whether VHS and check pattern in the argument are equal to VCA and check pattern in the response. Passing all these checks results in CMD8 response OK. In this case, set F8 to 1 and go to step (5). If one of the checks is failed, go to step (4).

(4) Initialization is stopped by CMD8 fails. The Host Driver should retry step (1) to (3) one more time (this is not described in the figure).

(5) SDIO OCR is available by issuing CMD5 with setting voltage window (bit 23 to 0) in the argument to 0. SDIO initialization is not started.

(6) No response means the card does not have SDIO function. Set SDIO flag to 0 and go to step (11). If the card responds to CMD5 and the response is OK, go to step (7). If the response is error, set SDIO flag to 0 and go to step (10). SDIO flag indicates whether SDIO functions are initialized or not.

(7) The SDIO portion starts initialization by CMD5 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to 1. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.

(8) If no response or error response is received, set SDIO flag to 0 and go to step (10). If good response is received, go to step (9).

(9) Check busy status in the response. If busy is released, set SDIO flag to 1 and go to step (10). Repeat from step (7) while busy is indicated. Detecting timeout of 1 second exits the loop. In this case, set SDIO flag to 0 and go to step (10).

(10) Good response in this step means that all responses received at (6) and (8) are valid. When response is good, MP (memory present) flag in the response can be checked. If the response valid and MP = 0, go to step (28). Otherwise, go to step (11).

(11) Check F8 flag set in step (3). If CMD8 is executed correctly (F8 = 1), go to step (19). Otherwise, go to step (12).

(12) OCR is available by issuing ACMD41 with the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. The response of CMD55 (ACMD41) may indicate illegal command error due to some SD cards do not recognize CMD8. The Host Driver should ignore this error or issue CMD0 before ACMD41 to clear this error status.

(13) If response of CMD55 is not received, the card is not SD cards and goes to (17). If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (14). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.

(14) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.

(15) If no response or error response is received, go to step (28). If good response is received, go to step (16).

(16) Check busy status in the response. If busy is released, go to step (18). Repeat from step (14) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).

(17) The host recognizes that the card is not SD memory card and quits SD card initialization.

(18) The host recognizes that the card is Version 1.xx Standard Capacity SD Memory Card. Go to Step (30).

(19) OCR is available by issuing ACMD41 with setting the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. Setting of HCS does not affect this operation.

(20) If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (21). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.

(21) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to 1. If the host can supply more than 150mA, XPC is set to 1. HCS in

the argument is set to 1, which indicates supporting High Capacity Memory Card. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.

(22) If no response or error response is received, go to step (28). If good response is received, go to step (23).

(23) Check busy status in the response. If busy is released, go to step (24). Repeat from step (21) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).

(24) CCS in the response is valid after busy is released. If CCS = 0, it indicates the Standard Capacity SD Memory Card and go to step (25). If CCS = 1, it indicates the High Capacity SD Memory Card or Extended Capacity Memory Card and go to Step (26).

(25) The host recognizes that the card is Ver2.00 or Ver3.00 Standard Capacity SD Memory Card. Optimal functions defined in Version 2.00 or higher are available. Go to Step (32).

(26) The host recognizes that the card is the High Capacity SD Memory Card or Extended Capacity Memory Card.

(27) Perform the signal voltage switch procedure and go to step (32).

(28) Check SDIO flag. If SDIO = 1, go to step (28). Otherwise, go to step (31).

(29) The host recognizes that the card is SDIO only card and go to step (30).

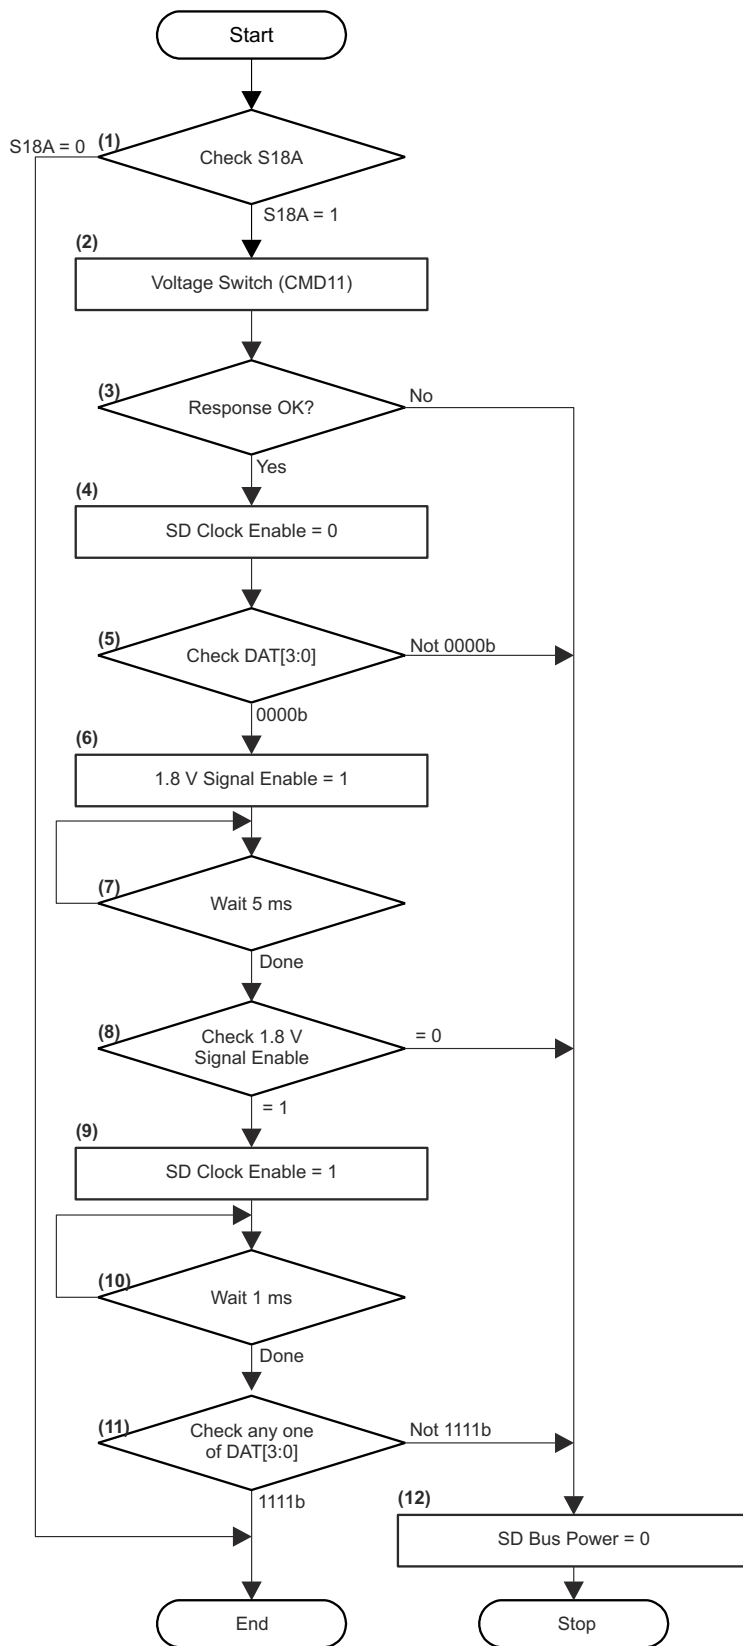

(30) Perform the signal voltage switch procedure and go to step (33).

(31) The host recognizes that the card is unusable.

(32) In case of memory card, CMD2 is issued to get CID and Go to Step (31).

(33) CMD3 is issued to get RCA. If the RCA number is 0, the Host should issue CMD3 again.

12.3.6.4.1.6.1 Signal Voltage Switch Procedure (for UHS-I)

mmscd-029

Figure 12-178. Signal Voltage Switch Procedure

- (1) If S18A of CMD5 or S18A of ACMD41 is set to 1, signal voltage switch is performed according to the following steps. Otherwise, exits from this procedure.
- (2) Issue CMD11.
- (3) Check response and if an error is detected, go to step (12).
- (4) Stop providing SD clock to the card.
- (5) Check DAT[3:0] level. If the level is 0000b, the card is ready to start voltage switch sequence. Otherwise, go to (12) to quit the sequence.
- (6) Set MMCSD0_HOST_CONTROL2[3] V1P8_SIGNAL_ENA bit.
- (7) Wait 5 ms. 1.8 V voltage regulator shall be stable within this period.
- (8) If MMCSD0_HOST_CONTROL2[3] V1P8_SIGNAL_ENA bit is cleared by Host Controller, go to step (12).
- (9) Provide SD Clock to the card again.
- (10) Wait 1 ms.
- (11) Check DAT[3:0] level. If the level is 1111b, switch to 1.8 V signal level is completed successfully. Otherwise, go to (12).
- (12) If an error occurs during voltage switch procedure, stop providing the power to the card. In this case, Host Driver should retry initialization procedure by setting S18R to 0 at step (7) and (21) in [Figure 12-176](#) and [Figure 12-177](#).

12.3.6.4.1.7 SD Transaction Generation

This section describes the sequences how to generate and control various kinds of SD transactions. SD transactions are classified into three cases:

- (1) Transactions that do not use the DAT line.
- (2) Transactions that use the DAT line only for the busy signal.
- (3) Transactions that use the DAT line for transferring data.

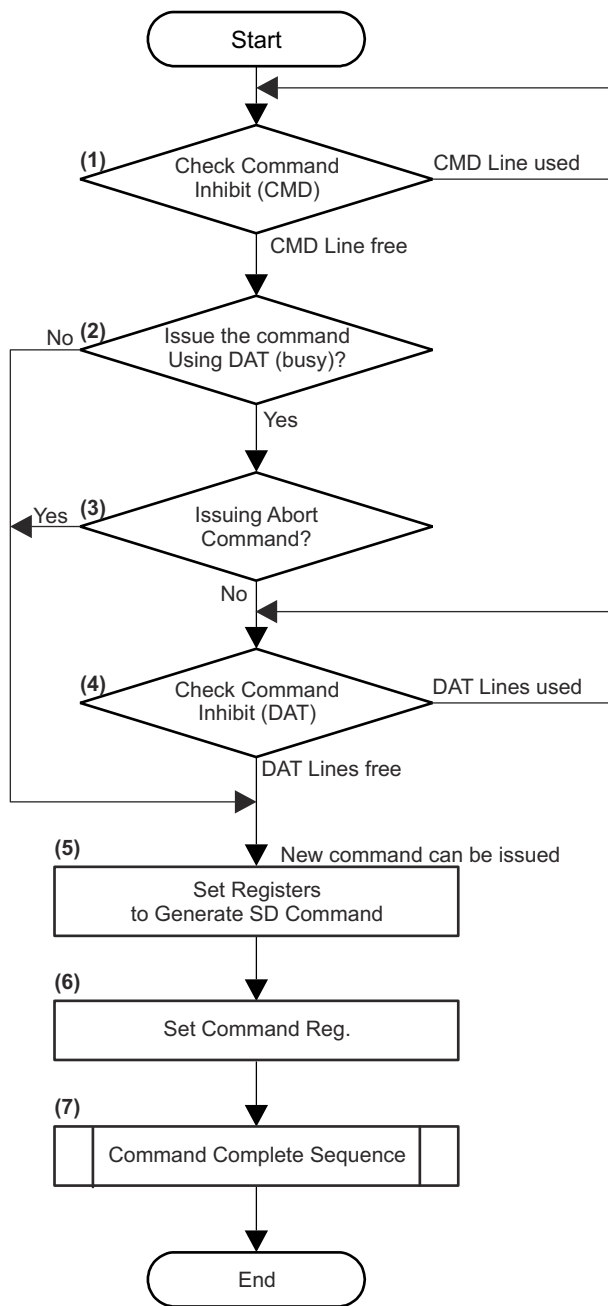

In this specification the first and the second case's transactions are classified as "Transaction Control without Data Transfer using DAT Line", the third case's transaction is classified as "Transaction Control with Data Transfer using DAT Line". Refer to the latest SD Physical Layer Specification and SDIO Specification for more detail about SD commands specification.

12.3.6.4.1.7.1 Transaction Control without Data Transfer Using DAT Line

In this section, the sequence for how to issue SD Command and how to complete SD Command is explained. [Figure 12-179](#) shows the sequence to issue a SD Command and [Figure 12-180](#) shows the sequence to finalize a SD Command.

12.3.6.4.1.7.1.1 The Sequence to Issue a SD Command

The sequence to issue the SD Command is detailed in [Figure 12-179](#).

mmcsd-030

Figure 12-179. SD Command Issue Sequence

(1) Check MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit. Repeat this step until MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit is 0. That is, when MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit is 1, the Host Driver shall not issue a SD Command.

(2) If the Host Driver issues a SD Command using DAT lines including busy signal, go to step (3). If without using DAT lines including busy signal, go to step (5).

(3) If the Host Driver is issuing an abort command, go to step (5). In the case of nonabort command, go to step (4).

(4) Check MMCSD0_PRESENTSTATE[1] INHIBIT_DAT bit. Repeat this step until MMCSD0_PRESENTSTATE[1] INHIBIT_DAT bit is set to 0.

(5) Set registers except the MMCSD0_COMMAND register.

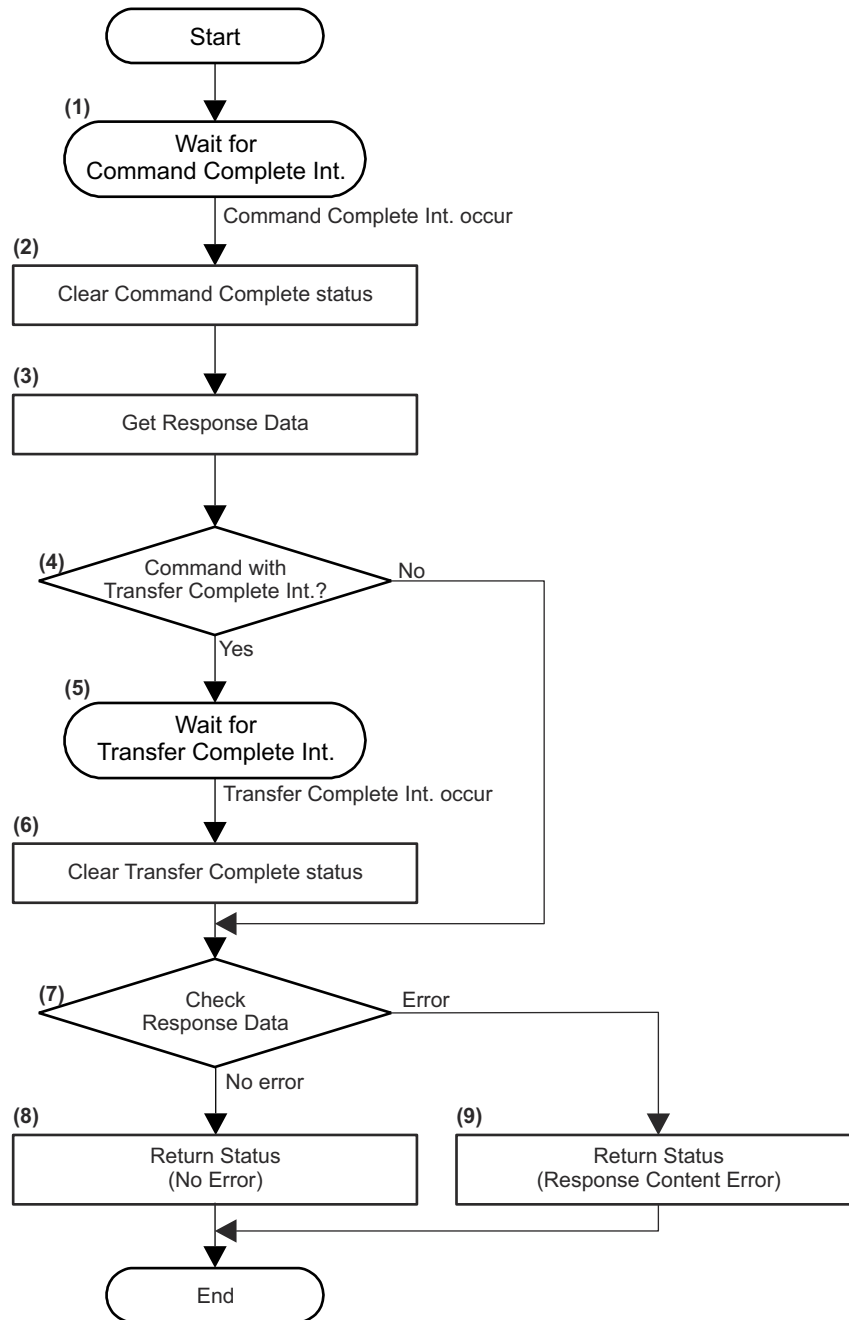

(6) Set the MMCSD0_COMMAND register.

Note: Writing the upper byte [3] in the MMCSD0_COMMAND register causes the Host Controller to issue a SD command to the SD card.

(7) Perform Command Completion Sequence in accordance.

12.3.6.4.1.7.1.2 The Sequence to Finalize a Command

Figure 12-180 shows the sequence to finalize a SD Command when response check is disabled. There is a possibility that some errors (Command Index/End bit/CRC/Timeout Error) occur during this sequence. If response check is enabled, error is indicated by Response Error Interrupt.

mmcsd-031

Figure 12-180. Command Complete Sequence

(1) If MMCSD0_TRANSFER_MODE[8] RESP_INTR_DIS bit is set to 1 (response check is enabled), go to step (4) else wait for the Command Complete Interrupt (MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE). If the Command Complete Interrupt has occurred, go to step (2).

(2) Write 1 to MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit to clear this bit.

(3) Read the Response register (see MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7) and get necessary information of the issued command.

(4) Judge whether the command uses the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE) or not. If it uses Transfer Complete, go to step (5). If not, go to step (7).

(5) Wait for the Transfer Complete Interrupt. If the Transfer Complete Interrupt has occurred, go to step (6).

(6) Write 1 to MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit to clear this bit.

(7) Check for errors in Response Data (MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7). If there is no error, go to step (8). If there is an error, go to step (9).

(8) Return Status of "No Error".

(9) Return Status of "Response Contents Error".

Note1: While waiting for the Transfer Complete interrupt, the Host Driver shall only issue commands that do not use the busy signal.

Note2: The Host Driver shall judge the Auto CMD12 complete by monitoring Transfer Complete.

Note3: When the last block of un-protected area is read using memory multiple block read command (CMD18), OUT_OF_RANGE error may occur even if the sequence is correct. The Host Driver should ignore it. This error will appear in the response of Auto CMD12 or in the response of the next memory command.

12.3.6.4.1.7.2 Transaction Control with Data Transfer Using DAT Line

Depending on whether DMA (optional) is used or not, there are two execution methods.

In addition, the sequences for SD transfers are classified into following three kinds according to how the number of blocks is specified:

(1) Single Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified is always one.

(2) Multiple Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified shall be one or more.

(3) Infinite Block Transfer: The number of blocks is not specified to the Host Controller before the transfer. This transfer is continued until an abort transaction is executed. This abort transaction is performed by CMD12 in the case of a SD memory card and by CMD52 in the case of a SDIO card.

12.3.6.4.1.7.2.1 Not using DMA

The sequence for not using DMA is shown in [Figure 12-181](#).

mmcsd-032

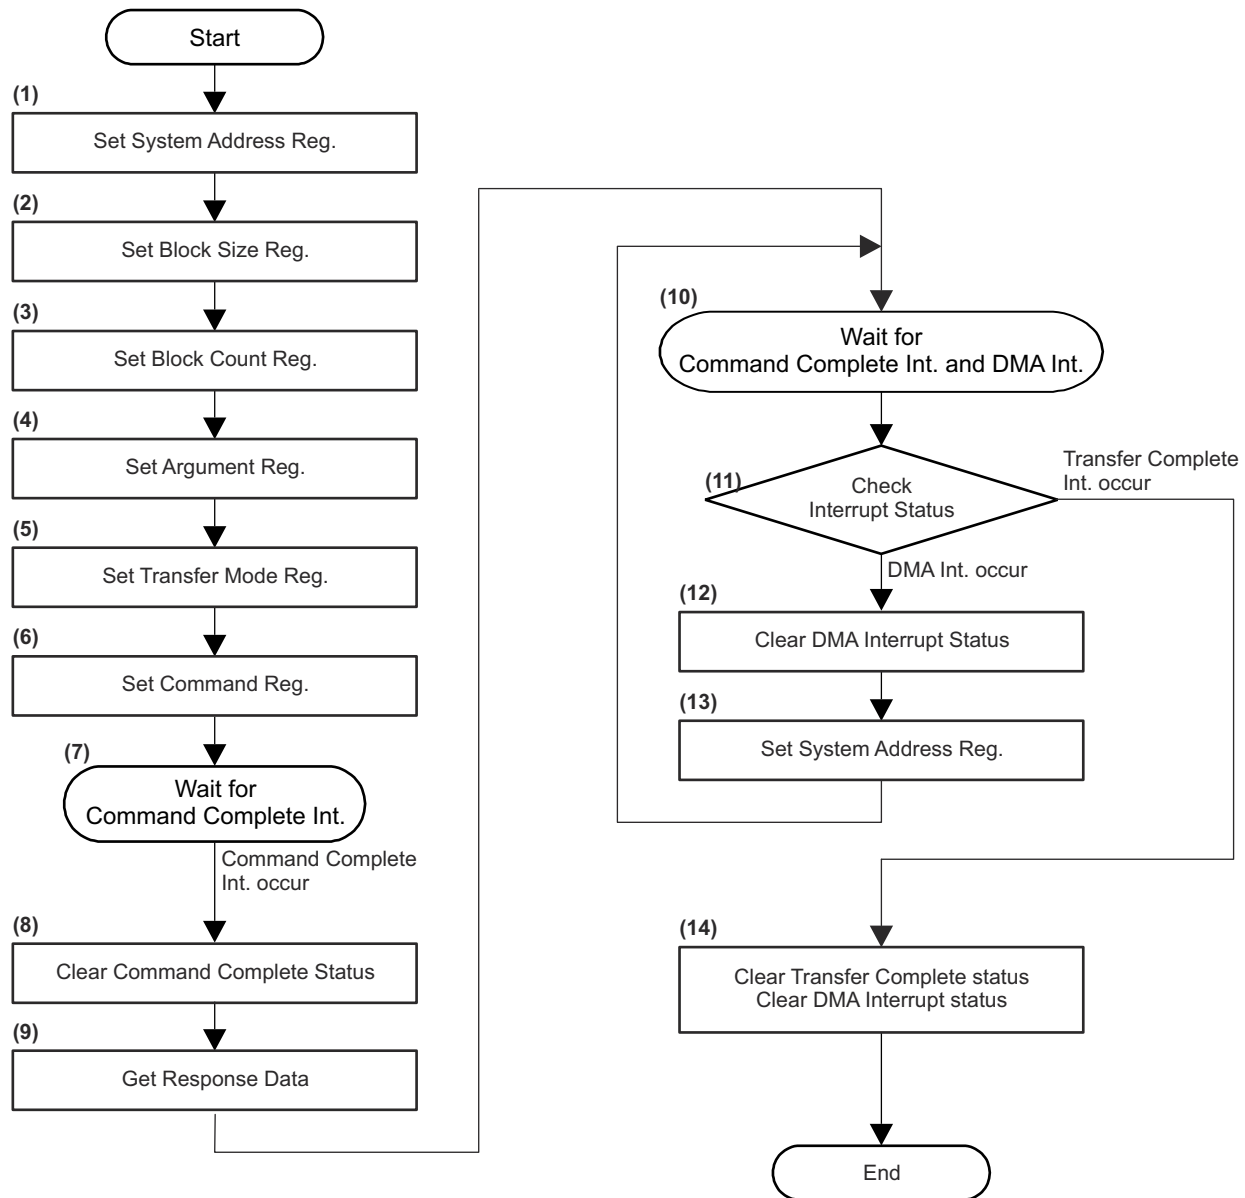

Figure 12-181. Transaction Control with Data Transfer Using DAT Line Sequence (Not using DMA)

- (1) Set the value corresponding to the executed data byte length of one block to the MMCSD0_BLOCK_SIZE register.
 - (2) Set the value corresponding to the executed data block count to the MMCSD0_BLOCK_COUNT register in accordance with *Determination of Transfer Type*.
 - (3) Set the argument value to Argument register (MMCSD0_ARGUMENT1_LO and MMCSD0_ARGUMENT1_HI).
 - (4) Set the value to the MMCSD0_TRANSFER_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSD0_TRANSFER_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*.
- If response check is enabled (MMCSD0_TRANSFER_MODE[7] RESP_ERR_CHK_ENA = 1), set MMCSD0_TRANSFER_MODE[8] RESP_INTR_DIS bit to 1 and select Response Type R1/R5 (MMCSD0_TRANSFER_MODE[6] RESP_TYPE).
- (5) Set the value to MMCSD0_COMMAND register.
- Note:** When writing the upper byte [3] of MMCSD0_COMMAND register, SD command is issued.
- (6) If response check is enabled, go to stop (9) else wait for the Command Complete Interrupt (MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit).
 - (7) Write 1 to the MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit for clearing this bit.
 - (8) Read Response register (MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7) and get necessary information of the issued command.
 - (9) In the case where this sequence is for write to a card, go to step (10). In case of read from a card, go to step (14).
 - (10) Then wait for Buffer Write Ready Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[4] BUF_WR_READY).
 - (11) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[4] BUF_WR_READY bit for clearing this bit.
 - (12) Write block data (in according to the number of bytes specified at the step (1)) to MMCSD0_DATA_PORT register.
 - (13) Repeat until all blocks are sent and then go to step (18).
 - (14) Then wait for the Buffer Read Ready Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[5] BUF_RD_READY).
 - (15) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[5] BUF_RD_READY bit for clearing this bit.
 - (16) Read block data (in according to the number of bytes specified at the step (1)) from the MMCSD0_DATA_PORT register.
 - (17) Repeat until all blocks are received and then go to step (18).
 - (18) If this sequence is for Single or Multiple Block Transfer, go to step (19). In case of Infinite Block Transfer, go to step (21).
 - (19) Wait for Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE).
 - (20) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit for clearing this bit.
 - (21) Perform the sequence for Abort Transaction in accordance with [Section 12.3.6.4.1.8, Abort Transaction](#).

Note: Step (1) and Step (2) can be executed at same time. Step (4) and Step (5) can be executed at same time.

12.3.6.4.1.7.2.2 Using SDMA

The sequence for using SDMA is shown in [Figure 12-182](#).

mmcsd-033

Figure 12-182. Transaction Control with Data Transfer Using DAT Line Sequence (Using SDMA)

- (1) Data location of system memory is set to the SDMA System Address register if MMCS0_HOST_CONTROL2[12] HOST_VER40_ENA = 0 or set to the MMCS0_ADMA_SYS_ADDRESS register if MMCS0_HOST_CONTROL2[12] HOST_VER40_ENA = 1.
- (2) Set the value corresponding to the executed data byte length of one block in the MMCS0_BLOCK_SIZE register.
- (3) Set the value corresponding to the executed data block count in the MMCS0_BLOCK_COUNT register in accordance with *Determination of Transfer Type*.
- (4) Set the argument value to the Argument register (MMCS0_ARGUMENT1_LO and MMCS0_ARGUMENT1_HI).
- (5) Set the value to the MMCS0_TRANSFER_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCS0_TRANSFER_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*. If response check is enabled (MMCS0_TRANSFER_MODE[7]

RESP_ERR_CHK_ENA = 1), set MMCSD0_TRANSFER_MODE[8] RESP_INTR_DIS bit to 1 and select Response Type R1/R5.

(6) Set the value to the MMCSD0_COMMAND register.

Note: When writing to the upper byte [3] of the MMCSD0_COMMAND register, the SD command is issued and SDMA is started.

(7) If response check is enabled, go to stop (10) else wait for the Command Complete Interrupt (MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit).

(8) Write 1 to the MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit to clear this bit.

(9) Read Response register (MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7) and get necessary information of the issued command.

(10) Wait for the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE) and DMA Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT).

(11) If MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit is set to 1, go to Step (14) else if MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT bit is set to 1, go to Step (12). The MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit is higher priority than the MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT bit.

(12) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT bit to clear this bit.

(13) Set the next system address of the next data position to the System Address register (MMCSD0_ADMA_SYS_ADDRESS) and go to Step (10).

(14) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit and MMCSD0_NORMAL_INTR_STS_ENA[3] DMA_INTERRUPT bit to clear this bit.

Note: Step (2) and Step (3) can be executed simultaneously. Step (5) and Step (6) can also be executed simultaneously.

12.3.6.4.1.7.2.3 Using ADMA

The sequence for using ADMA is shown in [Figure 12-183](#).

mmcsd-034

Figure 12-183. Transaction Control with Data Transfer Using DAT Line Sequence (Using ADMA)

- (1) Create Descriptor table for ADMA in the system memory.
- (2) Set the Descriptor address for ADMA in the MMCS0_ADMA_SYS_ADDRESS register.
- (3) Set the value corresponding to the executed data byte length of one block in the MMCS0_BLOCK_SIZE register.
- (4) Set the value corresponding to the executed data block count in the MMCS0_BLOCK_COUNT register in accordance with *Determination of Transfer Type*.
- (5) Set the argument value to the Argument register (MMCS0_ARGUMENT1_LO and MMCS0_ARGUMENT1_HI).
- (6) Set the value to the MMCS0_TRANSFER_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCS0_TRANSFER_MODE register. Multi/Single Block Select and Block Count Enable are determined according to *Determination of Transfer Type*. If response check is enabled (MMCS0_TRANSFER_MODE[7] RESP_ERR_CHK_ENA = 1), set MMCS0_TRANSFER_MODE[8] RESP_INTR_DIS bit to 1 and select Response Type R1/R5 (MMCS0_TRANSFER_MODE[6] RESP_TYPE).

(7) Set the value to the MMCSD0_COMMAND register.

Note: When writing to the upper byte [3] of the MMCSD0_COMMAND register, the SD command is issued and DMA is started.

(8) If response check is enabled, go to stop (11) else wait for the Command Complete Interrupt (MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit).

(9) Write 1 to the MMCSD0_NORMAL_INTR_STS[0] CMD_COMPLETE bit to clear this bit.

(10) Read Response register (MMCSD0_RESPONSE_0 - MMCSD0_RESPONSE_7) and get necessary information of the issued command.

(11) Wait for the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE) and ADMA Error Interrupt (MMCSD0_ADMA_ERR_STATUS[1-0] ADMA_ERR_STATE).

(12) If MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit is set to 1, go to Step (13) else if MMCSD0_ADMA_ERR_STATUS[1-0] ADMA_ERR_STATE bit field is set to 1, go to Step (14).

(13) Write 1 to the MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit to clear this bit.

(14) Write 1 to the MMCSD0_ADMA_ERR_STATUS[1-0] ADMA_ERR_STATE bit field to clear this bit.

(15) Abort ADMA operation. SD card operation should be stopped by issuing abort command. If necessary, the Host Driver checks MMCSD0_ADMA_ERR_STATUS register to detect why ADMA error is generated.

Note: Step (3) and Step (4) can be executed simultaneously. Step (6) and Step (7) can also be executed simultaneously.

12.3.6.4.1.8 Abort Transaction

An abort transaction is performed by issuing CMD12 for a SD memory card and by issuing CMD52 for a SDIO card. There are two cases where the Host Driver needs to do an Abort Transaction. The first case is when the Host Driver stops Infinite Block Transfers. The second case is when the Host Driver stops transfers while a Multiple Block Transfer is executing.

There are two ways to issue an Abort Command. The first is an asynchronous abort. The second is a synchronous abort. In an asynchronous abort sequence, the Host Driver can issue an Abort Command at any time unless MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit is set to 1. In a synchronous abort, the Host Driver shall issue an Abort Command after the data transfer stopped by using MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

12.3.6.4.1.8.1 Asynchronous Abort

The sequence for Asynchronous Abort is shown in [Figure 12-184](#).

Figure 12-184. Asynchronous Abort Sequence

(1) Issue Abort Command in accordance.

(2) Set both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit to 1 to do software reset.

(3) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit. If both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit are 0, go to "End". If either MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit or MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit is 1, go to step (3).

12.3.6.4.1.8.2 Synchronous Abort

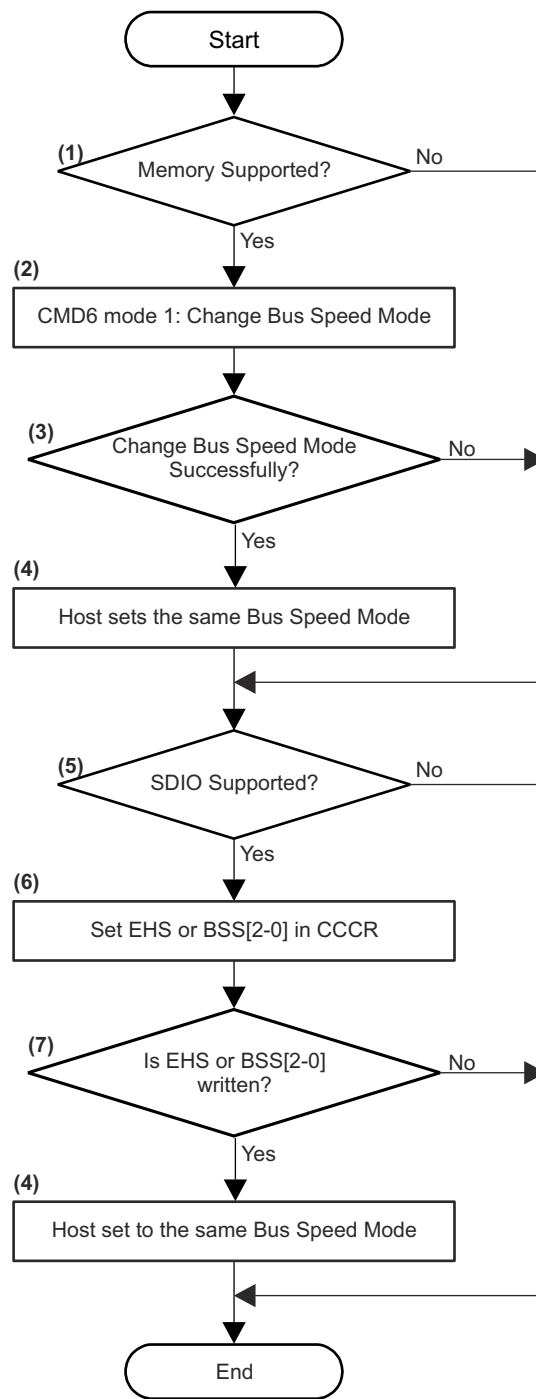

Figure 12-185. Synchronous Abort Sequence

- (1) Set the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit to 1 to stop SD transactions.
- (2) Wait for the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE).
- (3) Set the MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE bit to 1 to clear this bit.
- (4) Issue the Abort Command
- (5) Set both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit to 1 to do software reset.
- (6) Check both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit. If both MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit and MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit are 0, go to "End". If either MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit or MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit is 1, go to step (6).

12.3.6.4.1.9 Changing Bus Speed Mode

This section describes the sequence for switching the bus speed mode: Default Speed, High Speed mode and UHS-I mode. The switch command (CMD6) is used to change memory card bus speed mode. The EHS bit (SDIO Version 2.00) or BSS[2-0] bits (SDIO Version 3.00) in the CCCR register is used to change the bus speed mode for SDIO card. In case of Combo card, either of the switch method changes both memory and IO bus speed mode. This means the first switch is effective. Refer to the Physical Layer Specification Version 3.0x and the SDIO Specification Version 3.00 for more information about switching bus speed. [Figure 12-186](#) shows the sequence for switching bus speed mode for Combo Card. Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

mmcsd-037

Figure 12-186. Changing Bus Speed Mode

- (1) The Host Driver checks if the card supports memory. If not supported, go to (5).
- (2) Issue CMD6 with mode 1 to change bus speed mode (Default, High Speed mode or UHS-I mode).
- (3) Check the response of CMD6. If the card does not supports CMD6 (no response) or bus speed is not changed successfully, go to step (5). In this case, the card is in Default Speed mode.
- (4) The Host Driver changes the Host Controller bus speed mode to the same mode.
- (5) The Host Driver checks if the card supports SDIO. If not supported, go to the end.

(6) Issue CMD52 to write EHS bit or BSS[2-0] bits in CCCR to change bus speed mode (the same bus speed mode of (2) shall be set).

(7) If EHS or BSS[2-0] are not changed successfully, go to the end.

(8) The Host Driver changes the Host Controller bus speed to the same mode. In case of Combo card, bus speed is already changed at step (4) and this step does not affect changing bus speed.

12.3.6.4.1.10 Error Recovery

Figure 12-187. Error Report and Recovery

Figure 12-187 shows concept of error report and its recovery. The Host Controller has 2 interrupt status registers. If an error occurs in the SD Bus transaction, one of the bits is set in the MMCSD0_ERROR_INTR_STS register. If the function errors occur in the SDIO card, the card interrupt informs these function errors and the Card interrupt is set in the MMCSD0_NORMAL_INTR_STS_ENA register (the Card Interrupt is used to inform not only error statuses but also normal information. For example, to inform function ready). The Card Driver shall do function error recovery because the Host Driver does not know how to control the function. In the case that function error occurs due to SD Bus error, SD Bus error recovery is required before function error recovery. Abort command is used to recover SD Bus, and then the Host Driver should save error statuses related to SD Bus errors before issuing abort command and transfer these statuses to the Card Driver. These statuses may be used to recover function error. Following explanations are related to SD Bus error recovery. This specification does not specify the function error recovery.

When an error occurs during data transfer in 2L-HD UHS-II mode, there will be the case that Host Controller cannot drive D0 lane in input mode due to DIR LSS for retrieving lane direction is not detected. In this case, Host Driver cannot issue abort command for recovery. Then if DIR LSS is not detected, Host Controller sets MMCSD0_UHS2_ERR_INTR_STS[17] DEADLOCK_TIMEOUT bit. Host Driver should execute power cycle if MMCSD0_UHS2_ERR_INTR_STS[17] DEADLOCK_TIMEOUT bit is detected to recover from this error. Furthermore, if this type of error is detected several times in 2L-HD, Host Driver should use FD mode rather than using 2L-HD.

Implementation Note:

If the Card Driver cannot recover the function errors, the Host Driver should try following methods.

(9) Using IOEx for SDIO card

IOEx may be used as the reset per function basis. Sequence is as follows:

Clear IOEx = 0 and wait until IORx = 0 and then set IOEx = 1 again. SDIO may be recovered when IORx = 1.

(10) Using reset command for memory and SDIO card Re-initialization sequence is required.

(11) Off and on power supply for the SD Bus.

The card may be recovered by the power on reset. Re-initialization sequence is required.

The two cases where the Host Driver needs the "Error Recovery" sequence are classified as follows:

(1) Error Interrupt Recovery:

If error interrupt is indicated by the MMCSD0_ERROR_INTR_STS register, the Host Driver shall apply this sequence.

(2) Auto CMD12 Error Recovery:

If there are errors in Auto CMD12, the Host Driver shall apply this sequence. In terms of Return Status, Auto CMD12 Error Recovery is classified into 4 cases. It is shown in [Figure 12-188](#). If error occurs during memory write transfer, strongly recommend using ACMD22 and then in the following recovery sequence, retry to send remaining blocks not written.

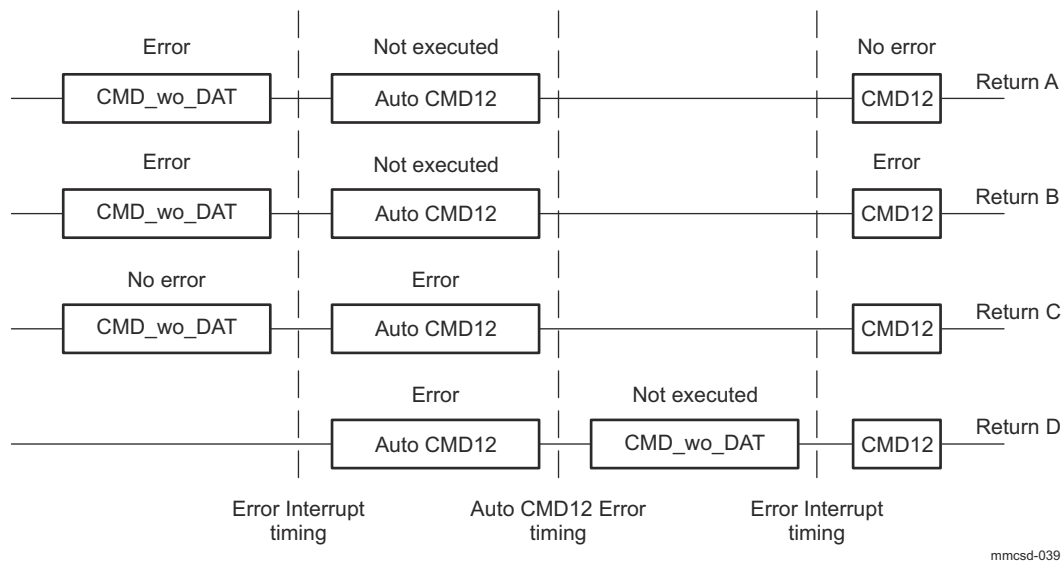

Figure 12-188. Return Status of Auto CMD12 Error Recovery

Implementation Note:

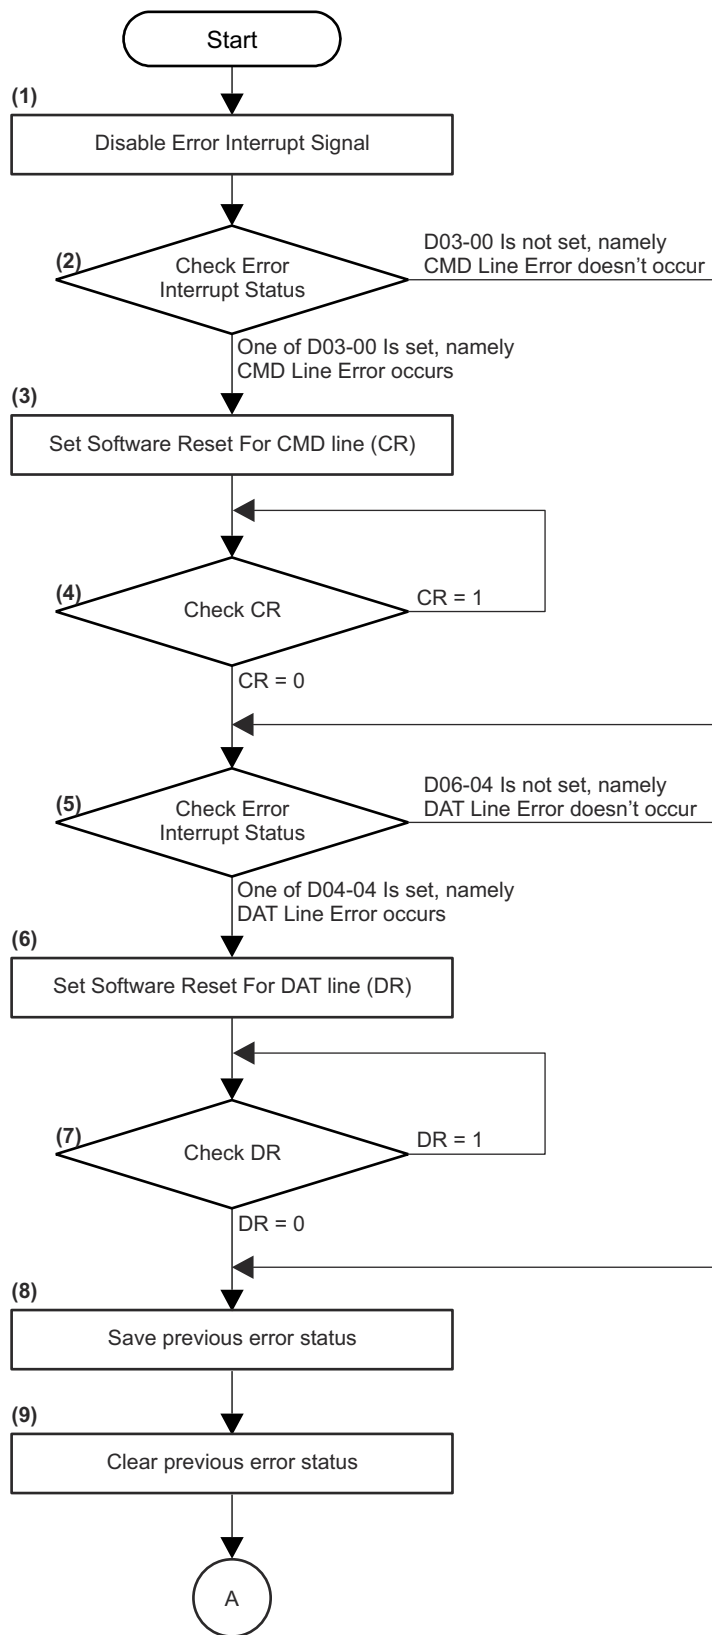

Abort command is used to recover from SD Bus error. SDIO transaction abort using CMD52 returns response but in the case of memory transaction abort using CMD12, response returns depending on the memory card state. If no response returns after issue CMD12, the Host Driver should check card state using CMD13. If the state is "tran" in the CURRENT_STATE, consider CMD12 is successful.

Implementation Note:

The following sequence is one possible error recovery flow. There may be another methods, sometimes using interrupts or polling. It can be possible to use another flows, based on Host System requirements.

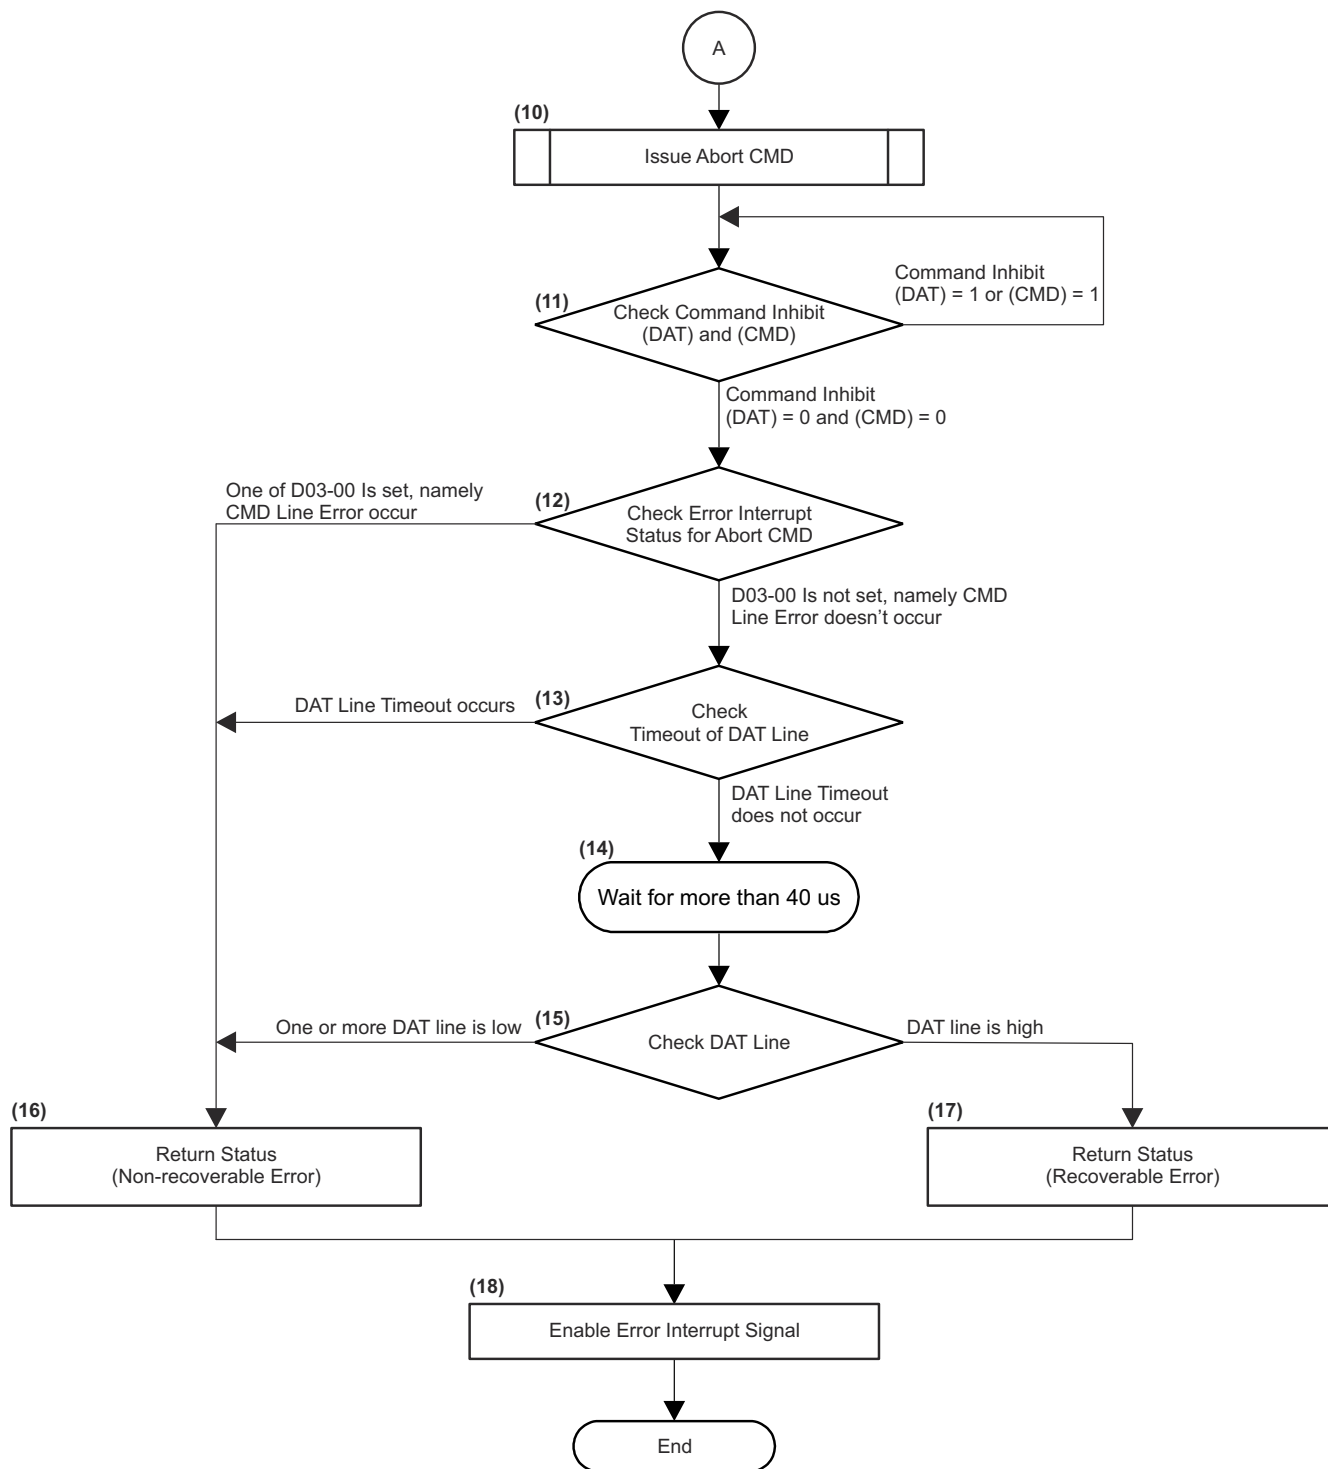

In these error recovery sequences, return statuses for the next sequence. When the Host Controller cannot issue the next command due to SD Bus error, the error recovery sequences return "Non-recoverable" status. In this case, the Host System may cut off power to the SD Bus and then power on SD Bus and initialize both the Host Controller and the SD card again.

12.3.6.4.1.10.1 Error Interrupt Recovery

mmscd-040

Figure 12-189. Error Interrupt Recovery Sequence (1)

mmcsd-041

Figure 12-190. Error Interrupt Recovery Sequence (2)

- (1) Disable the Error Interrupt Signal (MMCSD0_ERROR_INTR_SIG_ENA).
- (2) Check bits D03-00 in the MMCSD0_ERROR_INTR_STS register. If one of these bits (D03-00) is set to 1, go to step (3). If none are set to 1 (all are 0), go to step (5).
- (3) Set MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit to 1.

- (4) Check MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit. If MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit is 0, go to step (5). If it is 1, go to step (4).
- (5) Check bits D06-04 in the MMCSD0_ERROR_INTR_STS register. If one of these bits (D06-04) is set to 1, go to step (6). If none are set to 1 (all are 0), go to step (8).
- (6) Set MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit to 1 for software reset of the DAT line.
- (7) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit. If MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit is 0, go to step (8). If it is 1, go to step (7).
- (8) Save previous error status.
- (9) Clear previous error status with setting them to 1.
- (10) Issue Abort Command.
- (11) MMCSD0_PRESENTSTATE[1] INHIBIT_DAT bit and MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit. Repeat this step until both MMCSD0_PRESENTSTATE[1] INHIBIT_DAT bit and MMCSD0_PRESENTSTATE[0] INHIBIT_CMD bit are set to 0.
- (12) Check bits D03-00 in the MMCSD0_ERROR_INTR_STS register for Abort Command. If one of these bits is set to 1, go to step (16). If none of these bits are set to 1 (all are 0), go to step (13).
- (13) Check MMCSD0_ERROR_INTR_STS[4] DATA_TIMEOUT bit. If this bit is set to 1, go to step (16). If it is 0, go to step (14).
- (14) Wait for more than 40 us.
- (15) By monitoring the DAT [3:0] Line Signal Level in the MMCSD0_PRESENTSTATE register, judge whether the level of the DAT line is low or not. If one or more DAT lines are low, go to step (16). If the DAT lines are high, go to step (17).
- (16) Return Status of "Non-recoverable Error".
- (17) Return Status of "Recoverable Error".
- (18) Enable the Error Interrupt Signal (MMCSD0_ERROR_INTR_SIG_ENA).

12.3.6.4.1.10.2 Auto CMD12 Error Recovery

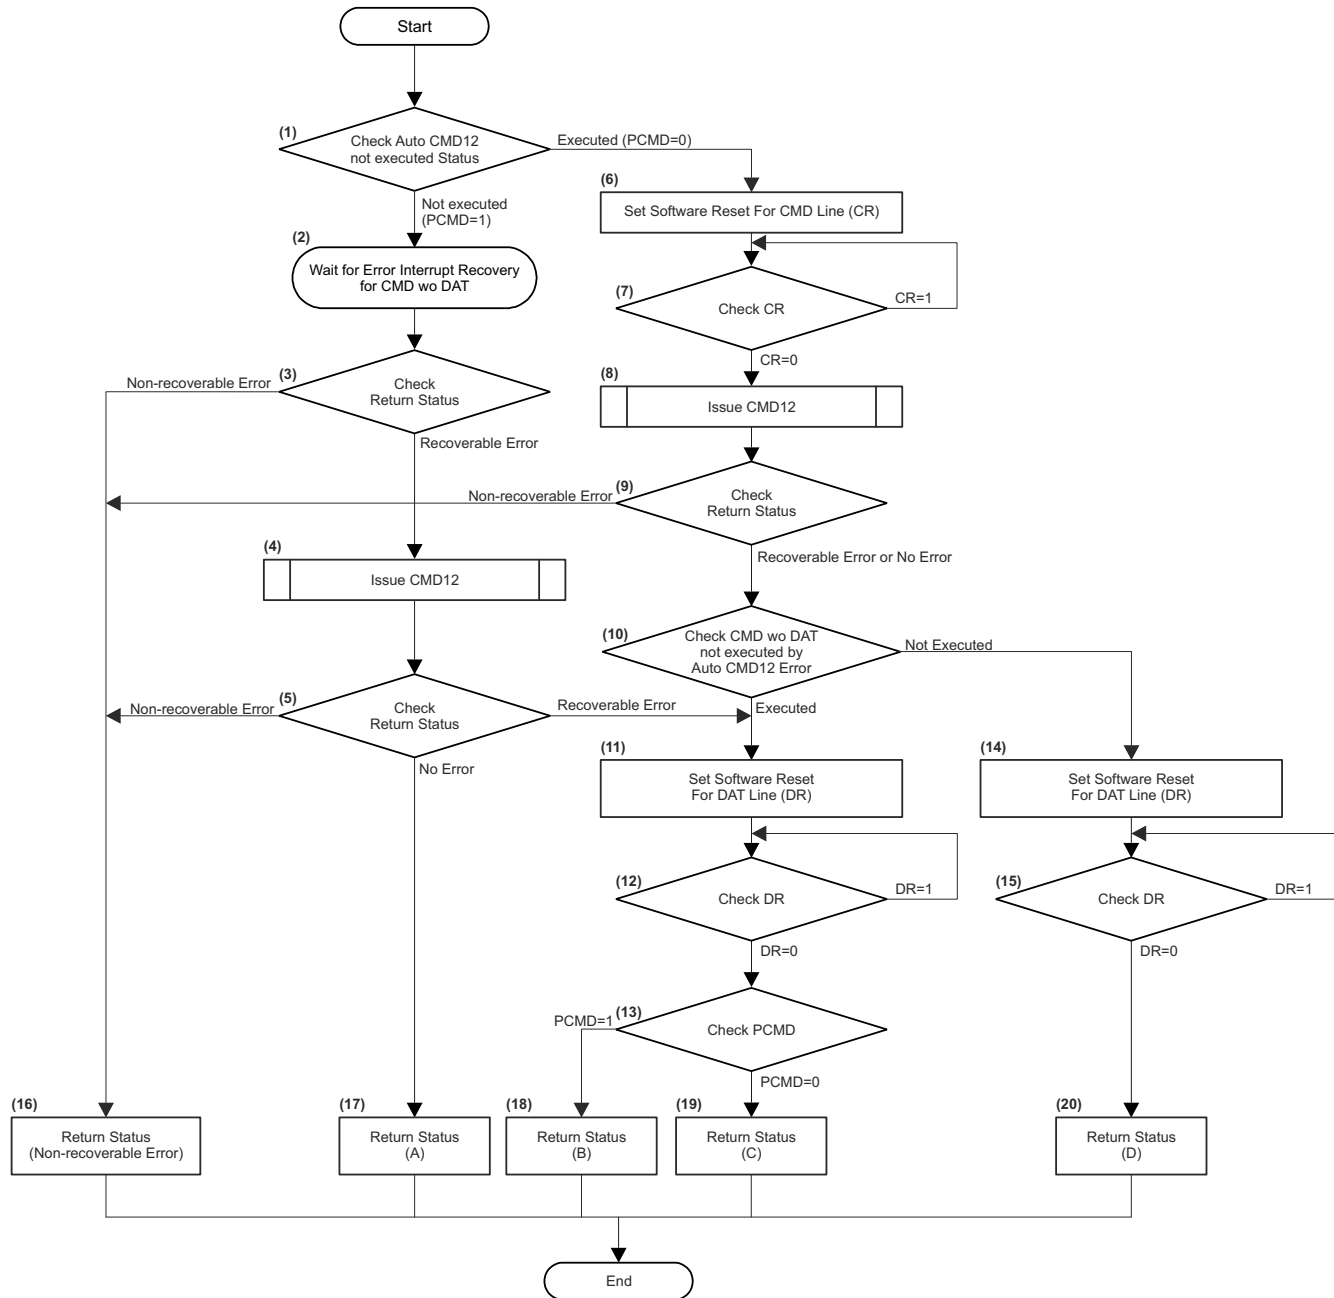

Figure 12-191. Auto CMD12 Error Recovery

The sequence for Auto CMD12 Error Recovery is shown in [Figure 12-191](#). Following four cases A-D shall be covered.

- A: An error occurred in CMD_wo_DAT, but not in the SD memory transfer.
- B: An error occurred in CMD_wo_DAT, and also occurred in the SD memory transfer.
- C: An error did not occur in CMD_wo_DAT, but an error occurred in the SD memory transfer.
- D: CMD_wo_DAT was not issued, and an error occurred in the SD memory transfer.

- (1) Check MMCSD0_AUTOCMD_ERR_STS[0] ACMD12_NOT_EXEC bit. If this bit is set to 1, go to step (2). If this bit is set to 0, go to step (6). In addition, the Host Driver shall define PCMD flag, which changes to 1 if MMCSD0_AUTOCMD_ERR_STS[0] ACMD12_NOT_EXEC bit is set to 1.
- (2) Wait for Error Interrupt Recovery for CMD_wo_DAT.
- (3) Check "Return Status". In the case of "Non-recoverable Error", go to step (16). In the case of "Recoverable Error", go to step (4).
- (4) Issue CMD12 .
- (5) If the CMD line errors occur for the CMD12 (one of D03-00 is set in the MMCSD0_ERROR_INTR_STS register), "Return Status" is "Non-recoverable Error" and go to step (16). If not CMD line error and busy timeout error occur (D04 is set in the MMCSD0_ERROR_INTR_STS register), "Return Status" is "Recoverable Error" and go to step (11). Otherwise, "Return Status" is "No error" and go to step (17).
- (6) Set MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit to 1 for software reset of the CMD line.
- (7) Check MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit. If MMCSD0_SOFTWARE_RESET[1] SWRST_FOR_CMD bit is 0, go to step (8). If it is 1, go to step (7).
- (8) Issue CMD12 . Acceptance of CMD12 depends on the state of the card. CMD12 may make the card to return to tran state. If the card is already in tran state, the card does not response to CMD12.
- (9) Check "Return Status" for CMD12. If "Return Status" returns "Non-recoverable Error", go to step (16). In the case of "Recoverable Error" or "No error", go to step (10).
- (10) Check the MMCSD0_AUTOCMD_ERR_STS[0] ACMD12_NOT_EXEC bit. If this bit is 0, go to step (11). If it is 1, go to step (14).
- (11) Set MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit to 1 for software reset of the DAT line.
- (12) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit. If MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit is 0, go to step (13). If it is 1, go to step (12).
- (13) Check the PCMD flag. If PCMD is 1, go to step (18). If it is 0, go to step (19).
- (14) Set MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit to 1 for software reset of the DAT line.
- (15) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit. If MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit is 0, go to step (20). If it is 1, go to step (15).
- (16) Return Status of "Non-recoverable Error".
- (17) Return Status that an error has occurred in CMD_wo_DAT, but not in the SD memory transfer.
- (18) Return Status that an error has occurred in both CMD_wo_DAT, and the SD memory transfer.
- (19) Return Status that an error has not occurred in CMD_wo_DAT, but has occurred in the SD memory transfer.
- (20) Return Status that CMD_wo_DAT has not been issued, and an error has occurred in the SD memory transfer.

12.3.6.4.1.11 Wakeup Control (Optional)

After the Host System goes into standby mode, the Host System can resume from standby via a wakeup event initiated by one of the following three events:

- (1) Interrupt from a SD card: If an SD card interrupt occurs, the Host System can resume from standby mode. If the Host System uses this wakeup factor, SD Bus power shall be kept on.
- (2) Insertion of SD card: If a SD card is inserted, the Host System can resume from standby mode.
- (3) Removal of SD card: If a SD card is removed, the Host System can resume from standby mode.

The sequence for preparing wakeup before the Host System goes into standby mode is shown in [Figure 12-192](#).

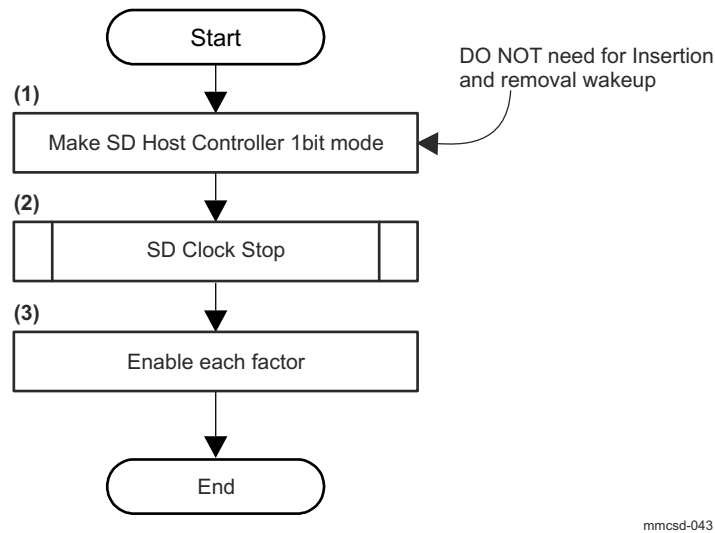

Figure 12-192. Wakeup Control before Standby Mode

- (1) Set MMCSD0_HOST_CONTROL1[1] DATA_WIDTH bit to 0.
- (2) Execute SD Clock Stop Sequence as described in [Section 12.3.6.4.1.2.2, SD Clock Supply and Stop Sequence](#).
- (3) Clear the MMCSD0_NORMAL_INTR_STS register and the MMCSD0_NORMAL_INTR_SIG_ENA register, and then set the enable bits of each wakeup event factor to 1 in the MMCSD0_WAKEUP_CONTROL register and set the bits of MMCSD0_ERROR_INTR_STS_ENA register to use wakeup.

The sequence for wakeup once in standby mode is shown in [Figure 12-193](#).

Figure 12-193. Wakeup from Standby

- (1) Wait for wakeup event.
- (2) Set the enable bits of each wakeup event factor to 0 in the MMCSD0_WAKEUP_CONTROL register and then clear event statuses in the MMCSD0_NORMAL_INTR_STS register. If necessary, set the MMCSD0_NORMAL_INTR_SIG_ENA register.

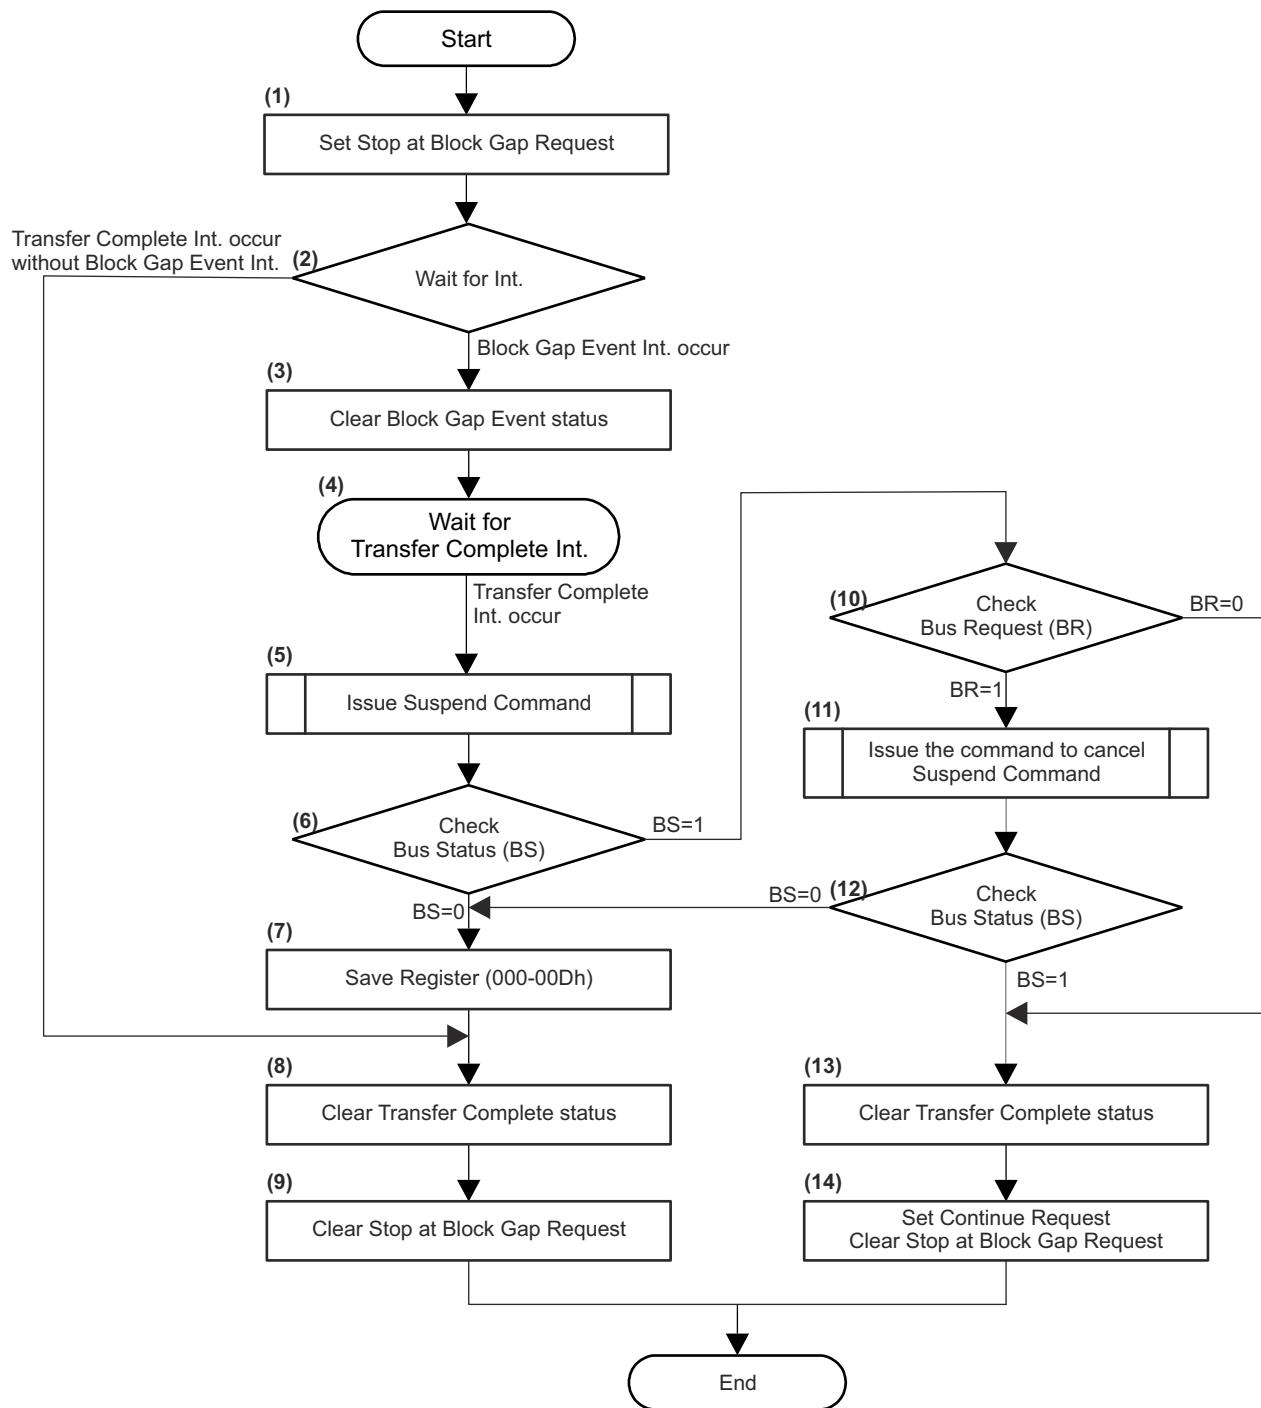

(3) Execute SD Clock Supply Sequence (see [Section 12.3.6.4.1.2.2, SD Clock Supply and Stop Sequence](#)).

(4) Set the SD Bus width (see [Section 12.3.6.4.1.4, Changing Bus Width](#)).

12.3.6.4.1.12 Suspend/Resume (Optional, Not Supported from Version 4.00)

If a SD card supports suspend and resume functionality, then the Host Controller can initiate suspend and resume. It is necessary for both the Host Controller and the SD card to support the function of "Read Wait". ADMA operation does not support this function.

12.3.6.4.1.12.1 Suspend Sequence

mmcsd-045

Figure 12-194. The Sequence for Suspend

- (1) Set MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit to 1 to stop the SD transaction.
- (2) Wait for an Interrupt. If MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit is set to 0 and MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit is set to 1, go to step (8). If MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit is set to 1, go to step (3).
- (3) Set MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit to 1 to clear this bit.
- (4) Wait for the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS_ENA[1] XFER_COMPLETE).
- (5) Issue the Suspend Command in accordance with [Section 12.3.6.4.1.7.1](#), *Transaction Control without Data Transfer Using DAT Line*.
- (6) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (10).
- (7) Save the register .
- (8) Set MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit to 1 to clear this bit.
- (9) Set MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit to 0 to clear this bit.
- (10) Check the BR value of the response data. If BR is 1, go to step (11). If BR is 0, go to step (13).
- (11) Issues the command to cancel the previous suspend command in accordance with [Section 12.3.6.4.1.7.1](#), *Transaction Control without Data Transfer Using DAT Line*.
- (12) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (13).
- (13) Set MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit to 1 to clear this bit.
- (14) Set MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit to 1 to continue the transaction. At the same time, write 0 to MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit to clear this bit.

Conditions			Suspend/Resume Function	
Host Suspend/Resume Support	Card Suspend/Resume Support	Card Read Wait Support	Write Suspend/Resume	Read Suspend/Resume
Not supported	Don't care	Don't care	Cannot be used	Cannot be used
Supported	Not supported	Don't care	Cannot be used	Cannot be used
Supported	Supported	Not supported	Can be used	Cannot be used
Supported	Supported	Supported	Can be used	Can be used

mmcsd-046

Figure 12-195. Suspend/Resume Condition

12.3.6.4.1.12.2 Resume Sequence

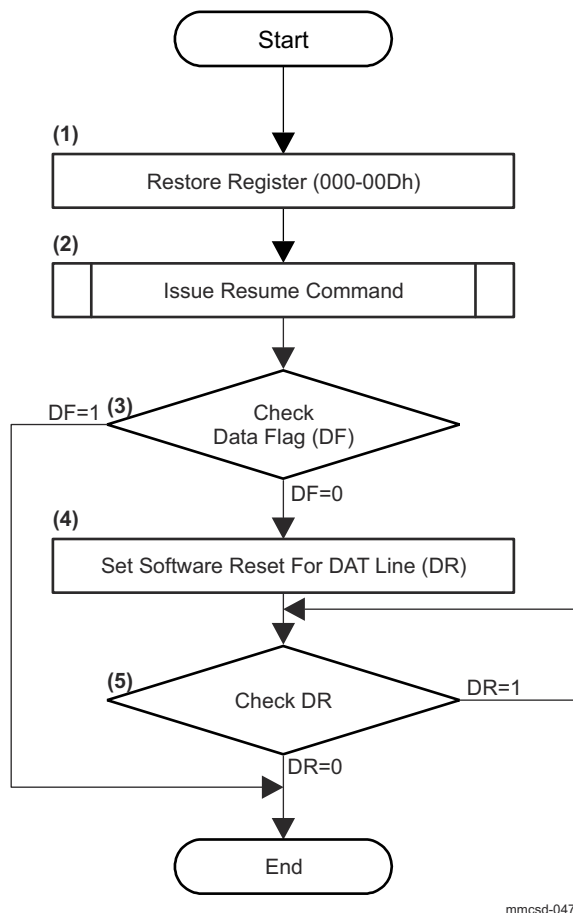

Figure 12-196. The Sequence for Resume

- (1) Restore the register .
- (2) Issue the Resume Command .
- (3) Check the DF value of the response data. If DF is 0, go to step (4). If DF is 1, go to "End".
- (4) Set MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit to 1 for software reset of the DAT line.
- (5) Check MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit. If MMCSD0_SOFTWARE_RESET[2] SWRST_FOR_DAT bit is 0, go to "End". If it is 1, go to step (5).

12.3.6.4.1.12.3 Stop At Block Gap/Continue Timing for Read Transaction

The timing of Stop At Block Gap Request and Continue Request. The Transfer Complete interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE) is always generated by setting MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit where data transfer is stopped. However, generation of the Block Gap Event interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT) is dependent on whether the last data block is sent or not. Block Gap Event is not generated If all data blocks are transferred (the last block is transferred). It is not necessary to enable Block Gap Event interrupt. The status can be checked when transfer complete interrupt is detected. It is not necessary to use Continue Request (MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE) if Block Gap Event status is not set because there is no further data to be transferred. If Read Wait is not supported, Host Controller stops SD Clock at the block gap.

Implementation Note:

The MMCSD0_BLOCK_GAP_CONTROL[2] RDWAIT_CTRL, MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE, MMCSD0_PRESENTSTATE[9] RD_XFER_ACTIVE bits shall be set and cleared by the Host Controller.

The MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit shall be set and cleared by the Host Driver. The MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit shall be set by the Host Driver and be cleared by the Host Controller. The MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit and MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit shall be set by the Host Controller and be cleared by the Host Driver.

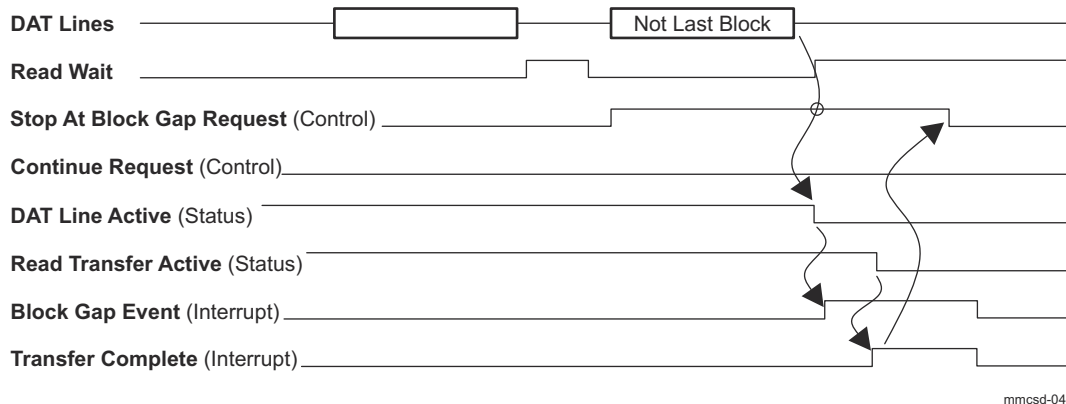

Figure 12-197. Wait Read Transfer by Stop At Block Gap Request

The Host Controller can accept a Stop At Block Gap Request (MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP) when all the following conditions are met.

- (1) It is at the block gap.
- (2) The Host Controller can assert read wait or it is already asserted.
- (3) The MMCSD0_BLOCK_GAP_CONTROL[2] RDWAIT_CTRL bit is set to 1.

After accepting the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit:

- (1) Clear MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and generate the Block Gap Event Interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT).
- (2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0_PRESENTSTATE[9] RD_XFER_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE).
- (3) After accepting MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit, clear the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

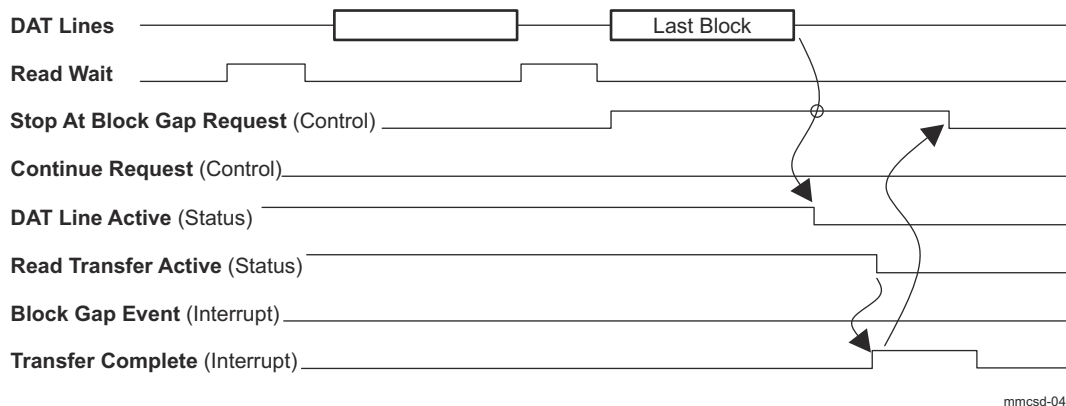

Figure 12-198. Stop At Block Gap Request is Not Accepted at the Last Block of the Read Transfer

If the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit and stops the transaction normally. The Block Gap Event Interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT) is not generated. When the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE) is generated, and if the MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit status is not set to 1, the driver shall clear the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

Figure 12-199. Continue Read Transfer by Continue Request

To restart a stopped data transfer, set the MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit to 1 (the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit shall be set to 0).

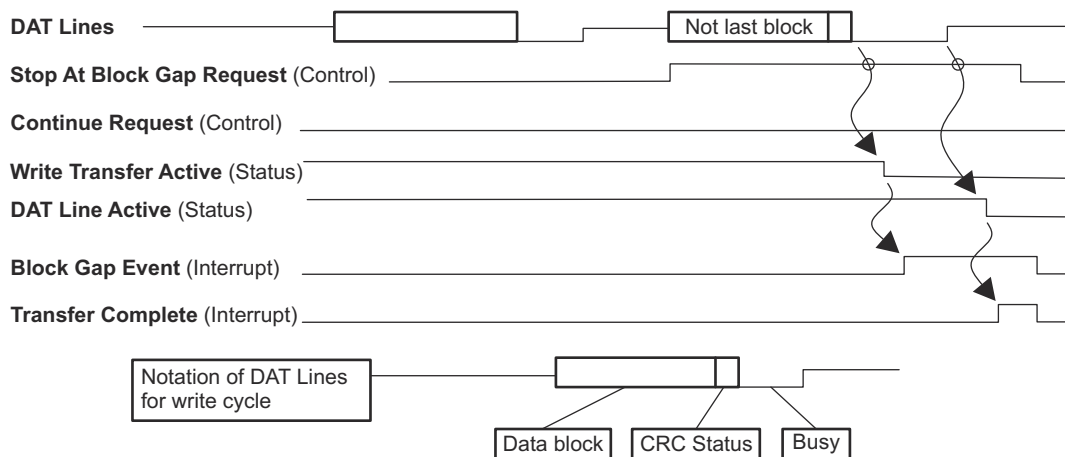

After accepting the MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit:

- (1) Release MMCSD0_BLOCK_GAP_CONTROL[2] RDWAIT_CTRL bit (if the data block can accept the next data).
- (2) Set the MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and the MMCSD0_PRESENTSTATE[9] RD_XFER_ACTIVE bit.
- (3) The MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit is automatically cleared by (2).

The end of the read transfer is specified by data length.

- (1) Clear the MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and do not generate the Block Gap Event Interrupt (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVENT bit).
- (2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0_PRESENTSTATE[9] RD_XFER_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit).

12.3.6.4.1.12.4 Stop At Block Gap/Continue Timing for Write Transaction

mmcsd-051

Figure 12-200. Wait Write Transfer by Stop At Block Gap Request

The Host Controller can accept the MMCSDBLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit when matches all following conditions:

- (1) It is at the block gap.
- (2) No valid write data remains in the Host Controller.

After accepting the MMCSDBLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

- (1) Clear the MMCSDPRESENTSTATE[8] WR_XFER_ACTIVE bit and generate the Block Gap Event Interrupt (MMCSDNORMAL_INTR_STS[2] BLK_GAP_EVENT bit).
- (2) After the busy signal is released, clear the MMCSDPRESENTSTATE[2] DATA_LINE_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSDNORMAL_INTR_STS[1] XFER_COMPLETE bit).
- (3) After accepting the Transfer Complete Interrupt (MMCSDNORMAL_INTR_STS[1] XFER_COMPLETE bit), clear the MMCSDBLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

mmcsd-052

Figure 12-201. Stop At Block Gap Request is Not Accepted at the Last Block of the Write Transfer

If the MMCSDBLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCSDBLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit and terminates the transaction normally. The Block Gap Event Interrupt (MMCSDNORMAL_INTR_STS[2] BLK_GAP_EVENT) is not generated. When the Transfer Complete Interrupt (MMCSDNORMAL_INTR_STS[1] XFER_COMPLETE) is generated, and if the MMCSDNORMAL_INTR_STS[2] BLK_GAP_EVENT bit is not set to 1, the driver shall clear the MMCSDBLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit.

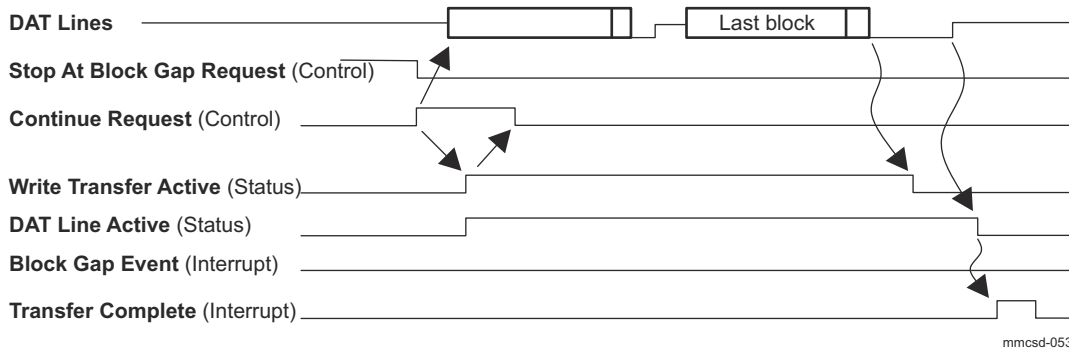

Figure 12-202. Continue Write Transfer by Continue Request

To restart a stopped data transfer, set the MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit to 1 (the MMCSD0_BLOCK_GAP_CONTROL[0] STOP_AT_BLK_GAP bit shall be set to 0).

After accepting the MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit:

(1) Set the MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and MMCSD0_PRESENTSTATE[8] WR_XFER_ACTIVE bit.

(2) The MMCSD0_BLOCK_GAP_CONTROL[1] CONTINUE bit is automatically cleared by (1).

The end of transfer is specified by data length.

(1) Clear the MMCSD0_PRESENTSTATE[8] WR_XFER_ACTIVE bit, and do not generate the (MMCSD0_NORMAL_INTR_STS[2] BLK_GAP_EVEN).

(2) After the busy signal is released, clear the MMCSD0_PRESENTSTATE[2] DATA_LINE_ACTIVE bit and generates the Transfer Complete Interrupt (MMCSD0_NORMAL_INTR_STS[1] XFER_COMPLETE bit).

12.3.6.4.2 Driver Flow Sequence

Note

This section is applicable for MMCSD0 and MMCSD1 but MMCSD0 registers are used in the content.

Note

UHSII is not supported. For more information, see *MMCSD Not Supported Features*.

12.3.6.4.2.1 Host Controller Setup and Card Detection

12.3.6.4.2.1.1 Host Controller Setup Sequence

Figure 12-203 and Table 12-291 show a Host Controller setup sequence.

mmcsd-054

Figure 12-203. Host Controller Setup Sequence

Table 12-291. Host Controller Setup Sequence

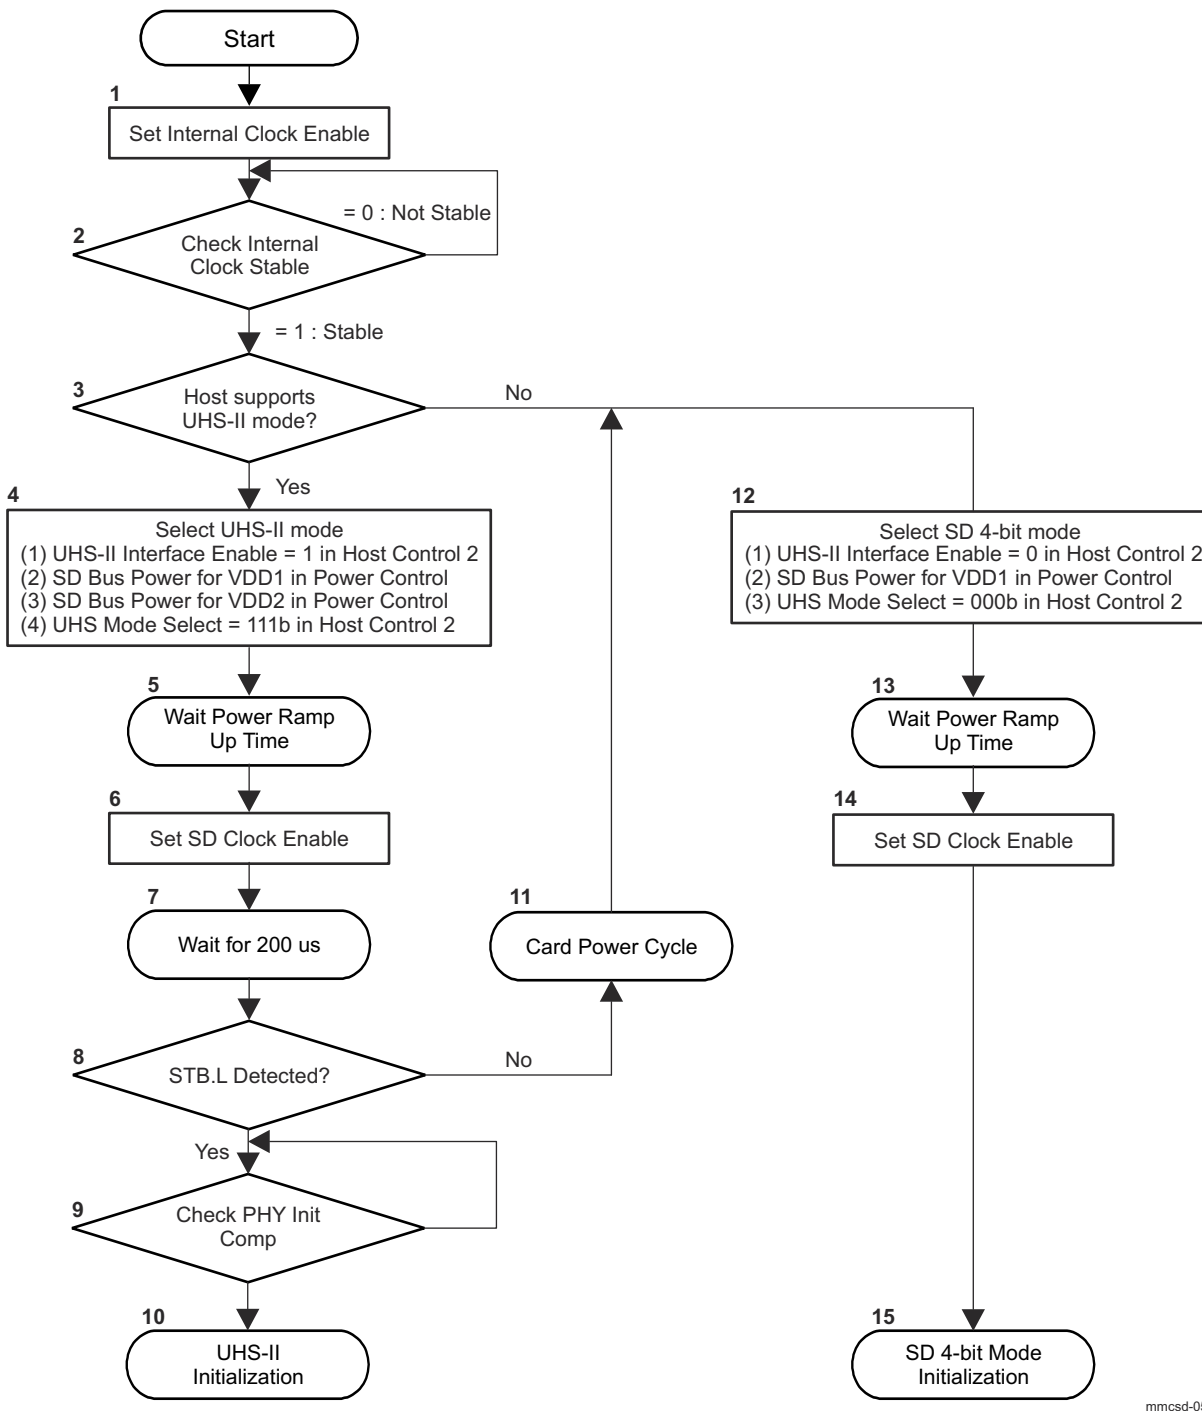

Step	Description
1	Set parameters for all Host Controller version. Set the MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE and MMCSD0_TIMEOUT_CONTROL[3-0] COUNTER_VALUE bit fields.
2	Read the MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM bit field.

Table 12-291. Host Controller Setup Sequence (continued)

Step	Description
3	If Specification Version number (MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM) is less than version 3, go to step (4), if it is version 3 or later go to step (5).
4	Set the MMCSD0_CLOCK_CONTROL register using 8-bit Divided Clock mode.
5	Set Version 3 parameters. The MMCSD0_CLOCK_CONTROL register is sets in 10-bit Divided Clock Mode or Programmable Clock Mode. If Clock Multiplier in the MMCSD0_CAPABILITIES register is not zero, Programmable Clock Mode should be used. If Preset Value is used, set Preset Values of SD I/F Modes in the Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set the MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit to 1.
6	If Specification Version number (MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM) is version 4, go to step (7), if it is less than version 4, exits.
7	Set Version 4 parameters. Set the MMCSD0_HOST_CONTROL2[12] HOST_VER40_ENA bit to 1. If the MMCSD0_CAPABILITIES[27] ADDR_64BIT_SUPPORT_V4 bit is set to 1, set the MMCSD0_HOST_CONTROL2[13] BIT64_ADDRESSING bit to 1. If UHS-II Support is set to 1 and 1.8 V VDD2 Support is set to 1 in the MMCSD0_CAPABILITIES register, set SD Bus Voltage Select for VDD2 to 1.8 V mode in the MMCSD0_POWER_CONTROL register, set preset value for UHS-II Mode to Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set Timeout Counter Value for CMD_RES and Timeout Counter Value for Deadlock in the MMCSD0_UHS2_TIMER_CONTROL register based on Timeout Clock Frequency and Timeout Clock Unit in the MMCSD0_CAPABILITIES register. If Asynchronous Interrupt Support in the MMCSD0_CAPABILITIES register is set to 1, set Asynchronous Interrupt Enable to 1 in the MMCSD0_HOST_CONTROL2 register.

12.3.6.4.2.1.2 Card Interface Detection Sequence

This procedure is invoked by the Card Insertion interrupt. [Figure 12-204](#) and [Table 12-292](#) show a card interface detection sequence.

mmcsd-055

Figure 12-204. Card Interface Detection Sequence**Table 12-292. Card Interface Detection Sequence**

Step	Description
1	Set Internal Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
2	Wait until Internal Clock Stable is set to 1 in the MMCSD0_CLOCK_CONTROL register.
3	If Host Supports UHS-II, go to step (4) else go to step (12).
4	Try to initialize a card to UHS-II mode. Set UHS-II Interface Enable to 1 in the MMCSD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 and SD Bus Power for VDD2 to 1 in the MMCSD0_POWER_CONTROL register, and set UHS Mode Select to 111b in the MMCSD0_HOST_CONTROL2 register.
5	Wait power ramp up time. It is dependent on a Host System.

Table 12-292. Card Interface Detection Sequence (continued)

Step	Description
6	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
7	Wait 200 μ s to check a card supports UHS-II mode.
8	Check STB.L Detection in the MMCSD0_PRESENTSTATE register. If UHS-II IF is detected, go to step (9). If UHS-II IF is not detected, go to step (11).
9	Wait until Lane Synchronization in the MMCSD0_PRESENTSTATE register is set to 1 (PHY Initialization is completed).
10	Perform UHS-II initialization.
11	Perform card power cycle.
12	Try to initialize a card to SD 4-bit mode. Set UHS-II Interface Enable to 0 in the MMCSD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 to 1 in the MMCSD0_POWER_CONTROL register, and set UHS Mode Select to 000b in the MMCSD0_HOST_CONTROL2 register.
13	Wait power ramp up time. It is dependent on a Host System.
14	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
15	Perform SD 4-bit mode initialization. Refer to Section 12.3.6.4.1.6, Card Initialization and Identification (for SD I/F) .

12.3.6.4.2.2 Boot Operation

The boot operation sequence is shown in [Figure 12-205](#).

mmcsd-056

Figure 12-205. Boot Operation Sequence**12.3.6.4.2.2.1 Normal Boot Operation: (For Legacy eMMC 5.0)**

The Host driver writes the boot timeout value into MMCSDD0_BOOT_TIMEOUT_CONTROL register as per the eMMC4.3+ spec.

When the Host driver sets the "BOOT_ENABLE" to 1 in MMCSDD0_BLOCK_GAP_CONTROL register and "DATA_XFER_DIR" bit to "1" in MMCSDD0_TRANSFER_MODE register, the Host controller drives the CMD line to "0" for boot operation.

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV_BOOT_ACK" interrupt to the driver (MMCSDD0_NORMAL_INTR_STS[13] RCV_BOOT_ACK). If the Host controller doesn't receive the boot

acknowledgement from the device within the timeout value, the Host controller will assert the data timeout error interrupt (MMCSD0_ERROR_INTR_STS[4] DATA_TIMEOUT).

After servicing the boot acknowledge interrupt or data timeout error interrupt, the driver programs the MMCSD0_BOOT_TIMEOUT_CONTROL register with boot data timeout value.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The Host controller terminates the boot operation when the programmed number of blocks is transferred to the System. The Driver can write "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register.

The boot operation can also be terminated in between the boot transfer (the Driver can set the "BOOT_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, the Host controller asserts soft reset for CMD line and DATA line internally once the driver clears the BOOT_COMPLETE interrupt (MMCSD0_NORMAL_INTR_STS[14] BOOT_COMPLETE), to reset all the state machines to idle state.

There is no need to perform error recovery sequence in case data timeout interrupt occurs during boot operation (ignore sending abort command, soft reset and just clear the timeout interrupt and proceed with the boot flow).

If the device sends wrong acknowledgement to the Host, the Host controller will assert Data CRC Error interrupt (MMCSD0_ERROR_INTR_STS[5] DATA_CRC) on the Driver. In this case, the Host driver has to stop the boot mode operation by setting "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register and write soft reset for CMD and data line.

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller will assert Data End Bit Error interrupt (MMCSD0_ERROR_INTR_STS[6] DATA_ENDBIT) on the Driver.

The Host driver stops the boot mode operation by setting "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register and write soft reset for CMD and data line.

Note: Enable the MMCSD0_BLOCK_GAP_CONTROL[7] BOOT_ACK_ENA bit during boot operation. If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

12.3.6.4.2.2 Alternate Boot Operation (For Legacy eMMC 5.0):

The Host driver writes the boot timeout value as per the eMMC4.3+ spec into MMCSD0_BOOT_TIMEOUT_CONTROL register.

If the "ALT_BOOT_MODE" and "BOOT_ENABLE" is set to 1 in MMCSD0_BLOCK_GAP_CONTROL register and "DATA_XFER_DIR" bit is set to 1 in MMCSD0_TRANSFER_MODE register, the host controller drives the CMD0 (0xFFFFFFFF) on the CMD line.

The system shall wait for command complete interrupt before "RCV_BOOT_ACK" interrupt (MMCSD0_NORMAL_INTR_STS[13] RCV_BOOT_ACK).

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV_BOOT_ACK" interrupt to the driver.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The System needs to send CMD0 to inform the device about the boot operation complete. The system shall program MMCSD0_COMMAND register with argument "00000000h" for the CMD0 and waits for command complete.

The Host controller terminates the boot operation when the programmed number of blocks are transferred to the System and the Driver shall send CMD0 to eMMC card and then program "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register.

The boot operation can be terminated at any time (the Driver can send CMD0 and set the "BOOT_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, all state machines in the Host controller need to move to IDLE state. The Host controller asserts the soft reset for CMD and data line internally when the driver clears the BOOT_COMPLETE interrupt (MMCSD0_NORMAL_INTR_STS[14] BOOT_COMPLETE) and all the state machine goes to the idle state.

If the Host controller doesn't receive the acknowledgement from the device with in timeout value the Host controller will assert the data timeout error interrupt (MCSD0_ERROR_INTR_STS[4] DATA_TIMEOUT).

The driver programs the MMCSD0_BOOT_TIMEOUT_CONTROL register with boot data timeout value.

There is no need to perform error recovery sequence in case of data timeout interrupt as mentioned above. If the device sends wrong acknowledgement to the Host, then Host controller will assert Data CRC Error interrupt to the Driver (MCSD0_ERROR_INTR_STS[5] DATA_CRC). The Host driver has to stop the boot mode operation by setting "ALT_BOOT_MODE" and "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register and write soft reset for CMD and data line.

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller asserts Data End Bit Error interrupt (MCSD0_ERROR_INTR_STS[6] DATA_ENDBIT) on the Driver. The Host driver stops the boot mode operation by setting "ALT_BOOT_MODE" and "BOOT_ENABLE" as "0" in MMCSD0_BLOCK_GAP_CONTROL register and write soft reset for CMD and data line.

Note: Enable the MMCSD0_BLOCK_GAP_CONTROL[7] BOOT_ACK_ENA bit during boot operation . If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

12.3.6.4.2.2.3 Boot Code Chunk Read Operation (For Legacy eMMC 5.0):

The following figure explains the boot code read done as chunks of data (the Driver can read the boot data as 2K, 4K, 1K and 8K etc. instead of 128K at a time

mmcsd-057

Figure 12-206. Boot Code Access Flow Diagram (1)

Figure 12-207. Boot Code Access Flow Diagram (2)

12.3.6.4.2.3 Retuning procedure (For Legacy Interface)

12.3.6.4.2.3.1 Sampling Clock Tuning

The SD bus can be operating in high clock frequency mode and then the data window from the card on CMD and DAT[3:0] lines gets smaller. The position of the data window will vary depending on the card and host system implementation. Therefore, the Host Controller shall support a tuning circuit when SDR104 or SDR50.

The Host Controller shall support a tuning circuit when SDR104 or SDR50 (if Use Tuning for SDR50 is set to 1 in the MMCSD0_CAPABILITIES register) is supported by executing the tuning procedure and adjusting the sampling clock. Execute Tuning and Sampling Clock Select in the MMCSD0_HOST_CONTROL2 register are used to control the tuning circuit.

12.3.6.4.2.3.2 Tuning Modes

The re-tuning timing is specified by two methods: Re-Tuning Request generated by Host Controller and expiration of a re-tuning timer prepared by Host Driver.

(1) Re-Tuning Mode 1 The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To

enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MB.

(2) Re-Tuning Mode 2 The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled.

12.3.6.4.2.3.3 Re-Tuning Mode 2

The [Figure 12-208](#) defines sampling clock tuning procedure supported by Host Controller. In default, for lower frequency operation, fixed sampling clock is used to receive signals on CMD and DAT[3:0]. Before using SDR104, sampling clock tuning is required. Start of sampling clock tuning is requested by setting Execute Tuning to 1 and Sampling Clock Select to 0.

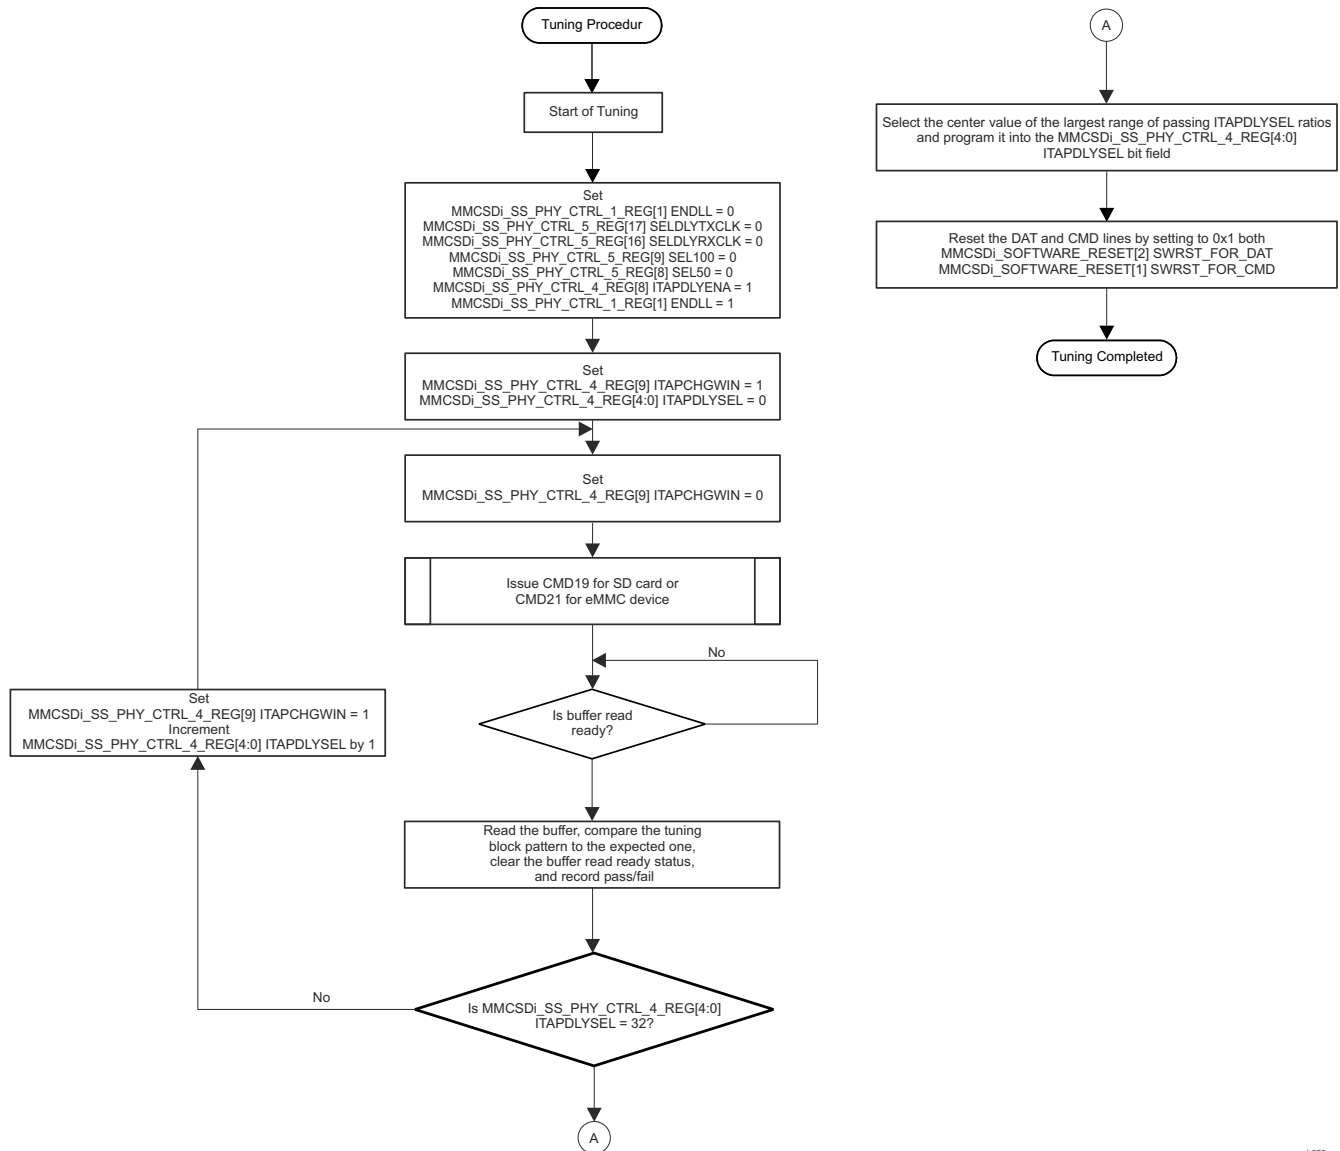

Figure 12-208. MMCSD Clock Tuning

Host driver issue CMD19 repeatedly until the host controller resets Execute Tuning to 0. Host Controller resets Execute Tuning to 0 when tuning is completed or tuning is not completed within 40 times. Host Driver can abort this loop by 40 times CMD19 issue or 150 ms time-out.

If tuning is completed successfully, Host Controller set Sampling Clock Select to 1 and this means the Host Controller start to use tuned sampling clock. If tuning is failed, Host Controller keeps Sampling Clock Select to 0. By writing Sampling Clock Select to 0, sampling clock is switched from tuned sampling clock to fixed sampling clock. Re-tuning time would be smaller than the first tuning time. CMD19 response errors are not indicated while tuning is performed.

The clock tuning tap delay values are selected using Variable sampling point detection. Fixed tap delay value is used for fixed tuning clock method.

12.3.6.4.2.4 Command Queuing Driver Flow Sequence

12.3.6.4.2.4.1 Command Queuing Initialization Sequence

Figure 12-209 and Table 12-293 show a Command Queuing initialization sequence.

Figure 12-209. Command Queuing Initialization Sequence

Table 12-293. Command Queuing Initialization Sequence

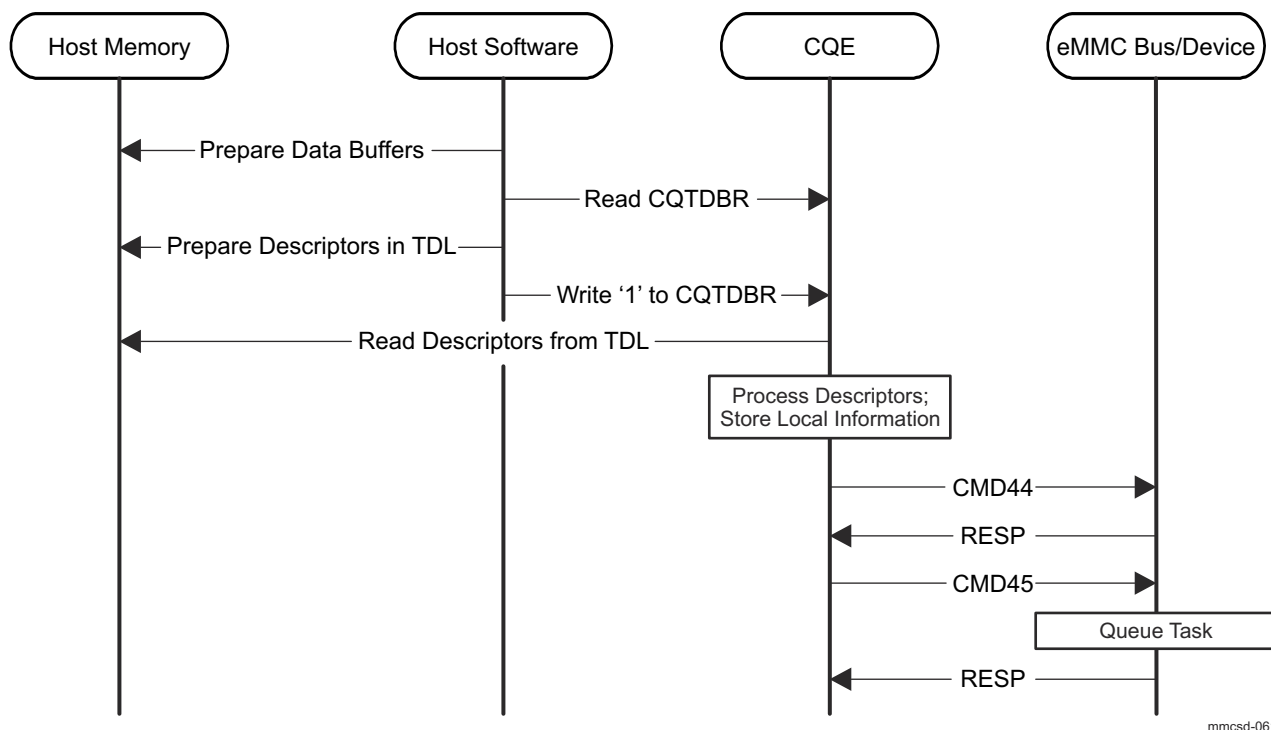

Step	Description
1	Initialize and enable Command Queueing in the device.
2	Configure Task Descriptor size in MMCSD0_CQ_CONFIG register.
3	Configure MMCSD0_CQ_TDL_BASE_ADDR and MMCSD0_CQ_TDL_BASE_ADDR_UPBITS registers to point to the memory location allocated to the TDL in host memory.
4	Configure CQSST and CQSSBC to control when SEND_QUEUE_STATUS commands are sent to the device by CQE.

Table 12-293. Command Queuing Initialization Sequence (continued)

Step	Description
5	Configure MMCSD0_CQ_INTR_COALESCING register to control the interrupt coalescing feature: enable/disable, set interrupt count and timer protection.
6	Configure MMCSD0_CQ_RESP_ERR_MASK register to control which errors may trigger a RED interrupt (if different from reset values).
7	Write '1' to MMCSD0_CQ_CONFIG register to enable CQE activity.

12.3.6.4.2.4.2 Task Issuance Sequence

Figure 12-210 and Table 12-294 show a task issuance sequence.

mmcscd-061

Figure 12-210. Task Issuance Sequence

Table 12-294. Task Issuance Sequence

Step	Description
1	Find an empty transfer request slot by reading the MMCSD0_CQ_TASK_DOOR_BELL register. An empty transfer request slot has its respective bit cleared to '0' in the MMCSD0_CQ_TASK_DOOR_BELL register.
2	Build a Task Descriptor at the 1st entry of the empty slot. Task Descriptor field values: <ul style="list-style-type: none"> 1. Valid = 1, to indicate the descriptor is effective. 2. End = 1, as required for Task Descriptors. 3. Int = 1, if an interrupt on completion is required. Otherwise, Int = 0. 4. Act = b101, to indicate a Task Descriptor . 5. Data Direction = 1 for read commands, and 0 for write commands. 6. Priority = 1 for high priority, and 0 for simple requests. 7. QBR = 1 if Queue Barrier functionality is required. 0 otherwise. 8. Forced Programming, Context ID, Tag Request, Reliable Write, Block Count, and Block Address programmed according to application requirements.

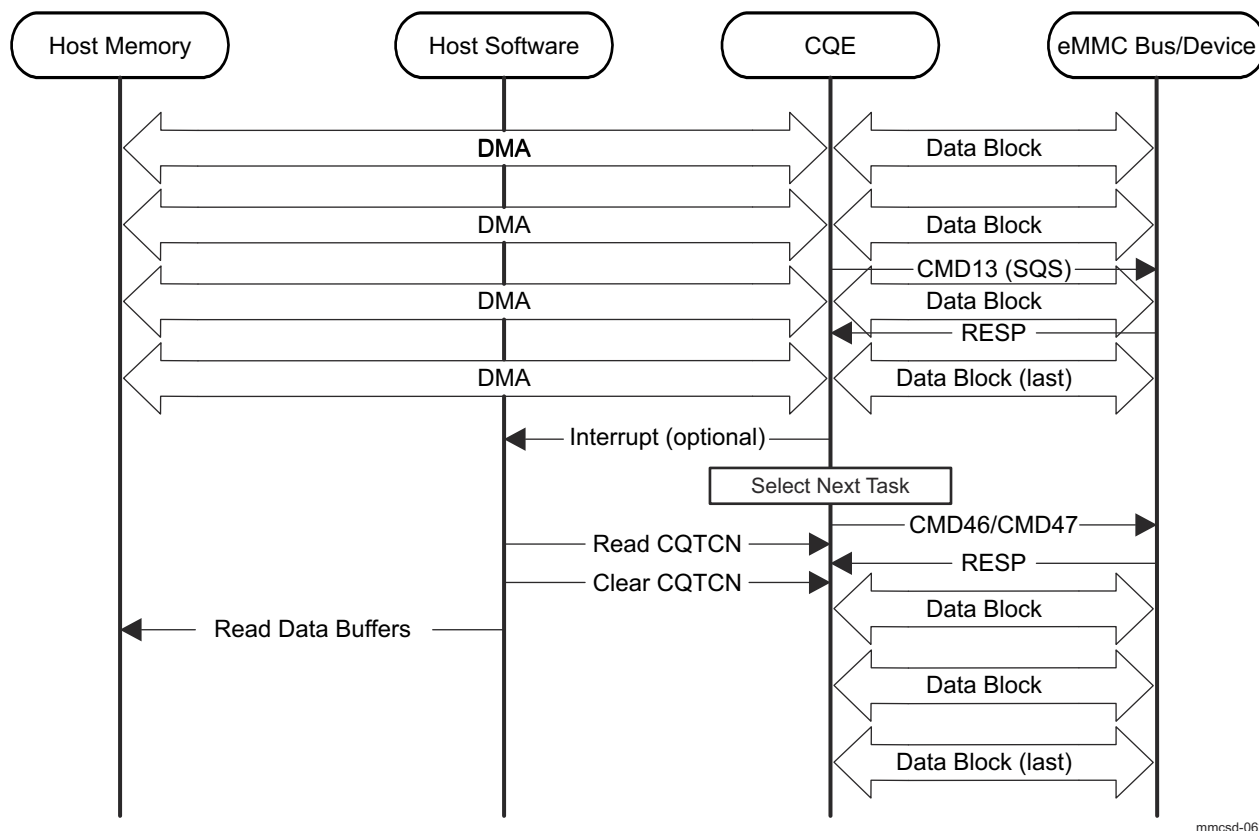

Table 12-294. Task Issuance Sequence (continued)

Step	Description
3	Build a Transfer Descriptor at the 2nd entry of the empty slot. Transfer Descriptor field values: <ul style="list-style-type: none"> 1. Valid = 1, to indicate the descriptor is effective. 2. End = 1, if a TRAN descriptor is used, to indicate the task only has one data buffer. End = 0 if LINK descriptor is used. 3. Int = 0. Ignore in Command queueing. 4. Act = b100, for TRAN descriptors, pointing directly to the task's single data buffer. Act = 401 b110, for LINK descriptors, point to a scatter/gather list (indirect). 5. Address and Length programmed according to the data buffer supplied by the application.
4	If more than one transfer is requested, repeat step 1-3 for all needed transfers.
5	Set MMCSD0_CQ_TASK_DOOR_BELL register to indicate to the CQE that one or more transfer requests are ready to be sent to the attached device. Host software shall only write a '1' to the bit position that corresponds to new tasks; all other bit positions within MMCSD0_CQ_TASK_DOOR_BELL register should be written with a '0', which indicates no change to their current values.

12.3.6.4.2.4.3 Task Execution and Completion Sequence

The CQE is responsible for task execution, communication with the device and moving the data to the buffers in the host memory.

Figure 12-211 and Table 12-295 show a task execution and completion sequence.

mmcsd-062

Figure 12-211. Task Execution and Completion Sequence

Table 12-295. Task Execution and Completion Sequence

Step	Description
1	Once the tasks are queued on the device side CQE sends CMD13 to determine the queue status. The queue status lets the CQE know which tasks are ready for execution.
2	The response to CMD13 may indicate no task is ready in which case the CQE is required to send CMD13 again at a later time as controlled CQSST register.

Table 12-295. Task Execution and Completion Sequence (continued)

Step	Description
3	If a task is ready for execution then the host sends EXECUTE_READ_TASK (CMD46) or EXECUTE_WRITE_TASK (CMD47) to the device with the task id ordering it to execute a task.
4	When the task execution is completed, an interrupt may be generated, if requested, or as determined by Interrupt Coalescing mechanism.
5	The host software reads MMCSD0_CQ_TASK_COMP_NOTIF register to determine which task(s) has(have) been completed. Each bit set in MMCSD0_CQ_TASK_COMP_NOTIF register represents by index which task has completed but hasn't yet been served by software.
6	For every task completed clear the appropriate MMCSD0_CQ_TASK_COMP_NOTIF register bit.
7	Repeat steps 1-6 for the pending tasks.

12.3.6.4.2.4.4 Task Discard and Clear Sequence

Figure 12-212 and Table 12-296 show a task discard and clear sequence.

mmcsd-063

Figure 12-212. Task Discard and Clear Sequence**Table 12-296. Task Discard and Clear Sequence**

Step	Description
1	While CQE is enabled write '1' to MMCSD0_CQ_CONTROL[0] HALT_BIT bit to halt CQE.
2	Poll on MMCSD0_CQ_INTR_STS[0] HALT_COMPLETE bit.
3	Read MMCSD0_CQ_TASK_DOOR_BELL register to determine if the task to be discarded is set to 1.
4	Read MMCSD0_CQ_DEV_PENDING_TASKS register to check if the task is queued in the device.
5	Send CMDQ_TASK_MGMT(CMD48) to discard task using the task id as the argument.
6	Write '1' to CQCTCLR[i] to clear task in CQE.
7	Poll on CQCTCLR[i] until it is '0'.

Table 12-296. Task Discard and Clear Sequence (continued)

Step	Description
8	Write '0' to MMCSD0_CQ_CONTROL register to resume CQE.

12.3.6.4.2.4.5 Error Detect and Recovery when CQ is enabled

Figure 12-213 and Table 12-297 show an error detect and recovery sequence.

Figure 12-213. Error Detect and Recovery Sequence

Table 12-297. Error Detect and Recovery Sequence

Step	Description
1	Read eMMC host controller MMCSD0_ERROR_INTR_STS register and determine error is related to CQE.
2	Write '1' to MMCSD0_CQ_CONTROL[0] HALT_BIT bit to halt CQE.
3	Wait for MMCSD0_CQ_CONTROL[0] HALT_BIT bit to read '1'. In some error cases, this may not happen, so software should proceed to the next step after a sufficient time-out.
4	Read MMCSD0_CQ_CMD_RESP_INDEX and MMCSD0_CQ_CMD_RESP_ARG registers to determine last response's index and argument.
5	Read MMCSD0_CQ_TASK_ERR_INFO register to determine the transmitted command's index and the index of the task to which it is related.

Table 12-297. Error Detect and Recovery Sequence (continued)

Step	Description
6	Perform error-specific recovery procedure.
7	Write '0' to MMCSD0_CQ_CONTROL register to resume operation.

12.3.7 Universal Flash Storage (UFS) Interface

This section describes the Universal Flash Storage (UFS) interface in the device.

12.3.7.1 UFS Overview

The Universal Flash Storage (UFS) interface is a standard-based serial interface engine.

There is one UFS module inside the device - UFS0. The UFS module includes one UFS 2.1 host controller (HC) with an integrated M-PHY.

The UFS module complies with the standards as listed in [Table 12-298](#).

Table 12-298. UFS Standards

Document	Version	Description
JESD220-1A	v1.1	Universal Flash Storage (UFS) Unified Memory Extension
JESD220-2	v1.0	Universal Flash Storage (UFS) Card Extension
JESD220C	v2.1, March 2016	Universal Flash Storage (UFS)
JESD223-1B	v1.1A	Universal Flash Storage Host Controller Interface (UFSHCI) Unified Memory Extension
JESD223C	v2.1, March 2016	Universal Flash Storage Host Controller Interface (UFSHCI)
JESD224	March 2013	Universal Flash Storage (UFS) Test
	November, 2001	Federal Information Processing Standards (FIPS) 197 Advanced Encryption Standard (AES)

	v1.60, 2013	MIPI Alliance Specification for Unified Protocol (UniProSM)
	Revision 24, August 2010	Small Computer System Interface (SCSI) Block Commands - 3
	Revision 27, October 2010	SCSI Primary Commands - 4

[Figure 12-214](#) shows the UFS module overview.

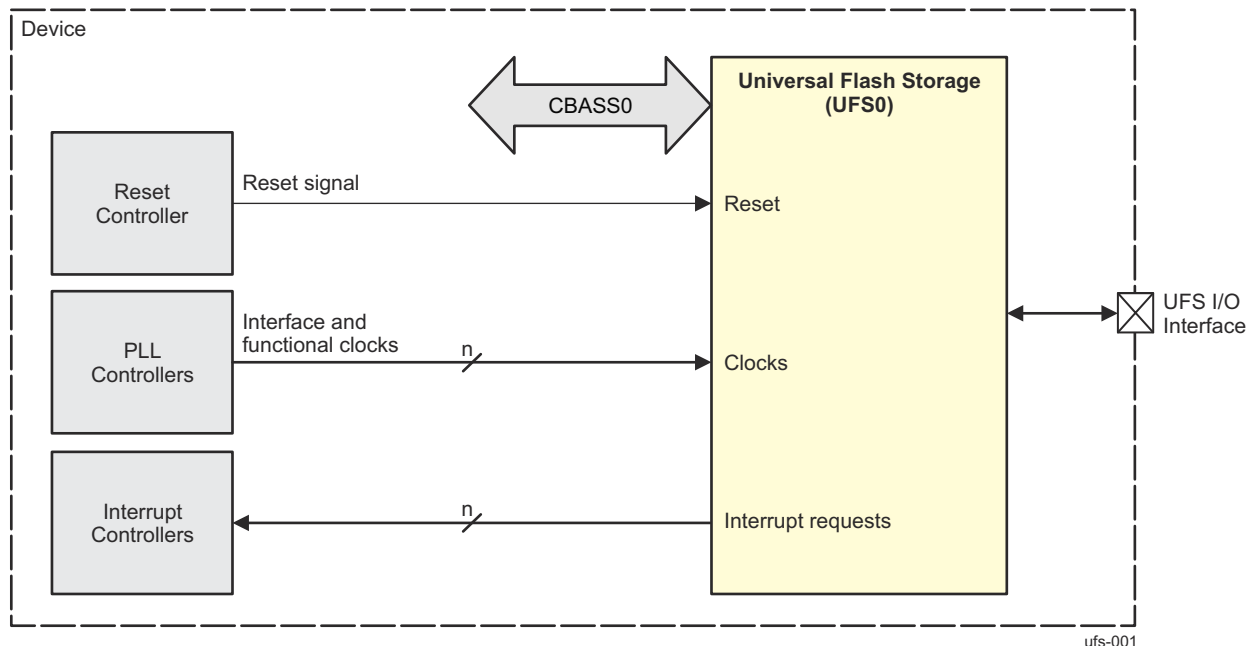

Figure 12-214. UFS Module Overview

12.3.7.1.1 UFS Features

Key Features:

- Supports Universal Flash Storage Host (UFS2.1, JESD220C)

- Supports Universal Flash Storage Host Controller Interface (UFSHCI, JESD223C)
- Supports UFS interconnect - MIPI UniPro and MIPI M-PHY
- Supports Gear 1: 1.46 Gbps, 2-lanes
- Supports Gear 2: 2.91 Gbps, 2-lanes
- Supports Gear 3: 5.83 Gbps, 2-lanes
- Supports all UFS mandatory SCSI commands required by JEDEC specification
- Supports power-on reset (POR), hardware (HW) reset, EndPoint reset, Logical Unit reset, and Warm reset

Master Bus Interfaces:

- Supports one 64-bit master interface (CBA4.0 VBUSM) for data transfers
- Supports 48-bit address width on the master interface
- Include embedded DMA controller within the host controller
- Supports little-endian mode only

Configuration Bus Interfaces:

- Supports one 32-bit slave interface (CBA4.0 VBUSP) for configuration access
- Supports linear incrementing addressing mode
- Supports aligned accesses only

Supports ECC on internal RAM's

M-PHY Features:

- Supports reference clock of 19.2 MHz and 26 MHz

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.3.7.1.2 UFS Ports

Table 12-299. UFS0 Clocks and Resets

Clocks	
Module Clock Input	Description
UFS_HCLK	UFS Interface Clock

Resets	
Module Reset Input	Description
UFS_RST	UFS Module Reset

Table 12-300. UFS0 Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
UFS_UFS_INTR_0	UFS Interrupt Request	Level
UFS_UFS_INTR_NONFATAL_0	UFS Non-Fatal Interrupt Request	Level
UFS_UFS_INTR_FATAL_0	UFS Fatal Interrupt Request	Level
UFS_HCLK_ECC_CORR_LVL_0	UFS ECC Correctable Error Interrupt Request	Level
UFS_HCLK_ECC_UNCORR_LVL_0	UFS ECC Uncorrectable Error Interrupt Request	Level

12.3.7.2 UFS Environment

This section describes the UFS external connections (environment).

Figure 12-215 shows the UFS I/O interface signals.

Figure 12-215. UFS I/O Interface Signals

Table 12-301 describes the UFS I/O signals.

Table 12-301. UFS I/O Signals

Module Pin	I/O ⁽¹⁾	Description
UFS0		
RX_DP0	I	UFS Lane0 RX Data Positive
RX_DN0	I	UFS Lane0 RX Data Negative
TX_DP0	O	UFS Lane0 TX Data Positive
TX_DN0	O	UFS Lane0 TX Data Negative
RX_DP1	I	UFS Lane1 RX Data Positive
RX_DN1	I	UFS Lane1 RX Data Negative
TX_DP1	O	UFS Lane1 TX Data Positive
TX_DN1	O	UFS Lane1 TX Data Negative
REF_CLK	O	UFS Reference Clock Signal to Slave
RSTn	O	UFS Reset Signal to Slave

(1) I = Input; O = Output

Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables Pin Attributes and Pin Multiplexing in the device-specific Datasheet.

12.3.7.3 UFS Functional Description

12.3.7.3.1 UFS Block Diagrams

The UFS subsystem includes one UFS 2.1 host controller with an integrated M-PHY. The UFS host controller is a standard-based serial interface engine.

The UFS host controller is compliant with the *Universal Flash Storage (UFS) Specification* and *UFS Host Controller Interface (UFSHCI) Specification* (see [Table 12-298](#)).

[Figure 12-216](#) shows the UFS subsystem block diagram.

Figure 12-216. UFS Subsystem Block Diagram

Figure 12-217 presents an example of UFS Integrated Protocol Stack (IPS) subsystem.

The UFS host controller is provided with additional hierarchy to support M-PHY integration.

These additional levels of hierarchy make up the IPS. Both the UFS host controller and the M-PHY share the same control interface (APB) and in further description is assumed they are mapped into single area in APB subsystem.

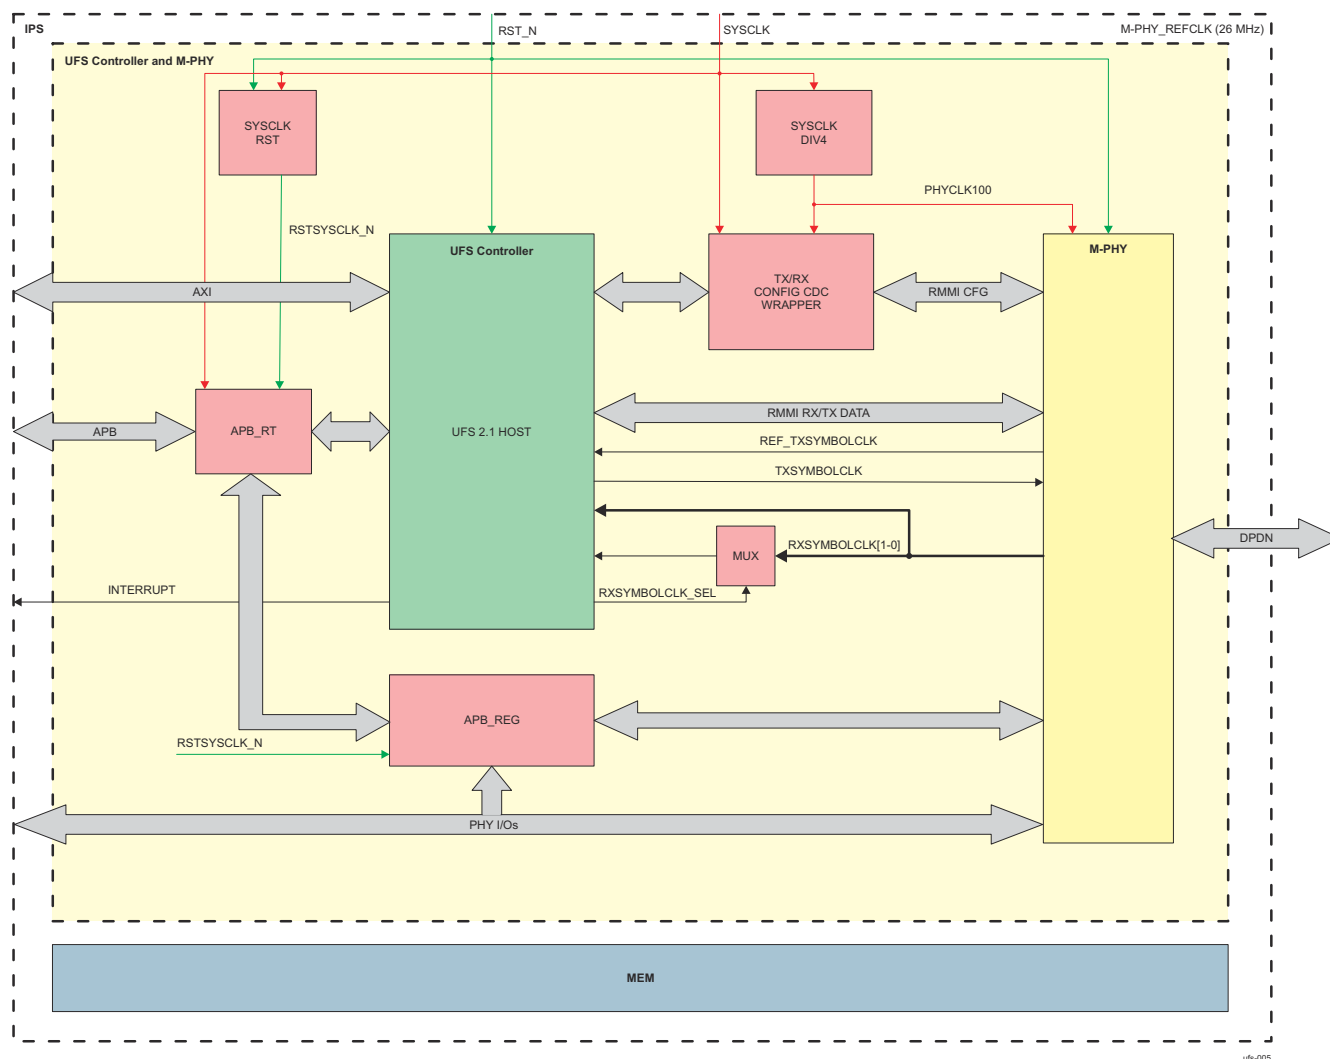

Figure 12-217. UFS IPS Subsystem

Figure 12-218 shows UFS controller block diagram.

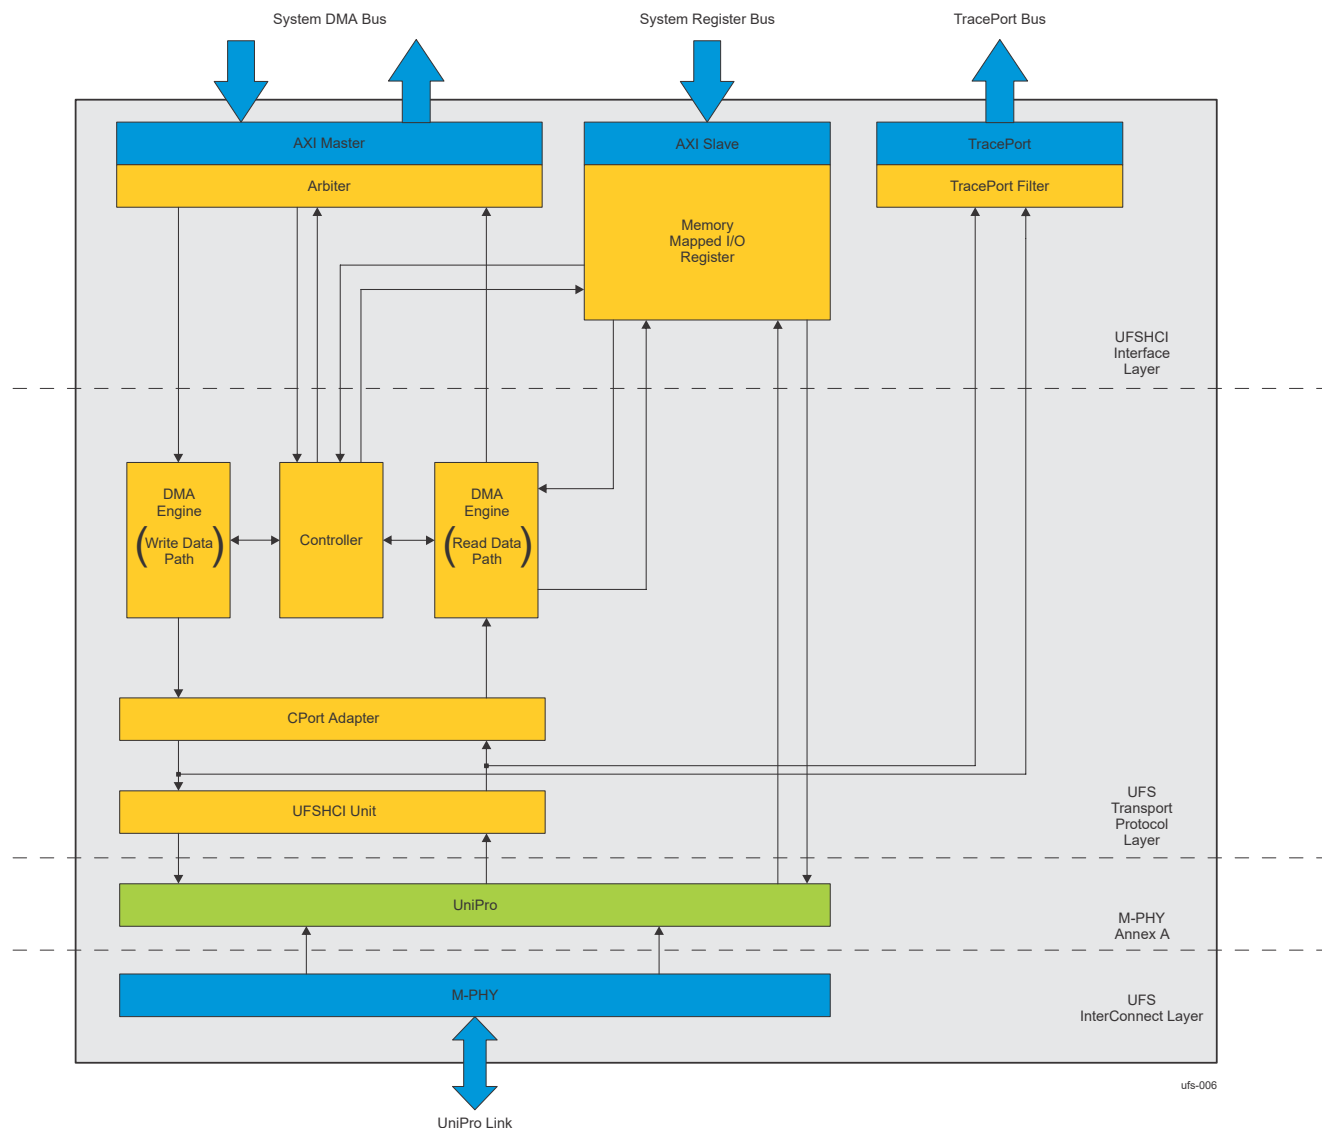

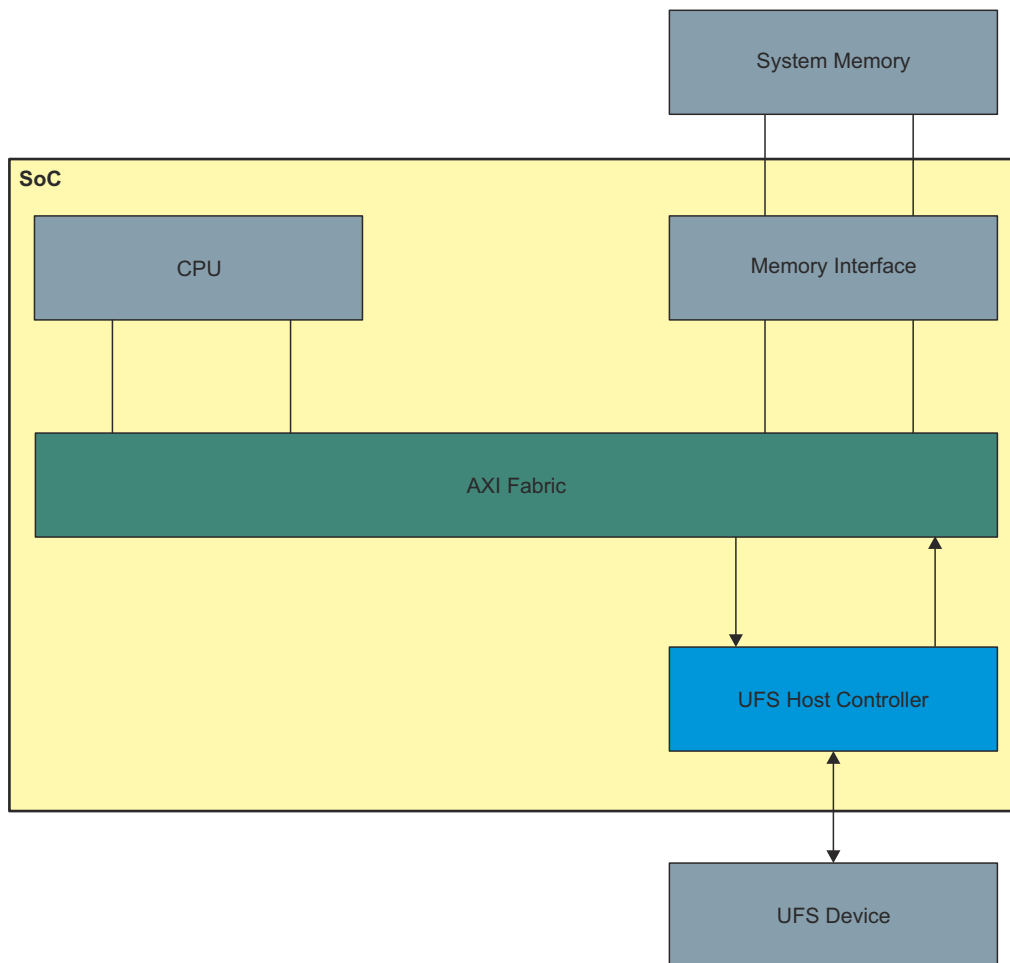

Figure 12-218. UFS Controller Block Diagram

Figure 12-219 presents an example of UFS system level block diagram.

ufs-007

Figure 12-219. UFS System Level Block Diagram

Figure 12-220 shows UFS system model. The application layer of the UFS host controller connects to a UniPro protocol stack and M-PHY, both of which can be considered part of the UFS host controller.

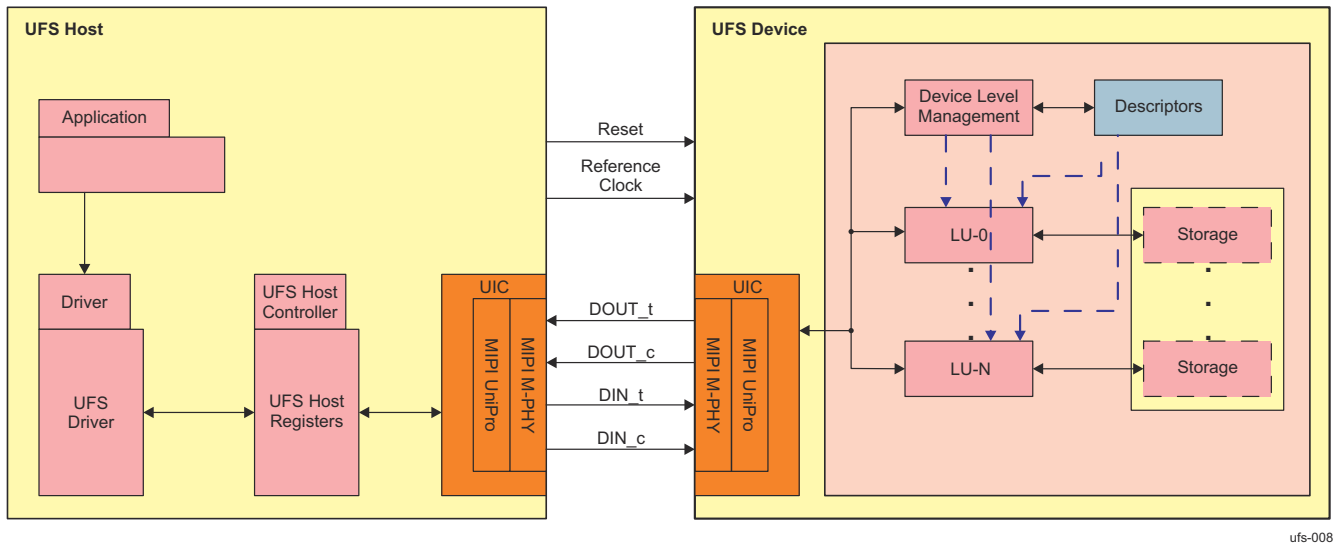

Figure 12-220. UFS System Model

12.3.7.3.2 UFS ECC Support

The UFS module supports Error Correcting Code (ECC). The ECC is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

Note

For more information about ECC Aggregator, refer to *ECC Aggregator*.

For more information about UFS ECC Aggregator Registers, refer to *UFS0_HCLK_ECC_AGGR_CFG Registers*.

12.3.7.4 UFS Programming Guide

Note

It is assumed that the reader of this section has an in-depth understanding of the following documents:

- JEDEC Standard Universal Flash Storage Unified Host Controller Interface
- JEDEC Standard Universal Flash Storage
- MIPI Alliance Specification for M-PHY
- MIPI Alliance Specification for Unified Protocol (UniPro®)
- SCSI Architecture Model

12.3.7.4.1 UFS Start-Up Sequence

The initialization of the UFS host controller can be split up into the following four phases:

- Configuring and initializing the UniPro stack. This step can be further split up into the following tasks:
 - Initiate module enable and link startup
 - Set power mode related attributes
 - Start power mode change procedure
 - Set local and peer Layer 2 attributes
- Configuring the UFS host controller
- Initializing the UFS external device
- Refining the UFS host controller setup and configuring the host software driver

Note

While certain attributes and features of the external device may not be known from the start, commands and transaction will use default values known to work (minimal subset, probably lower performance).

12.3.7.4.1.1 UniPro Initialization

12.3.7.4.1.1.1 UniPro Layer 2 Configuration

Layer 2 configuration can be separated into two parts: thresholds and timers.

The calculation and selection of these attribute values have major influence on the performance of a UniPro system as they program the generation of AFC frames. Careful selection of these values is therefore very important. [Section 12.3.7.4.1.1.1.1](#) and [Section 12.3.7.4.1.1.1.5](#) describe these attributes in detail and give some advice on their configuration values.

Note

AFC frames for acknowledge generation are generated independently from AFC frames for credit exchange.

12.3.7.4.1.1.1.1 Layer 2 Threshold Value Calculation

Layer 2 defines three configurable threshold values:

- DL_TC0TXFCThreshold (see [Section 12.3.7.4.1.1.1.2](#))
- DL_AFC0CreditThreshold (see [Section 12.3.7.4.1.1.1.3](#))
- DL_C0OutAckThreshold (see [Section 12.3.7.4.1.1.1.4](#))

These threshold values are used to control AFC frame and credit transmission between the two devices on the link.

12.3.7.4.1.1.1.2 DL_TC0TXFCThreshold

A change in DL_TC0TXFCThreshold influences the required level of available credits (1 credit = 32 bytes) in a transmitter before the Protection Timer is started to request an update of credit information.

For example, if this threshold value for TC0 is locally set to 10 credits, the local TX will start the Protection Timer when less than 10 credits are available for sending data to the peer device. If the Protection Timer expires, the local TX sends an AFC0 frame to the peer device with CReq set to 1 to request an update of the peer RX credit information. When the peer device answers with an AFC0 frame at any time, the Protection Timer is restarted if there are still 10 or fewer credits available or stopped otherwise.

This mechanism should prevent that the local TX runs out of credits and needs to stall its data transmissions, when for any reason the credit update was lost or not sent in time.

As a general guideline, this threshold value can be set to its maximum value (1 less than the maximum number of credits of the receive buffer for the corresponding TC, which is stored in the attribute DL_PeerTC0RxInitCreditVal). With this setting the local TX will try to get an update of the local credit information as long as it has not all possible credits available. The overhead for sending the AFC frames depends on the counter value of the Protection Timer, but should not have a negative impact on the link performance.

DLTCxTXFCThreshold = DLPeerTxTXInitCrediVal - 1;

12.3.7.4.1.1.1.3 DL_AFC0CreditThreshold

This threshold value is the counterpart of the DL_TC0TXFCThreshold value in the receiver. It defines the amount of credits, which have become available since the last credit update but are not communicated to the peer device yet, before an AFC credit update is triggered.

For example, if this value is set to 5 credits, the device will not update its credit information to the peer device before at least 5×32 bytes are read from the receive buffer of the corresponding traffic class since the last credit update.

Changing this attribute to a lower value will increase the number of AFC frames sent for only updating credit information. A higher value however, might lead to a stall for data transmission on the peer device as not enough credits might be available. The maximum value is defined by the size of the RxBuffer in credits. A higher value for the threshold attribute would break credit handling.

As a guideline, setting this attribute to the credit value corresponding to the maximum size of a frame for this traffic class (MaxFrameSizeTC0), should give reasonable results. In this case, the receiver sends its credit update when at least one additional frame of MaxFrameSizeTC0 can be stored in its buffer.

DL_AFC0CreditThreshold = MaxFrameSizeTC0[credits];

12.3.7.4.1.1.4 DL_TC0OutAckThreshold

This attribute defines the number of frames (+1) to be received before an AFC frame is sent to the peer device.

For example, if this attribute is set to 2, the device will send an AFC frame back when three frames were received for the corresponding traffic class. Setting this attribute to a lower value will increase the number of AFC frames on the link. A higher value might have negative impact on the transmitter, if its own TX buffer reaches its limit as too many unacknowledged frames are stored.

As a guideline, this value should be set according to the two related buffers on each side of the link. The maximum number of frames that can be stored in the smaller buffer (peer TX or local RX) defines the upper bound for this attribute. A value at least 1 or two frames lower gives the AFC frame some time to traverse to the peer side.

DL_TC0OutAckThresholdmax = min(PeerTXBufferSizeTC0, LocalRxBufferSizeTC0)[frames];

12.3.7.4.1.1.1.5 Layer 2 Timer Value Calculation

Layer 2 uses three timers to keep the link operational in case of wrong configuration or unstable communication with the peer device. These timers can be separately configured using three attributes:

- DL_FC0ProtectionTimeOutVal (see [Section 12.3.7.4.1.1.1.6](#))
- DL_TC0ReplayTimeOutVal (see [Section 12.3.7.4.1.1.1.7](#))
- DL_AFC0ReqTimeOutVal (see [Section 12.3.7.4.1.1.1.7](#))

12.3.7.4.1.1.1.6 DL_FC0ProtectionTimeOutVal

The Protection Timer is used in conjunction with DL_TC0TCXFCThreshold described in [Section 12.3.7.4.1.1.1.1](#). Its purpose is to "protect" the link against the loss of an AFC frame and the resulting stall in communication, if required credits were not delivered.

This timer is running whenever less credits than DL_TC0TCXFCThreshold are available. After expiration, the local UniPro sends an AFC frame to the peer device requesting a credit information update (CReq set to 1). When this AFC request is sent, the timer is restarted. If the peer device does not respond within the second timer period, the link is automatically reinitialized, as the request seems to be lost.

The configuration of the Protection Timer has very little impact on the system performance. If the timer is set to a low value, the amount of AFC request frames may increase (depending on the threshold value). A too high value results in longer periods of inactivity if the link gets broken.

As a consequence setting this timeout value to any value between 512 and 1023 should result in a good compromise between additional AFC frame generation and latency in case of errors:

$$512 \leq \text{DL_FC0ProtectionTimeOutVal} \leq 1023;$$

12.3.7.4.1.1.1.7 DL_TC0ReplayTimeOutVal and DL_AFC0ReqTimeOut

The Replay Timer of one device is closely connected to the Request Timer on the other device of the link. In general, one Replay Timer for each traffic class is running when transmitted frames are not acknowledged yet and is reset every time a new frame is sent or one or more frames are acknowledged. This timer protects the protocol against lost AFC or NAC frames. When for a period of DL_TC0ReplayTimeOutVal μs when no AFC is received and no new frame is sent for this traffic class, the timer expires and the link is re-initialized automatically and a retransmission is started.

An UFS device has two methods of generating an AFC frame for acknowledging data reception. The **DL_TC0OutAck - Threshold value + 1** defines the number of received frames before an AFC is automatically generated. In addition, the AFC Request Timer at the receiver is used to trigger AFC generation before the Replay Timer at the transmitter is expired even when the DL_TC0OutAckThreshold value is not reached.

To secure proper operation, the AFC Request Timer needs to be programmed to a significantly smaller value than the Replay Timer on the other side. The configuring application should take care that the Replay Timer value includes the AFC Request value, internal processing of a new AFC frame generation, and transmission over the link. To be on the safe side, the local Request Timer should be programmed with a value twice the remote AFC Request Timer value. With this rule the allowed accuracy of the timers of $\pm 10\%$ should also be accounted for.

The AFC Request Timer should also have a quite high minimum value in order to not generate more AFC frames than actually needed. The following formula gives a general guideline for programming these two timer values.

$$1024 \leq 2 \times \text{DL_AFC0RequestTimeOutVal} \leq \text{DL_TC0ReplayTimeOutVal} \leq 4095;$$

12.3.7.4.1.1.2 UniPro CPort Connection Management

For this particular case of UFS, as application layer, the connections are setup statically by having reset values for the UFS host controller and a UFS device predefined at reset. The predefined reset values are given in [Table 12-302](#).

Note that these reset values are different from the default reset values given by the *MIPI UniPro Specification* but are in line with the reset values given by the *JEDEC UFS Specification*. Furthermore, the reset values for the device are only assumed reset values.

Table 12-302. Reset Values for Some UniPro Attributes

UniPro Attribute	Reset Value of the UFS Host Controller	Expected UFS Device Reset Value
N_DeviceID	0	1
N_DeviceID_valid	TRUE	TRUE
T_PeerDeviceID	1	0
T_PeerCPortID	0	0
T_TrafficClass	0	0
T_CPortFlags	6 (E2E_FC off, CSD off, CSV off)	6 (E2E_FC off, CSD off, CSV off)
T_ConnectionState	1 (CONNECTED)	1 (CONNECTED)

At link startup and after exiting from the Auto-Hibernate state the UFS host controller will set the UniPro CPort attributes as shown in the following sequence:

CPort 0 Configuration:

- 4020h **T_ConnectionState** 0h
- 4021h **T_PeerDeviceID** 1h
- 4022h **T_PeerCPortID** 0h
- 4023h **T_TrafficClass** 0h
- 4025h **T_CPortFlags** 6h
- 4020h **T_ConnectionState** 1h

Additionally, if the value of the UFS_XCNF[17-16] PCPCONFEX bit field is set to 3h, the UFS host controller will configure also the CPorts of the PEER device as follows:

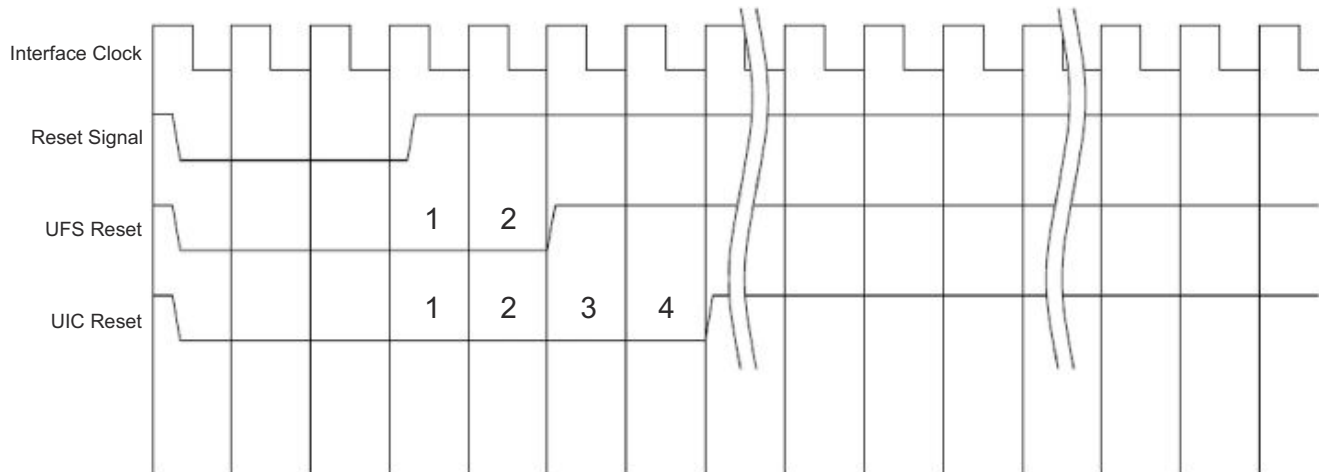

If the value of the UFS_XCNF[17-16] PCPCONFEX bit field is set to 2h, the UFS host controller will poll the T_ConnectionState attribute of CPort0 of the PEER device. Only CPort0 will be polled.

12.3.7.4.1.2 UFS Host Controller Initialization

The following procedure shall be applied to initialize the UFS host controller:

1. Assert reset signal. For more information about the UFS reset signal, see *UFS0 Clocks and Resets*.
2. De-assert reset signal and wait for at least 4 interface clock cycles (see [Figure 12-221](#)). For more information about the UFS interface clock, see *UFS0 Clocks and Resets*.
3. Write appropriate value into the FS_HCLKDIV register.
4. Write a 1h to the FS_SS_CTRL[0] RST_N_PCS bit to take UFS slave device out of reset.
5. Write a 1h to the UFS_HCE register in order to enable the UFS host controller. This triggers an autonomous basic initialization of the local UIC layer. The initialization sequence shall consist of a *DME_RESET* and a *DME_ENABLE* command. Further commands, such as *DME_SET* commands may be added, depending on the implementation needs. During the basic initialization sequence, the UFS_HCE register is read as 0h.
6. Wait until the UFS_HCE register is read as 1h before continuing. This indicates that the basic initialization sequence is completed.
7. Additional commands, such as *DME_SET* commands may be sent from the system host to the UFS host controller to provide configuration flexibility.
8. Optionally set the UFS_IE[10] UCCE bit to 1h in order to enable the interrupt (UFS_IS[10] UCCS).
9. Send *DME_LINKSTARTUP* command to start the link startup procedure.
10. Completion of the *DME_LINKSTARTUP* command sets the UFS_IS[10] UCCS bit and may flag an interrupt to the system host if the UFS_IE[10] UCCE bit is set. This interrupt will be flagged independently from the GenericErrorCode.
11. In case the GenericErrorCode of the completed *DME_LINKSTARTUP* command is *SUCCESS*, the UFS_HCS[0] DP bit is set in addition to the UFS_IS[10] UCCS bit.
12. Check the value of the UFS_HCS[0] DP bit and make sure that there is a device attached to the Link. If presence of a device is detected, go to step **13**; otherwise, resend the *DME_LINKSTARTUP* command after the UFS_IS[7] ULLS bit has been set to 1h (go to step **8**). The UFS_IS[7] ULLS bit equal 1h indicates that the UFS Device is ready for a link startup.
13. Enable additional interrupts by programming the UFS_IE register.

14. Initialize the Interrupt Aggregation Control register (UFS_UTRIACR) with the desired values for the threshold (UFS_UTRIACR[12-8] IACTH) and timeout (UFS_UTRIACR[7-0] IATOVAL).
15. For example, write value 81010664h to initialize with the following parameters:
 - The UFS_UTRIACR[31] IAEN bit is set.
 - The UFS_UTRIACR[24] IAPWEN bit is set.
 - The UFS_UTRIACR[16] CTR bit is set.
 - The UFS_UTRIACR[12-8] IACTH bit field is set to 6h.
 - The UFS_UTRIACR[7-0] IATOVAL bit field is set to 64h (4.0 ms).
16. **Note:** The UFS_UTRIACR register initialization may be executed at any time when the Run/Stop register (FS_UTRLRSR) is not enabled or when no requests are outstanding.
17. Complete the UFS host controller configuration via *UIC* command interface if required.
18. Allocate and initialize UTP Task Management Request List.
19. Program the UTP Task Management Request List Base Address (UFS_UTMRLBA) with a 32-bit address pointing to the starting address of the UTP Task Management Request List created at the step **15**.
20. Allocate and initialize UTP Transfer Request List.
21. Program the UTP Transfer Request List Base Address (UFS_UTRLBA) with a 32-bit address pointing to the starting address of the UTP Transfer Request List created at the step **17**.
22. Enable the UTP Task Management Request List by setting the UTP Task Management Request List Run Stop register (UFS_UTMRLRSR) to 1h. This operation allows the UFS host controller to begin accepting UTP Task Management Request via the UTP Task Management Request Door Bell mechanism (UFS_UTMRLDBR).
23. Enable the UTP Transfer Request List by setting the UTP Transfer Request List Run Stop register (UFS_UTRLRSR) to 1h. This operation allows the UFS host controller to begin accepting UTP Transfer Request via the UTP Transfer Request Door Bell mechanism (UFS_UTRLDBR).
24. At this point, the UFS host controller is up and running.

ufs-009

Figure 12-221. UFS Host Controller Reset Waveform

12.3.7.4.1.3 HCE Bit

When the Host Controller Enable (UFS_HCE) bit transitions from 0h to 1h, the UFS host controller will go through an initialization sequence that is outlined as follows:

- Warm hardware reset of the UFS host controller
- *DME_RESET* (Warm)
- *DME_ENABLE*
- *LINK_STARTUP*

As a part of the Link Startup procedure, the UFS interface will configure the CPort Attributes of the local and eventually the peer UniPro. Refer to [Section 12.3.7.4.1.1.2, UniPro CPort Connection Management](#).

12.3.7.4.2 UFS Host Controller Programming

12.3.7.4.2.1 UFS Software Model

This section provides details on the transactions, protocol elements, and data structures which need to be used to control the UFS host controller, MIPI UniPro stack, and external device. The transactions are built by the system hosts and sent to the UFS controller via the UTP Transfer Request List, the UTP Task Management Request List, and the UTP Command Descriptors.

While some transactions are already prepared as UPIU packets by the host software, for some other transactions (mainly the transfer of the raw data), the UPIU packets need to be constructed first. The construction takes place on the fly in the UFS Controller as listed in [Table 12-303](#).

Table 12-303. UFS Host Controller Commands

Command	Format	Action
UTP Command	UTP Transfer Request List	Send to device
DME Command	Register Access	Access UniPro stack
Task Management Command	UTP Task Management Request List	Send to device

To send commands to the UFS host controller, UniPro stack, and UFS device, the system host needs to perform a series of setup and configurations steps. The following list gives a brief summary on the necessary sequence:

- Find an empty slot in the UTP Transfer Request List (UTP Task Management Request List) by reading the UFS_UTRLDBR (UFS_UTMRLDBR) register.
- Program the required transactions in the UTP Transfer Request List (UTP Task Management Request List) and depending on the transfer setup a UTP Command Descriptor.
- Then setup the appropriate bit in the UFS_UTRLDBR (UFS_UTMRLDBR) register.

For a detailed description, refer to [Section 12.3.7.4.2.2, UFS Theory of Operation](#).

The UFS host controller starts processing the UTP Transfer Request List and UTP Task Management Request List.

Once the UFS host controller has finished processing a command, it updates the status field in the UTP Transfer Request List (UTP Task Management Request List) or UTP Command Descriptor respectively.

The UFS Transport Protocol (UTP) commands are commands based on UPIU packets. To set up the communication, both the transaction lists as well as the command descriptors need to be programmed.

12.3.7.4.2.1.1 UFS Layers

The UFS interface is based on master/slave architecture. Direct device-to-device communication is not supported. The information flow is packet based and the packets are sent in a request/response method where the Initiator sends a request to a Target and the Target must always respond. There is only one UFS host controller on the physical interface and most requests are typically initiated by the UFS host controller. The requests initiated by UFS device could be an interrupt or any other request for service actions.

The communication between the UFS host controller and the device is layer oriented. The UFS specification defines the following layers:

- UFS communication is layered communication architecture. The information is packetized at different layer with the appropriate header.
- UFS InterConnect Layer (UIC) - the UIC Layer is based on MIPI M-PHY and the MIPI UniPro stack:
 - MIPI M-PHY supports two signaling schemes: Low-Speed mode with pulse-with-modulation (PWM) signaling scheme and High-Speed Burst mode with Non-Return-to-Zero (NRZ) signaling scheme. The UIC Layer defines the electrical characteristics of the port and the physical connection between devices, and between UFS host controller and devices.
 - MIPI UniPro is responsible managing the UIC Layer. It also provides mechanisms to exchange information in a reliable and power efficient method.
- UFS Transport Protocol UTP Layer - the UTP Layer is responsible for encapsulating the protocol into the appropriate frame structure for the UIC layer. A subset of the SCSI commands, defined in the SCSI Architecture Model Specification (see *SCSI Architecture Model*), is supported.

- UFS Host Controller - the UFS Host Controller is responsible for managing the interface and the data transfer. This includes interface management, power management, and control. Also included in the UFS host controller is the data transfer and programming model.

12.3.7.4.2.1.2 UFS Protocol Elements

The UFS protocol elements are organized as request/response packets and act as the glue between different layers of the UFS protocol stack. The UFS specification defines the UFS Protocol Information Unit (UPIU) as the packet type which is used as request/response packet between the different layers. While UPIUs are exchanged between several layers, two distinct communication levels are important:

- The interface between the device driver (system host) and the UFS host controller. The communication on this level is initiated by the system host and facilitated by the host driver.
- The interface between the UFS host controller and the UFS device. This level of communication will run independently of the device driver and establishes the communication between the UFS host controller and UFS device over the MIPI UniPro MPHY.

Currently, UFS is using the MIPI UniPro Protocol and the corresponding M-PHY as the Service Delivery Subsystem. The UPIU packets will be handed off to the MIPI UniPro as UniPro Service Data (T_SDU) without modification.

12.3.7.4.2.1.2.1 UPIU Types

Figure 12-222 provides an overview about the general UPIU format.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DW1	Reserved				Command Set Type				Query Function/Task Management Function								Response								Status							
DW2	Total EHS Length								Device Information								Data Segment Length															
DW3	Transaction Specification Fields																															
DW4	Extra Header Segment 0																															
DWx	■ ■ ■																															
DWx	Extra Header Segment N																															
DWx	Header E2ECRC																															
DWx	Data Segment 0																															
DWx	■ ■ ■																															
DWx	Data Segment K																															
DWx	Data E2ECRC																															

ufs-012

Figure 12-222. General UPIU Structure

The UPIU total size will vary depending upon the UPIU transaction type but all UPIU sizes will be an integer multiple of 32 bits, and they shall be stored on a 4-byte boundary. If the aggregation of data and header segments does not end on a 32-bit boundary, then additional padding with 0h data will be added to round up the UPIU to the next 32-bit address boundary.

12.3.7.4.2.1.2.2 UFS Protocol

As described earlier, the communication between the host system host and the external device is based on UPIU packets. These packets are used to define the following protocols:

- UTP: the SCSI Architecture Model (SAM) is used as general architectural model for the UFS SCSI. This model uses the SCSI command set and the SAM Task Management features to establish the communication between the system host and the UFS device. For the UFS implementation a reduced SCSI command set is used.
- Native UFS communication: native UFS commands are used to communicate with the UFS host controller and the MIPI UniPro stack outside of the SCSI protocol.

12.3.7.4.2.1.3 UFS Host Data Structure

Most of the communication between host software and the UFS host controller or the UFS device respectively is via system memory tables, descriptors and buffers. These memory locations describe commands to be executed, the data transfer operations that are part of the commands, store status information coming back from the device and provide buffer space for data transactions.

Note

For additional information on host data structures and programming procedures, refer to *Universal Flash Storage Host Controller Interface (UFSHCI)*, JESD223C.

12.3.7.4.2.2 UFS Theory Of Operation

As described in [Section 12.3.7.4.2.1.3, UFS Host Data Structure](#), the host software presents a list of commands to the UFS host controller. Independent from the system host, this list is then being processed by the UFS host controller which asserts an interrupt line in case a command finishes.

On order to post new commands to the UFS host controller, the system host needs to find empty slots in the command list. In case no empty slot is available, the host thread needs to wait until a command finishes and the driver software has made a new slot available.

Nevertheless, the UFS host controller continuously looks at the UFS_UTRLDBR and UFS_UTMRLDBR registers to determine if there are commands ready to be processed. The processing order depends on three factors:

- Time at which the bit(s) inside the UFS_UTRLDBR and UFS_UTMRLDBR registers have been asserted.
- Index inside the UFS_UTRLDBR and UFS_UTMRLDBR registers.
- Command type (UTP or Task Management).

The processing rules are as follows:

1. Task Management commands have higher priority than UTP commands.
2. Commands with lower time stamp have higher priority than commands with higher time stamps.
3. Within the same time stamp, commands with lower doorbell register index have higher priority than commands with a higher doorbell register index.

While there is no indicator about active commands, it is not possible to know in advance when a particular command is being processed, or how the command will remain in the command list respectively.

To add an additional level of uncertainty, any UFS device is allowed to accept more than one command and is allowed to process those commands out-of-order. As a consequence, commands placed in the command list need to be robust enough to get arbitrarily re-ordered. In cases where this may cause problems, only one command at a time may be placed into the command list.

[Section 12.3.7.4.2.2.1, Building a UTP Transfer Request](#) provide more detail on the low-level driver to explain how the communication and data transfer is handled between system host, the UFS host controller, and UFS device.

12.3.7.4.2.2.1 Building A UTP Transfer Request

Typically a command for the UFS host controller consists of a UTP Transfer Request List entry and a command table element. Thus, the host software needs to start by finding an empty slot inside the UTP Transfer Request List first.

Here are the basic steps for setting up the command list:

- Find an empty command list slot by reading the UFS_UTRLDBR register.
- In case there are no empty slots, wait and try again.
- In case there is at least one empty slot, start setting up the UTP Transfer Request Descriptor:
 - Write CT: define command type.
 - Write DD: define data direction.
 - Write I: define whether or not an interrupt has to be generated.
 - Initialize OCS with the value Fh.
- Allocate space inside the system memory for an UTP Command Descriptor.

- Initialize Command UPIU field of the UTP Command Descriptor:
 - Write TTY: transaction type, here 1h.
 - Write FL: specific flags for this command.
 - Write LUN: the SCSI address this command is directed to.
 - Write TT: task tag, a unique number to identify the task.
 - Write CST: command set type, 0h for SCSI commands.
 - Write TEL: total EHS Length, always 0h.
 - Write DSL: data segment length, always 0h.
 - Write EDTL: expected data transfer length. This field indicates the amount of data to be transferred between the Initiator and Target (read or write). Data is stored in system memory.
 - Write CDB: write the SCSI command into the following 16 bytes.
- Initialize Response UPIU field of the UTP Command Descriptor with zero.
- Initialize PRD field of the UTP Command Descriptor with the required data scatter/gather buffer information.
- Now the UTP Command Descriptor has been set up and the UTP Transfer Request List Descriptor needs to be completed:
 - Write UCDBA: base address of the UTP Command Descriptor.
 - Write UCDBAU: upper 32 bit of the UCDBA, always 0h.
 - Program field RUO with the offset (from the starting address of UCD) of Response UPIU within UCD.
 - Program field RUL with the length of Response UPIU.
 - Program field PRDTO with the offset (from the starting address of UCD) of the PRD table within UCD if required.
 - Program field PRDTL with the length of the PRD table if required.
- Repeat this procedure for all commands which need to be set up.
- Check the UFS_UTRLRSR register and make sure it is read 1h before continuing.
- Set UTP Transfer Request Interrupt Aggregation Control Register (UFS_UTRIACR) enable bit to 1h to enable the interrupt.
- Set Counter and Timer Reset (UFS_UTRIACR[16] CTR) bit to 1h to reset the counter and timer associated with the interrupt.
- Program field Interrupt aggregation counter threshold (UFS_UTRIACR[12-8] IACTH) with the number of command completions that are required to generate an interrupt.
- Program field Interrupt aggregation timeout value (UFS_UTRIACR[7-0] IATOVAL) with the maximum time allowed between a response arrival to the UFS host controller and the generation of an interrupt.
- Set the UFS_UTRLDBR register to ring the doorbell register to indicate to the UFS host controller that one or more transfer requests are ready to be sent to the attached device. The host software shall only write a 1h to the bit position that corresponding to the new command. All other bit positions within the UFS_UTRLDBR register should be written with a 0h, which indicates no change to their current values.

Now the UFS host controller will take over and process the command list without further software interaction.

12.3.7.4.2.2 Processing UTP Task Management Request Completion

The host software processes the interrupt generated by the UFS host controller for command completion. In the interrupt service routine, the host software checks the UFS_IS register to determine if there is an interrupt pending. If the UFS host controller has an interrupt pending:

- The host software determines the cause of the interrupt by reading the UFS_IS register. If the UFS_IS[9] UTMRCs bit is set this indicates that a UTP Task Management Request has completed.
- The host software clears appropriate bits in the UFS_IS register corresponding to the cause of the interrupt.
- The host software reads the UFS_UTMRLDBR register, and compares the current value to the list of commands previously issued by the host software that are still outstanding. The host software completes with success any outstanding command whose corresponding bit has been cleared in the respective register. The UFS_UTMRLDBR register is a volatile. The software should only use its value to determine commands that have completed, not to determine which commands have previously been issued.
- If there were errors, noted in the UFS_IS register, the host software performs error recovery actions.

12.3.7.4.2.2.3 Building UTP Task Management Request

Typically a command for the UFS host controller consists of a UTP Transfer Request List entry and a command table element. Thus, the host software needs to start by finding an empty slot inside the UTP Task Management Request List first.

Basic steps for setting up the Task Management Request:

- Find an empty command list slot by reading the UFS_UTMRLDBR register.
- In case there are no empty slots, wait and try again.
- In case there is at least one empty slot, start setting up the UTP Task Management Request Descriptor:
 - Write I: define whether or not an interrupt has to be generated.
 - Initialize OCS with the value Fh.
- Allocate space inside the system memory for an UTP Command Descriptor.
- Repeat the above procedure for all task management commands that need to be set up.
- Check UTP Task Management Request List Run Stop register (UFS_UTMRLRSR) and make sure it is read 1h before continuing.
- Set UTP Transfer Request Interrupt Aggregation Control register (UFS_UTRIACR) enable bit to 1h to enable the interrupt.
- Set the UFS_IE[9] UTMRC bit to 1h to enable the interrupt.
- Set UTP Task Management Request List Doorbell register (UFS_UTMRLDBR) to ring the doorbell register to indicate to the UFS host controller that one or more transfer requests are ready to be sent to the attached device. The host software shall only write a 1h to the bit position that corresponding to the new command. All other bit positions within the UFS_UTMRLDBR register should be written with a 0h, which indicates no change to their current values.

Now the UFS host controller will take over and process the command list without further software interaction.

12.3.7.4.2.2.4 Processing UTP Transfer Request Completion

Control will be given back to the software by assertion of the Transfer Request Completion Status interrupt (UFS_IS[0] UTRCS). The UFS_IS[0] UTRCS bit is set when at least one of the following 4 conditions is met:

- The UTRD.I bit is set (Interrupt Command).
- The counter, after incrementing, reaches the value configured in the UFS_UTRIACR[12-8] IACTH bit field.
- The IA (Interrupt Aggregation) timer reaches the value configured in the UFS_UTRIACR[7-0] IATOVAL bit field (this event may occur at any time, not necessarily coupled with request completion).
- The Overall Command Status (OCS) of the completed command is unequal to "SUCCESS".

An interrupt is generated by the write operation if the completion interrupt is not masked (disabled) by the UFS_IE[0] UTRCE bit.

The host software processes the interrupt generated by the UFS host controller for command completion. In the interrupt service routine, the host software checks the UFS_IS register to determine if there is an interrupt pending. If the UFS host controller has an interrupt pending:

1. If there were errors, noted in the UFS_IS register, the host software performs error recovery actions.
2. In the case of the Transfer Request Completion Status interrupt (UFS_IS[0] UTRCS), the host software clears the interrupt and then may use one of two methods to determine which UTP transfer requests (TRs) have completed:
 - a. Read the UFS_UTRLDBR register, and compare the current value to the list of commands previously issued by the host software that are still outstanding. For any transfer request which is outstanding, a value of 0h in bit *i* (where *i* is the UTRL slot through which the TR is issued) of the UFS_UTRLDBR register means that the TR has completed. The UFS_UTRLDBR register is a volatile. The software should only use its value to determine commands that have completed, not to determine which commands have previously been issued.
 - b. Read the UTP Transfer Request List Completion Notification register (UFS_UTRLCNR). For any TR, a value of 1h in bit *i* (where *i* is the UTRL slot through which the TR is issued) of the UFS_UTRLCNR register means that the TR has completed.
3. For every TR *i* whose completion is detected, the software repeats the following steps:
 - a. Processes the request completion as required by higher OS layers (for example: file system).

- b. Clears bit *i* of the UFS_UTRLCNCR register, by writing 1h to it.
 - c. Marks slot *i* as available for reuse (software only).
4. After processing all previously detected TRs, the software may reset and restart Interrupt Aggregation mechanism by writing 80010000h to the UFS_UTRIACR register.
5. The software determines if new TRs have completed since step 2, by repeating one of the two methods described in step 2. If new TRs have completed, the software repeats the sequence from step 3.

12.3.7.4.2.2.5 UFS Host Processing

The host processing of the commands initiated by the system host is done independent of the system host and software. The exact steps the UFS host controller will perform may vary, but the baseline steps for a read/write operation are given below:

- The UFS host controller will read the selected command list entry with one 4-beat burst.
- Depending on the command type, further actions are taken. In case the command is read/write:
 - The UFS host controller will fetch the first part of the UPIU (till the data segment) in 4-beat bursts. This will bring the header information and the SCSI command into the controller.
 - The UFS host controller will read the first PRD entry with a 2-beat burst.
 - Now the UFS host controller will set up its internal data structure and variables.
 - To start the device communication, the UFS host controller will send the already fetched UPIU packet to the device.
- Now the device will initiate the data transfer phase by sending Ready-To-Transfer (RTT) UPIUs to the UFS host controller.
 - The device either sends a RTT UPIU (in case of a write) or directly a Data In UPIU (in case of a read). The size of the Data In UPIU is not predefined.
 - The UFS host controller either sends back the requested data with a Data Out UPIU, or takes the data and stores it in an internal buffer.

The above transactions between the UFS host controller and the device are executed until all data is transferred or an error occurred.

In parallel to the transactions between the UFS host controller and device, the data is transferred between the UFS host controller and system memory.

- On receiving the Response UPIU, the UFS host controller updates the Transfer Response field of the UTP Command Descriptor with the received UPIU.
- Once a command has been completed, depending on the Interrupt Enable register (UFS_IE), an interrupt may be asserted to signal the system host that the transfer is done.

12.3.7.4.2.2.6 UFS Response Management And Command Completion

Although not a command, the management of command completion, response management, and error handling can be considered to be related to the command interface.

There are essentially three steps to perform when a response UPIU arrives:

- Analyzing the packet.
- Storing of the sense data which might be part of the response packet.
- Modification of the Response UPIU field in the related UPIU command table entry.

As a last step and depending on the command setup, the UFS host controller will set the interrupt flag.

12.3.7.4.3 UFS PHY Programming

This section details specific steps on how to program the M-PHY.

The M-PHY registers can be used to configure and read the status of the M-PHY. These M-PHY registers are part of the common UFS host controller address space. For detailed description of the UFS and M-PHY registers, refer to *UFS0_P2A_WRAP_CFG_VBP_UFSHCI Registers*.

UFS and M-PHY address spaces:

- UFS address space: 04E8 0000h – 04E8 1103h
- M-PHY address space: 04E8 1104h – 04E8 1193h

The M-PHY configuration and status bits are connected directly either to the top-level ports or to the M-PHY register bank or to both exclusively.

The UFS_MPHY_MMIO_A[0] MMIO_A configuration bit is being used to choose if the dual-connection M-PHY configuration bits are connected to the registers or to IOs. After the reset, the UFS_MPHY_MMIO_A register value is 0h, so the M-PHY configuration bits are connected to the IOs by default. These bits are listed in [Table 12-304](#).

Table 12-304. The Dual Connection M-PHY Configuration Bits

UFS_MPHYCFG_VCONTROL		UFS_MPHYCFG_MISC		UFS_MPHY_MMIO_A = 1	UFS_MPHY_MMIO_A = 0
Offset	1188h	Offset	1184h		
Bits	Name	Bits	Name		
16	VCONTROL_LA_SA_SEL	29	CMN_MPX_EN_MMIO	Registers	I/Os
11-10	VCONTROL_DEEMP_SEL	28-26	CMN_MPX_SEL_MMIO		
9-0	VCONTROL	25	TX0_TEST_15_MMIO		
		24	TX1_TEST_15_MMIO		
		17	REFCLK_NOGATED		
		16-15	REFCLK_FREQ_SEL		
		6-0	DEBUG_SEL		

Note

To enlarge the M-PHY HS-Gear mode initialization time, set M-PHY configuration for the digital part register (UFS_MPHYCFG_XCFGD1) to 01000000h.

The UFS_MPHY_MMIO_A register will be stuck at zero in test mode in order to prevent toggling any of the dependent M-PHY input ports during scan procedure.

12.3.7.4.4 UFS Hibernate Timings Considerations

Software should take care of the following hibernate timings specifics:

1. An additional 22us needs to be added to the default TActivate time after establishing a link. This can be achieved by adjusting the host's *PA_Granularity* and *PA_TActivate* attributes in the Unipro layer as follows:

```

If (PA_Granularity == 6)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate*100 + 22;
else if (PA_Granularity == 5)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate*32 + 22;
else if (PA_Granularity == 4)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate*16 + 22;
else if (PA_Granularity == 3)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate*8 + 22;
else if (PA_Granularity == 2)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate*4 + 22;

```

```
else if (PA_Granularity == 1)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate + 22;
```

2. The TActivate time at hibernate exit on the peer side needs to be increased, by changing the *RX_Advanced_Min_ActivateTime_Capability* attribute default value from 0x04 to 0x0A in the M-PHY layer on host side.
3. The connection of differential termination resistance needs to be enabled, by setting to '1' the *Termination_Force_Enable* attribute in the M-PHY layer on host side.

12.4 Industrial and Control Interfaces

This section describes the industrial and control Interfaces in the device.

12.4.1 Enhanced Capture (ECAP) Module

This section describes the Enhanced Capture (ECAP) module in the device.

12.4.1.1 ECAP Overview

The Enhanced Capture (ECAP) module can be used for:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The device has three instances of the ECAP module.

12.4.1.1.1 ECAP Features

The ECAP module includes the following features:

- 32-bit time base counter
- 4 × 32 bits event time-stamp capture registers (ECAP_CAP1 through ECAP_CAP4)
- 4-stage sequencer (Mod4 counter), synchronized to external events (ECAPx pin edges)
- Independent edge polarity (rising / falling edge) selection for all 4 sequenced time-stamp capture events
- Input capture signal pre-scaling (from 1 to 16)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Interrupt capabilities on any of the 4 capture events
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.4.1.1.2 ECAP Ports

Table 12-305. ECAP Clocks and Resets

Clocks	
Module Clock Input	Description
ECAP_FICLK	ECAP functional and interface clock
Resets	
Module Reset Input	Description
ECAP_RST	Module Reset

Table 12-306. ECAP Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
ECAP_ECAP_INT_0	ECAP interrupt	Pulse

12.4.1.2 ECAP Environment

This section describes the ECAP external connections (environment).

[Table 12-307](#) describes the ECAP I/O signals.

Table 12-307. ECAP I/O Signals

Module Pin	I/O ⁽¹⁾	Description
ECAP0_CAPIN_APWMOUT	I/O	ECAP0 Capture input / PWM output
ECAP1_CAPIN_APWMOUT	I/O	ECAP1 Capture input / PWM output
ECAP2_CAPIN_APWMOUT	I/O	ECAP2 Capture input / PWM output

(1) I = Input; O = Output

12.4.1.3 ECAP Functional Description

The ECAP module represents one complete capture channel, which has the following independent key resources:

- Dedicated input capture pin
- 32 events selection mapping capability to the input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers (ECAP_CAP1 through ECAP_CAP4)
- 4-stage sequencer (Mod4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (ECAP_CAP1 through ECAP_CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

Multiple identical ECAP modules can be contained in a system as shown in [Figure 12-223](#). For actual number of the ECAP modules integrated in the device, refer to the *ECAP Integration*. The letter x within a signal or module name is used to indicate a generic ECAP instance on a device. For example, output interrupt request, ECAP1INT belongs to ECAP1, ECAP2INT belongs to ECAP2, and so forth.

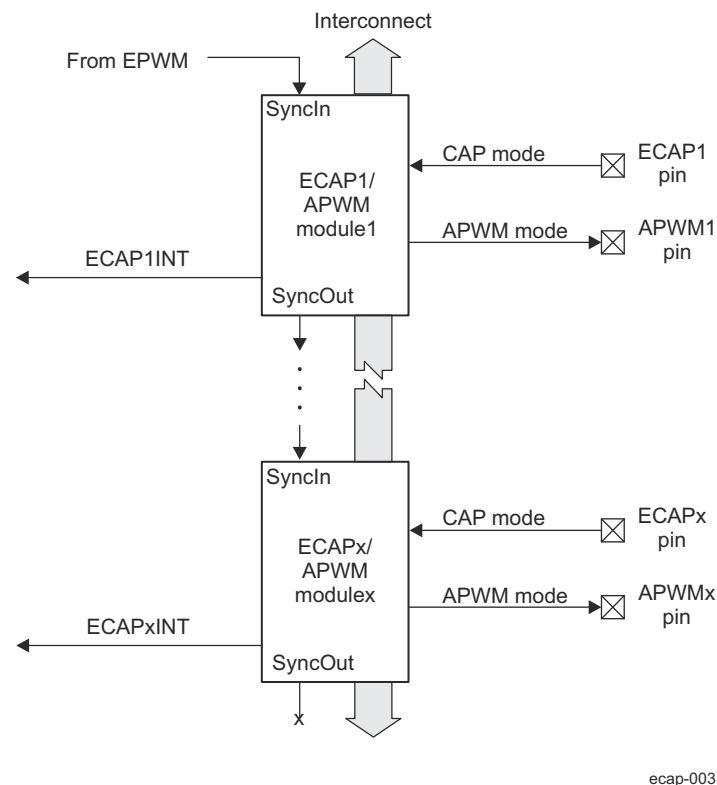

Figure 12-223. Multiple ECAP Modules

12.4.1.3.1 Capture and APWM Operating Modes

The ECAP module resources can be used to implement a single-channel PWM generator (with 32-bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The ECAP_CAP1 and ECAP_CAP2 registers become the active period and compare registers, respectively, while the ECAP_CAP3 and ECAP_CAP4 registers become the period and capture shadow registers, respectively. [Figure 12-224](#) is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

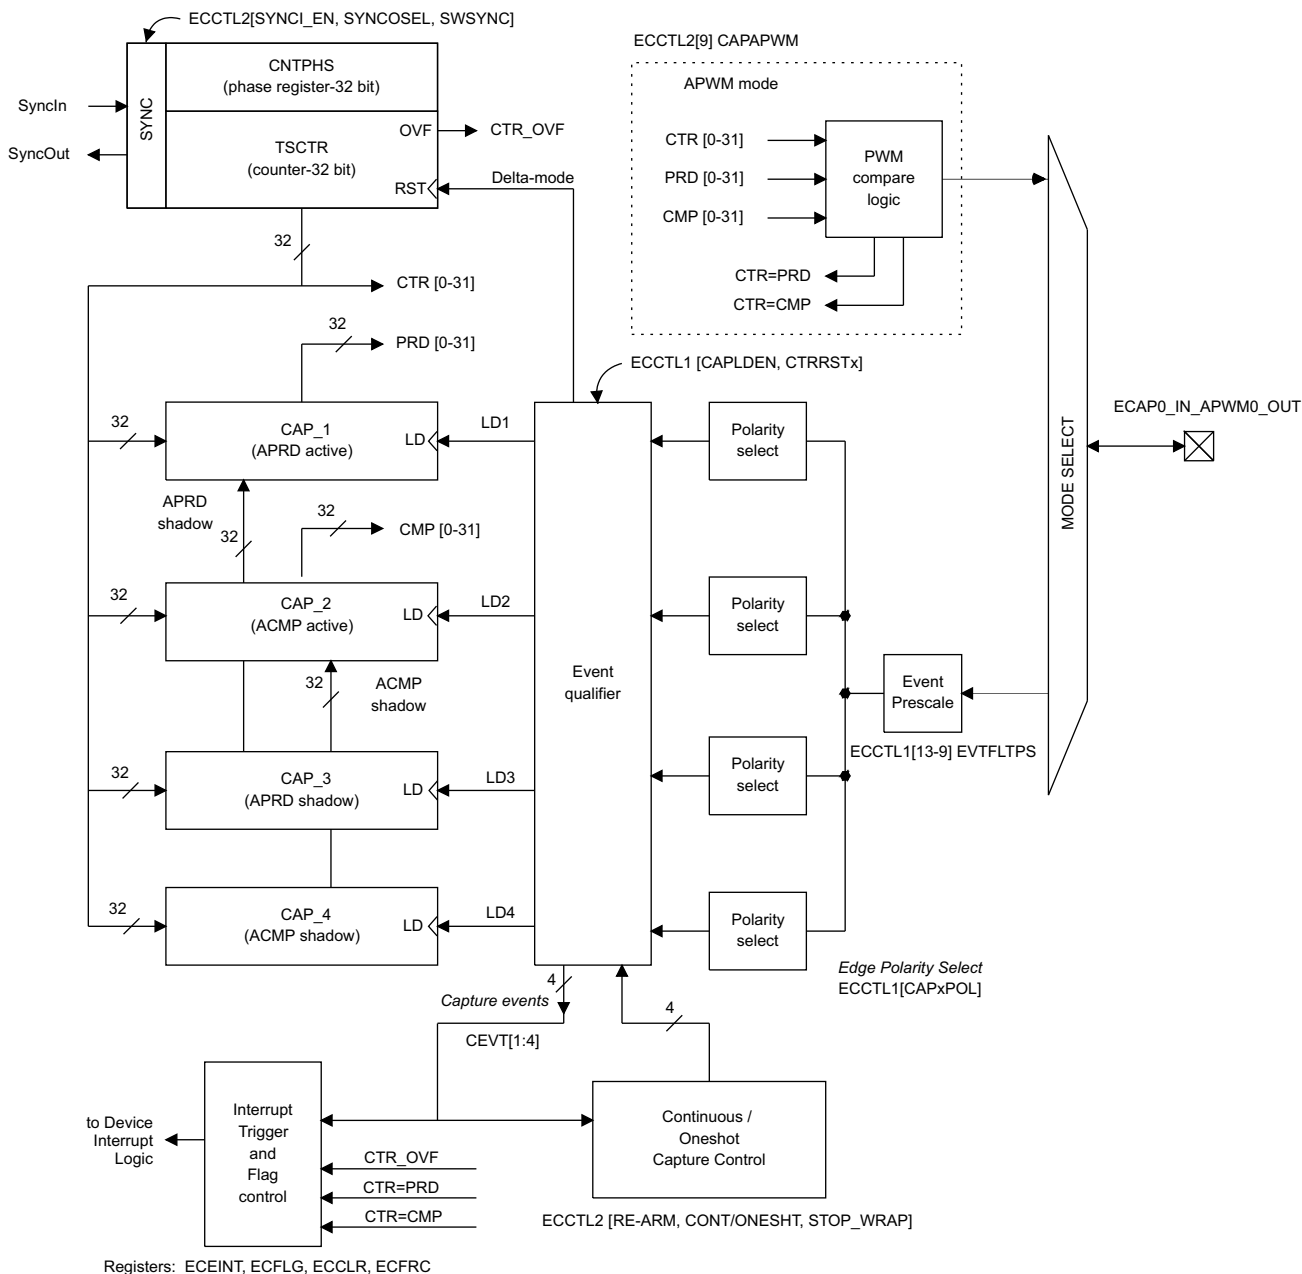

- A. A single pin is shared between CAP and APWM functions. In capture mode, it is an input. In APWM mode, it is an output.
- B. In APWM mode, writing any value to the ECAP_CAP1/ECAP_CAP2 active registers also writes the same value to the corresponding shadow registers (ECAP_CAP3/ECAP_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP_CAP3/ECAP_CAP4) invokes the shadow mode.

Figure 12-224. Capture and APWM Modes of Operation

12.4.1.3.1.1 ECAP Capture Mode Description

Figure 12-225 shows the various components that implement the capture function.

ecap-005

Figure 12-225. Capture Function Diagram

12.4.1.3.1.1.1 ECAP Event Prescaler

An input capture signal (pulse train) can be prescaled by $N = 2-62$ (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 12-226 shows a functional diagram and Figure 12-227 shows the operation of the prescale function.

- A. When a prescale value of 1 is chosen (ECAP_ECCTL1[13-9] EVTFLTPS = 0b0000) the input capture signal by-passes the prescale logic completely.

Figure 12-226. Event Prescale Control

Figure 12-227. Prescale Function Waveforms

12.4.1.3.1.1.2 ECAP Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Mod4 sequencer.
- The edge event is gated to its respective CAP n register by the Mod4 counter. The CAP n register is loaded on the falling edge.

12.4.1.3.1.1.3 ECAP Continuous/One-Shot Control

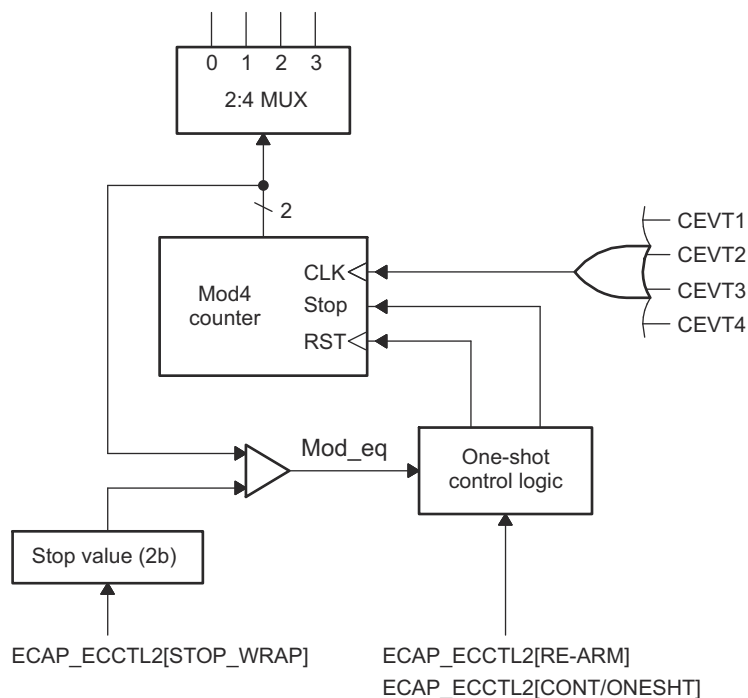

- The Mod4 (2-bit) counter is incremented via edge qualified events CEVT1 through CEVT4 (see the ECAP_ECINT_EN_FLG register).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output; when equal the Mod4 counter stops and inhibits further loads of the ECAP_CAP1 through ECAP_CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block (Figure 12-228) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the ECAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of the ECAP_CAP1 through ECAP_CAP4 registers (time-stamps).

Re-arming prepares the ECAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of the ECAP_CAP1 through ECAP_CAP4 registers again, providing the ECAP_ECCTL[8] CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0), the one-shot action is ignored, and capture values continue to be written to the ECAP_CAP1 through ECAP_CAP4 registers in a circular buffer sequence.

ecap-008

Figure 12-228. ECAP Continuous/One-shot Block Diagram

12.4.1.3.1.1.4 ECAP 32-Bit Counter and Phase Control

This counter (Figure 12-229) provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1 through LD4 signals.

Figure 12-229. ECAP Counter and Synchronization Block Diagram

12.4.1.3.1.1.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via the control ECAP_ECCTL[8] CAPLDEN bit. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

The ECAP_CAP1 and ECAP_CAP2 registers become the active period and compare registers, respectively, in APWM mode.

The ECAP_CAP3 and ECAP_CAP4 registers become the respective shadow registers (APRD and ACMP) for the ECAP_CAP1 and ECAP_CAP2 registers during APWM operation.

12.4.1.3.1.1.6 ECAP Interrupt Control

An interrupt can be generated on capture events CEVT1 through CEVT4, CINTOVF (see the ECAP_ECINT_EN_FLG[21] CINTOVF_FLG bit) or APWM events (TSCNT = PRD, TSCNT = CMP). See [Figure 12-230](#).

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CINTOVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the ECAP_n module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CINTOVF, TSCNT = PRD, TSCNT = CMP) can be generated. The interrupt enable register (ECAP_ECINT_EN_FLG) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECAP_ECINT_EN_FLG) indicates if any interrupt event has been latched and contains the global interrupt flag ECAP_ECINT_EN_FLG[16] INT_FLG bit. An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1h, and the INT_FLG flag bit is 0h. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECAP_ECINT_CLR_FRC) before any other interrupt pulses are generated. The interrupt force register (ECAP_ECINT_CLR_FRC) can force an interrupt event. This is useful for test purposes.

12.4.1.3.1.1.7 ECAP Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of the ECAP_CAP1 or ECAP_CAP2 registers from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to the ECAP_CAP1 or ECAP_CAP2 register immediately upon writing a new value.
- On period equal, CTR[31-0] = PRD[31-0]

Note

The CEVT1_FLG, CEVT2_FLG, CEVT3_FLG, CEVT4_FLG flags are only active in capture mode (ECAP_ECCTL[25] CAP_APWM == 0h). The TSCNT = PRD, TSCNT = CMP flags are only valid in APWM mode (ECAP_ECCTL[25] CAP_APWM == 1h). CINTOVF_FLG flag is valid in both modes.

ecap-010

Figure 12-230. Interrupts in ECAP Module

12.4.1.3.1.2 ECAP APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When the ECAP_CAP1/ECAP_CAP2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via the shadow registers - APRD and ACMP (ECAP_CAP3/ECAP_CAP4). The shadow register contents are transferred over to ECAP_CAP1/ECAP_CAP2 registers either immediately upon a write, or on a TSCNT = PRD trigger.
- In APWM mode, writing to the ECAP_CAP1/ECAP_CAP2 active registers will also write the same value to the corresponding shadow registers (ECAP_CAP3/ECAP_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP_CAP3/ECAP_CAP4) will invoke the shadow mode.
- During initialization, software must write the PRD and CMP values to the active registers. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, software should use only shadow registers.

Figure 12-231. PWM Waveform Details of ECAP APWM Mode Operation

The behavior of APWM active-high mode (APWMPOL == 0) is:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active-low mode (APWMPOL == 1) is:

CMP = 0x00000000, output high for duration of period (0% duty)

CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

12.4.1.3.2 Summary of ECAP Functional Registers

[Table 12-308](#) shows the ECAP module control and status register set. All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode.

Note

In APWM mode, writing to the ECAP_CAP1/ECAP_CAP2 active registers also writes the same value to the corresponding shadow registers (ECAP_CAP3/ECAP_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP_CAP3/ECAP_CAP4) invokes the shadow mode.

Table 12-308. ECAP Control and Status Functional Registers

Offset	Register Name	Description	Size (×16)
0h	ECAP_TSCNT	Time-Stamp Counter Register	2
4h	ECAP_CNTPHS	Counter Phase Offset Value Register	2
8h	ECAP_CAP1	Capture 1 Register	2
Ch	ECAP_CAP2	Capture 2 Register	2
10h	ECAP_CAP3	Capture 3 Register	2
14h	ECAP_CAP4	Capture 4 Register	2
28h	ECAP_ECCTL	Capture Control Register	2
2Ch	ECAP_ECINT_EN_FLG	Capture Interrupt Enable and Flag Register	2
30h	ECAP_ECINT_CLR_FRC	Capture Interrupt Clear and Forcing Register	2
5Ch	ECAP_PID	Revision ID Register	2

Note

For more information on the ECAP registers, see *ECAP Registers*.

12.4.1.4 ECAP Use Cases

The following sections will provide applications examples and code snippets to show how to configure and operate the ECAP module. For clarity and ease of use, below are useful #defines which will help in the understanding of the examples.

```
// ECCTL1 ( ECAP Control Reg 1)
//=====
// CAPxPOL bits
#define EC_RISING          0x0
#define EC_FALLING        0x1
// CTRRSTx bits
#define EC_ABS_MODE        0x0
#define EC_DELTA_MODE      0x1
// PRESCALE bits
#define EC_BYPASS          0x0
#define EC_DIV1            0x0
#define EC_DIV2            0x1
#define EC_DIV4            0x2
#define EC_DIV6            0x3
#define EC_DIV8            0x4
#define EC_DIV10           0x5
// ECCTL2 ( ECAP Control Reg 2)
//=====
// CONT/ONESHOT bit
#define EC_CONTINUOUS       0x0
#define EC_ONESHOT         0x1
// STOPVALUE bit
#define EC_EVENT1          0x0
#define EC_EVENT2          0x1
#define EC_EVENT3          0x2
#define EC_EVENT4          0x3
// RE-ARM bit
#define EC_ARM              0x1
// TSCTRSTOP bit
#define EC_FREEZE          0x0
#define EC_RUN              0x1
// SYNCO_SEL bit
#define EC_SYNCIN          0x0
#define EC_CTR_PRD         0x1
#define EC_SYNCO_DIS       0x2
// CAP/APWM mode bit
#define EC_CAP_MODE        0x0
#define EC_APWM_MODE       0x1
// APWMPOL bit
#define EC_ACTV_HI         0x0
#define EC_ACTV_LO         0x1
// Generic
#define EC_DISABLE          0x0
#define EC_ENABLE          0x1
#define EC_FORCE            0x1
```

12.4.1.4.1 Absolute Time-Stamp Operation Rising Edge Trigger Example

Figure 12-232 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (maximum value), it wraps around to 0000 0000h (not shown in Figure 12-232), if this occurs, the CANTOVF_FLG (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured time-stamps are valid at the point indicated by the diagram, after the 4-th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPn registers.

Figure 12-232. Capture Sequence for Absolute Time-Stamp, Rising Edge Detect

Table 12-309. ECAP Initialization for CAP Mode Absolute Time, Rising Edge Trigger

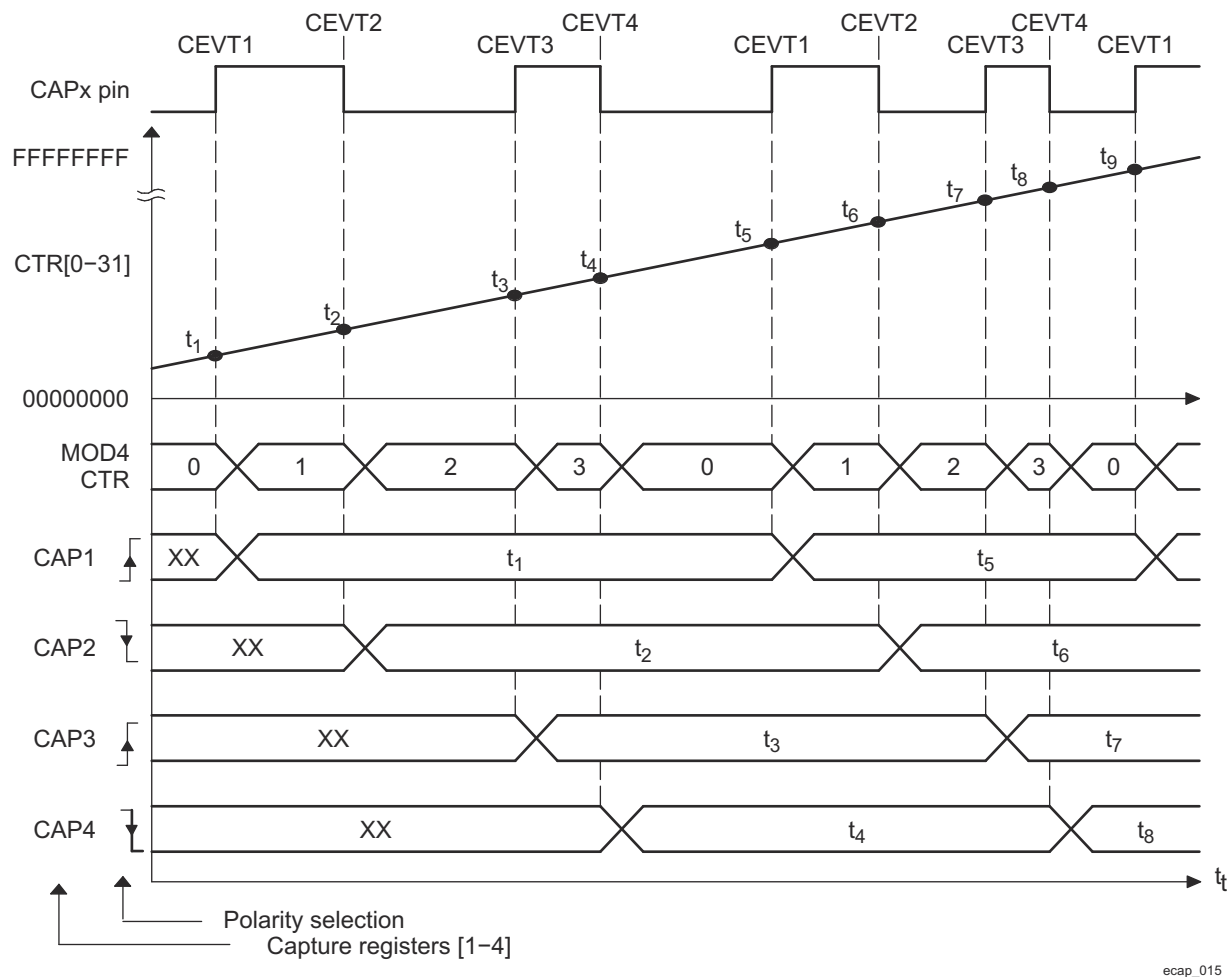

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_ABS_MODE
ECCTL1	CTRRST2	EC_ABS_MODE
ECCTL1	CTRRST3	EC_ABS_MODE
ECCTL1	CTRRST4	EC_ABS_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

Example 12-1. Code Snippet for CAP Mode Absolute Time, Rising Edge Trigger

```
// Code snippet for CAP mode Absolute Time, Rising edge trigger
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;      // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;      // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;      // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;      // Fetch Time-Stamp captured at t4
Period1 = TSt2-TSt1;         // Calculate 1st period
Period2 = TSt3-TSt2;         // Calculate 2nd period
Period3 = TSt4-TSt3;         // Calculate 3rd period
```

12.4.1.4.2 Absolute Time-Stamp Operation Rising and Falling Edge Trigger Example

In Figure 12-233 the ECAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information: $\text{Period1} = t_3 - t_1$, $\text{Period2} = t_5 - t_3$, ...etc. $\text{Duty Cycle1 (on-time \%)} = (t_2 - t_1) / \text{Period1} \times 100\%$, etc. $\text{Duty Cycle1 (off-time \%)} = (t_3 - t_2) / \text{Period1} \times 100\%$, etc.

Example 12-2. Code Snippet for CAP Mode Absolute Time, Rising and Falling Edge Trigger

```
// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;      // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;      // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;      // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;      // Fetch Time-Stamp captured at t4
Period1 = TSt3-TSt1;        // Calculate 1st period
DutyOnTime1 = TSt2-TSt1;     // Calculate On time
DutyOffTime1 = TSt3-TSt2;    // Calculate Off time
```

12.4.1.4.3 Time Difference (Delta) Operation Rising Edge Trigger Example

Figure 12-234 shows how the ECAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (maximum value), before the next event, it wraps around to 0000 0000h and continues, a CINTOVF_FLG (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPn contents directly give timing data without the need for CPU calculations: Period1 = T_1 , Period2 = T_2 ,...etc. As shown in Figure 12-234, the CEVT1 event is a good trigger point to read the timing data, T_1 , T_2 , T_3 , T_4 are all valid here.

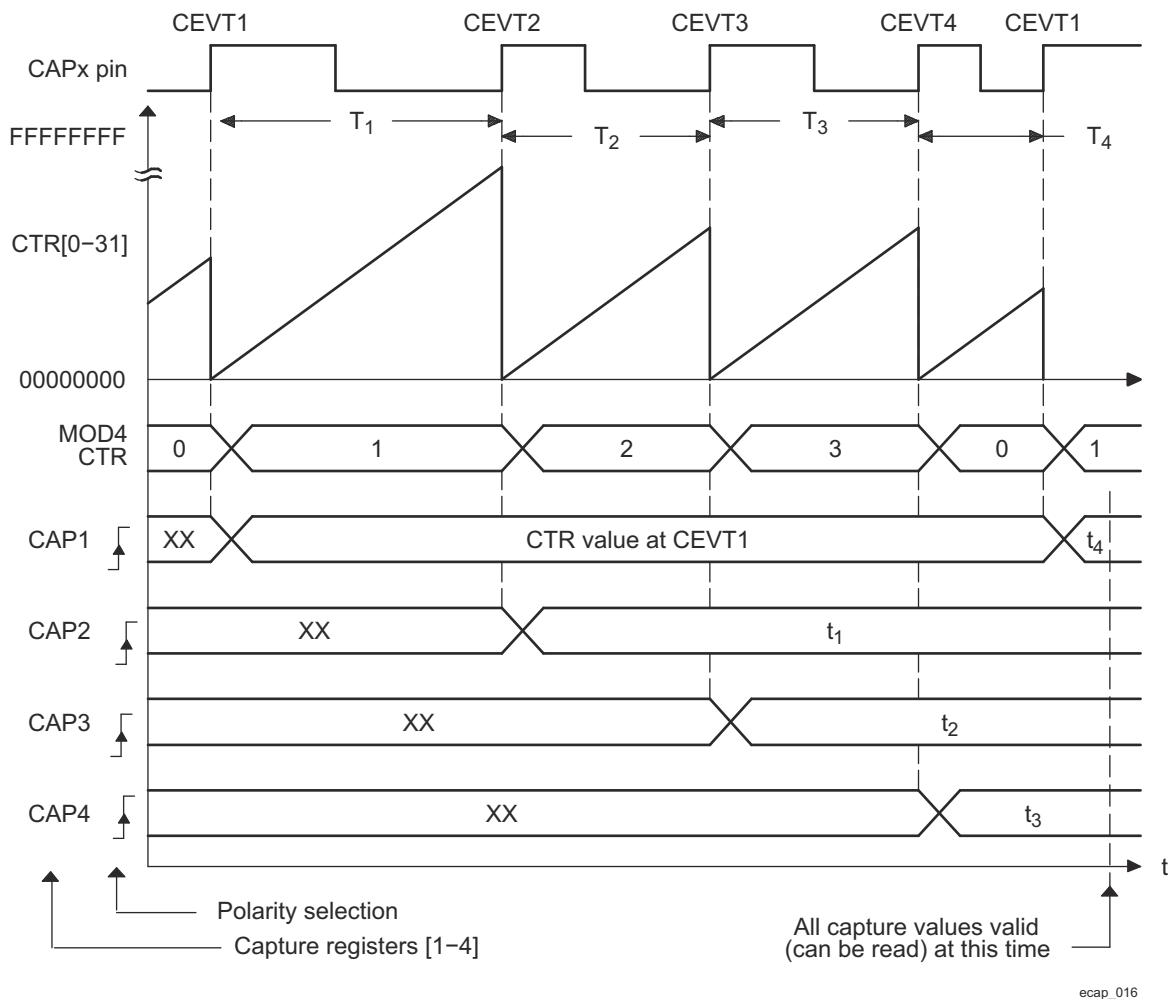

Figure 12-234. Capture Sequence for Delta Mode Time-Stamp, Rising Edge Detect

Table 12-311. ECAP Initialization for CAP Mode Delta Time, Rising Edge Trigger

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_DELTA_MODE

ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

Example 12-3. Code Snippet for CAP Mode Delta Time, Rising Edge Trigger

```
// Code snippet for CAP mode Delta Time, Rising edge trigger
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Period value.
Period4 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1
Period1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
Period2 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
Period3 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
```

12.4.1.4.4 Time Difference (Delta) Operation Rising and Falling Edge Trigger Example

In Figure 12-235 the ECAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information: Period1 = $T_1 + T_2$, Period2 = $T_3 + T_4$, ...etc Duty Cycle1 (on-time %) = $T_1 / \text{Period1} \times 100\%$, etc Duty Cycle1 (off-time %) = $T_2 / \text{Period1} \times 100\%$, etc.

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, that is, during run-time, only the shadow registers must be used.

Figure 12-235. Capture Sequence for Delta Mode Time-Stamp, Rising and Falling Edge Detect

Table 12-312. ECAP Initialization for CAP Mode Delta Time, Rising and Falling Edge Triggers

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_FALLING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_FALLING

Example 12-4. Code Snippet for CAP Mode Delta Time, Rising and Falling Edge Triggers

```
// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Duty cycle values.
DutyOnTime1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
DutyOffTime1 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
DutyOnTime2 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
DutyOffTime2 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1
Period1 = DutyOnTime1 + DutyOffTime1;
Period2 = DutyOnTime2 + DutyOffTime2;
```

12.4.1.4.5 Application of the APWM Mode

12.4.1.4.5.1 Simple PWM Generation (Independent Channel/s) Example

In this example, the ECAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWM n . The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

Figure 12-236. PWM Waveform Details of APWM Mode Operation

Table 12-313. ECAP Initialization for APWM Mode

Register	Bit	Value
CAP1	CAP1	0x1000
CTRPHS	CTRPHS	0x0
ECCTL2	CAP_APWM	EC_APWM_MODE
ECCTL2	APWMPOL	EC_ACTV_HI
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSCTRSTOP	EC_RUN

Example 12-5. Code Snippet for APWM Mode

```
// Code snippet for APWM mode Example 1
// Run Time (Instant 1, e.g. ISR call)
//=====
ECAPxRegs.CAP2 = 0x300;      // Set Duty cycle i.e. compare value
// Run Time (Instant 2, e.g. another ISR call)
//=====
ECAPxRegs.CAP2 = 0x500;      // Set Duty cycle i.e. compare value
```

12.4.1.4.5.2 Multichannel PWM Generation with Synchronization Example

Figure 12-237 takes advantage of the synchronization feature between the ECAP modules. Here 4 independent PWM channels are required with different frequencies, but at integer multiples of each other to avoid "beat" frequencies. Hence one ECAP module is configured as the Master and the remaining 3 are Slaves all receiving their synch pulse (CTR = PRD) from the master. Note the Master is chosen to have the lower frequency ($F_1 = 1/20,000$) requirement. Here Slave2 Freq = $2 \times F_1$, Slave3 Freq = $4 \times F_1$ and Slave4 Freq = $5 \times F_1$. Note here values are in decimal notation. Also, only the APWM1 output waveform is shown.

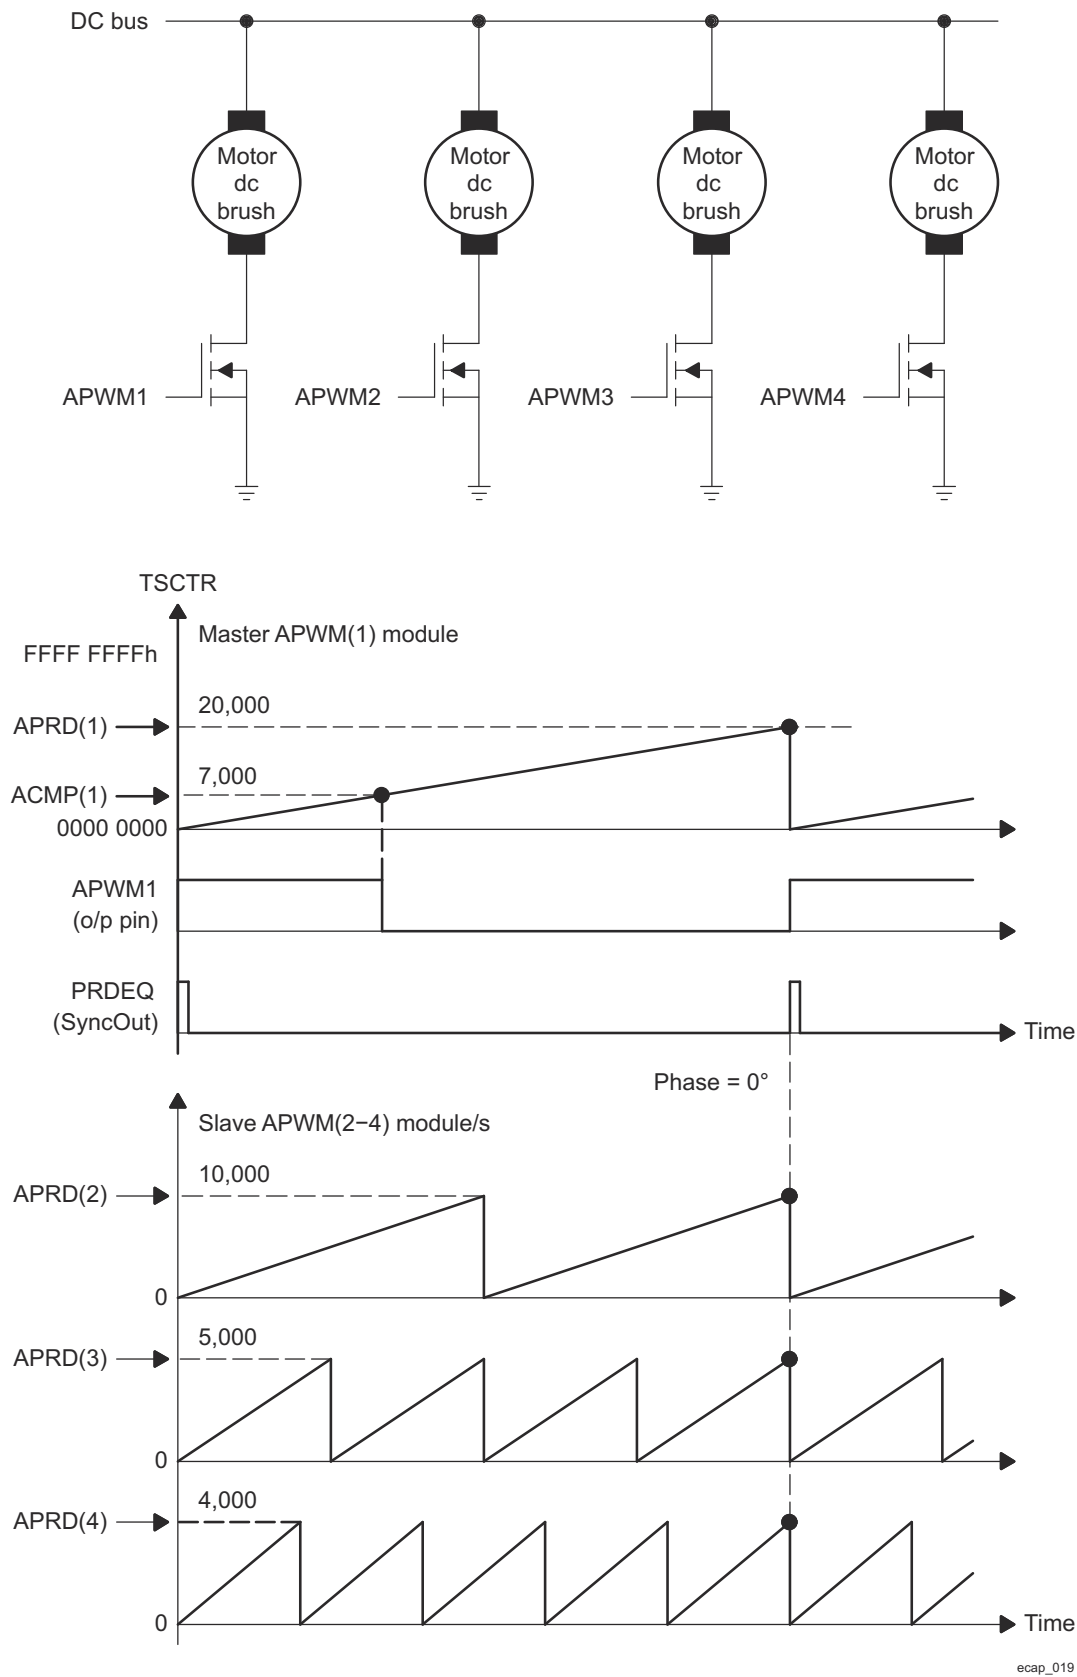

Figure 12-237. Multichannel PWM Example Using 4 ECAP Modules

Table 12-314. ECAP1 Initialization for Multichannel PWM Generation with Synchronization

ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSCTRSTOP	EC_RUN

Example 12-6. Code Snippet for Multichannel PWM Generation with Synchronization

```
// Code snippet for APWM mode Example 2
// Run Time (Note: Example execution of one run-time instant)
//=====
ECAP1Regs.CAP2 = 7000;    // Set Duty cycle i.e., compare value = 7000
ECAP2Regs.CAP2 = 2000;    // Set Duty cycle i.e., compare value = 2000
ECAP3Regs.CAP2 = 550;     // Set Duty cycle i.e., compare value = 550
ECAP4Regs.CAP2 = 6500;    // Set Duty cycle i.e., compare value = 6500
```

12.4.1.4.5.3 Multichannel PWM Generation with Phase Control Example

In [Figure 12-238](#), the Phase control feature of the APWM mode is used to control a 3 phase Interleaved DC/DC converter topology. This topology requires each phase to be off-set by 120° from each other. Hence if "Leg" 1 (controlled by APWM1) is the reference Leg (or phase), that is, 0° , then Leg 2 need 120° off-set and Leg 3 needs 240° off-set. The waveforms in [Figure 12-238](#) show the timing relationship between each of the phases (Legs). Note ECAP1 module is the Master and issues a SyncOut pulse to the slaves (modules 2, 3) whenever TSCTR = Period value.

Figure 12-238. Multiphase (channel) Interleaved PWM Example Using 3 ECAP Modules

Example 12-7. Code Snippet for Multichannel PWM Generation with Phase Control

```
// Code snippet for APWM mode Example 3
// Run Time (Note: Example execution of one run-time instant)
//=====
// All phases are set to the same duty cycle
ECAP1Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP2Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP3Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
```

12.4.2 Enhanced Pulse Width Modulation (EPWM) Module

This chapter describes the Enhanced PWM (EPWM) module in the device.

12.4.2.1 EPWM Overview

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The EPWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the EPWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In the further description the letter x within a signal or module name is used to indicate a generic EPWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the EPWMx

instance. Thus, EPWM1A and EPWM1B belong to EPWM1, EPWM2A and EPWM2B belong to EPWM2, and so forth.

The EPWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. A given EPWM module functionality can be extended with the so called **High-Resolution Pulse Width Modulator**. Refer to the *EPWM Integration*, to determine which EPWM instances include the HRPWM feature. The HRPWM functionalities are described in [Section 12.4.2.3.9](#).

As also described in *Daisy-Chain Connectivity between EPWM Modules*, the EPWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, the EPWM integration allows this synchronization scheme to be extended to the capture peripheral modules (ECAP). The number of modules is device-dependent and based on target application needs. Modules can also operate stand-alone.

The device has six instances of the EPWM modules.

12.4.2.1.1 EPWM Features

Each EPWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
 - Two independent PWM outputs with single-edge operation
 - Two independent PWM outputs with dual-edge symmetric operation
 - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software
- Programmable phase-control support for lag or lead operation relative to other EPWM modules
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs
- Allows events to trigger both CPU interrupts and ADC start of conversions
- Programmable event prescaling minimizes CPU overhead on interrupts
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives
- High-resolution module with programmable delay line:
 - Programmable on a per PWM period basis
 - Can be inserted either on the rising edge or falling edge of the PWM pulse or both or not at all.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

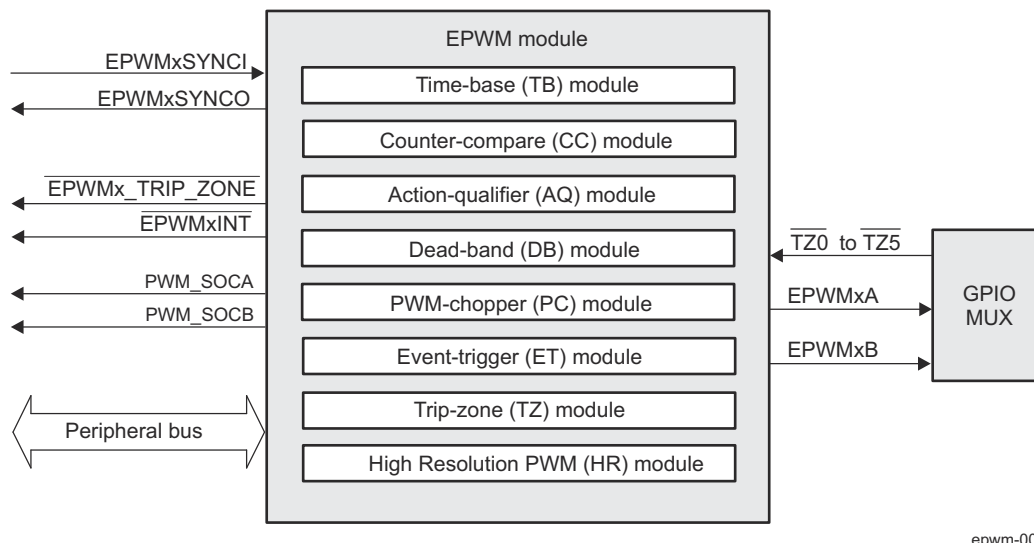

Each EPWM module is connected to the input/output signals shown in [Figure 12-239](#). The signals are described in detail in subsequent sections.

The order in which the EPWM modules are connected may differ from what is shown in [Figure 12-239](#). See *Daisy-Chain Connectivity between EPWM Modules* for the actual synchronization scheme implemented in the device. Each EPWM module consists of eight submodules and is connected within a system via the signals shown in [Figure 12-240](#).

epwm-001

Figure 12-239. Multiple EPWM Modules

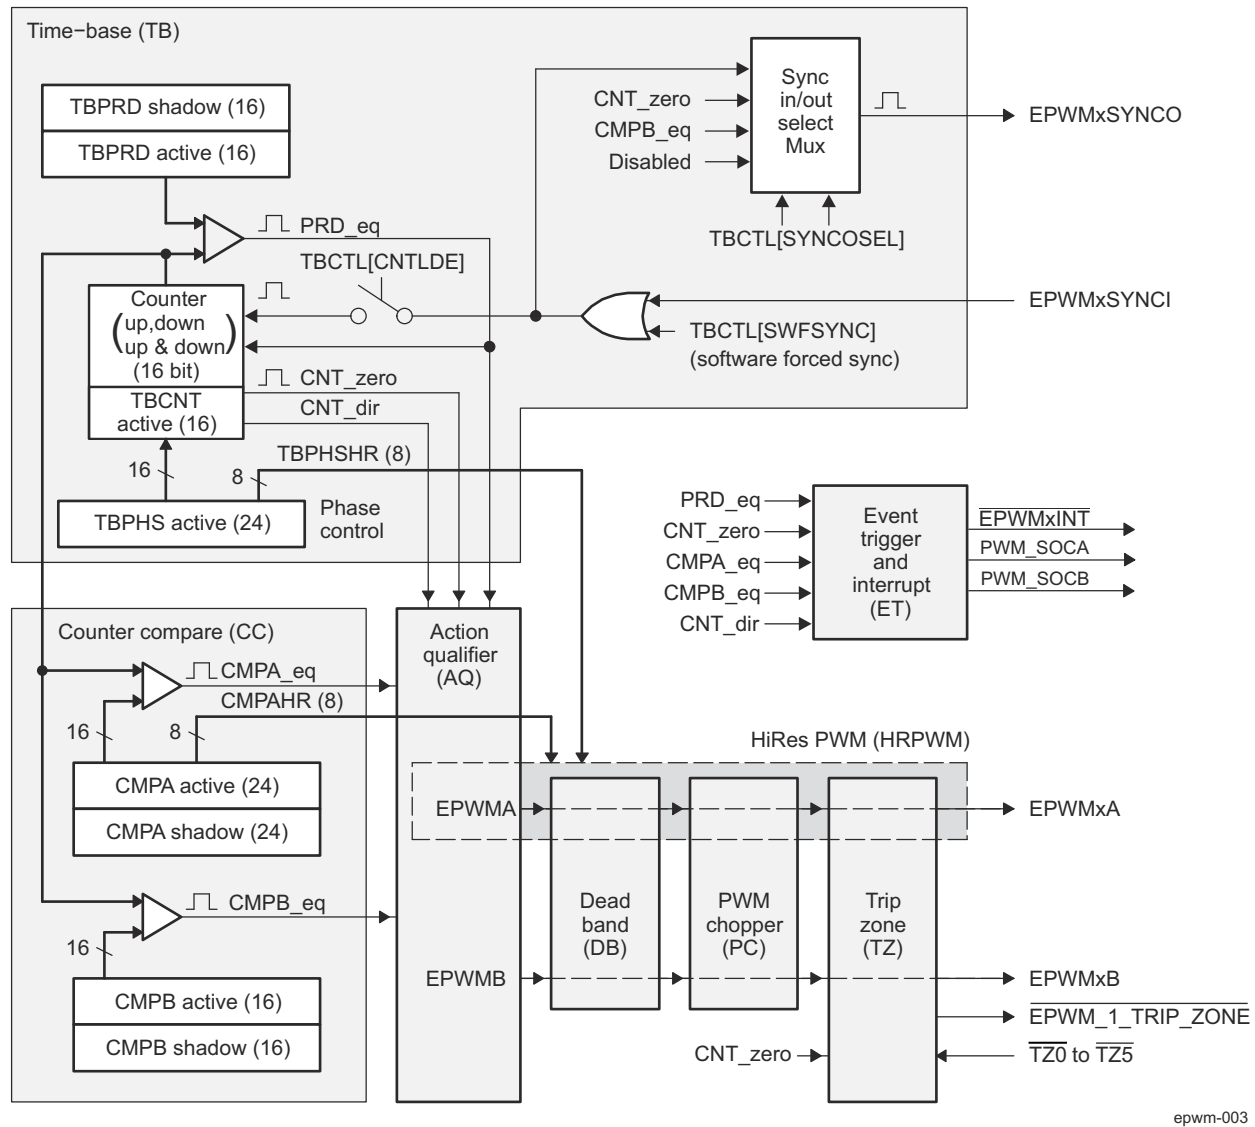

epwm-002

Figure 12-240. Submodules and Signal Connections for an EPWM Module

Figure 12-241 shows more internal details of a single EPWM module. The main signals used by the EPWM module are:

- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for the device.
- **Trip-zone signals (TZ0 to TZ5).** These input signals alert the EPWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral.
- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the EPWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins for EPWM0 (EPWM module 0) and EPWM3. The EPWM5 synchronization output (EPWM5SYNCO) is also connected to the input SYNCIN of the Enhanced Capture Module (ECAP0).
- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).** Each EPWM module has two ADC start of conversion signals (one for each sequencer). Any EPWM module can trigger a start of conversion for either sequencer. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the EPWM.
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the EPWM register file.

Figure 12-241 also shows the key internal submodule interconnect signals. Each submodule is described in Section 12.4.2.3.

12.4.2.3 EPWM Functional Description

8 submodules are included in each EPWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

12.4.2.3.1 EPWM Submodule Features

Table 12-324 lists the eight key submodules together with a list of their main configuration parameters.

Table 12-324. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	<ul style="list-style-type: none"> Scale the time-base clock (TBCLK) relative to the system clock (FICLK). Configure the PWM time-base counter (TBCNT) frequency or period. Time-base counter mode selection: <ul style="list-style-type: none"> count-up mode: used for asymmetric PWM count-down mode: used for asymmetric PWM count-up-and-down mode: used for symmetric PWM Configure the time-base phase relative to another EPWM module. Synchronize the time-base counter between modules through hardware or software. Configure the direction (up or down) of the time-base counter after a synchronization event. Configure how the time-base counter will behave when the device is halted by an emulator. Specify the source for the synchronization output of the EPWM module: <ul style="list-style-type: none"> Synchronization input signal Time-base counter equal to zero Time-base counter equal to counter-compare B (CMPB) No output synchronization signal generated
Counter-compare (CC)	<ul style="list-style-type: none"> Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB Specify the time at which switching events occur on the EPWMxA or EPWMxB output
Action-qualifier (AQ)	<ul style="list-style-type: none"> Specify the type of action taken when a time-base or counter-compare submodule event occurs: <ul style="list-style-type: none"> No action taken Output EPWMxA and/or EPWMxB switched high Output EPWMxA and/or EPWMxB switched low Output EPWMxA and/or EPWMxB toggled Force the PWM output state through software control Configure and control the PWM dead-band through software
Dead-band (DB)	<ul style="list-style-type: none"> Control of traditional complementary dead-band relationship between upper and lower switches Specify the output rising-edge-delay value Specify the output falling-edge delay value Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification
PWM-chopper (PC)	<ul style="list-style-type: none"> Create a chopping (carrier) frequency Pulse width of the first pulse in the chopped pulse train Duty cycle of the second and subsequent pulses Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.

Table 12-324. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	<ul style="list-style-type: none"> Configure the EPWM module to react to one, all, or none of the trip-zone pins Specify the tripping action taken when a fault occurs: <ul style="list-style-type: none"> Force EPWMxA and/or EPWMxB high Force EPWMxA and/or EPWMxB low Force EPWMxA and/or EPWMxB to a high-impedance state Configure EPWMxA and/or EPWMxB to ignore any trip condition Configure how often the EPWM will react to the trip-zone pin: <ul style="list-style-type: none"> One-shot Cycle-by-cycle Enable the trip-zone to initiate an interrupt Bypass the trip-zone module entirely
Event-trigger (ET)	<ul style="list-style-type: none"> Enable the EPWM events that will trigger an interrupt. Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) Poll, set, or clear event flags

12.4.2.3.2 EPWM Time-Base (TB) Submodule

This section describes the Time-Base (TB) submodule in the PWM module.

12.4.2.3.2.1 Overview

Each EPWM module has its own time-base submodule that determines all of the timing events. Built-in synchronization logic allows the time-base of multiple EPWM modules (EPWMx) to work together as a single system. [Figure 12-242](#) illustrates the time-base module's place within the EPWM.

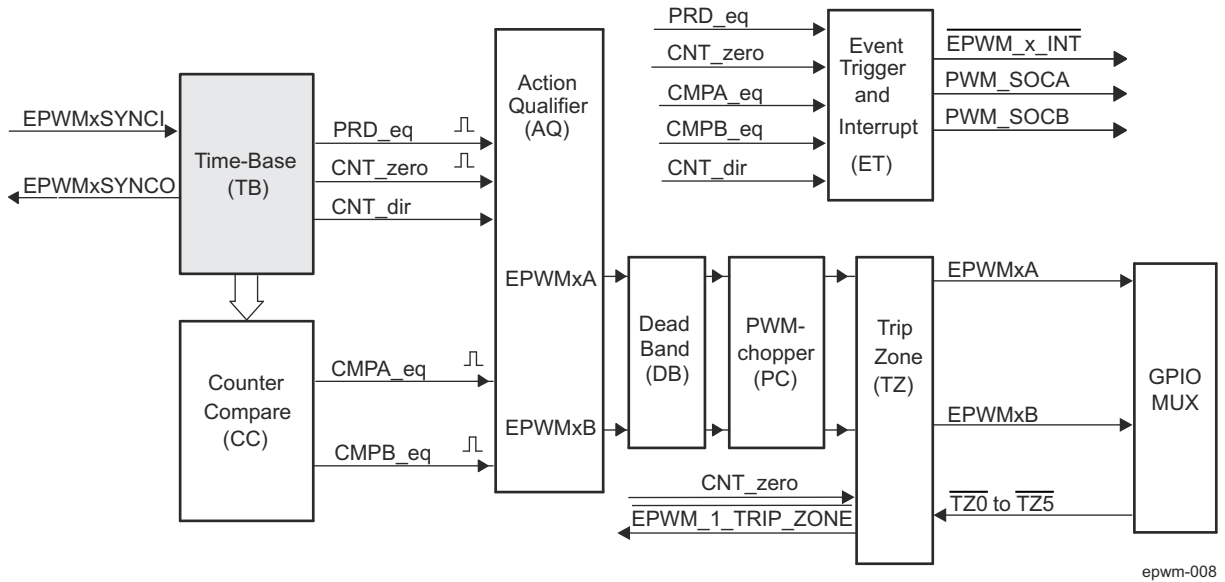

Figure 12-242. EPWM Time-Base Submodule

The TB module generates the period (or frequency) of the PWM output waveforms and consists of a 16-bit counter that can be configured for up, down or up and down counting. The time base for the counter is a pre-scaled version of the system clock (FICLK/n) which can be programmed for a pre-scale of 1, that is same as system clock.

TB module features:

- Specify the EPWMx time-base counter (TBCNT) frequency or period in the EPWM_TBCNT register to control how often events occur.
- Manage time-base synchronization with other EPWMx modules.
- Maintain a phase relationship with other EPWMx modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
 - PRD_eq (Time-base counter (EPWM_TBCNT register) equal to the specified period in EPWM_TBPRD register (that is TBCNT = TBPRD)).
 - CNT_zero (Time-base counter equal to zero (TBCNT = 0000h)).
- Configure the rate of the time-base clock; a prescaled version of the CPU m clock (FICLK). This allows the time-base counter to increment/decrement at a slower rate.

12.4.2.3.2.2 Controlling and Monitoring the EPWM Time-Base Submodule

[Table 12-325](#) lists the registers used to control and monitor the time-base submodule.

Table 12-325. EPWM Time-Base Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCTL	Time-Base Control Register	0h	No
EPWM_TBSTS	Time-Base Status Register	2h	No
HRPWM_TBPHSHR	HRPWM extension Phase Register ⁽¹⁾	4h	No
EPWM_TBPHS	Time-Base Phase Register	6h	No

Table 12-325. EPWM Time-Base Submodule Registers (continued)

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCNT	Time-Base Counter Register	8h	No
EPWM_TBPRD	Time-Base Period Register	Ah	Yes

- (1) This register is available only on EPWM instances that include the high-resolution extension (HRPWM). On EPWM modules that do not include the HRPWM, this location is reserved. See *EPWM Integration* to determine which EPWM instances include this feature.

Figure 12-243 shows the critical signals and registers of the time-base submodule. Table 12-326 provides descriptions of the key signals associated with the time-base submodule.

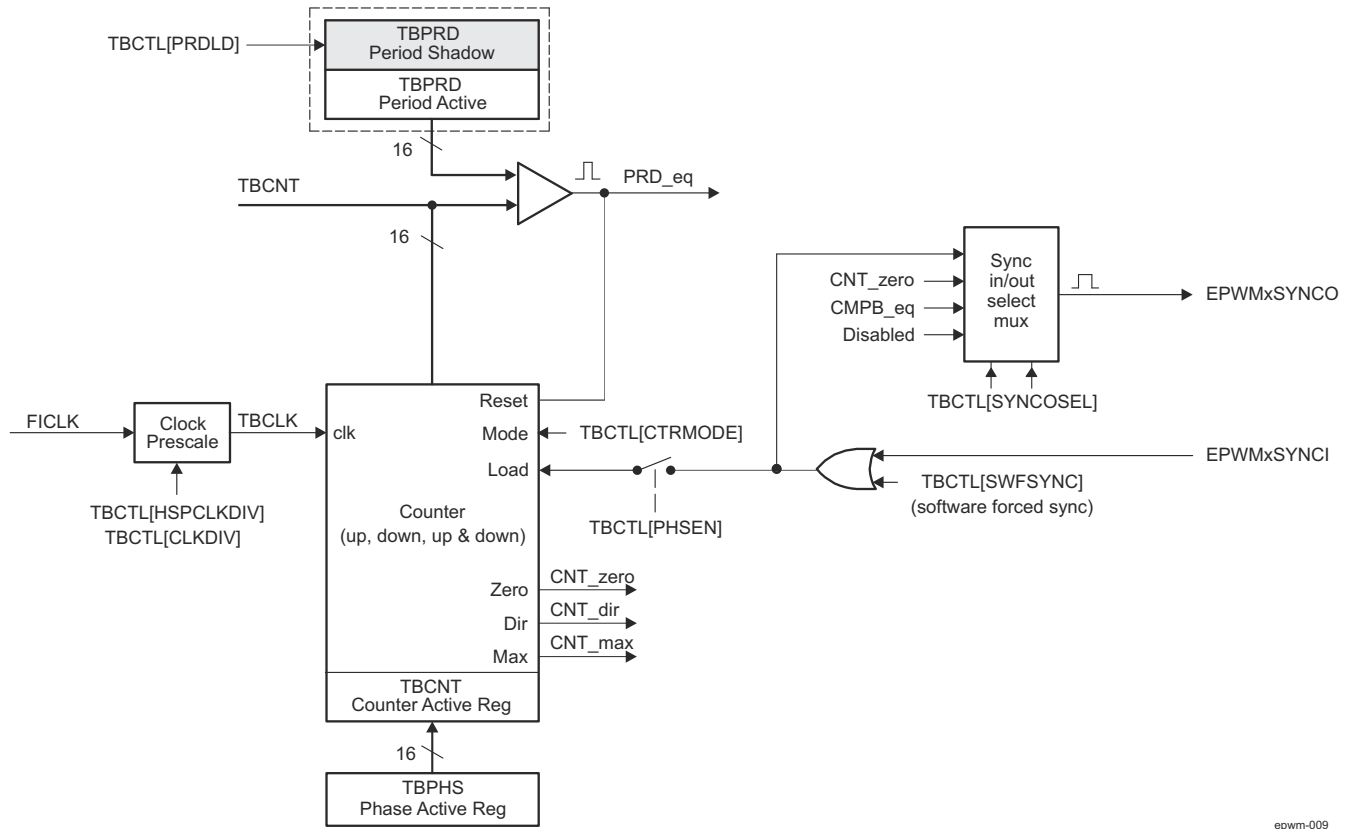

Figure 12-243. EPWM Time-Base Submodule Signals and Registers

Table 12-326. EPWM Time-Base Submodule Key Signals

Signal	Description
EPWMxSYNCl	<p>Time-base synchronization input.</p> <p>Input pulse used to synchronize the time-base counter with the counter of another EPWM module earlier in the synchronization chain. An EPWM peripheral can be configured to use or ignore this signal. For the first EPWM module (EPWM0) this signal comes from a device pin. For subsequent EPWM modules this signal is passed from another EPWM peripheral. For example, EPWM2SYNCl is generated by the EPWM1 peripheral and the EPWM3SYNCl is generated (optional through internal multiplexer) by EPWM2 or from a device pin. See Section 12.4.2.3.2.3.2 for information on the synchronization order of a particular device.</p>
EPWMxSYNCO	<p>Time-base synchronization output.</p> <p>This output pulse is used to synchronize the counter of an EPWM module later in the synchronization chain. The EPWM module generates this signal from one of three event sources:</p> <ol style="list-style-type: none"> 1. EPWMxSYNCl (Synchronization input pulse) 2. TBCNT = 0: The time-base counter (EPWM_TBCNT register) equal to zero (TBCNT = 0000h). 3. TBCNT = CMPB: The time-base counter (EPWM_TBCNT register) equal to the counter-compare B register — EPWM_CMPB (that is bitfield TBCNT = bitfield CMPB).

Table 12-326. EPWM Time-Base Submodule Key Signals (continued)

Signal	Description
PRD_eq	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.
CNT_zero	Time-base counter equal to zero. This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.
CMPB_eq	Time-base counter equal to active counter-compare B register (TBCNT = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic.
CNT_dir	Time-base counter direction. Indicates the current direction of the EPWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CNT_max	Time-base counter equal max value (TBCNT = FFFFh). Generated event when the EPWM_TBCNT register value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock. This is a prescaled version of the system clock — FICLK and is used by all submodules within the EPWMn. This clock determines the rate at which time-base counter increments or decrements.

12.4.2.3.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period register (EPWM_TBPRD) and the mode of the time-base counter. [Figure 12-244](#) shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (EPWM_TBPRD[15:0] TBPRD = 0x4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (FICLK).

The time-base counter has three modes of operation selected by the time-base control register (EPWM_TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset back to the period value and it repeats this pattern.

Figure 12-244. EPWM Time-Base Frequency and Period

12.4.2.3.2.3.1 EPWM Time-Base Period Shadow Register

The time-base period register (EPWM_TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the EPWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the EPWM_TBCTL[3] PRDL D bit. This bit enables and disables the EPWM_TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The EPWM_TBPRD shadow register is enabled when EPWM_TBCTL[3] PRDL D = 0h. Reads from and writes to the EPWM_TBPRD register memory address go to the shadow register. The shadow register contents are transferred to the active register (EPWM_TBPRD (Active) ← EPWM_TBPRD (shadow)) when the time-base counter register (EPWM_TBCNT) equals zero (TBCNT = 0000h). By default the EPWM_TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (EPWM_TBCTL[3] PRDL D = 1h), then a read from or a write to the TBPRD memory address goes directly to the active register.

12.4.2.3.2.3.2 EPWM Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the EPWM modules on a device. Each EPWM module has a synchronization input (EPWMxSYNCl) and a synchronization output (EPWMxSYNCO). The input

synchronization for the first instance (EPWM0) comes from an external pin. For the device EPWM environment sync pin details refer to *EPWM Environment*. The possible synchronization connections for the remaining EPWM modules is shown in [Figure 12-245](#).

epwm-011

Figure 12-245. EPWM Time-Base Counter Synchronization Scheme 1

Each EPWM module can be configured to use or ignore the synchronization input. If the EPWM_TBCTL[2] PHSEN bit is set, then the time-base counter (TBCNT) of the EPWM module (EPWM_TBCNT register) will be automatically loaded with the phase register (EPWM_TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (EPWM_TBPHS → EPWM_TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1h to the EPWM_TBCTL[6] SWFSYNC control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

This feature enables the EPWM module to be automatically synchronized to the time base of another EPWM module. Lead or lag phase control can be added to the waveforms generated by different EPWM modules to synchronize them. In up-down-count mode, the EPWM_TBCTL[13] PHSDIR bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See [Figure 12-246](#) through [Figure 12-249](#) for examples.

Clearing the EPWM_TBCTL[2] PHSEN bit configures the EPWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other EPWM modules. In this way, a controller time-base (for example, EPWM1) and downstream modules (EPWM2–EPWMx) can be set and they may select to run in synchronization with the controller.

12.4.2.3.2.4 Phase Locking the Time-Base Clocks of Multiple EPWM Modules

As already described in *EPWM Modules Time-Base Clock Gating*, TB_CLKEN bit in the EPWMn_CTRL (where n = 0 to 5) register of the device CTRL_MMR0 can be used to individually control or globally synchronize the time-base clocks of all enabled EPWM modules on a device. When all TB_CLKEN bits are set to 0b0, the time-base clocks of all EPWMx (where x = 0 to 5) modules are stopped (default). When all TB_CLKEN bits are simultaneously set in software to 0b1, all EPWMx modules time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the EPWM_TBCTL register of each EPWM module must be set identically. The proper procedure for enabling the EPWM clocks is as follows:

1. Enable the EPWM module clocks.
2. Set TB_CLKEN = 0. This will stop the time-base clock within any enabled EPWMx module.
3. Configure the prescaler values and desired EPWM modes per each involved EPWMx.
4. Simultaneously set TB_CLKEN bits to 0b1.

12.4.2.3.2.5 EPWM Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, [Figure 12-246](#) to [Figure 12-249](#) show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

Figure 12-246. EPWM Time-Base Up-Count Mode Waveforms

12.4.2.3.3 EPWM Counter-Compare (CC) Submodule

This section describes the Counter-Compare (CC) submodule in the PWM module.

12.4.2.3.3.1 Overview

Figure 12-250 illustrates the counter-compare submodule within the EPWM. Figure 12-251 shows the basic structure of the counter-compare submodule.

epwm-016

Figure 12-250. EPWM Counter-Compare Submodule

CC module features:

- Generates events based on programmable time stamps using the EPWM_CMPA and EPWM_CMPB registers
 - CMPA_eq (Time-base counter equals counter-compare A register (TBCNT = CMPA)).
 - CMPB_eq (Time-base counter equals counter-compare B register (TBCNT = CMPB)).
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle.

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (EPWM_CMPA) and counter-compare B (EPWM_CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

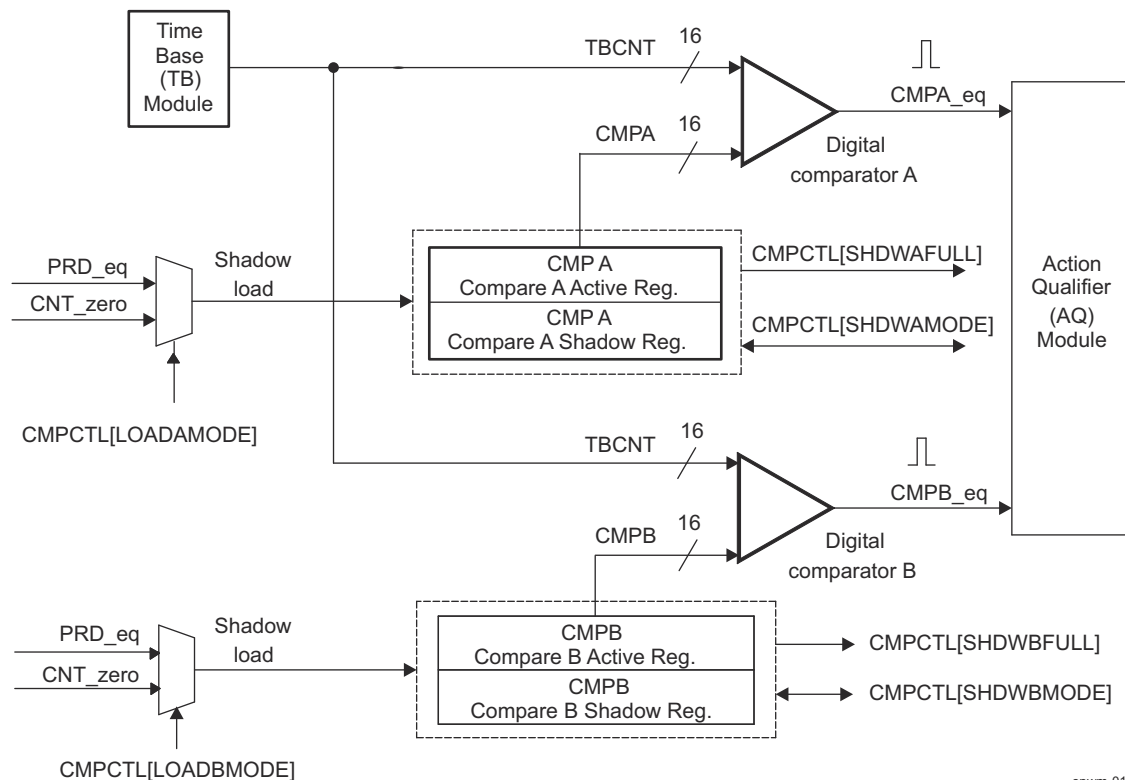

12.4.2.3.3.2 Controlling and Monitoring the EPWM Counter-Compare Submodule

Table 12-327 lists the registers used to control and monitor the counter-compare submodule. Table 12-328 lists the key signals associated with the counter-compare submodule.

Table 12-327. EPWM Counter-Compare Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_CMPCTL	Counter-Compare Control Register.	Eh	No
HRPWM_CMPAHR	HRPWM Counter-Compare A Extension Register ⁽¹⁾	10h	Yes
EPWM_CMPA	Counter-Compare A Register	12h	Yes
EPWM_CMPB	Counter-Compare B Register	14h	Yes

(1) This register is available only on the EPWM modules with the high-resolution extension (HRPWM). On the EPWM modules that do not include the HRPWM, this location is reserved. See *EPWM Integration* to determine which EPWM instances include this feature.

epwm-017

Figure 12-251. EPWM Counter-Compare Submodule Signals and Registers

Table 12-328. EPWM Counter-Compare Submodule Key Signals

Signal	Description of Event	Register Bitfields Compared
CMPA_eq	Time-base counter equal to the active counter-compare A value	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the active counter-compare B value	TBCNT = CMPB
PRD_eq	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCNT = 0000h

12.4.2.3.3.3 Operational Highlights for the EPWM Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CMPA: Time-base counter equal to counter-compare A register (EPWM_TBCNT = EPWM_CMPA).
2. CMPB: Time-base counter equal to counter-compare B register (EPWM_TBCNT = EPWM_CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 12.4.2.3.4](#) for more details.

The counter-compare EPWM_CMPA and EPWM_CMPB registers each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the EPWM_CMPCTL[4] SHDWAMODE and EPWM_CMPCTL[6] SHDWBMODE bits. These bits enable and disable the EPWM_CMPA shadow register and EPWM_CMPB shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Load Mode:**

The shadow mode for the EPWM_CMPA register is enabled by clearing the EPWM_CMPCTL[4] SHDWAMODE bit and the shadow register for EPWM_CMPB register is enabled by clearing the EPWM_CMPCTL[6] SHDWBMODE bit. Shadow mode is enabled by default for both EPWM_CMPA and EPWM_CMPB register.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:

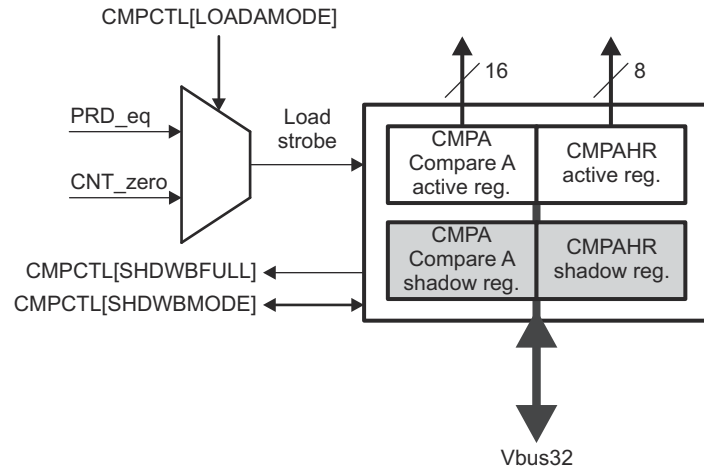

- PRD_eq: Time-base counter equal to the period (TBCNT = TBPRD).
- CNT_zero: Time-base counter equal to zero (TBCNT = 0000h)
- Both PRD_eq and CNT_zero events occurrence

Which of these three events will drive the counter compare module is specified by the EPWM_CMPCTL[1-0] LOADAMODE and EPWM_CMPCTL[3-2] LOADBMODE register bit fields. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

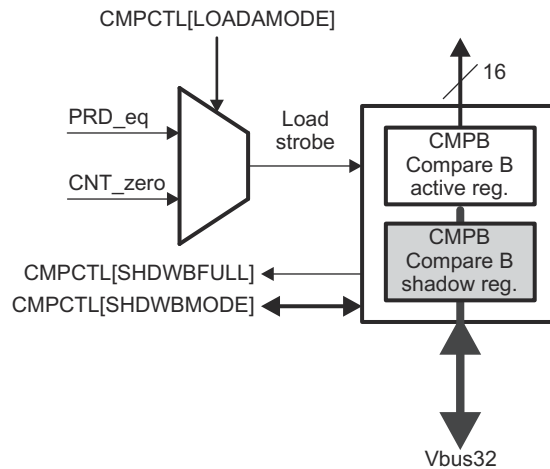

- **Immediate Load Mode:**

If immediate load mode is selected (EPWM_CMPCTL[4] SHDWAMODE = 1h or EPWM_CMPCTL[6] SHDWBMODE = 1h), then a read from or a write to the register will go directly to the active register.

[Figure 12-252](#) and [Figure 12-253](#) show Compare A and B Dual Shadow registers.

epwm-050

Figure 12-252. Compare A Dual Shadow register

epwm-051

Figure 12-253. Compare B Dual Shadow register**Note**

In HRPWM mode the user must perform a single 32-bit write access to both the HRPWM_CMPAHR and EPWM_CMPA registers. Two 16-bit accesses are not allowed.

12.4.2.3.3.4 EPWM Counter-Compare Submodule Timing Waveforms

As described in [Section 12.4.2.3.2](#), the Time Base (TB) module can be configured to operate in 3 distinct count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

The timing diagrams in [Figure 12-254](#) to [Figure 12-257](#) show how CMPA and CMPB events are generated in each of the 3 count modes and how the EPWMxSYNCI signal interacts.

An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

12.4.2.3.4 EPWM Action-Qualifier (AQ) Submodule

This section describes the Action-Qualifier (AQ) submodule in the PWM module.

12.4.2.3.4.1 Overview

Figure 12-258 shows the action-qualifier (AQ) submodule in the EPWM system. This submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 12-258. EPWM Action-Qualifier Submodule

AQ module features:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
 - PRD_eq: Time-base counter equal to the period (TBCNT = TBPRD)
 - CNT_zero: Time-base counter equal to zero (TBCNT = 0000h)
 - CMPA_eq: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
 - CMPB_eq: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

12.4.2.3.4.2 Controlling and Monitoring the EPWM Action-Qualifier Submodule

Table 12-329 lists the registers used to control and monitor the action-qualifier submodule.

Table 12-329. EPWM Action-Qualifier Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_AQCTLA	Action-Qualifier Control Register For Output A (EPWMxA)	16h	No
EPWM_AQCTLB	Action-Qualifier Control Register For Output B (EPWMxB)	18h	No
EPWM_AQSFRC	Action-Qualifier Software Force Register	1Ah	No
EPWM_AQCSFRC	Action-Qualifier Continuous Software Force	1Ch	Yes

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers as shown in Figure 12-259. The possible input events are summarized again in Table 12-330.

Figure 12-259. EPWM Action-Qualifier Submodule Inputs and Outputs

Table 12-330. EPWM Action-Qualifier Submodule Possible Input Events

Signal	Description	Register Bitfield Compared
PRD_eq	Time-base counter equal to the period value	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero	TBCNT = 0000h
CMPA_eq	Time-base counter equal to the counter-compare A	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the counter-compare B	TBCNT = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by EPWM_AQSFRC and EPWM_AQCSFRC registers.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts. See the Event_Trigger (ET) submodule description in [Section 12.4.2.3.8](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 12-260](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
<div>SW ×</div>	<div>Z ×</div>	<div>CA ×</div>	<div>CB ×</div>	<div>P ×</div>	Do Nothing
<div>SW ↓</div>	<div>Z ↓</div>	<div>CA ↓</div>	<div>CB ↓</div>	<div>P ↓</div>	Clear Low
<div>SW ↑</div>	<div>Z ↑</div>	<div>CA ↑</div>	<div>CB ↑</div>	<div>P ↑</div>	Set High
<div>SW T</div>	<div>Z T</div>	<div>CA T</div>	<div>CB T</div>	<div>P T</div>	Toggle

epwm-024

Figure 12-260. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

12.4.2.3.4.3 EPWM Action-Qualifier Event Priority

It is possible for the EPWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is: events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 12-331](#). A priority level 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

Table 12-331. EPWM Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event if TBCNT is Incrementing TBCNT = 0 up to TBCNT = TBPRD	Event if TBCNT is Decrementing TBCNT = TBPRD down to TBCNT = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD in EPWM_TBPRD active register)
5	Counter equals CMPB on down-count (CBD) ⁽¹⁾	Counter equals CMPB on up-count (CBU) ⁽¹⁾
6 (Lowest)	Counter equals CMPA on down-count (CAD) ⁽¹⁾	Counter equals CMPA on up-count (CBU) ⁽¹⁾

- (1) To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

[Table 12-332](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 12-332. EPWM Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

[Table 12-333](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 12-333. EPWM Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 12-334](#).

Table 12-334. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAU/CBU
Up-Count Mode	If CMPA/CMPB \leq TBPRD period, then the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $>$ TBPRD, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If CMPA/CMPB $<$ TBPRD, the event will occur on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB \geq TBPRD, the event will occur on a period match (TBCNT = TBPRD).
Up-Down-Count Mode	If CMPA/CMPB $<$ TBPRD and the counter is incrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB is \geq TBPRD, the event will occur on a period match (TBCNT = TBPRD).	If CMPA/CMPB $<$ TBPRD and the counter is decrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB \geq TBPRD, the event occurs on a period match (TBCNT = TBPRD).

12.4.2.3.4.4 Waveforms for Common EPWM Configurations

Note

The waveforms in this chapter show the EPWMs behavior for a static compare register value. In a running system, the active compare registers (EPWM_CMPA and EPWM_CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place — either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If EPWM_CMPA / EPWM_CMPB is loaded on zero, then use EPWM_CMPA / EPWM_CMPB values greater than or equal to 1.
- If EPWM_CMPA / EPWM_CMPB is loaded on period, then use EPWM_CMPA / EPWM_CMPB values less than or equal to TBPRD - 1.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

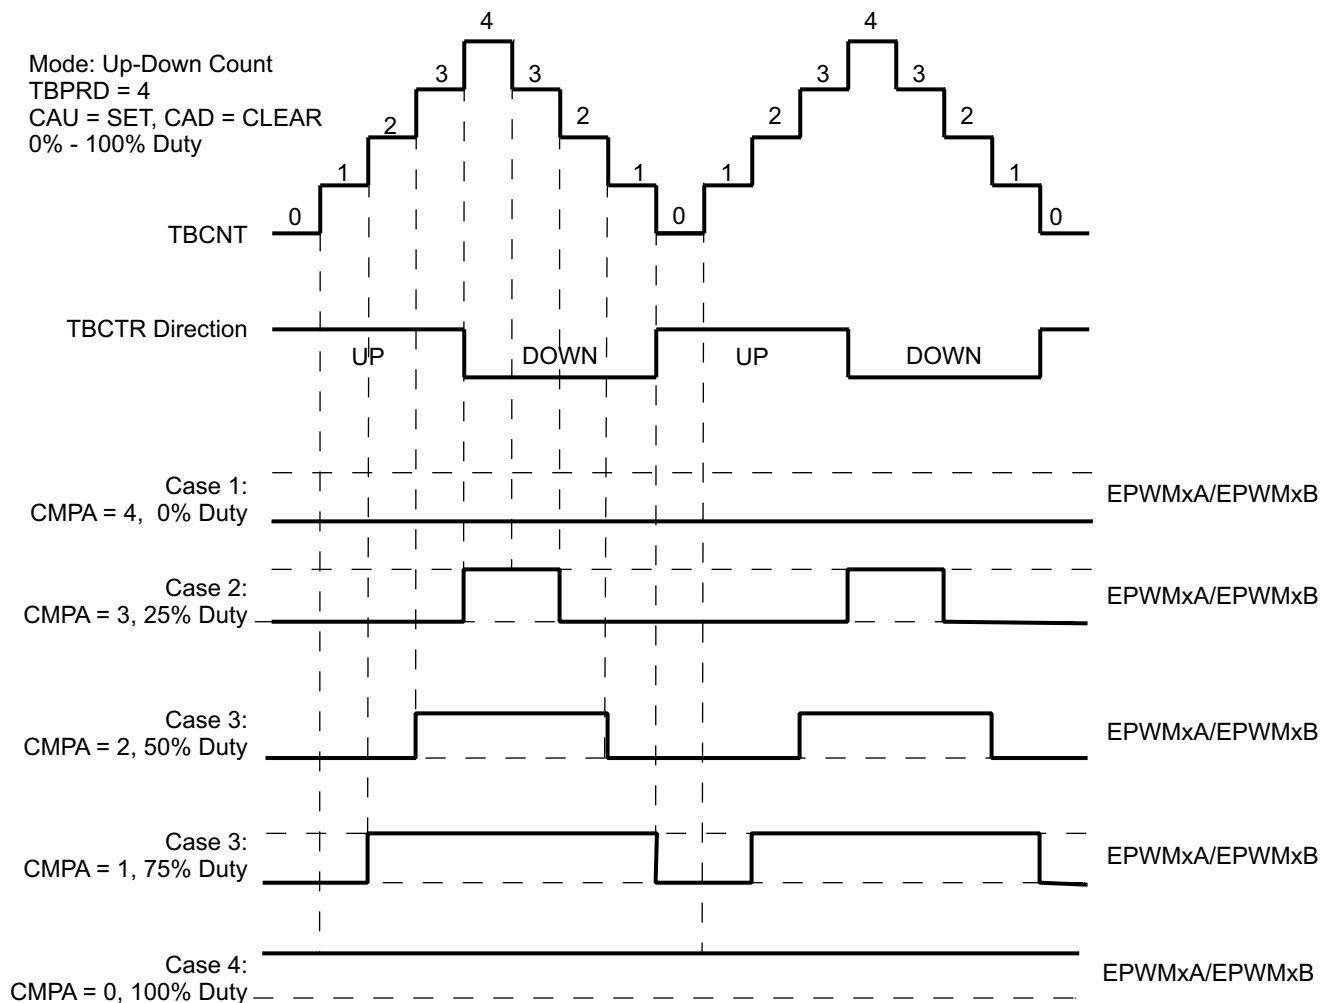

- To achieve 50-0% asymmetric PWM use the following configuration: Load EPWM_CMPA / EPWM_CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50-0% PWM duty.

When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load EPWM_CMPA / EPWM_CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

Figure 12-261 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When $CMPA = 0$, the PWM signal is low for the entire period giving the 0% duty waveform. When $EPWM_CMPA = EPWM_TBPRD$, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if $CMPA/CMPB$ is loaded on zero, then use $CMPA/CMPB$ values greater than or equal to 1. If $CMPA/CMPB$ is loaded on period, then use $CMPA/CMPB$ values less than or equal to $TBPRD - 1$. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

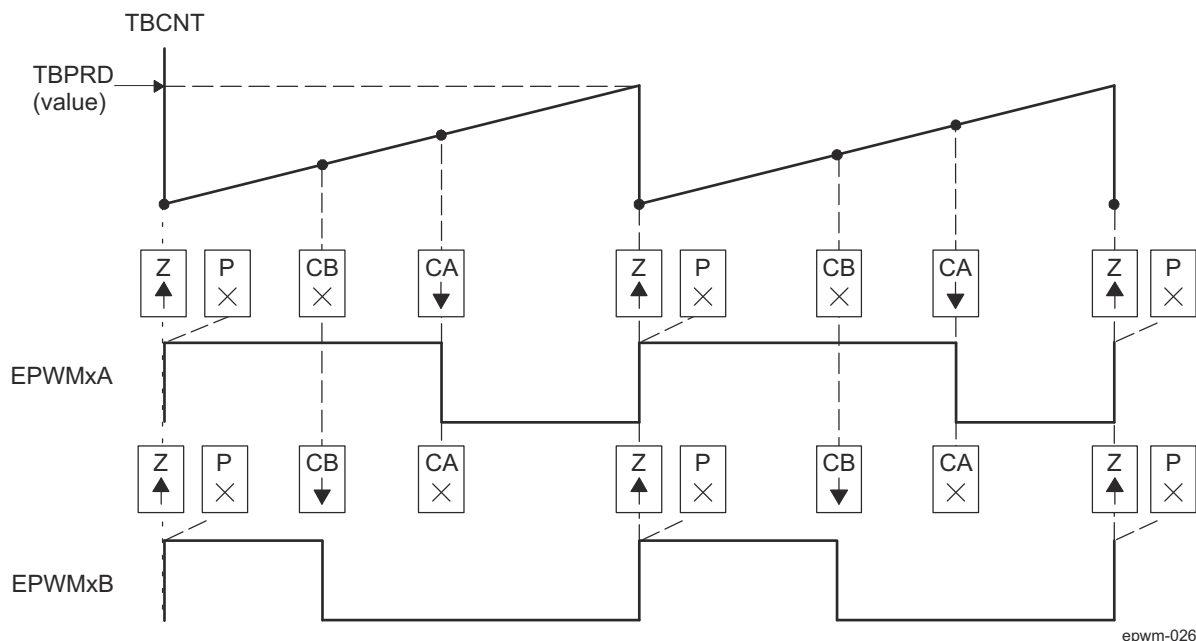

epwm-025

Figure 12-261. EPWM Up-Down-Count Mode Symmetrical Waveform

The PWM waveforms in [Figure 12-262](#) through [Figure 12-267](#) show some common action-qualifier configurations. Some conventions used in the figures are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers (EPWM_TBPRD, EPWM_CMPA, and EPWM_CMPB). The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from EPWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

[Table 12-335](#) and [Table 12-336](#) contains initialization and runtime register configurations for the waveforms in [Figure 12-262](#).

- PWM period = $(TBPRD + 1) \times T_{TBCLK}$
- Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.
- Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

12.4.2.3.5 EPWM Dead-Band Generator (DB) Submodule

This section describes the Dead-Band Generator (DB) submodule in the PWM module.

12.4.2.3.5.1 Overview

Figure 12-268 illustrates the dead-band generator submodule within the EPWM module.

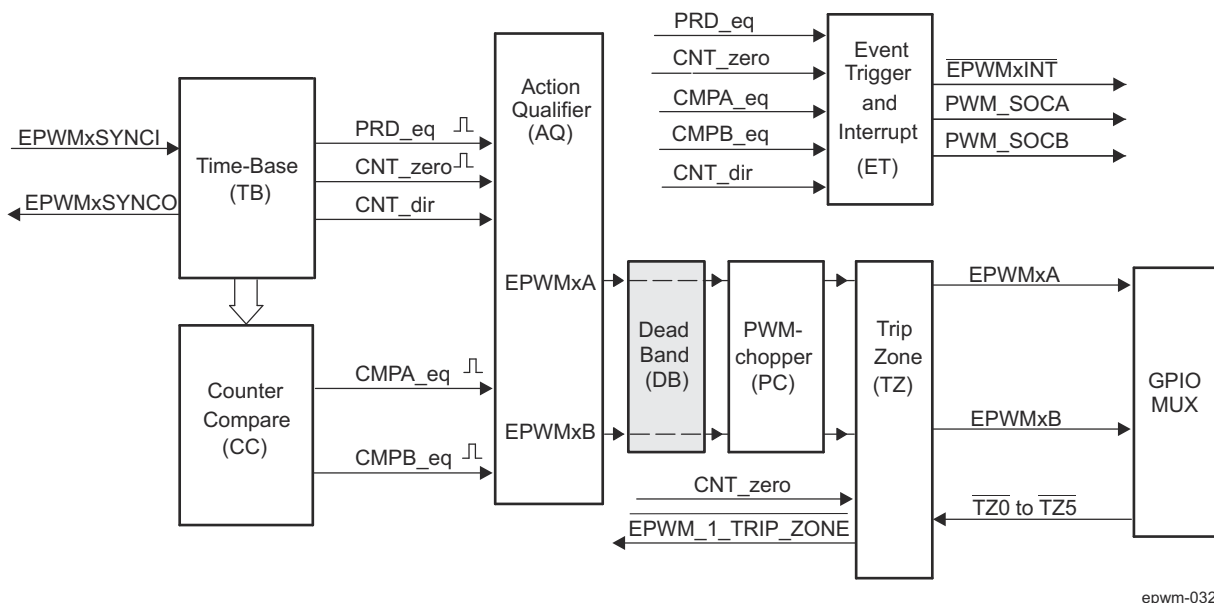

Figure 12-268. Dead-Band Generator Submodule

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the EPWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
 - Active high (AH)
 - Active low (AL)
 - Active high complementary (AHC)
 - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in Figure 12-268)

12.4.2.3.5.2 Controlling and Monitoring the EPWM Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

Table 12-347. Dead-Band Generator Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_DBCTL	Dead-Band Control Register	1Eh	No
EPWM_DBRED	Dead-Band Rising Edge Delay Count Register	20h	No
EPWM_DBFED	Dead-Band Falling Edge Delay Count Register	22h	No

12.4.2.3.5.3 Operational Highlights for the EPWM Dead-Band Generator Submodule

The dead-band submodule has two groups of independent selection options as shown in Figure 12-269.

- **Input Source Selection:** The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the EPWM_DBCTL[5-4] IN_MODE control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
 - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
 - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
 - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
 - EPWMxB In is the source for both falling-edge and rising-edge delay.
- **Output Mode Control:** The output mode is configured by way of the EPWM_DBCTL[1-0] OUT_MODE bit fields. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- **Polarity Control:** The polarity control (EPWM_DBCTL[3-2] POLSEL) allows to be specified whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

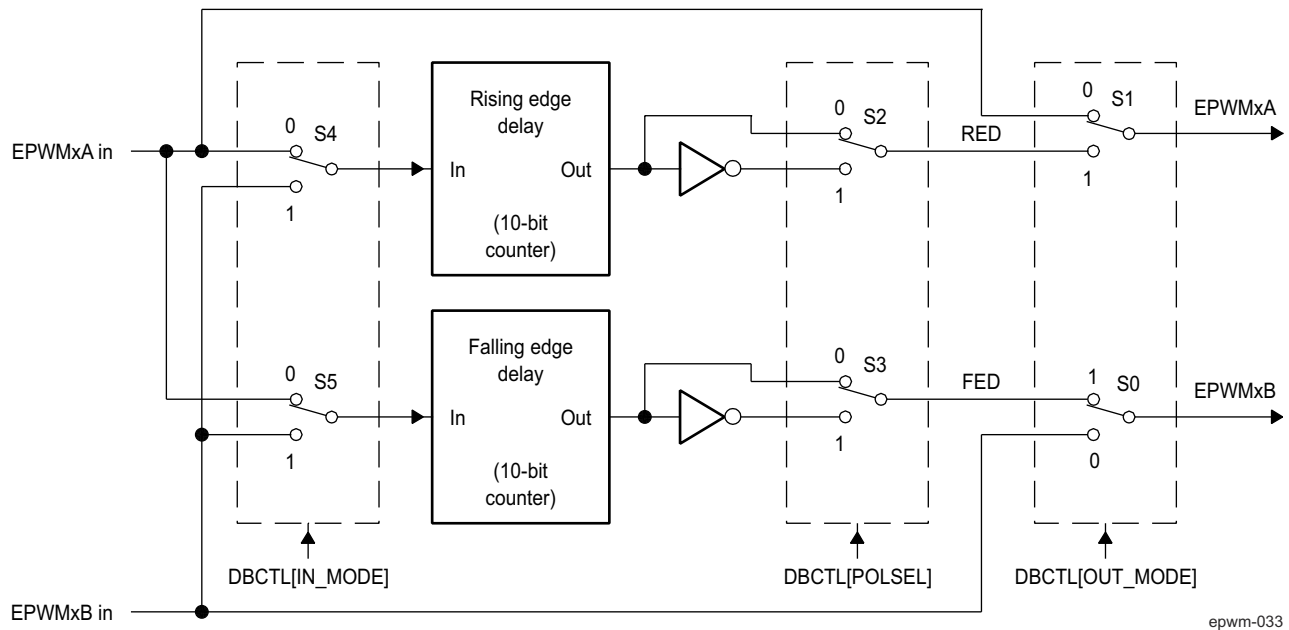

Figure 12-269. Configuration Options for the EPWM Dead-Band Generator Submodule

Although all combinations are supported, not all are typical usage modes. [Table 12-348](#) lists some classical dead-band configurations. These modes assume that the EPWM_DBCTL[5-4] IN_MODE is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 12-348](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows to be fully disabled the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 12-270](#). Note that to generate equivalent waveforms to [Figure 12-270](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in [Table 12-348](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

Table 12-348. Classical Dead-Band Operating Modes

Mode	Mode Description ⁽¹⁾	EPWM_DBCTL[3-2] POLSEL		EPWM_DBCTL[1-0] OUT_MODE	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	x	x	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

(1) These are classical dead-band modes and assume that EPWM_DBCTL[5-4] IN_MODE = 0b00. That is, EPWMxA in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the IN_MODE configuration.

[Figure 12-270](#) shows waveforms for typical cases where 0% < duty < 100%.

Figure 12-270. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the EPWM_DBRED and EPWM_DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formulas to calculate falling-edge-delay and rising-edge-delay are:

$$\text{FED} = \text{EPWM_DBFED} \times T_{\text{TBCLK}}$$

$$\text{RED} = \text{EPWM_DBRED} \times T_{\text{TBCLK}}$$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of FICLK.

12.4.2.3.6 EPWM-Chopper (PC) Submodule

This section describes the PWM-Chopper (PC) submodule in the PWM module.

12.4.2.3.6.1 Overview

Figure 12-271 illustrates the PWM-chopper (PC) submodule within the EPWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if a pulse transformer-based gate drivers to control the power switching elements is needed.

Figure 12-271. PWM-Chopper Submodule

PC module key features:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

12.4.2.3.6.2 Controlling the EPWM-Chopper Submodule

The EPWM-chopper submodule operation is controlled via the register in [Table 12-349](#).

Table 12-349. EPWM-Chopper Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_PCCTL	PWM-chopper Control Register	3Ch	No

12.4.2.3.6.3 Operational Highlights for the EPWM-Chopper Submodule

Figure 12-272 shows the operational details of the EPWM-chopper submodule. The carrier clock is derived from FICLK. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the EPWM_PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

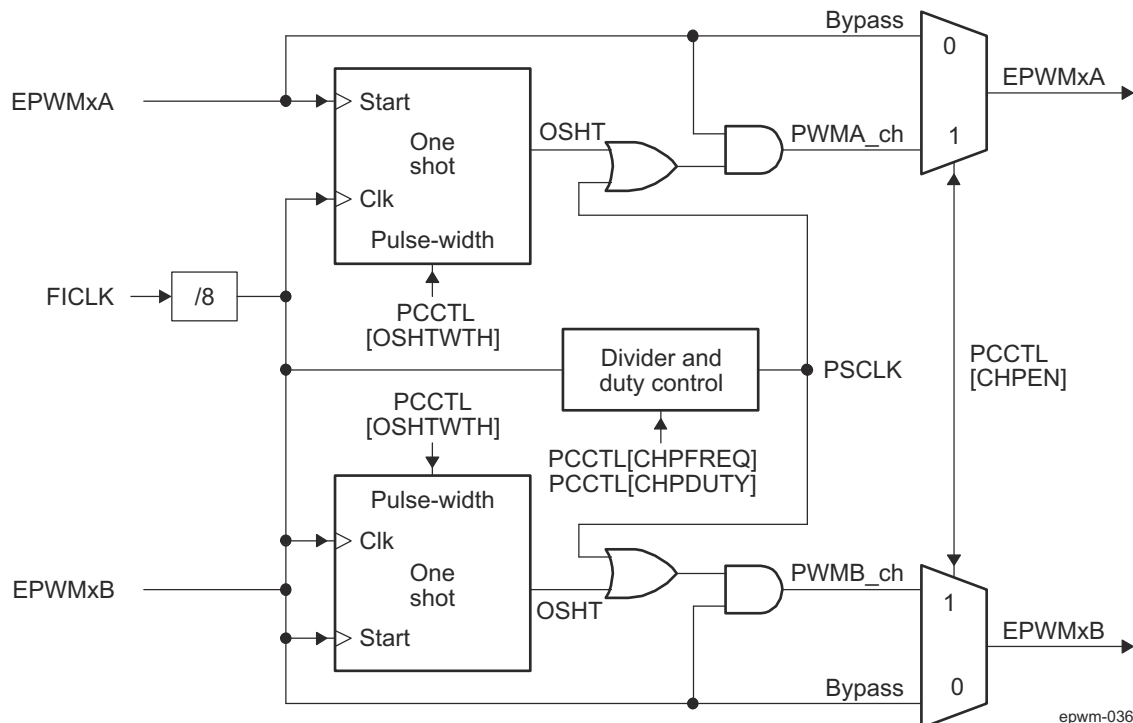

Figure 12-272. PWM-Chopper Submodule Signals and Registers

12.4.2.3.6.4 EPWM-Chopper Waveforms

Figure 12-273 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 12-273. Simple EPWM-Chopper Submodule Waveforms Showing Chopping Action Only

12.4.2.3.6.4.1 EPWM-Chopper One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{FICLK} \times 8 \times OSHTWTH$$

Where T_{FICLK} is the period of the system clock (FICLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 12-274 shows the first and subsequent sustaining pulses.

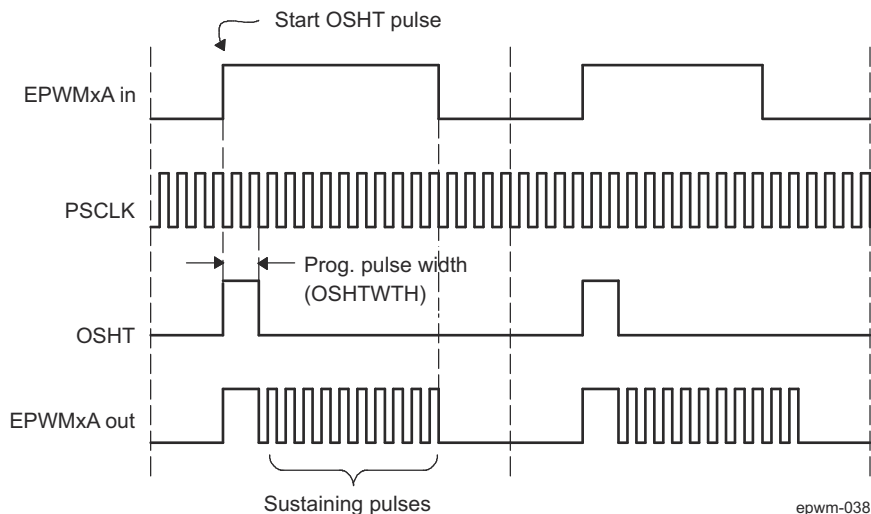

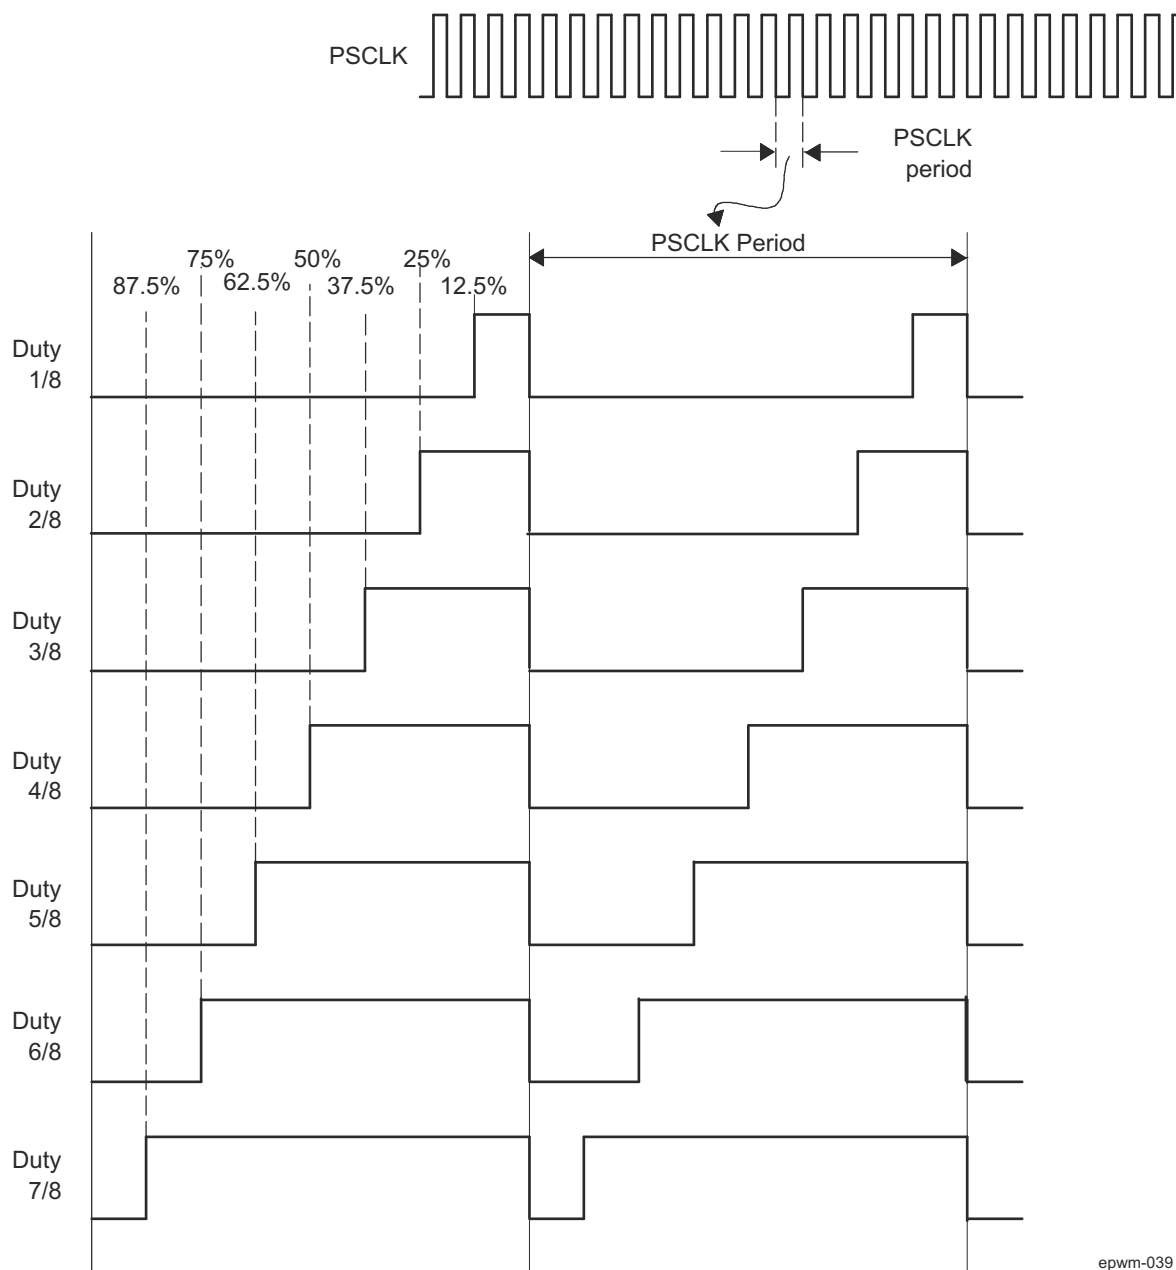

Figure 12-274. EPWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

12.4.2.3.6.4.2 EPWM-Chopper Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 12-275 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5 to 87.5%.

epwm-039

Figure 12-275. EPWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

12.4.2.3.7 EPWM Trip-Zone (TZ) Submodule

This section describes the Trip-Zone (TZ) submodule in the PWM module.

12.4.2.3.7.1 Overview

Figure 12-276 shows how the trip-zone (TZ) submodule fits within the EPWM module. Each EPWM module is connected to six TZ signals (TZ0 to TZ5) that are sourced from the GPIO MUX. These signals indicate external fault or trip conditions, and the EPWM outputs can be programmed to respond accordingly when faults occur. See *EPWM Integration* to determine the number of trip-zone pins available for the device.

Figure 12-276. EPWM Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs TZ0 to TZ5 can be flexibly mapped to any EPWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
 - High
 - Low
 - High-impedance
 - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

Note

For each EPWMx module, 6 tripzone input events are supported (EPWMx_TRIP_TZ[5:0]). Each tripzone input for all EPWMx modules (where x = 0 to 5) are tied to a common tripzone input pin, so that any EPWMx can be triggered by any of the six tripzone inputs.

12.4.2.3.7.2 Controlling and Monitoring the EPWM Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 12-350. EPWM Trip-Zone Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TZSEL	Trip-Zone Select Register ⁽¹⁾	24h	No
EPWM_TZCTL	Trip-Zone Control Register ⁽¹⁾	28h	No
EPWM_TZEINT	Trip-Zone Enable Interrupt Register ⁽¹⁾	2Ah	No
EPWM_TZFLG	Trip-Zone Flag Register ⁽¹⁾	2Ch	No
EPWM_TZCLR	Trip-Zone Clear Register ⁽¹⁾	2Eh	No
EPWM_TZFRC	Trip-Zone Force Register ⁽¹⁾	30h	No

(1) All trip-zone registers are EALLOW protected and can be modified only after executing the EALLOW instruction.

12.4.2.3.7.3 Operational Highlights for the EPWM Trip-Zone Submodule

The trip-zone signals at pin $\overline{TZ0}$ to $\overline{TZ5}$ is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. Each EPWM module can be individually configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used by a particular EPWM module is determined by the EPWM_TZSEL register for that specific EPWM module. The trip-zone signal may or may not be synchronized to the system clock (FICLK). A minimum of 1 FICLK low pulse on the $\overline{TZ0}$ to $\overline{TZ5}$ inputs is sufficient to trigger a fault condition in the EPWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the $\overline{TZ0}$ to $\overline{TZ5}$ inputs.

The $\overline{TZ0}$ to $\overline{TZ5}$ inputs can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a EPWM module. The configuration is determined by the EPWM_TZSEL[5-0] CBCK and EPWM_TZSEL[13-8] OSHTk bit field (where k = 0 to 5 corresponds to the trip pin), respectively.

- **Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the EPWM_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 12-351](#) lists the possible actions. In addition, the cycle-by-cycle trip event flag (EPWM_TZFLG[1] CBC) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM_TZEINT register.

The specified condition on the pins is automatically cleared when the EPWM time-base counter reaches zero (EPWM_TBCNT[15-0] TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The EPWM_TZFLG[1] CBC flag bit will remain set until it is manually cleared by writing to the EPWM_TZCLR[1] CBC bit. If the cycle-by-cycle trip event is still present when the EPWM_TZFLG[1] CBC bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the EPWM_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 12-351](#) lists the possible actions. In addition, the one-shot trip event flag (EPWM_TZFLG[2] OST) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM_TZEINT register. The one-shot trip condition must be cleared manually by writing to the EPWM_TZCLR[2] OST bit.

The action taken when a trip event occurs can be configured individually for each of the EPWM output pins by way of the EPWM_TZCTL[1-0] TZA and EPWM_TZCTL[3-2] TTB register bit field. One of four possible actions, shown in [Table 12-351](#), can be taken on a trip event.

Table 12-351. Possible Actions On an EPWM Trip Event

EPWM_TZCTL[1-0] TZA and/or EPWM_TZCTL[3-2] TZB	EPWMxA and/or EPWMxB	Comment
0	High-Impedance	Tripped
1h	Force to High State	Tripped
2h	Force to Low State	Tripped
3h	No Change	Do Nothing. No change is made to the output.

Example of EPWM Trip-Zone Configurations

A one-shot trip event on $\overline{TZ0}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the EPWM1 registers as follows:
 - EPWM_TZSEL[8] OSHT1 = 1: enables \overline{TZ} as a one-shot event source for EPWM1
 - EPWM_TZCTL[1-0] TZA = 2: EPWM1A will be forced low on a trip event
 - EPWM_TZCTL[3-2] TZB = 2: EPWM1B will be forced low on a trip event
- Configure the EPWM2 registers as follows:
 - EPWM_TZSEL[8] OSHT1 = 1: enables \overline{TZ} as a one-shot event source for EPWM2
 - EPWM_TZCTL[1-0] TZA = 1: EPWM2A will be forced high on a trip event
 - EPWM_TZCTL[3-2] TZB = 1: EPWM2B will be forced high on a trip event

12.4.2.3.7.4 Generating EPWM Trip-Event Interrupts

Figure 12-277 and Figure 12-278 illustrate the trip-zone submodule control and interrupt logic, respectively.

Figure 12-277. EPWM Trip-Zone Submodule Mode Control Logic

Figure 12-278. EPWM Trip-Zone Submodule Interrupt Logic

This section describes the Event-Trigger (ET) submodule in the PWM module.

Figure 12-279 shows the event-trigger (ET) submodule in the EPWM system. The event-trigger submodule manages the events generated by the time-base submodule and the counter-compare submodule to generate an aggregated interrupt request.

Figure 12-279. EPWM Event-Trigger Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base and counter-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests at:
 - Every event
 - Every second event
 - Every third event
- Provides full visibility of event generation via event counters and flags

12.4.2.3.8.2 Controlling and Monitoring the EPWM Event-Trigger Submodule

The key registers used to configure the event-trigger submodule are shown in [Table 12-352](#):

Table 12-352. EPWM Event-Trigger Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_ETSEL	Event-Trigger Selection Register	32h	No
EPWM_ETPS	Event-Trigger Prescale Register	34h	No
EPWM_ETFLG	Event-Trigger Flag Register	36h	No
EPWM_ETCLR	Event-Trigger Clear Register	38h	No
EPWM ETFRC	Event-Trigger Force Register	3Ah	No

12.4.2.3.8.3 Operational Overview of the EPWM Event-Trigger Submodule

Each EPWM module has one interrupt request line as shown in [Figure 12-280](#). Mapping interrupt lines to device host interrupt controllers is device specific and is covered in *EPWM Integration*.

Figure 12-280. EPWM Event-Trigger Submodule Inter-Connectivity to Interrupt Controller

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 12-281) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

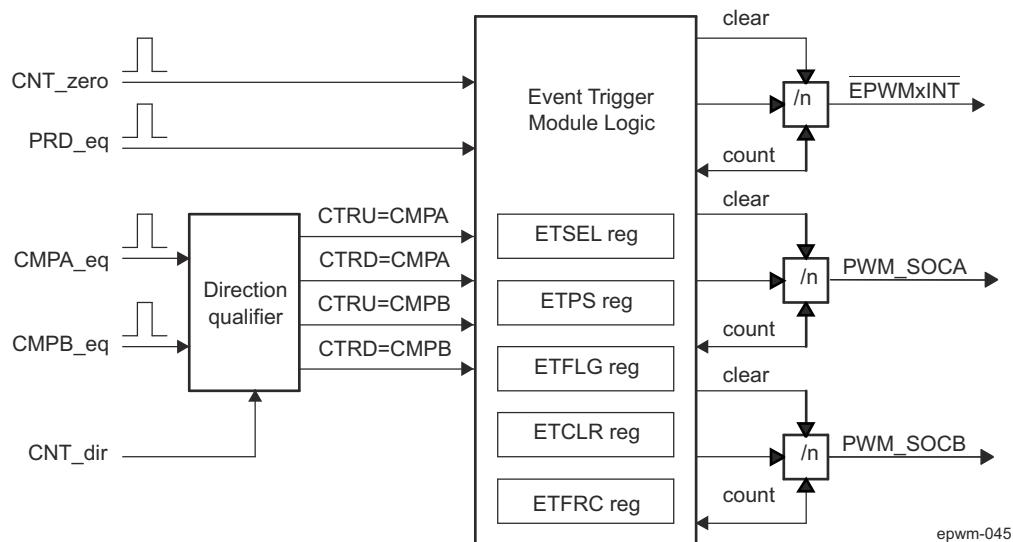

Figure 12-281. EPWM Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

- ETSEL — This selects which of the possible events will trigger an interrupt.
- ETPS — This programs the event prescaling options previously mentioned.
- ETFLG — These are flag bits indicating status of the selected and prescaled events.
- ETCLR — These bits allow to clear the flag bits in the EPWM_ETFLG register via software.
- ETFRC — These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in [Figure 12-282](#).

[Figure 12-282](#) shows the event-trigger's interrupt generation logic. The interrupt-period (EPWM_ETPS[1-0] INTPRD) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (EPWM_ETSEL[2-0] INTSEL) bits. The event can be one of the following:

- Time-base counter equal to zero (EPWM_TBCNT[15-0] TBCNT = 0000h).
- Time-base counter equal to period (EPWM_TBCNT[15-0] TBCNT = EPWM_TBPRD[15-0] TBPRD).
- Time-base counter equal to the compare A register (EPWM_CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (EPWM_CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (EPWM_CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (EPWM_CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (EPWM_ETPS[3-2] INTCNT) register bits. That is, when the specified event occurs the EPWM_ETPS[3-2] INTCNT bits are incremented until they reach the value specified by the EPWM_ETPS[1-0] INTPRD bit field. When EPWM_ETPS[3-2] INTCNT = EPWM_ETPS[1-0] INTPRD the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When EPWM_ETPS[3-2] INTCNT reaches EPWM_ETPS[1-0] INTPRD, one of the following behaviors will occur:

- If interrupts are enabled, EPWM_ETSEL[3] INTEN = 1h and the interrupt flag is clear, EPWM_ETFLG[0] INT = 0h, then an interrupt pulse is generated and the interrupt flag is set, EPWM_ETFLG[0] INT = 1h, and the event counter is cleared EPWM_ETPS[3-2] INTCNT = 0h. The counter will begin counting events again.
- If interrupts are disabled, EPWM_ETSEL[3] INTEN = 0, or the interrupt flag is set, EPWM_ETFLG[0] INT = 1h, the counter stops counting events when it reaches the period value EPWM_ETPS[3-2] INTCNT = EPWM_ETPS[1-0] INTPRD.
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[0] INT flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1h to the EPWM ETFRC[0] INT bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0h, the counter is disabled and hence no events will be detected and the EPWM ETFRC[0] INT bit is also ignored.

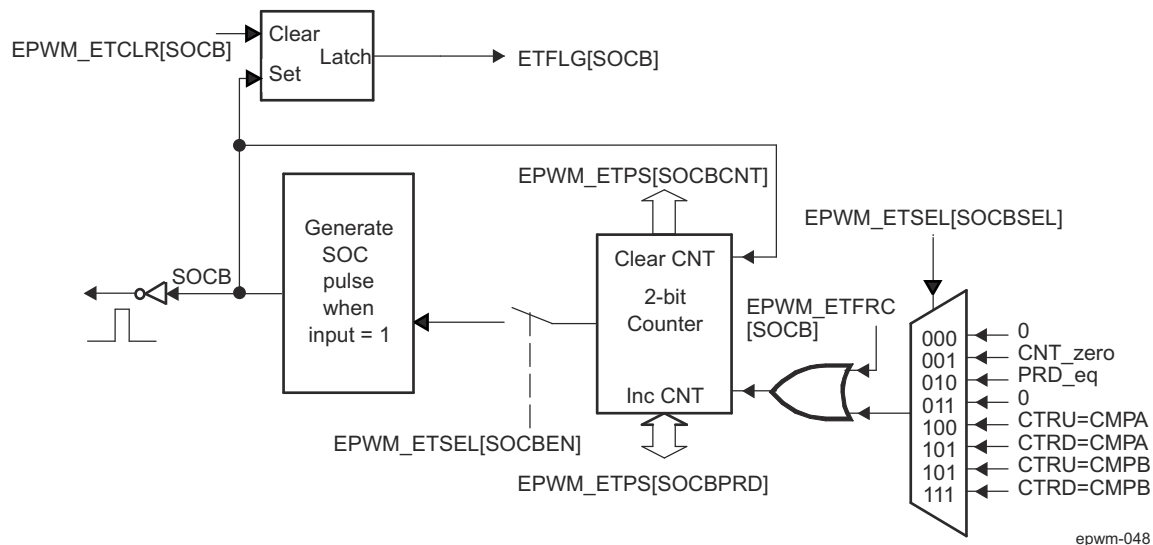

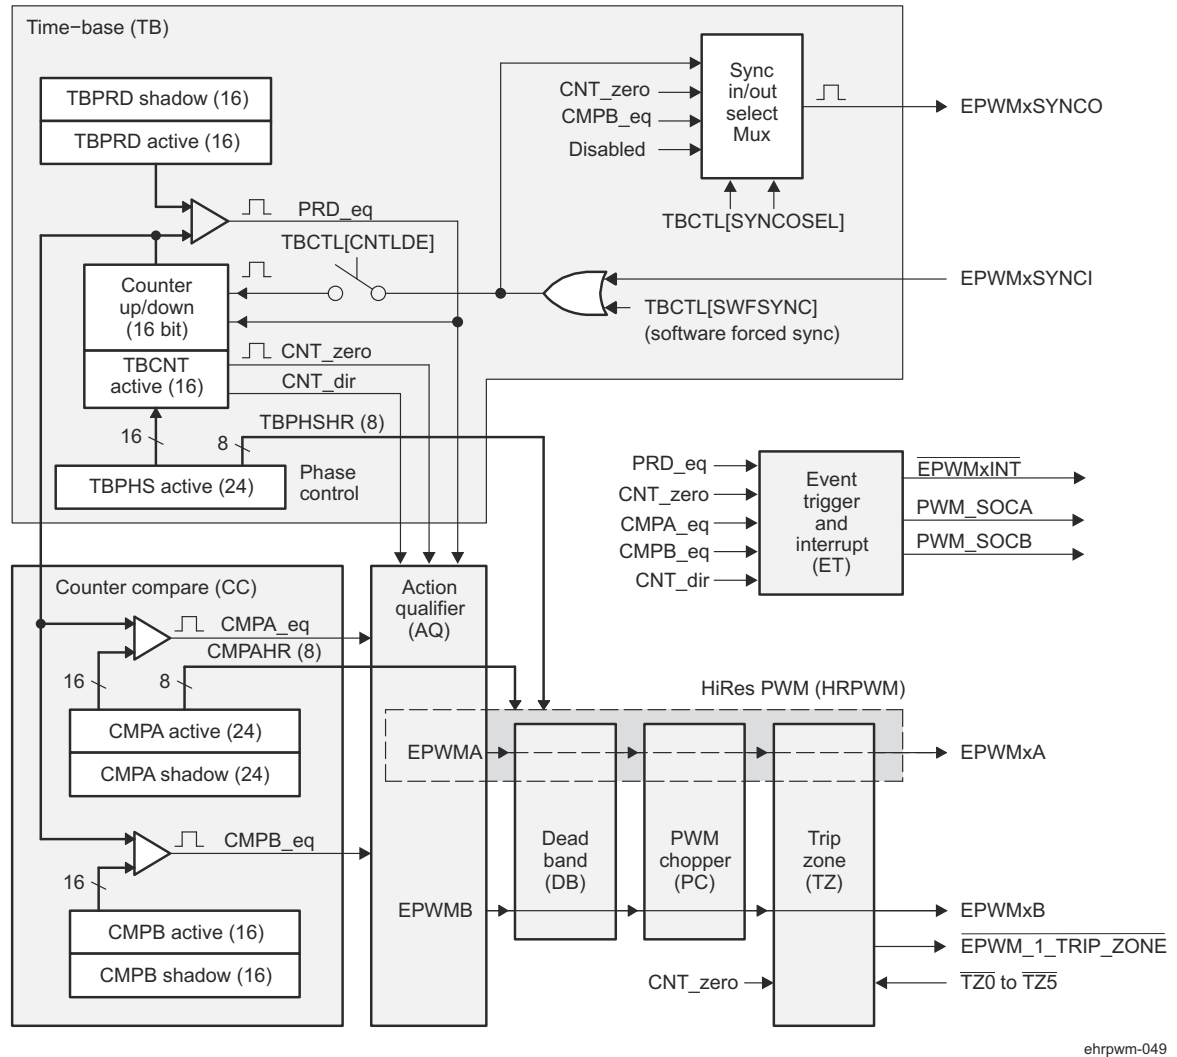

Figure 12-284. EPWM Event-Trigger SOCB Pulse Generator

12.4.2.3.9 EPWM High Resolution (HRPWM) Submodule

This section describes the High-Resolution PWM (HRPWM) submodule in the PWM module.

12.4.2.3.9.1 Overview

Figure 12-285 shows the high-resolution PWM (HRPWM) submodule in the EPWM system. Some devices include the high-resolution PWM submodule, see *EPWM Integration* to determine which EPWM instances include this feature.

ehrpwm-049

Figure 12-285. HRPWM System Interface

The high-resolution pulse-width modulator (HRPWM) extends the time resolution capabilities of the conventionally derived digital pulse-width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~9-10 bits.

The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
- Implemented using the A signal path of PWM, that is, on the EPWMxA output. **EPWMxB output has conventional PWM capabilities**

The EPWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in [Figure 12-286](#), the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

Figure 12-286. Resolution Calculations for Conventionally Generated PWM

Use HRPWM when the required PWM operating frequency does not offer sufficient resolution in PWM mode. As an example of improved performance offered by HRPWM, [Table 12-353](#) shows resolution in bits for various PWM frequencies. [Table 12-353](#) values assume a MEP step size of 180 ps. See the device-specific Datasheet for typical and maximum performance specifications for the MEP.

Table 12-353. Resolution for PWM and HRPWM

PWM Frequency (kHz)	Regular Resolution (PWM)		High Resolution (HRPWM)	
	Bits	%	Bits	%
20	12.3	0.0	18.1	0.000
50	11.0	0.0	16.8	0.001
100	10.0	0.1	15.8	0.002
150	9.4	0.2	15.2	0.003
200	9.0	0.2	14.8	0.004
250	8.6	0.3	14.4	0.005
500	7.6	0.5	13.8	0.007
1000	6.6	1.0	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2.0	11.4	0.036

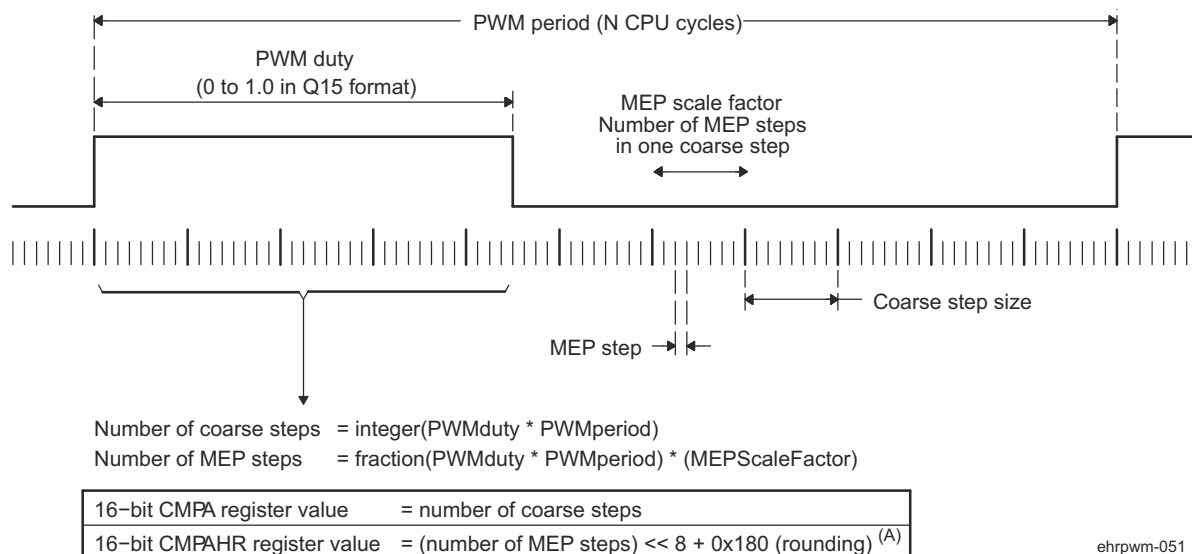

Although each application may differ, typical low-frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

12.4.2.3.9.2 Architecture of the High-Resolution PWM Submodule

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions.

[Figure 12-287](#) shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (HRPWM_CMPAHR).

A. For MEP range and rounding adjustment.

Figure 12-287. Operating Logic Using MEP

To generate an HRPWM waveform of a given frequency and polarity, the user needs to configure the TBM (Time-Base Module), CCM (Counter-Compare Module), and AQM (Action-Qualifier Module) registers. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical.

12.4.2.3.9.3 Controlling and Monitoring the High-Resolution PWM Submodule

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit EPWM_TBPHS and EPWM_CMPA registers used to control PWM operation.

- HRPWM_TBPHSHR — Time-Base Phase High-Resolution Register
- HRPWM_CMPAHR — Counter-Compare A High-Resolution Register.

Table 12-354 lists the registers used to control and monitor the high-resolution PWM submodule.

Table 12-354. HRPWM Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
HRPWM_TBPHSHR	Extension Register for HRPWM Phase	4h	No
HRPWM_CMPAHR	Extension Register for HRPWM Duty	10h	Yes
HRPWM_HRCTL	HRPWM Configuration Register	40h	No

12.4.2.3.9.4 Configuring the High-Resolution PWM Submodule

Once the EPWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRPWM_HRCTL register located at offset address 40h. This register provides configuration options for the following key operating modes:

- **Edge Mode:** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE), or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge.
- **Control Mode:** The MEP is programmed to be controlled either from the HRPWM_CMPAHR register (duty cycle control) or the HRPWM_TBPHSHR register (phase control). RE or FE control mode should be used with the HRPWM_CMPAHR register. BE control mode should be used with the HRPWM_TBPHSHR register.
- **Shadow Mode:** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the HRPWM_CMPAHR register and should be chosen to be the same as the regular load option for the CMPA register. If the HRPWM_TBPHSHR register is used, then this option has no effect.

12.4.2.3.9.5 Operational Highlights for the High-Resolution PWM Submodule

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps, each of which has a time resolution on the order of 150 ps. The MEP works with the TBM (Time-Base Module) and CCM (Counter-Compare Module) registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. [Table 12-355](#) shows the typical range of operating frequencies supported by the HRPWM.

Table 12-355. Relationship Between MEP Steps, PWM Frequency and Resolution

System (MHz)	MEP Steps Per FICLK ⁽¹⁾ (2) (3)	PWM Minimum (Hz) ⁽⁴⁾	PWM Maximum (MHz)	Resolution at Maximum (Bits) ⁽⁵⁾
50.0	111	763	2.50	11.1
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

- (1) System frequency = FICLK, that is, CPU clock. TBCLK = FICLK.
- (2) Table data based on a MEP time resolution of 180 ps (this is an example value).
- (3) MEP steps applied = $T_{FICLK}/180$ ps in this example.
- (4) PWM minimum frequency is based on a maximum period value, TBPRD = 65 535. PWM mode is asymmetrical up-count.
- (5) Resolution in bits is given for the maximum PWM frequency stated.

12.4.2.3.9.5.1 HRPWM Edge Positioning

In a typical power control loop (switch modes, digital motor control (DMC), uninterruptible power supply (UPS)), a digital controller (PID, 2pole/2zero, lag/lead, and so forth) issues a duty command, usually expressed in a per unit or percentage terms.

In the following example, assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on-time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. Figure 12-288 shows that duty cycle of 40% (a compare value of 32 counts) is the closest to 40.5%. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 12-356.

Utilizing MEP allows to achieve an edge position much closer to the desired point of 324 ns. Table 12-356 shows that in addition to the CMPA value, 22 steps of the MEP (HRPWM_CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ns.

Figure 12-288. Required PWM Waveform for a Requested Duty = 40.5%

Table 12-356. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)

CMPA (count) ^{(1) (2) (3)}	DUTY (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

- (1) System clock, FICLK and TBCLK = 100 MHz, 10 ns
(2) For a PWM Period register value of 80 counts, PWM Period = 80 × 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz
(3) Assumed MEP step size for the above example = 180 ps

12.4.2.3.9.5.2 HRPWM Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard (EPWM_CMPA) and MEP (HRPWM_CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

System clock, FICLK	=	10 ns (100 MHz)
PWM frequency	=	1.25 MHz (1/800 ns)
Required PWM duty cycle, PWMDuty	=	0.405 (40.5%)
PWM period in terms of coarse steps, PWMperiod (800 ns/10 ns)	=	80
Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), MEP_SF	=	55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	=	180h

Step 1: Percentage Integer Duty value conversion for EPWM_CMPA register

EPWM_CMPA register value	=	$\text{int}(\text{PWMDuty} \times \text{PWMperiod})$; int means integer part
	=	$\text{int}(0.405 \times 80)$
	=	$\text{int}(32.4)$
EPWM_CMPA register value	=	32 (20h)

Step 2: Fractional value conversion for HRPWM_CMPAHR register

HRPWM_CMPAHR register value	=	$(\text{frac}(\text{PWMDuty} \times \text{PWMperiod}) \times \text{MEP_SF}) \ll 8) + 180\text{h}$; frac means fractional part
	=	$(\text{frac}(32.4) \times 55 \ll 8) + 180\text{h}$; Shift is to move the value as CMPAHR high byte
	=	$((0.4 \times 55) \ll 8) + 180\text{h}$
	=	$(22 \ll 8) + 180\text{h}$
	=	$22 \times 256 + 180\text{h}$; Shifting left by 8 is the same multiplying by 256.
	=	$5632 + 180\text{h}$
	=	$1600\text{h} + 180\text{h}$
HRPWM_CMPAHR value	=	1780h; HRPWM_CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.

12.4.2.3.9.5.3 HRPWM Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational 3 FICLK cycles after the period starts.

Duty cycle range limitations are illustrated in [Figure 12-289](#). This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle.

Figure 12-289. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz

If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in [Figure 12-290](#). In this case low percent duty limitation is no longer an issue.

Figure 12-290. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz

12.4.2.3.10 EPWM / HRPWM Functional Register Groups

The [Table 12-357](#) lists the groups of EPWM and the high-resolution PWM module registers according to their functionalities.

Table 12-357. EPWM / HRPWM Module Control and Status Registers Grouped by Submodule

Register Name	Offset	Size (×16)	Shadow	Register Description
Time-Base (TB) Submodule Registers				
EPWM_TBCTL	0h	1	No	Time-Base Control Register
EPWM_TBSTS	2h	1	No	Time-Base Status Register
EPWM_TBPHS	6h	1	No	Time-Base Phase Register

Table 12-357. EPWM / HRPWM Module Control and Status Registers Grouped by Submodule (continued)

Register Name	Offset	Size (×16)	Shadow	Register Description
EPWM_TBCNT	8h	1	No	Time-Base Counter Register
EPWM_TBPRD	Ah	1	Yes	Time-Base Period Register
Counter-Compare (CC) Submodule Registers				
EPWM_CMPCTL	Eh	1	No	Counter-Compare Control Register
EPWM_CMPA	12h	1	Yes	Counter-Compare A Register
EPWM_CMPB	14h	1	Yes	Counter-Compare B Register
Action-Qualifier (AQ) Submodule Registers				
EPWM_AQCTLA	16h	1	No	Action-Qualifier Control Register for Output A (EPWMxA)
EPWM_AQCTLB	18h	1	No	Action-Qualifier Control Register for Output B (EPWMxB)
EPWM_AQSFRC	1Ah	1	No	Action-Qualifier Software Force Register
EPWM_AQCSFRC	1Ch	1	Yes	Action-Qualifier Continuous S/W Force Register Set
Dead-Band (DB) Generator Submodule Registers				
EPWM_DBCTL	1Eh	1	No	Dead-Band Generator Control Register
EPWM_DBRED	20h	1	No	Dead-Band Generator Rising Edge Delay Count Register
EPWM_DBFED	22h	1	No	Dead-Band Generator Falling Edge Delay Count Register
Trip-Zone (TZ) Submodule Registers				
EPWM_TZSEL	24h	1	No	Trip-Zone Select Register
EPWM_TZCTL	28h	1	No	Trip-Zone Control Register ⁽¹⁾
EPWM_TZEINT	2Ah	1	No	Trip-Zone Enable Interrupt Register ⁽¹⁾
EPWM_TZFLG	2Ch	1	No	Trip-Zone Flag Register ⁽¹⁾
EPWM_TZCLR	2Eh	1	No	Trip-Zone Clear Register ⁽¹⁾
EPWM_TZFRC	30h	1	No	Trip-Zone Force Register ⁽¹⁾
Event-Trigger (ET) Submodule Registers				
EPWM_ETSEL	32h	1	No	Event-Trigger Selection Register
EPWM_ETPS	34h	1	No	Event-Trigger Pre-Scale Register
EPWM_ETFLG	36h	1	No	Event-Trigger Flag Register
EPWM_ETCLR	38h	1	No	Event-Trigger Clear Register
EPWM_ETFRC	3Ah	1	No	Event-Trigger Force Register
PWM-Chopper Submodule Registers				
EPWM_PCCTL	3Ch	1	No	PWM-Chopper Control Register
High-Resolution PWM (HRPWM) Submodule Registers				
HRPWM_TBPHSHR	4h	1	No	Extension for HRPWM Phase Register
HRPWM_CMPAHR	10h	1	No	Extension for HRPWM Counter-Compare A Register
HRPWM_HRCTL	40h	1	No	HRPWM Control Register

(1) EALLOW protected registers.

12.4.2.3.11 Proper EPWM Interrupt Initialization Procedure

When the EPWM peripheral clock is enabled it is possible that interrupt flags may be set due to spurious events as the EPWM registers not being properly initialized. The proper procedure for initializing the EPWM peripheral is:

1. Disable global interrupts (CPU INTM flag)
2. Disable EPWM interrupts
3. Initialize peripheral registers
4. Clear any spurious EPWM flags
5. Enable EPWM interrupts

6. Enable global interrupts

12.4.3 Enhanced Quadrature Encoder Pulse (EQEP) Module

This section describes the Enhanced Quadrature Encoder Pulse (EQEP) module in the device.

12.4.3.1 EQEP Overview

The Enhanced Quadrature Encoder Pulse (EQEP) peripheral is used for direct interface with a linear or rotary incremental encoder to get position, direction and speed information from a rotating machine for use in high performance motion and position control system. The disk of an incremental encoder is patterned with a single track of slots patterns, as shown in [Figure 12-291](#). These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position and zero reference.

Figure 12-291. Optical Encoder Disk

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90 degrees out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vice versa as shown in [Figure 12-292](#).

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 kHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

The diagram shows the timing of the QEP module signals. The signals are:

- QEPA**: A square wave with period T_0 .
- QEPB**: A square wave with period T_0 , phase-shifted by $0.25T_0$ relative to QEPA.
- QEPI (gated to A and B)**: A square wave with period $0.25T_0 + 0.1T_0$.
- QEPI (gated to A)**: A square wave with period $0.5T_0 + 0.1T_0$.
- QEPI (ungated)**: A square wave with period $T_0 + 0.5T_0$.

The diagram also shows the relationship between the period T_0 and the time intervals for the gated and ungated signals. The time intervals are labeled as $0.25T_0 + 0.1T_0$, $0.5T_0 + 0.1T_0$, and $T_0 + 0.5T_0$.

General Issues: Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$V(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad \text{eqep-004} \quad (19)$$

$$V(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad \text{eqep-005} \quad (20)$$

where

$v(k)$: Velocity at time instant k

$x(k)$: Position at time instant k

$x(k-1)$: Position at time instant $k - 1$

T : Fixed unit time or inverse of velocity calculation rate

ΔX : Incremental position movement in unit time

$t(k)$: Time instant " k "

$t(k-1)$: Time instant " $k - 1$ "

X : Fixed unit position

ΔT : Incremental time elapsed for unit position movement.

[Equation 19](#) is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity $[x(k) - x(k-1)]$ is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant $1/T$ (where T is the constant time between unit time events and is known in advance).

Estimation based on [Equation 19](#) has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T . For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, [Equation 20](#) provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. [Equation 20](#) can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation of [Equation 19](#). A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use [Equation 20](#) at low speed and have the software switch over to [Equation 19](#) when the motor speed rises above some specified threshold.

The device has three instances of the EQEP modules.

12.4.3.1.1 EQEP Features

The EQEP module includes the following features:

- Input synchronization
- Three stage/six stage digital noise filter
- Quadrature decoder unit

- Position counter and control unit for position measurement
- Quadrature edge capture unit for low-speed measurement
- Unit time base for speed and frequency measurement
- Watchdog timer for detecting stalls
- EQEP inputs (A/B/INDEX and STROBE) are available at chip level
- EQEP phase error output is also available. The status of the phase error can be observed by software through the CTRLMMR_EQEP_STAT register in the CTRL_MMR0 module.

12.4.3.1.2 EQEP Ports

Interrupt Requests		
Module Interrupt Signal	Description	Type
EQEP_EQEP_INT_0	EQEP interrupt	Pulse

12.4.3.2 EQEP Environment

This section describes the EQEP external connections (environment).

[Table 12-360](#) describes the EQEP I/O signals.

Table 12-360. EQEP I/O Signals

Module Pin	I/O Type ⁽¹⁾	Description
EQEP0_A	I	EQEP0 Quadrature input A
EQEP0_B	I	EQEP0 Quadrature input B
EQEP0_INDEX	I/O ⁽²⁾	EQEP0 Index input/output
EQEP0_STROBE	I/O ⁽²⁾	EQEP0 Strobe input/output
EQEP1_A	I	EQEP1 Quadrature input A
EQEP1_B	I	EQEP1 Quadrature input B
EQEP1_INDEX	I/O ⁽²⁾	EQEP1 Index input/output
EQEP1_STROBE	I/O ⁽²⁾	EQEP1 Strobe input/output
EQEP2_A	I	EQEP2 Quadrature input A
EQEP2_B	I	EQEP2 Quadrature input B
EQEP2_INDEX	I/O ⁽²⁾	EQEP2 Index input/output
EQEP2_STROBE	I/O ⁽²⁾	EQEP2 Strobe input/output

(1) I = Input; O = Output

(2) Output functionality is not supported. Only inputs are pinned out. For more information see *Device Specific EQEP Features*.

12.4.3.3 EQEP Functional Description

This section provides the EQEP functional description and corresponding functional details about EQEPx inputs.

Note

Multiple identical EQEP modules can be contained in a system. For actual number of EQEP modules integrated in the device, refer to *EQEP Integration*. The letter x within a signal or module name is used to indicate a generic EQEP instance on a device. For example, output interrupt request, EQEP0 EQEP INT 0 belongs to EQEP0, EQEP1 EQEP INT 0 belongs to EQEP1, and so forth.

The EQEP peripheral contains the following major functional units (as shown in [Figure 12-294](#)):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Three stage/six stage digital noise filter
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG).

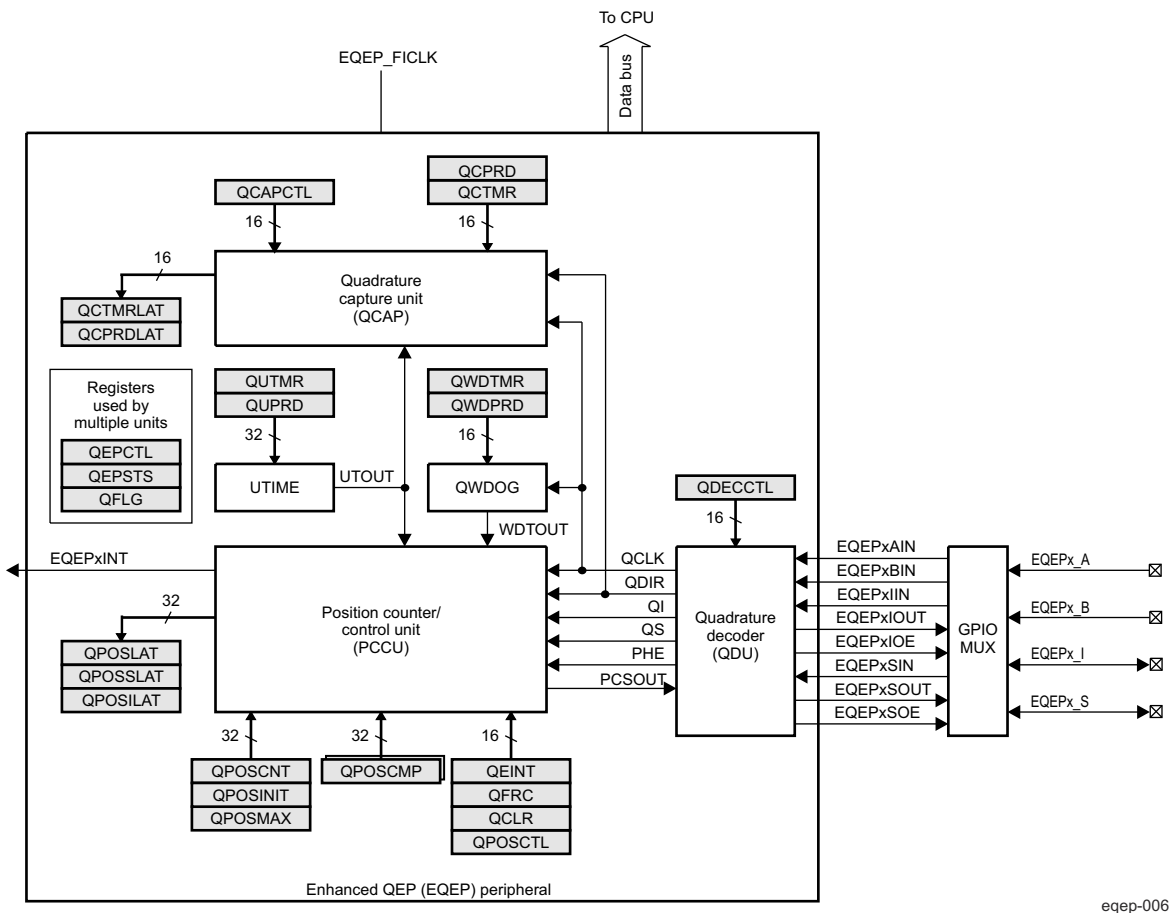

Figure 12-294. Functional Block Diagram of the EQEP Peripheral

12.4.3.3.1 EQEP Inputs

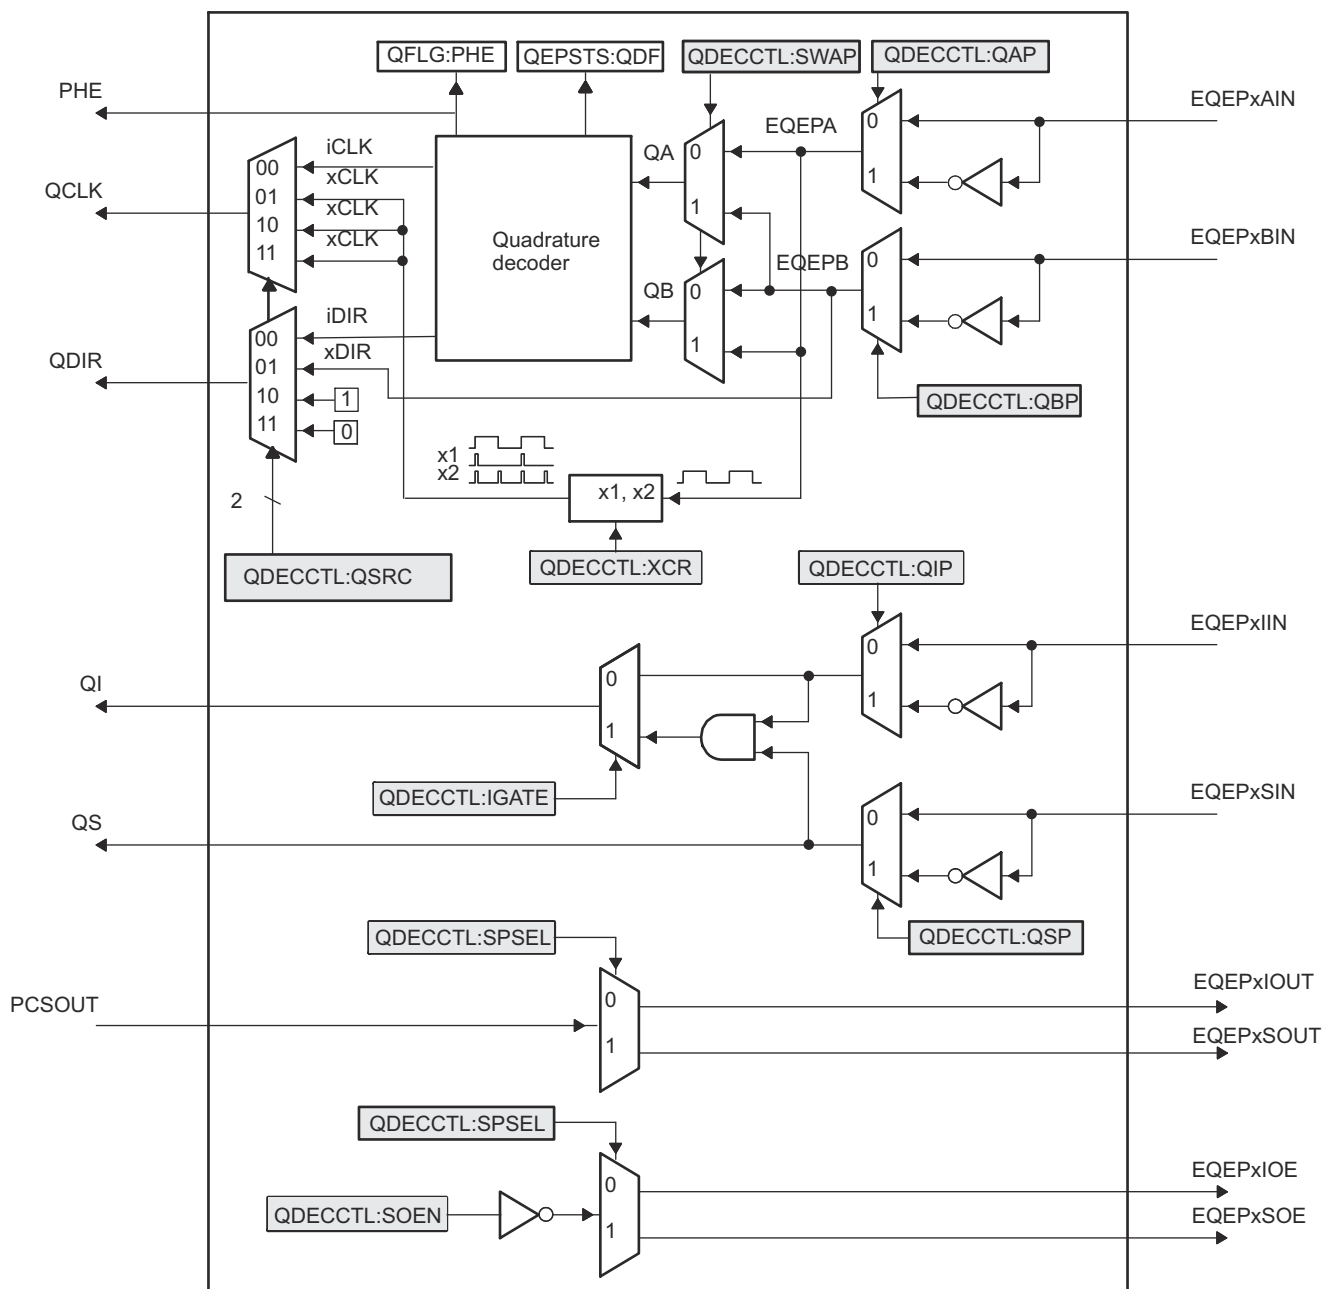

The EQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- EQEPx A and EQEPx B: These two pins can be used in quadrature-clock mode or direction-count mode.

- Quadrature-clock mode: The EQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of EQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
- Direction-count mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The EQEPx_A pin provides the clock input and the EQEPx_B pin provides the direction input.
- EQEPx_I: Index or Zero Marker: The EQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the EQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- EQEPx_S: Strobe Input: This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

12.4.3.3.2 EQEP Quadrature Decoder Unit (QDU)

Figure 12-295 shows a functional block diagram of the QDU.

eqep-007

Figure 12-295. Functional Block Diagram of Decoder Unit

12.4.3.3.2.1 EQEP Position Counter Input Modes

Clock and direction input to position counter is selected using the QSRC bit in the EQEP decoder and control register (EQEP_QDEC_QEP_CTL), based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode.

12.4.3.3.2.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

Direction Decoding The direction decoding logic of the EQEP circuit determines which one of the sequences (EQEPA, EQEPB) is the leading sequence and accordingly updates the direction information in the QDF bit in the EQEP status register (EQEP_QEP_STS_CT). [Table 12-361](#) and [Figure 12-296](#) show the direction decoding logic in truth table and state machine form. Both edges of the EQEPA and EQEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the EQEP logic is four times that of each input sequence. [Figure 12-297](#) shows the direction decoding and clock generation from the EQEP input signals.

Phase Error Flag In normal operating conditions, quadrature inputs EQEPA and EQEPB will be 90 degrees out of phase. The phase error flag (QPEI_FLG) is set in the EQEP_QINT_EN_FLG register when edge transition is detected simultaneously on the EQEPA and $\overline{\text{EQEPB}}$ signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 12-296](#) are invalid transitions that generate a phase error.

Count Multiplication The EQEP position counter provides 4× times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both EQEP input clocks (EQEPA and EQEPB) as shown in [Figure 12-297](#).

Reverse Count In normal quadrature count operation, EQEPA input is fed to the QA input of the quadrature decoder and the EQEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the EQEP decoder and control register (EQEP_QDEC_QEP_CTL). This will swap the input to the quadrature decoder thereby reversing the counting direction.
