

Figure 12-296. Quadrature Decoder State Machine

Figure 12-297. Quadrature-clock and Direction Decoding

12.4.3.3.2.1.2 EQEP Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. EQEPA input will provide the clock for position counter and the EQEPB input will have the direction information. The position counter is incremented on every rising edge of a EQEPA input when the direction input is high and decremented when the direction input is low.

12.4.3.3.2.1.3 EQEP Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the EQEP decoder and control register (EQEP_QDEC_QEP_CTL) enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2× factor.

12.4.3.3.2.1.4 EQEP Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the EQEP decoder and control register (EQEP_QDEC_QEP_CTL) enables clock generation to the position counter on both edges of a EQEPA input, thereby increasing the measurement resolution by 2× factor.

12.4.3.3.2.2 EQEP Input Polarity Selection

Each EQEP input can be inverted using the in the EQEP decoder and control register (EQEP_QDEC_QEP_CTL[8-5]) control bits. As an example, setting of the QIP bit in EQEP_QDEC_QEP_CTL inverts the index input.

12.4.3.3.2.3 EQEP Position-Compare Sync Output

The EQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (EQEP_QPOSCNT) and the position-compare register (EQEP_QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the SOEN bit in the EQEP decoder and control register (EQEP_QDEC_QEP_CTL) enables the position-compare sync output and the SPSEL bit in EQEP_QDEC_QEP_CTL selects either an EQEP index pin or an EQEP strobe pin.

12.4.3.3.3 EQEP Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (EQEP_QDEC_QEP_CTL and EQEP_QCAP_QPOS_CTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

12.4.3.3.3.1 EQEP Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement).

In all the above operating modes, position counter is reset to 0 on overflow and to QPOSMAX bifield value in EQEP_QPOSMAX register on underflow. Overflow occurs when the position counter counts up after QPOSMAX

value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in EQEP_QINT_EN_FLG register.

12.4.3.3.3.1.1 EQEP Position Counter Reset on Index Event (EQEP_QDEC_QEP_CTL[29-28] PCRM] = 0b00)

If the index event occurs during the forward movement, then position counter is reset to 0 on the next EQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP_QPOSMAX register on the next EQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP_QEP_STS_CT[1] FIMF) and direction on the first index event marker (EQEP_QEP_STS_CT[6] FIDF) in EQEP_QEP_STS_CT registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of EQEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of EQEPB for the forward rotation and on the rising edge of EQEPB for the reverse rotation as shown in [Figure 12-298](#).

The position-counter value is latched to the EQEP_QPOSILAT register and direction information is recorded in the EQEP_QEP_STS_CT[4] QDLF bit on every index event marker. The position-counter error flag (EQEP_QEP_STS_CT[0] PCEF) and error interrupt flag (EQEP_QINT_EN_FLG[17] PCEI_FLG) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (EQEP_QEP_STS_CT[0] PCEF) is updated on every index event marker and an interrupt flag (EQEP_QINT_EN_FLG[17] PCEI_FLG) will be set on error that can be cleared only through software.

The index event latch configuration EQEP_QDEC_QEP_CTL[21-20] IEL bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

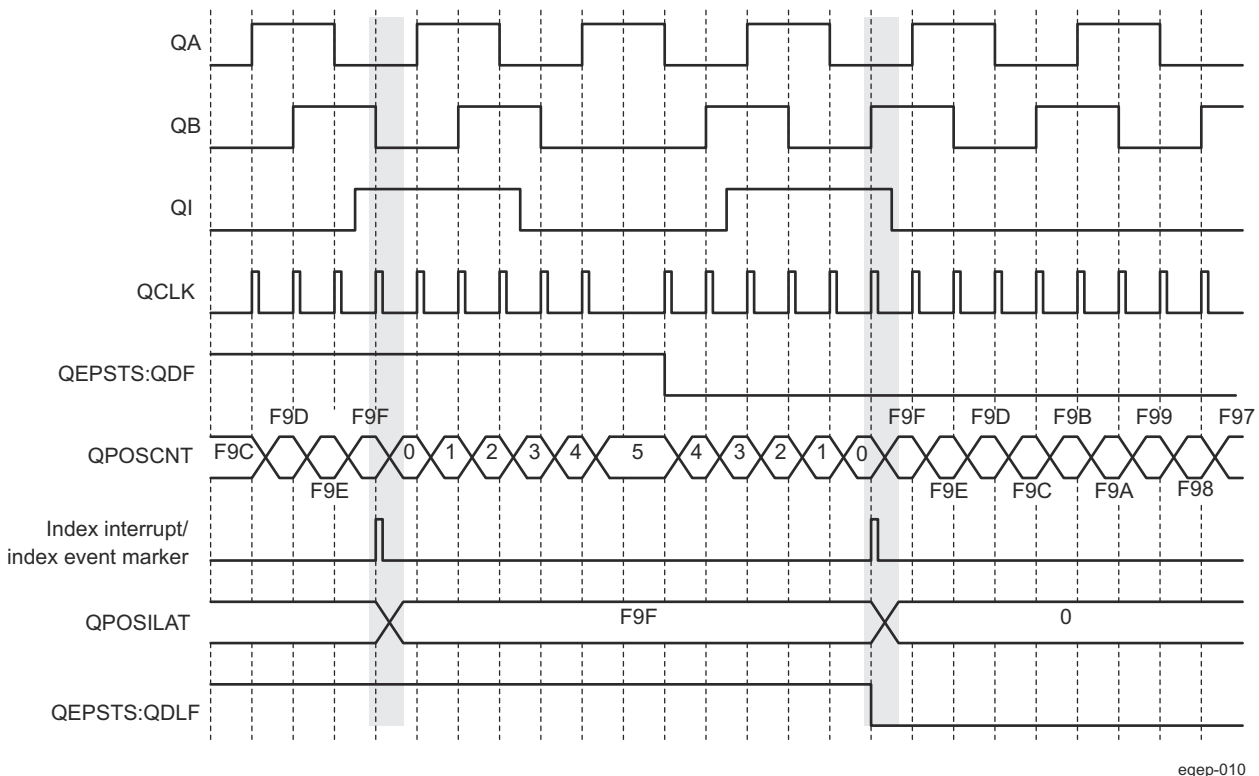

Figure 12-298. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or F9Fh)

12.4.3.3.3.1.2 EQEP Position Counter Reset on Maximum Position (EQEP_QDEC_QEP_CTL[29-28] PCRM=0b01)

If the position counter is equal to QPOS MAX (in EQEP_QPOS MAX register), then the position counter is reset to 0 on the next EQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to 0, then the position counter is reset to QPOS MAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 12-299 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP_QEP_STS_CT[1] FIMF) and direction on the first index event marker (EQEP_QEP_STS_CT[6] FIDF); it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (EQEP_QDEC_QEP_CTL[21-20] IEL= 0b11).

Figure 12-299. Position Counter Underflow/Overflow (QPOS MAX = 4)

eqep-011

12.4.3.3.3.1.3 Position Counter Reset on the First Index Event (EQEP_QDEC_QEP_CTL[29-28] PCRM = 0b10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next EQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP_QPOSMAX register on the next EQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in [Section 12.4.3.3.3.1.2](#).

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP_QEP_STS_CT[1] FIMF) and direction on the first index event marker (EQEP_QEP_STS_CT[6] FIDF) in EQEP_QEP_STS_CT registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (EQEP_QDEC_QEP_CTL[21-20] IEL = 0b11).

12.4.3.3.3.1.4 Position Counter Reset on Unit Time out Event (EQEP_QDEC_QEP_CTL[29-28] PCRM = 0b11)

In this mode, the QPOSCNT value is latched to the EQEP_QPOSILAT register and then the QPOSCNT field is reset (to 0 or the QPOSMAX value in the EQEP_QPOSMAX register, depending on the direction mode selected by EQEP_QDEC_QEP_CTL[15-14] QSRC bits on a unit time event). This is useful for frequency measurement.

12.4.3.3.3.2 EQEP Position Counter Latch

The EQEP index and strobe input can be configured to latch the position counter QPOSCNT (EQEP_QPOSCNT) into QPOSILAT (EQEP_QPOSILAT register) and QPOSSLAT (EQEP_QPOSSLAT register) bitfields, respectively, on occurrence of a definite event on these pins.

12.4.3.3.3.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (EQEP_QDEC_QEP_CTL[29-28] PCRM = 0b01 and EQEP_QDEC_QEP_CTL[29-28] PCRM = 0b10 modes).

In such cases, the EQEP position counter can be configured to latch on the following events and direction information is recorded in the EQEP_QEP_STS_CT[4] QDLF bit on every index event marker.

- Latch on Rising edge (EQEP_QDEC_QEP_CTL[21-20] IEL = 0b01)
- Latch on Falling edge (EQEP_QDEC_QEP_CTL[21-20] IEL = 0b10)
- Latch on Index Event Marker (EQEP_QDEC_QEP_CTL[21-20] IEL = 0b11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (EQEP_QINT_EN_FLG[26] IELI_FLG) is set when the position counter is latched to the EQEP_QPOSILAT register. The index event latch configuration bits are ignored when EQEP_QDEC_QEP_CTL[29-28] PCRM = 0b00.

When Position counter reset on an index event mode is selected through EQEP_QDEC_QEP_CTL[29-28] PCRM bit field (value: 0h), EQEP_QDEC_QEP_CTL[21-20] IEL bit field must be configured to 0h and position counter value is latched into the EQEP_QPOSILAT[31-0] QPOSILAT register for every index marker.

Latch on Rising Edge

(EQEP_QDEC_QEP_CTL[21-20] IEL = 0b01)

The position counter value (QPOSCNT) is latched to the EQEP_QPOSILAT register on every rising edge of an index input.

Latch on Falling Edge

(EQEP_QDEC_QEP_CTL[21-20] IEL = 0b10)

The position counter value (QPOSCNT) is latched to the EQEP_QPOSILAT register on every falling edge of index input.

Latch on Index Event

Marker/Software Index Marker
(EQEP_QDEC_QEP_CTL[21-20] IEL = 0b11)

The first index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP_QEP_STS_CT[1] FIMF) and direction on the first index event marker (EQEP_QEP_STS_CT[6] FIDF) in the EQEP_QEP_STS_CT registers. It also remembers the

Figure 12-300 shows the position counter latch using an index event marker.

Figure 12-300. Software Index Marker for 1000-line Encoder (EQEP_QDEC_QEP_CTL[21-20] IEL = 0b01)

12.4.3.3.3.2 EQEP Strobe Event Latch

The position-counter value is latched to the EQEP_QPOSSLAT register on the rising edge of the strobe input (QCLK) by clearing the EQEP_QDEC_QEP_CTL[22] SEL bit. Latching on the falling edge of the strobe input (QCLK) can be done by inverting the strobe input using the EQEP_QDEC_QEP_CTL[5] QSP bit.

If the EQEP_QDEC_QEP_CTL[22] SEL bit is set, then the position counter value is latched to the EQEP_QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in [Figure 12-301](#).

The strobe event latch interrupt flag (EQEP_QINT_EN_FLG[25] SEL1_FLG) is set when the position counter is latched to the EQEP_QPOSSLAT register.

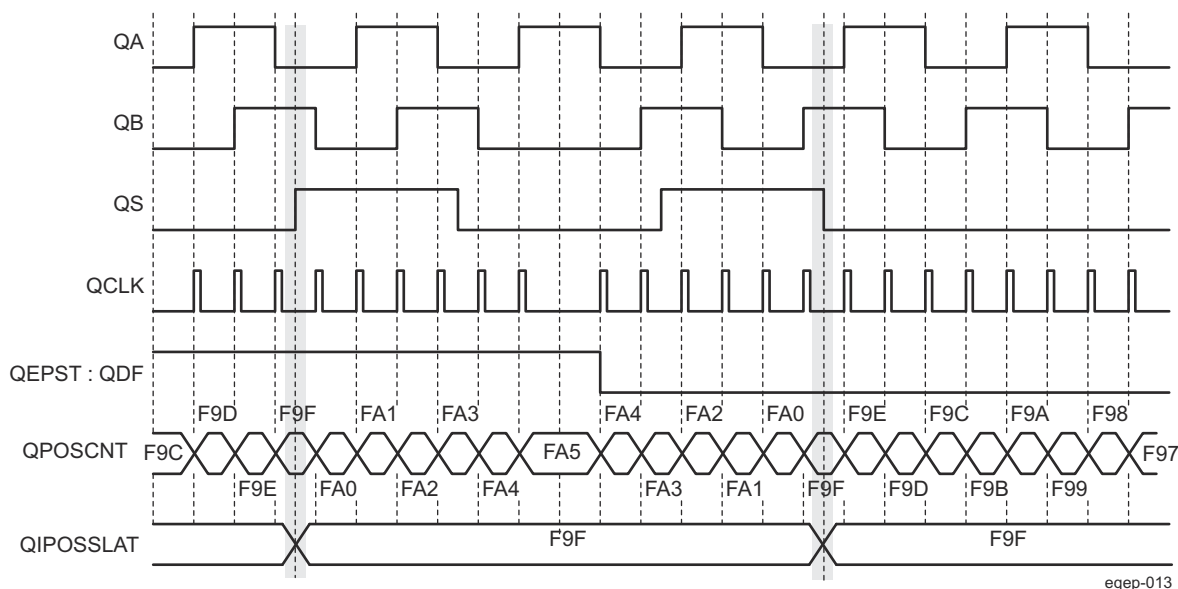

Figure 12-301. EQEP Strobe Event Latch (EQEP_QDEC_QEP_CTL[22] SEL = 0b1)

12.4.3.3.3 EQEP Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization.

Note

When all of the above events occur simultaneously, the sequence of priority is as follows: 1) Software Initialization, 2) strobe event initialization, 3) Index Event Initialization.

Index Event Initialization (IEI)

The EQEPx_I index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input.

If the EQEP_QDEC_QEP_CTL[25-24] IEI bits are 2h, then the position counter (EQEP_QPOSCNT) is initialized with a value in the EQEP_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The index event initialization interrupt flag (EQEP_QDEC_QEP_CTL[25-24] IEI) is set when the position counter is initialized with a value in the EQEP_QPOSINIT register.

If EQEP_QDEC_QEP_CTL[25-24] IEI bit field is configured with value 0h (default) or 1h, the index event initialization of position counter is disabled.

If EQEP_QDEC_QEP_CTL[25-24] IEI bit field is configured with value 3h, then the the position counter (EQEP_QPOSCNT) is initialized with a value in the EQEP_QPOSINIT register on the falling edge of strobe input signal.

Strobe Event Initialization (SEI)

If the EQEP_QDEC_QEP_CTL[27-26] SEI bits are 2h, then the position counter is initialized with a value in the EQEP_QPOSINIT register on the rising edge of strobe input.

If the EQEP_QDEC_QEP_CTL[27-26] SEI bits are 3h, then the position counter (EQEP_QPOSCNT) is initialized with a value in the EQEP_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The strobe event initialization interrupt flag (EQEP_QDEC_QEP_CTL[27-26] SEI) is set when the position counter is initialized with a value in the EQEP_QPOSINIT register.

If EQEP_QDEC_QEP_CTL[27-26] SEI bit field is configured with value 0h (default) or 1h, the strobe event initialization of position counter is disabled.

Software Initialization (SWI)

The position counter can be initialized in software by writing a 1h to the EQEP_QDEC_QEP_CTL[23] SWI bit, which will automatically be cleared after initialization.

12.4.3.3.4 EQEP Position-Compare Unit

The EQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. [Figure 12-302](#) shows a diagram. The position-compare (EQEP_QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the EQEP_QCAP_QPOS_CTL[31] PCSHDW bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

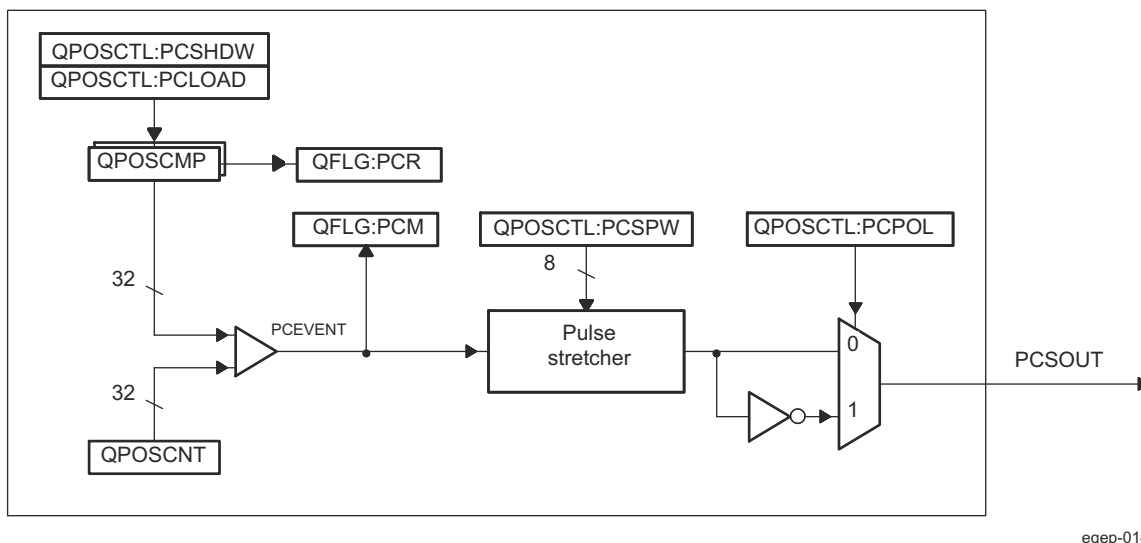

Figure 12-302. EQEP Position-compare Unit

In shadow mode, SW can configure the position-compare unit (EQEP_QCAP_QPOS_CTL[30] PCLOAD) to load the shadow register value into the active register on the following events and to generate the position-compare ready (EQEP_QINT_EN_FLG[23] PCRI_FLG) interrupt after loading.

- Load on compare match
- Load on position-counter zero event.

The position-compare match (EQEP_QINT_EN_FLG[24] PCMI_FLG) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (EQEP_QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if EQEP_QPOSCMP bitfield POSCMP = 0x2, the position-compare unit generates a position-compare event on the transition from 1 to 2 of the EQEP position counter for forward counting direction and on the transition from 3 to 2 of the EQEP position counter for reverse counting direction (see [Figure 12-303](#)).

Note

When EQEP_QCAP_QPOS_CTL[30] PCLOAD=0h, the shadow register is loaded into the active register as soon as POSCNT becomes zero, and it should not generate another shadow load if the POSCNT continues to stay at zero

Figure 12-303. EQEP Position-compare Event Generation Points

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 12-304.

Figure 12-304. EQEP Position-compare Sync Output Pulse Stretcher

12.4.3.3.4 EQEP Edge Capture Unit

The EQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in Figure 12-305. This feature is typically used for low speed measurement using the following equation:

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (21)$$

eqep-017

where,

- X - Unit position is defined by integer multiple of quadrature edges (see Figure 12-306)
- ΔT - Elapsed time between unit position events
- $v(k)$ - Velocity at time instant "k"

The EQEP capture timer (QCTMR bitfield in EQEP_QCTMR register) runs from prescaled SYSCLKOUT and the prescaler is programmed by the EQEP_QCAP_QPOS_CTL[6-4] CCPS bits. The capture timer QCTMR value is latched into the capture period register (EQEP_QC_PRD_TLAT) on every unit position event and then the capture timer is reset.

Time measurement (ΔT) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the EQEP overflow error flag (EQEP_QEP_STS_CT[3] COEF) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (EQEP_QEP_STS_CT[2] CDEF).

Capture Timer (EQEP_QCTMR register) and Capture period register (EQEP_QC_PRD_TLAT) can be configured to latch on following events.

- CPU read of EQEP_QPOSCNT register
- Unit time-out event

If the EQEP_QDEC_QEP_CTL[18] QCLM bit is cleared, then the capture timer and capture period values are latched into the EQEP_QC_PRD_TLAT and EQEP_QCPRDLAT registers, respectively, when the CPU reads the position counter in EQEP_QPOSCNT.

Note

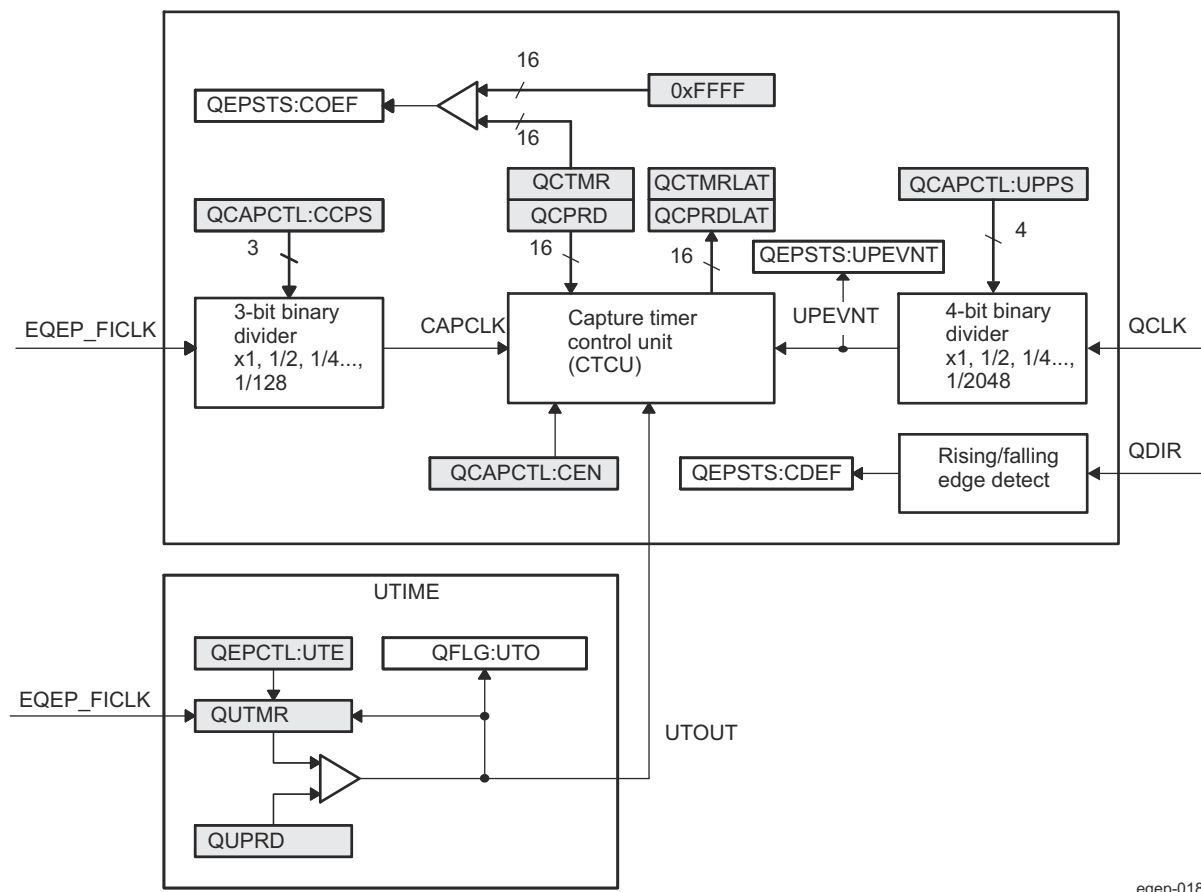

Capture timer and capture period values are not latched for an emulation read.

If the EQEP_QDEC_QEP_CTL[18] QCLM bit is set, then the position counter, capture timer, and capture period values are latched into the EQEP_QPOSLAT, EQEP_QC_PRD_TLAT and EQEP_QCPRDLAT registers, respectively, on unit time out.

Figure 12-307 shows the capture unit operation along with the position counter.

Note

The EQEP_QCAP_QPOS_CTL register should not be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLKOUT/4 to SYSCLKOUT/8, where SYSCLKOUT is equivalent to EQEPx_FICLK). The capture unit must be disabled before changing the prescaler.

eqep-018

Figure 12-305. EQEP Edge Capture Unit

N - Number of quadrature periods selected using EQEP_QCAP_QPOS_CTL[3-0] UPPS bits

Figure 12-306. Unit Position Event for Low Speed Measurement (EQEP_QCAP_QPOS_CTL[UPPS] = 0010)

Figure 12-307. EQEP Edge Capture Unit - Timing Details

Velocity Calculation Equations:

$$V(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad \text{or} \quad V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T}$$

(22)

eqep_021

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX : Incremental position movement in unit time

X: Fixed unit position

ΔT : Incremental time elapsed for unit position movement

t(k): Time instant "k"

t(k-1): Time instant "k - 1"

Unit time (T) and unit period (X) are configured using the EQEP_QUPRD and EQEP_QCAP_QPOS_CTL[3-0] UPPS registers. Incremental position output and incremental time output is available in the EQEP_QOSLAT and EQEP_QCPRLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (EQEP_QUPRD)
ΔX	Incremental Position = QOSLAT(k) - QOSLAT(k - 1)
X	Fixed unit position defined by sensor resolution and QCAPCTL[3-0] UPPS bits
ΔT	Capture Period Latch (QCPRLAT)

12.4.3.3.5 EQEP Watchdog

The EQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The EQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer will time out and the watchdog interrupt flag will be set (EQEP_QINT_EN_FLG[20] WTOI_FLG). The time-out value is programmable through the watchdog period bit field (EQEP_QWD_TMR_PRD[31-16] QWDPRD).

eqep-022

Figure 12-308. EQEP Watchdog Timer

12.4.3.3.6 Unit Timer Base

The EQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (EQEP_QINT_EN_FLG[27] UTOI_FLG) when the unit timer (QUTMR) matches the unit period register (EQEP_QUPRD).

The EQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event. The latched values are used for velocity calculation as described in Section [Section 12.4.3.3.4](#).

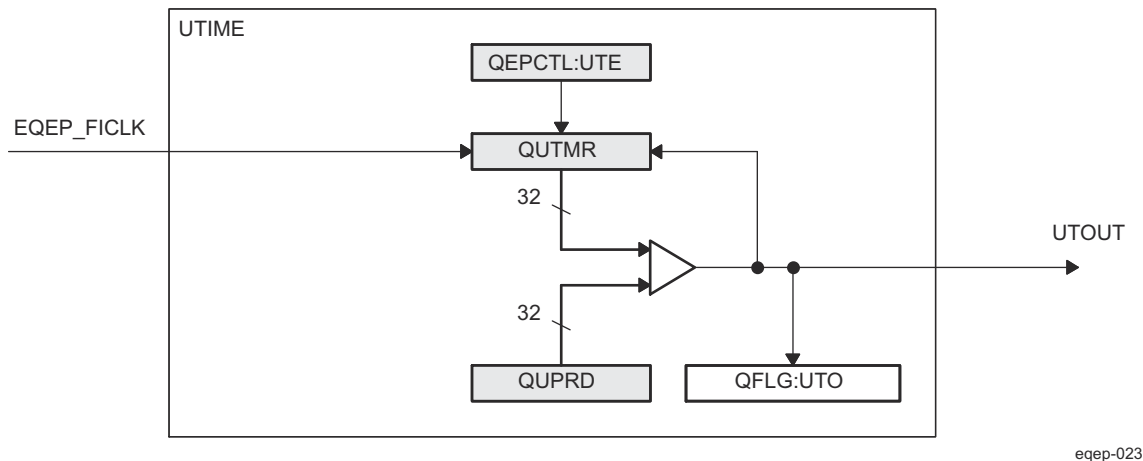

Figure 12-309. EQEP Unit Time Base

12.4.3.3.7 EQEP Interrupt Structure

Figure 12-310 shows how the interrupt mechanism works in the EQEP module.

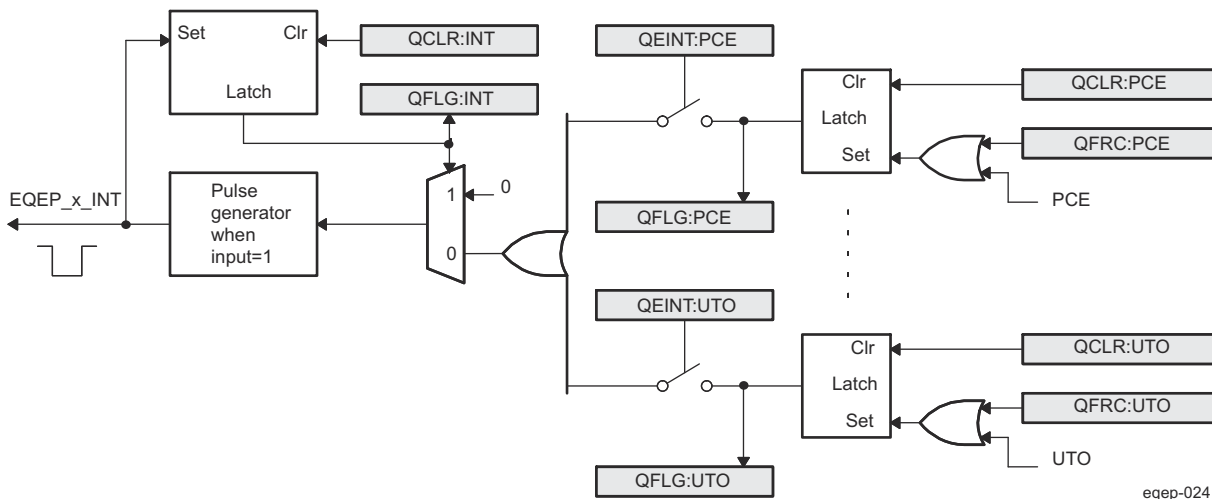

Figure 12-310. EQEP Interrupt Generation

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL, and UTO) can be generated. The interrupt control register (EQEP_QINT_EN_FLG) is used to enable/disable individual interrupt event sources. The interrupt flag register (EQEP_QINT_EN_FLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is only generated to the interrupt controller if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (EQEP_QINT_CLR_FRC), before any other interrupt pulses are generated. SW can force an interrupt event by way of the interrupt force register (EQEP_QINT_CLR_FRC), which is useful for test purposes.

12.4.3.3.8 Summary of EQEP Functional Registers

Table 12-362 lists the registers with their memory locations, sizes, and reset values.

Table 12-362. EQEP Control and Status Functional Registers

12.4.4 Controller Area Network (MCAN)

This section describes the Controller Area Network (MCAN) modules in the device.

12.4.4.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control. CAN has high immunity to electrical interference. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

They connect to the physical layer of the CAN network through external (for the device) transceivers. Each MCAN module supports flexible bit rates greater than 1 Mbps and is compliant to ISO 11898-1:2015.

12.4.4.1.1 MCAN Features

Each MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- SAE J1939 support
- AUTOSAR support
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements
- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock/Host clock)
- Parity/ECC support - Message RAM single error correction and double error detection (SECDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.4.4.2 MCAN Environment

This section describes the MCAN external connections (environment).

[Table 12-365](#) describes the MCAN I/O signals.

Table 12-365. MCAN I/O Signals

Module Pin	I/O ⁽¹⁾	Description
RX	I	Serial data input from external CAN transceiver
TX	O	Serial data output to external CAN transceiver

(1) I = Input; O = Output; HiZ = High Impedance

12.4.4.3 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values greater than 1 Mbps. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 12-311 shows the MCAN module block diagram.

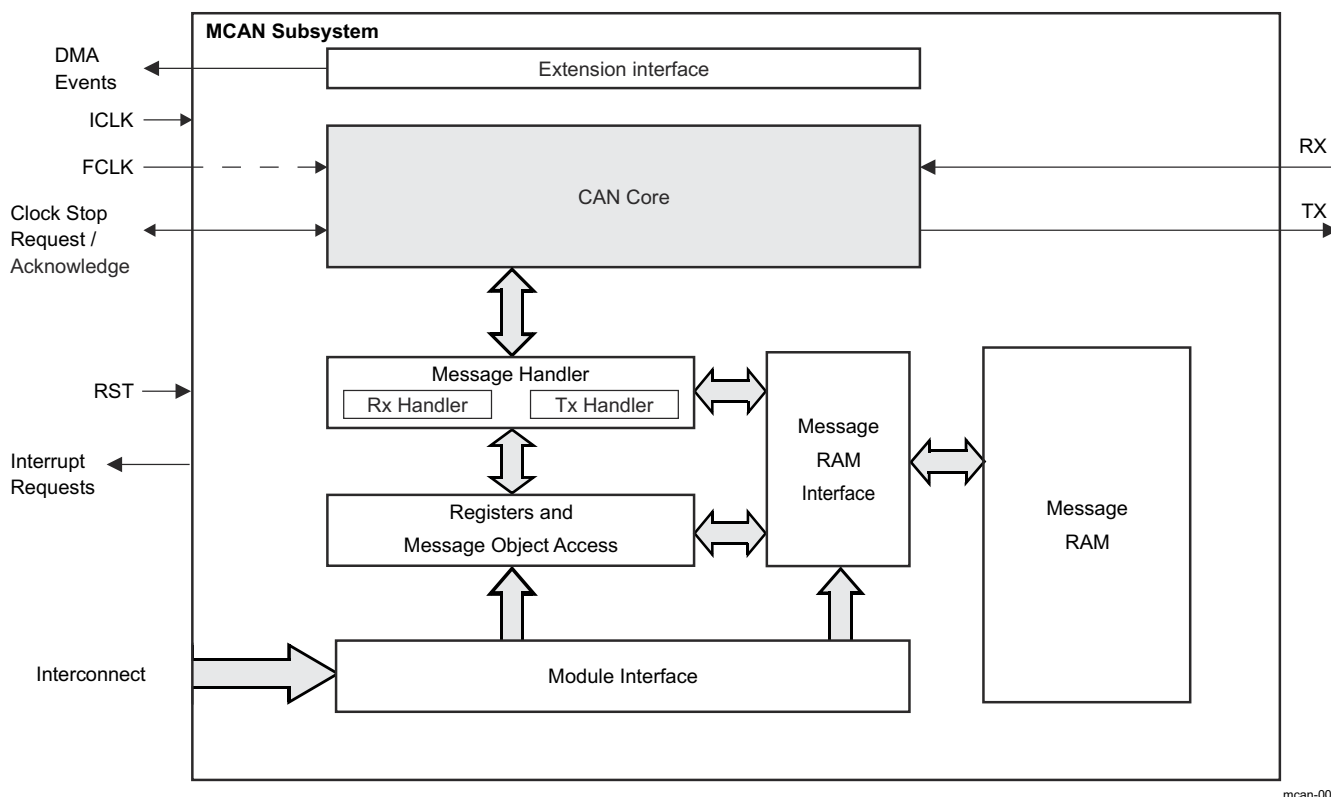

Figure 12-311. MCAN Block Diagram

The MCAN module blocks description:

- **CAN Core:** the CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler:** the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and the Interrupt/DMA request generation as programmed in the control registers.
- **Message RAM:** the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see *Message RAM*).
- **Message RAM Interface:** enables connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access:** data consistency is ensured by indirect accesses to the message objects. The interface registers have the same word-length as the Message RAM.
- **Module Interface:** provides connection to the Registers and Message Object Access block and Message RAM Interface block

- **Clocking:** two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock ICLK) and the peripheral asynchronous clock (functional clock - FCLK). For more information, see *MCU_MCAN Clocks and Resets* and *MCAN Clocks and Resets*.
- **Extension Interface:** this interface is used for DMA requests signaling (see *DMA Requests*).

12.4.4.3.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There is synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal to the Host clock domain and to the CAN clock domain.

Note

ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated ICLK has to be considered:

$$f_{0,ICLK} \pm \Delta f_{FM,ICLK} \geq f_{FCLK}$$

For more information on how to configure the relevant clock source registers, see *Clocking* and the device-specific Datasheet.

12.4.4.3.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode is requesting or forcing (based on MCANSS_CTRL[3] DBGSUSP_FREE bit) the MCAN module to go into initialization mode (see MCAN_CCCR[0] INIT bit) in which new interrupts and DMA requests will not be issued, that is to prevent the interrupt and DMA requests from propagating to the Host CPU (for more information, see [Section 12.4.4.3.3.8.2, Suspend Mode](#)).

12.4.4.3.2.1 Interrupt Requests

The MCAN module has two interrupt lines. There are 30 internal interrupt sources. Each source can be configured to drive one of the two interrupt lines. The interrupts are 'level high' interrupts.

The MCAN core provides two interrupt requests (for Line 0 and Line 1).

For more information, see the following registers:

- Interrupt Register (MCAN_IR)
- Interrupt Enable (MCAN_IE)
- Interrupt Line Select (MCAN_ILS)
- Interrupt Line Enable (MCAN_ILE)

The MCAN module is capable of issuing ECC interrupts. After clearing the ECC interrupt source, the application software must also write 1 to EOI register (MCANSS_ECC_SEC_EOI_REG/MCANSS_ECC_DED_EOI_REG). For more information, see *ECC Aggregator*.

The MCAN module supports External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see *External Timestamp Counter*).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS_ICS)
- Interrupt Raw Status Register (MCANSS_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS_IECS)
- Interrupt Enable Register (MCANSS_IE)
- Interrupt Enable Status Register (MCANSS_IES)
- End Of Interrupt Register (MCANSS_EOI)
- External Timestamp Prescaler Register (MCANSS_EXT_TS_PRESCALER)

- External Timestamp Unserviced Interrupts Counter Register (MCANSS_EXT_TS_UNSERVICED_INTR_CNTR)

For more information about available Interrupt Requests, see *MCU_MCAN Hardware Requests* and *MCAN Hardware Requests*.

12.4.4.3.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extension Interface. The DMA signaling uses a simple DMA request active high pulse.

The active high pulse indicates a pending message is transmitted (see MCAN_TXBRP). This pulse can be used to transfer another message to the Tx Buffer, which would need to be followed by writing 1 to the corresponding MCAN_TXBAR[0] AR bit to mark a new Tx message pending transmission.

The Parity on Tx DMA Events is available using an EDC Controller which can be accessed through the ECC Aggregator.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle pulses (ICLK).

12.4.4.3.3 Operating Modes

12.4.4.3.3.1 Software Initialization

Setting the MCAN_CCCR[0] INIT bit to 1 starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off state. While the MCAN_CCCR[0] INIT bit is set, the message transfer is stopped and the status of the output TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN_CCCR[0] INIT bit does not change any configuration register. Resetting the MCAN_CCCR[0] INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are set (write protection).

The MCAN_CCCR[1] CCE bit can only be set/reset while the MCAN_CCCR[0] INIT = 1. The MCAN_CCCR[1] CCE bit is automatically reset when the MCAN_CCCR[0] INIT bit is reset.

The following registers are reset when the MCAN_CCCR[1] CCE bit is set:

- MCAN_HPMS - High Priority Message Status
- MCAN_RXF0S - Rx FIFO 0 Status
- MCAN_RXF1S - Rx FIFO 1 Status
- MCAN_TXFQS - Tx FIFO/Queue Status
- MCAN_TXBRP - Tx Buffer Request Pending
- MCAN_TXBTO - Tx Buffer Transmission Occurred
- MCAN_TXBCF - Tx Buffer Cancellation Finished
- MCAN_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN_TOCV[15-0] TOC field is preset to the value configured by the MCAN_TOCC[31-16] TOP field when the MCAN_CCCR[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while MCAN_CCCR[1] CCE = 1.

The following registers are only writeable while MCAN_CCCR[1] CCE = 0

- MCAN_TXBAR - Tx Buffer Add Request
- MCAN_TXBCR - Tx Buffer Cancellation Request

MCAN_CCCR[7] TEST and MCAN_CCCR[5] MON bits can only be set by the Host CPU while MCAN_CCCR[0] INIT = 1 and MCAN_CCCR[1] CCE = 1. Both bits may be reset at any time. The MCAN_CCCR[6] DAR bit can only be set/reset while MCAN_CCCR[0] INIT = 1 and MCAN_CCCR[1] CCE = 1.

Table 12-366 shows the steps to configure the MCAN module.

Table 12-366. Steps to Configure MCAN Module

Step	Operation	Description	Pseudo Code
1	Initialize MCAN_CCCR	Set MCAN_CCCR[0] INIT bit and check that it has been set	INIT = 1; If INIT ≠ 1, wait until it is
2	Unlock protected registers	Set MCAN_CCCR[1] CCE bit	CCE = 1;
3	Configure CAN mode	Set MCAN_CCCR[8] FDOE bit to CAN FD	FDOE = 1 for CAN FD FDOE = 0 for CAN
4	Configure Bit Rate Switching	Set MCAN_CCCR[9] BRSE bit	BRSE = 1 with bit rate switching BRSE = 0 without bit rate switching
5	Set bit timing	Set MCAN_NBTP register	
6	Lock protected registers	Clear MCAN_CCCR[1] CCE bit	CCE = 0;
7	Return MCAN module to normal operation	Clear MCAN_CCCR[0] INIT bit and check it has been cleared	INIT = 0; If INIT ≠ 0, wait until it is

12.4.4.3.3.2 Normal Operation

Once the MCAN module is initialized and the MCAN_CCCR[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

Note

Automated transmission on reception of remote frames is not supported.

12.4.4.3.3.3 CAN FD Operation

The CAN FD standard allows extended frames to be sent, up to 64 data bytes in a single frame at a higher bit rate for the data phase of a frame, up to 8 Mbps. The CAN FD standard introduces the ability to switch from one bit rate to another. Extended Data Length (EDL), as shown in Figure 12-312, sets a data length of up to 8 or up to 64 data bytes. Bit Rate Switching (BRS) indicates whether two bit rates (the data phase is transmitted at a different bit rate to the arbitration phase) are enabled.

* 17 bit CRC for data fields with up to 16 bytes

mcan-004a

Figure 12-312. CAN FD Frame

Note

Figure 12-312 presents CAN FD frame according to the Non-ISO CAN FD (legacy) protocol. In the new ISO CAN FD protocol the CRC Field includes additional 5 bits (three stuff bit counter (SBC) bits and two parity bits). With these additional bits, a weakness identified in the error detection scheme chosen by the original protocol is removed. By setting MCAN_CCCR[15] NISO bit, the ISO or Non-ISO CAN FD format can be chosen. In CAN network ISO CAN FD and non-ISO CAN FD devices should never mix.

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN_PSR[14] EXE bit. When Protocol Exception Handling is enabled (MCAN_CCCR[12] PXHD = 0), this causes the operation state to change from Receiver (MCAN_PSR[4-3] ACT = 10) to Integrating (MCAN_PSR[4-3] ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN_CCCR[12] PXHD = 1), the MCAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN_CCCR[8] FDOE bit. In case MCAN_CCCR[8] FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN_CCCR[8] FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN_CCCR[8] FDOE and MCAN_CCCR[9] BRSE bits can only be changed while the MCAN_CCCR[0] INIT and MCAN_CCCR[1] CCE bits are both set. With MCAN_CCCR[8] FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN_CCCR[8] FDOE = 1 and MCAN_CCCR[9] BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN_CCCR[8] FDOE = 1 and MCAN_CCCR[9] BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wakeup messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

In the CAN FD format, the DLC coding differs from the standard CAN format (see Table 12-367).

Table 12-367. DLC Coding

DLC	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Number of Data Bytes in Standard CAN	0	1	2	3	4	5	6	7	8	8	8	8	8	8	8	8
Number of Data Bytes in CAN FD	0	1	2	3	4	5	6	7	8	12	16	20	24	32	48	64

For CAN FD frames, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see [Figure 12-313](#)) is used as configured by the Nominal Bit Timing and Prescaler Register MCAN_NBTP. In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register MCAN_DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

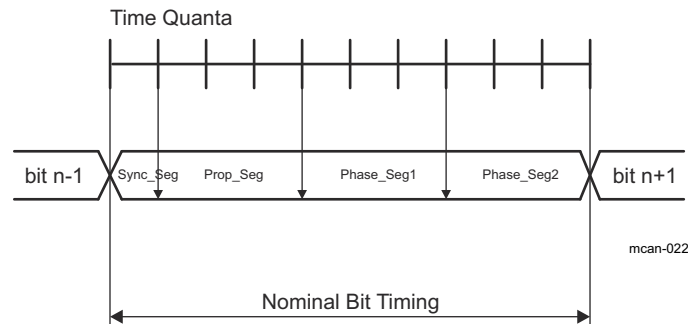

Figure 12-313. CAN Bit Timing

The maximum configurable data phase bit timing depends on the CAN clock frequency (FCLK). Example: with FCLK = 20 MHz and the shortest configurable bit time of 4 t_q (time quanta), the bit rate in the data phase is 5 Mbps.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see MCAN_PSR[11] RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

12.4.4.3.3.4 Transmitter Delay Compensation

12.4.4.3.3.4.1 Description

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the TX pin the MCAN module receives the transmitted data from its local CAN transceiver via the RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN_DBTP[23] TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output TX pin through the transceiver to the receive input RX pin plus the transmitter delay compensation offset configured by the MCAN_TDCR[14-8] TDCO field (see [Figure 12-314](#)). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq .

The actual transmitter delay compensation value can be checked by reading the MCAN_PSR[22-16] TDCV field. This field is cleared when the MCAN_CCCR[0] INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN_DBTP[23] TDC bit is set.

mcan-005

Figure 12-314. Transmitter Delay Measurement

12.4.4.3.3.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN_DBTP[23] TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input RX pin of the transmitter. The resolution of this measurement is one mtq (see Figure 12-314). The mtq (minimum time quantum) dimension is equal to the CAN clock period (FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming MCAN_TDCR[6-0] TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the RX pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN_TDCR[6-0] TDCF field and the RX pin is low.

The following boundary conditions have to be considered:

- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN_TDCR[14-8] TDCO field) has to be less than 6 bit times in the data phase.
- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (MCAN_TDCR[14-8] TDCO) field has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

12.4.4.3.3.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The receive and transmit error counters (MCAN_ECR[14-8] REC and MCAN_ECR[7-0] TEC) are frozen while CAN error logging (MCAN_ECR[23-16] CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting MCAN_CCCR[2] ASM bit. The bit can only be set by the Host CPU at any time when both MCAN_CCCR[2] CCE and MCAN_CCCR[0] INIT bits are set to 1.

- Corresponding Tx Buffer Cancellation Finished MCAN_TXBCF[xx] CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

12.4.4.3.3.8 Power Down (Sleep Mode)

The entering in Power Down mode is controlled via two sources:

- PSC (via clock stop request signal)
- Software (by writing to the MCAN_CCCR[4] CSR bit)

As long as the clock stop request signal is active, the MCAN_CCCR[4] CSR bit is read as 1.

When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN_CCCR[0] INIT bit to 1 to prevent any further CAN transfers.

The MCAN module acknowledges that it is ready for power down:

- By asserting clock stop acknowledge signal to the PSC (in case of PSC source).
- By setting the MCAN_CCCR[3] CSA flag bit to 1 (in case of Software source).

In this state, before the clocks are switched off, further register accesses can be made. Now the module clock inputs ICLK and FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN_CCCR[4] CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN_CCCR[3] CSA flag bit. Afterwards, the application can restart CAN communication by resetting the MCAN_CCCR[0] INIT bit.

Restoring the clocks from clock stop mode, needs to be done according to how the clock stop was initiated:

- If Software asserts the MCAN_CCCR[3] CSA flag bit, once the MCAN module goes idle, the MCAN_CCCR[0] INIT bit is set. To get it started again, Software needs to write 0 to the MCAN_CCCR[0] INIT bit.
- If PSC is issuing a clock stop request, than there are two options for waking up:
 - After removing clock stop request signal, Software would need to write 0 to the MCAN_CCCR[0] INIT bit, or
 - If the MCANSS_CTRL[5] AUTOWAKEUP bit is set, than after removing clock stop request signal, an FSM inside the MCAN module will reset the MCAN_CCCR[0] INIT bit (without Software).

12.4.4.3.3.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 12.4.4.3.3.8.3, Wakeup request](#)). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

12.4.4.3.3.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS_CTRL[3] DBGSUSP_FREE bit), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that

point the MCAN_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading MCAN_CCCR[0] INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 12.4.4.3.3.8.3, Wakeup request](#)). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN_CCCR[0] INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN_ECR[23-16] CEL
- MCAN_PSR[2-0] LEC
- MCAN_PSR[10-8] DLEC
- MCAN_PSR[11] RESI
- MCAN_PSR[12] RBRS
- MCAN_PSR[13] RFDF
- MCAN_PSR[14] PXE

12.4.4.3.3.8.3 Wakeup request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS_CTRL[5] AUTOWAKEUP and MCANSS_CTRL[4] WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN_CCCR[0] INIT bit and the MCAN core will resume operation.

If the MCANSS_CTRL[4] WAKEUPREQEN bit is set, the MCAN module provides a wakeup request on the following wakeup event:

- The receive RX pin is dominant (logical 0)

The wakeup request is de-asserted when any of the following conditions occur:

- Clock stop request is removed and clock stop acknowledge is de-asserted
- A reset is applied to the MCAN module

12.4.4.3.3.9 Test Modes

The MCAN_TEST register write access is enabled by setting the test mode enable MCAN_CCCR[7] TEST bit to 1. The MCAN_TEST register allows the configuration of the test modes and test functions.

The CAN transmit TX pin has four output functions. One of those functions can be selected by programming the MCAN_TEST[6-5] TX field. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

The actual value of the CAN receive RX pin can be monitored from MCAN_TEST[7] RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (FCLK) and Host clock (ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN_TEST[6-5] TX field until the new configuration is visible at the output TX pin. This applies also when reading input RX pin via the MCAN_TEST[7] RX bit.

Note

Test modes should be used for self test only. The software control for TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

12.4.4.3.3.9.1 Internal Loopback Mode

The MCAN module can be set into Internal Loopback Mode by programming MCAN_TEST[4] LBCK and MCAN_CCCR[5] MON bits to 1. The Internal Loopback Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the TX and RX pins. In this mode RX pin is disconnected from the MCAN module and TX pin is held recessive. [Figure 12-316](#) shows the connection of the TX and RX pins to the MCAN module in case of Internal Loopback Mode.

Figure 12-316. Internal Loopback Mode

12.4.4.3.4 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN_TSCC[19-16] TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the MCAN_TSCV[15-0] TSC field. A write access to the MCAN_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN_IR[16] TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15-0]) or Tx Event FIFO (TXTS[15-0]) element. For more information, see [Section 12.4.4.3.10, Message RAM](#).

12.4.4.3.4.1 External Timestamp Counter

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN_TSCC[1-0] TSS field.

The External Timestamp Counter uses the interface clock (ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS_EXT_TS_PRESCALER[23-0] PRESCALER bit field). The External Timestamp Counter can be enabled or disabled through the MCANSS_CTRL[6] EXT_TS_CNTR_EN bit. When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the MCAN timestamp interrupt is generated.

When the timestamp rolls over the MCANSS_IRS register is set (see [Figure 12-317](#)). The MCANSS_IE register can be affected by writing to the MCANSS_IESS register to set or to the MCANSS_IECS register to clear. The MCANSS_IESS register is a shadow register mapped to the same address as the MCANSS_IE register. The level interrupt is a reflection of both MCANSS_IRS and MCANSS_IE being set. The MCANSS_IES register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the MCANSS_ICS register to clear the MCANSS_IRS register will also decrement the interrupt counter. Writing to the MCANSS_EOI register will issue another pulse if the interrupt counter is not zero.

The rollover event can be artificially simulated by software through writing to the Interrupt Set Shadow register (MCANSS_ISS). The MCANSS_ISS register is a shadow register mapped to the same address as the MCANSS_IRS register.

mcan-021

Figure 12-317. External Timestamp Counter Interrupt

12.4.4.3.5 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the MCAN_TOCC register. It is enabled via the MCAN_TOCC[0] ETOC bit. The Timeout Counter operates as down-counter and uses the same prescaler programmed by the MCAN_TSCC[19-16] TCP field as the Timestamp Counter. The actual counter value can be monitored from the MCAN_TOCV[15-0] TOC field. The Timeout Counter can be started only when MCAN_CCCR[0] INIT = 0 and stopped when MCAN_CCCR[0] INIT = 1 (example: when the MCAN enters Bus_Off state). The operation mode is selected by the MCAN_TOCC[2-1] TOS field. When Continuous Mode is selected, the counter starts when MCAN_CCCR[0] INIT = 0, a write to the MCAN_TOCV register presets the counter to the value configured by the MCAN_TOCC[31-16] TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN_TOCC[31-16] TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN_IR[18] TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the MCAN_TOCC[31-16] TOP field.

12.4.4.3.6 ECC Support

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC Aggregator.

12.4.4.3.6.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

12.4.4.3.6.2 ECC Aggregator

Note

For more information about ECC Aggregator, refer to [Section 12.10.6, ECC Aggregator](#).

12.4.4.3.7 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

12.4.4.3.7.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
 - Range Filter (from - to)
 - Filter for specific IDs (for one or two dedicated IDs)
 - Classic Bit Mask Filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register
- Extended ID AND Mask (MCAN_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in [Section 12.4.4.3.10, Message RAM](#)) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single ICLK pulse. For more information, see [Section 12.4.4.3.2.1, DMA Requests](#).
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN_IR[8] HPM
- Set High Priority Message interrupt flag MCAN_IR[8] HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:

New Data flag (MCAN_NDAT1/MCAN_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see MCAN_PSR[2-0] LEC respectively MCAN_PSR[10-8] DLEC fields).

- Rx FIFO:
Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see MCAN_PSR[2-0] LEC respectively MCAN_PSR[10-8] DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in [Section 12.4.4.3.7.2.2](#) have to be considered.

12.4.4.3.7.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see [Section 12.4.4.3.10.5, Standard Message ID Filter Element](#) and [Section 12.4.4.3.10.6, Extended Message ID Filter Element](#).

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN_XIDAM) is not used for Range Filtering.

12.4.4.3.7.1.2 Filter for specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT = 01/Extended Filter Type EFT = 01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see [Section 12.4.4.3.10.5, Standard Message ID Filter Element](#) and [Section 12.4.4.3.10.6, Extended Message ID Filter Element](#).

12.4.4.3.7.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT = 10/Extended Filter Type EFT = 10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

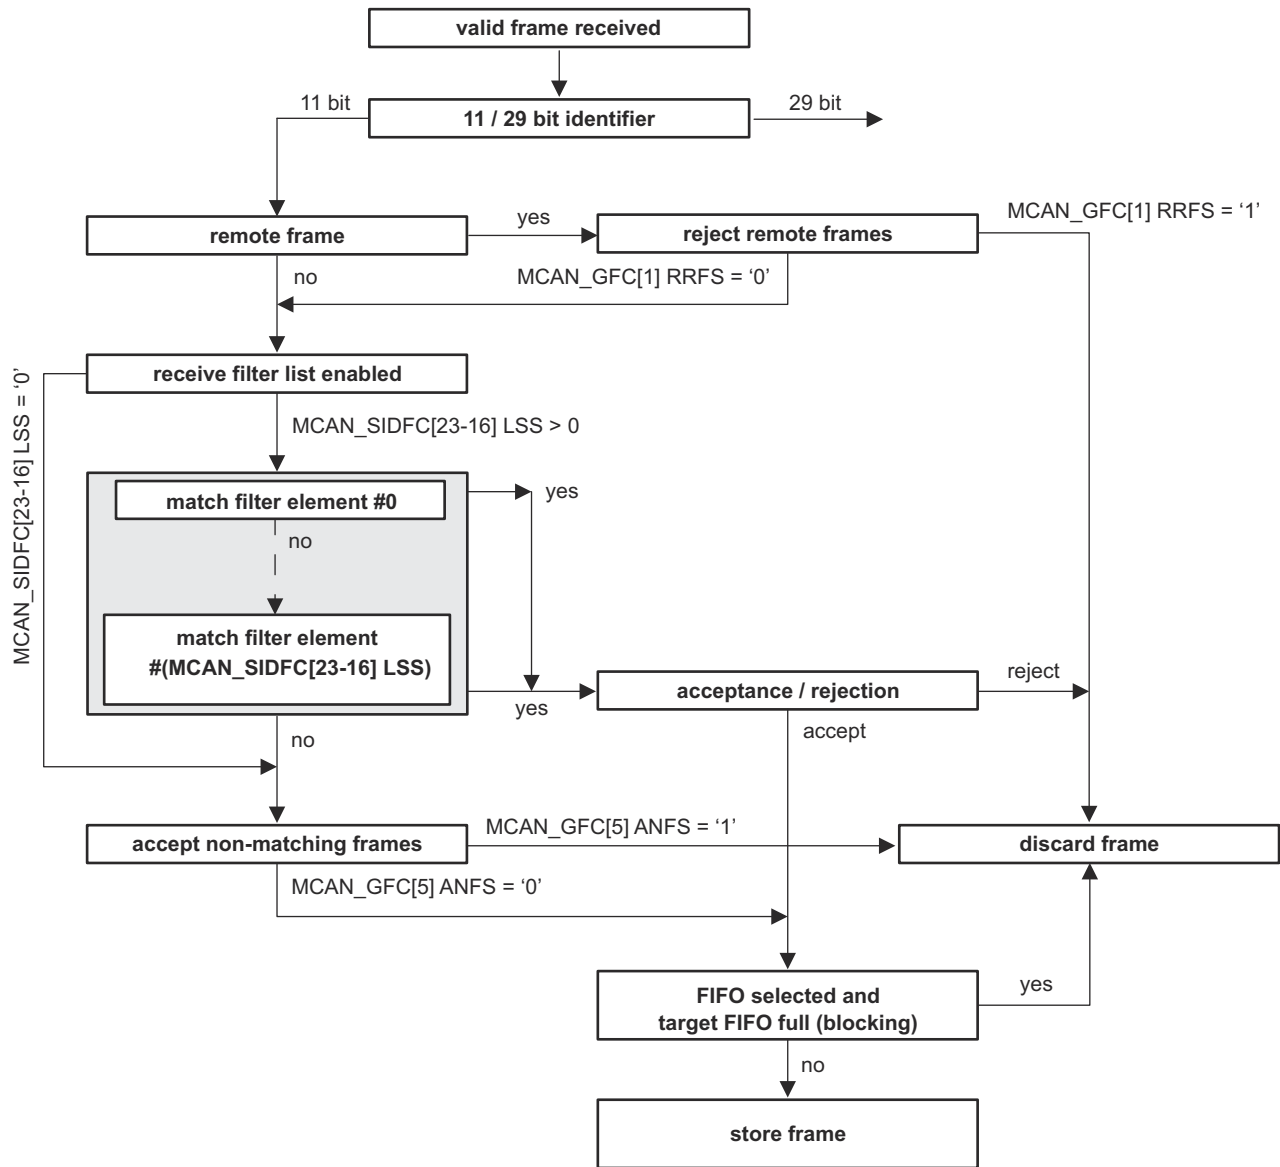

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

12.4.4.3.7.1.4 Standard Message ID Filtering

The standard Message ID (11-bit ID) filtering flow is shown in [Figure 12-318. Section 12.4.4.3.10.5, Standard Message ID Filter Element](#) describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Standard ID Filter Configuration (MCAN_SIDFC) register

mcan-009

Figure 12-318. Standard Message ID Filter Path**12.4.4.3.7.1.5 Extended Message ID Filtering**

The extended Message ID (29-bit ID) filtering flow is shown in [Figure 12-319](#). [Section 12.4.4.3.10.6, Extended Message ID Filter Element](#) describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN_GFC) register
- Extended ID Filter Configuration (MCAN_XIDFC) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask (MCAN_XIDAM).

mcan-010

Figure 12-319. Extended Message ID Filter Path

12.4.4.3.7.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the MCAN_RXF0C and MCAN_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in [Section 12.4.4.3.7.1, Acceptance Filtering](#). [Section 12.4.4.3.10.2, Rx Buffer and FIFO Element](#) describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN_RXFnC[30-24] FnWM field (where: n = 0 or 1) an interrupt flag MCAN_IR[1] RF0W/MCAN_IR[5] RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN_RXFnS[21-16] FnPI = MCAN_RXFnS[13-8] FnGI) an Rx FIFO Full condition is signalled by the MCAN_RXFnS[24] FnF status bit and interrupt flag MCAN_IR[2] RF0F/MCAN_IR[6] RF1F is set. [Figure 12-320](#) shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN_RXFnS[6-0] FnFL field (the number of elements stored in Rx FIFO).

**Figure 12-320. Rx FIFO Status**

Rx FIFOs start address in the Message RAM (MCAN_RXFnC[15-2] FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN_RXFnS[13-8] FnGI). [Table 12-368](#) presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer/Rx FIFO Data Field Size which is configured via the MCAN_RXESC register.

Table 12-368. Rx Buffer/Rx FIFO Element Size

MCAN_RXESC[10-8] RBDS MCAN_RXESC[2-0] F0DS/ MCAN_RXESC[6-4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

12.4.4.3.7.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN_RXFnC[31] FnOM = 0.

If an Rx FIFO full condition is reached (MCAN_RXFnS[21-16] FnPI = MCAN_RXFnS[13-8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN_RXFnS[24] FnF = 1 and interrupt flag MCAN_IR[2] RF0F/MCAN_IR[6] RF1F is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN_RXFnS[25] RFnL = 1 and interrupt flag MCAN_IR[3] RFnL/MCAN_IR[25] RFnL is set.

12.4.4.3.7.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN_RXFnC[31] FnOM = 1. When an Rx FIFO full condition is reached (MCAN_RXFnS[21-16] FnPI = MCAN_RXFnS[13-8] FnGI) signalled by MCAN_RXFnS[24] FnF = 1,

the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. [Figure 12-321](#) shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 12-321. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN_RXFnA[5-0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN_RXFnS[24] FnF = 0).

12.4.4.3.7.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via MCAN_RXBC[15-2] RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10-9] = 00 has to be configured (see [Section 12.4.4.3.10.5, Standard Message ID Filter Element](#) and [Section 12.4.4.3.10.6, Extended Message ID Filter Element](#)).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag MCAN_IR[19] DRX (Message stored in Dedicated Rx Buffer) is set.

[Table 12-369](#) shows Example Filter Configuration for Rx Buffers.

Table 12-369. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10-0] EFID1[28-0]	SFID2[10-9] EFID2[10-9]	SFID2[5-0] EFID2[5-0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN_NDAT1/MCAN_NDAT2 is set. As long as the New Data flag is set, the respective

Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

12.4.4.3.7.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN_IR[19] DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

12.4.4.3.7.4 Debug on CAN Support

Debug DMA is not supported feature. Debug messages can be traced through the RX FIFO (see [Section 12.4.4.3.7.2](#)).

12.4.4.3.8 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers/Tx FIFO or dedicated Tx Buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. [Section 12.4.4.3.10.3](#) describes the Tx Buffer Element. [Table 12-370](#) shows the possible configurations for message transmission.

Table 12-370. Possible Configurations for Message Transmission

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending MCAN_TXBRP register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

12.4.4.3.8.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN_CCCR[14] TXP bit. By default this bit is disabled (MCAN_CCCR[14] TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times

occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

12.4.4.3.8.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the MCAN_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 12-371 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN_TXFQS[20-16] TFQPI) × Element Size to the Tx Buffer Start Address MCAN_TXBC[15-2] TBSA field.

Table 12-371. Tx Buffer/Tx FIFO/Tx Queue Element Size

MCAN_TXESC[2-0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

12.4.4.3.8.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN_TXBC[30] TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN_TXFQS[12-8] TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN_TXFQS[5-0] TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20-16] TFQPI field. After each Add Request (MCAN_TXBAR[x] ARn = 1) the Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN_TXFQS[20-16] TFQPI = MCAN_TXFQS[12-8] TFGI), Tx FIFO Full condition is signalled by bit MCAN_TXFQS[21] TFQF = 1. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level MCAN_TXFQS[5-0] TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN_TXFQS[5-0] TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see Table 12-371). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index

MCAN_TXFQS[20-16] TFQPI (from 0 to 31) \times Element Size to the Tx Buffer Start Address MCAN_TXBC[15-2] TBSA field.

12.4.4.3.8.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN_TXBC[30] TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN_TXFQS[20-16] TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN_TXFQS[21] TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the MCAN_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see Table 12-371). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN_TXFQS[20-16] TFQPI (from 0 to 31) \times Element Size to the Tx Buffer Start Address MCAN_TXBC[15-2] TBSA field.

12.4.4.3.8.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21-16] NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the MCAN_TXBC[29-24] TFQS field

If the MCAN_TXBC[29-24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN_TXFQS[12-8] TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 12-322 shows Mixed Dedicated Tx Buffers/Tx FIFO example.

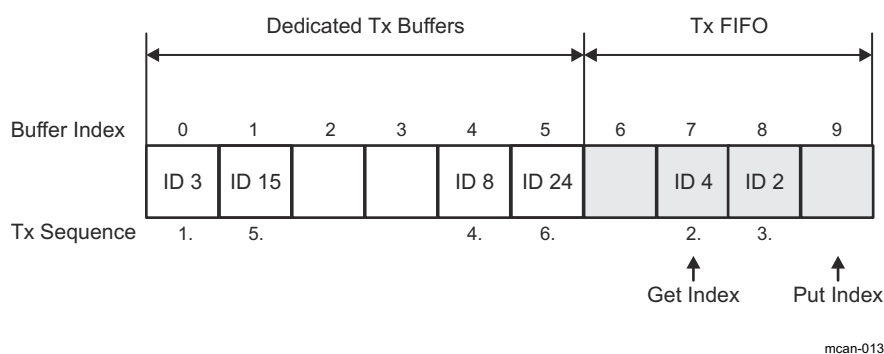

Figure 12-322. Mixed Dedicated Tx Buffers/Tx FIFO (example)

12.4.4.3.8.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN_TXBC[21-16] NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the MCAN_TXBC[29-24] TFQS field

If MCAN_TXBC[29-24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 12-323 shows Mixed Dedicated Tx Buffers/Tx Queue example.

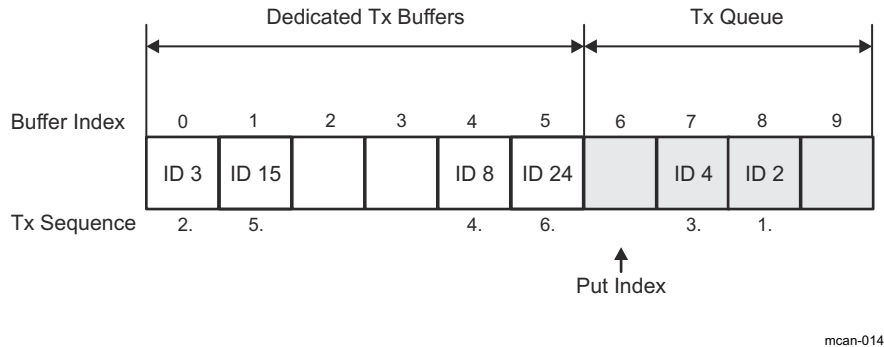

Figure 12-323. Mixed Dedicated Tx Buffers/Tx Queue (example)

12.4.4.3.8.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the MCAN_TXBCF register (MCAN_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN_TXBTO[n] TOn and MCAN_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN_TXBCF[n] CFn = 1.

Note

If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

12.4.4.3.8.8 Tx Event Handling

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. Section 12.4.4.3.10.4 describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the MCAN_IR[14] TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN_TXEFS[12-8] EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN_IR[15] TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN_TXEFC[29-24] EFWM field, interrupt flag MCAN_IR[13] TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index

MCAN_TXEFS[12-8] EFGI field has to be added to the Tx Event FIFO start address MCAN_TXEFC[15-2] EFSA field.

12.4.4.3.9 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN_RXF0A, MCAN_RXF1A, and MCAN_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

Note

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

12.4.4.3.10 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

12.4.4.3.10.1 Message RAM Configuration

The MCAN module is configured to allocate 4352 words in the Message RAM. The Message RAM has a width of 32 bits.

The Message RAM is capable to include each of the sections listed in [Figure 12-324](#). It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the MCAN_RXESC[2-0] F0DS field
- Rx FIFO 1 via the MCAN_RXESC[6-4] F1DS field
- Rx Buffers via the MCAN_RXESC[10-8] RBDS field
- Tx Buffers via the MCAN_TXESC[2-0] TBDS field

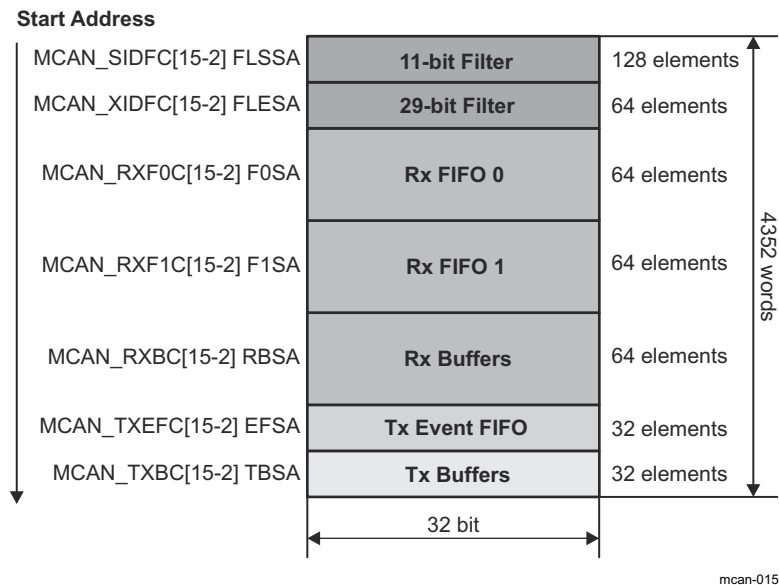

Figure 12-324. Message RAM Configuration

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

Note

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

12.4.4.3.10.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_RXESC register.

Figure 12-325 shows Rx Buffer/Rx FIFO element structure.

mcan-016

Rn	15-8	DBm-2[7-0]	Data Byte m-2
	7-0	DBm-3[7-0]	Data Byte m-3

Note: Depending on the configuration of the element size (MCAN_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

12.4.4.3.10.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO/Tx Queue via the MCAN_TXBC[29-24] TFQS and MCAN_TXBC[21-16] NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN_TXESC register.

Figure 12-326 shows Tx Buffer element structure.

12.5 Audio Interfaces

12.5.1 Audio Tracking Logic (ATL)

This chapter describes the integration of the Audio Tracking Logic (ATL) subsystem in the device.

12.5.1.1 ATL Overview

The Audio Tracking Logic (ATL) is used by HD Radio™ applications to synchronize the digital audio output to the baseband clock. This same IP can also be used generically to track errors between two reference signals (such as frame syncs) and generate a modulated clock output (using software-controlled cycle stealing) which averages to some desired frequency. This process can be used as a hardware assist for asynchronous sample rate conversion algorithms.

12.5.1.1.1 ATL Features Overview

The ATL module supports the following features:

- One ATL module, containing four ATL instances, for HD Radio support and asynchronous sample rate conversion assistance
- Each instance tracks the time error between two syncs (local audio word select [AWS] and baseband word select [BWS])
- Each instance generates modulated ATCLK clock signals with software-initiated pulse stealing. The intention is to use these clocks to derive audio output bit clock on MCASP
- Selection between ATL_VCLK clock or functional ATL_PCLK to run error counting timers and to derive modulated ATCLK clock outputs.
- Clock and reset management: Receives clock and reset signals from the device PSC module. The ATL module receives hardware reset.
- Power management: The ATL belongs to the PD0 power domain.
- Local software reset

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.5.1.1.2 ATL Ports

Table 12-377. ATL Clocks and Resets

Clocks	
Module Clock Input	Description
ATL_VCLK	ATL interface clock
ATL_PCLK	ATL functional clock.
Resets	
Module Reset Input	Description
ATL_RST	ATL reset

12.5.2 Multichannel Audio Serial Port (MCASP)

This section describes the Multichannel Audio Serial Port (MCASP).

12.5.2.1 MCASP Overview

This section introduces the Multichannel Audio Serial Port (MCASP) module and describes its main functions and connections in the device.

The MCASP functions as a general-purpose audio serial port are optimized to the requirements of various audio applications. The MCASP module can operate in both transmit and receive modes. The MCASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an inter-component digital audio interface transmission (DIT). The MCASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

Although inter-component digital audio interface reception (DIR) mode (this is, S/PDIF stream receiving) is not natively supported by the MCASP module, a specific TDM mode implementation for the MCASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

12.5.2.1.1 MCASP Features

Each MCASP module includes the following main features:

- Independent serializer for each AXRx channel of each MCASP module
- Clock stop request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- Interconnect interface port for CBASS0
- Two independent clock generator modules for transmit and receive (clocking flexibility allows the MCASP to receive and transmit at different rates. For example, the MCASP can receive data at 48 kHz, but output up-sampled data at 96 kHz or 192 kHz)
- Each MCASP module functional clock can be generated:
 - Internally (master mode)
 - Supplied over MCASP serial interface (slave mode)
 - Has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
 - Programmable clock and frame sync generator
 - TDM streams from 2 to 32, and 384 time slots
 - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits
 - Data formatter for bit manipulation
- Glueless connection to audio Analog-to-Digital Converters (ADC), Digital-to-Analog Converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components
- Wide variety of I2S and similar bit-stream format
- Integrated digital audio interface transmitter (DIT):
 - S/PDIF, IEC60958-1, AES-3 formats
 - Enhanced channel status/user data RAM
- 384-slot TDM with external digital audio interface receiver (DIR) device
 - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the MCASP receive section
- Support for 2 × DMA requests (one per direction):
 - 1 level-sensitive transmit direct memory access (DMA) request common for all of the MCASP serializers
 - 1 level-sensitive receive direct memory access (DMA) request common for all of the MCASP serializers
 - All transmit DMA requests are mapped to the device DMA controllers
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupts

Note

Because a serializer receive and transmit channels data is shared on the same MCASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.5.2.1.2 MCASP Ports

Table 12-378. MCASP Clocks and Resets

Clocks

(1) I = Input; O = Output; I/O = Bidirectional

12.5.2.3 MCASP Functional Description

In the text throughout this section a single instance of MCASP is described assuming that all modules are functionally identical. For module availability and integration differences, see *MCASP Environment* and *MCASP Integration*.

12.5.2.3.1 MCASP Block Diagram

Figure 12-330 shows the major blocks of the MCASP module. The MCASP0 has 16 serializers, the MCASP1 has 12 serializers, the MCASP2 has 6 serializers. The serializers share a clock and frame-sync generator, format unit, and error-checking logic independently for the receive and transmit part.

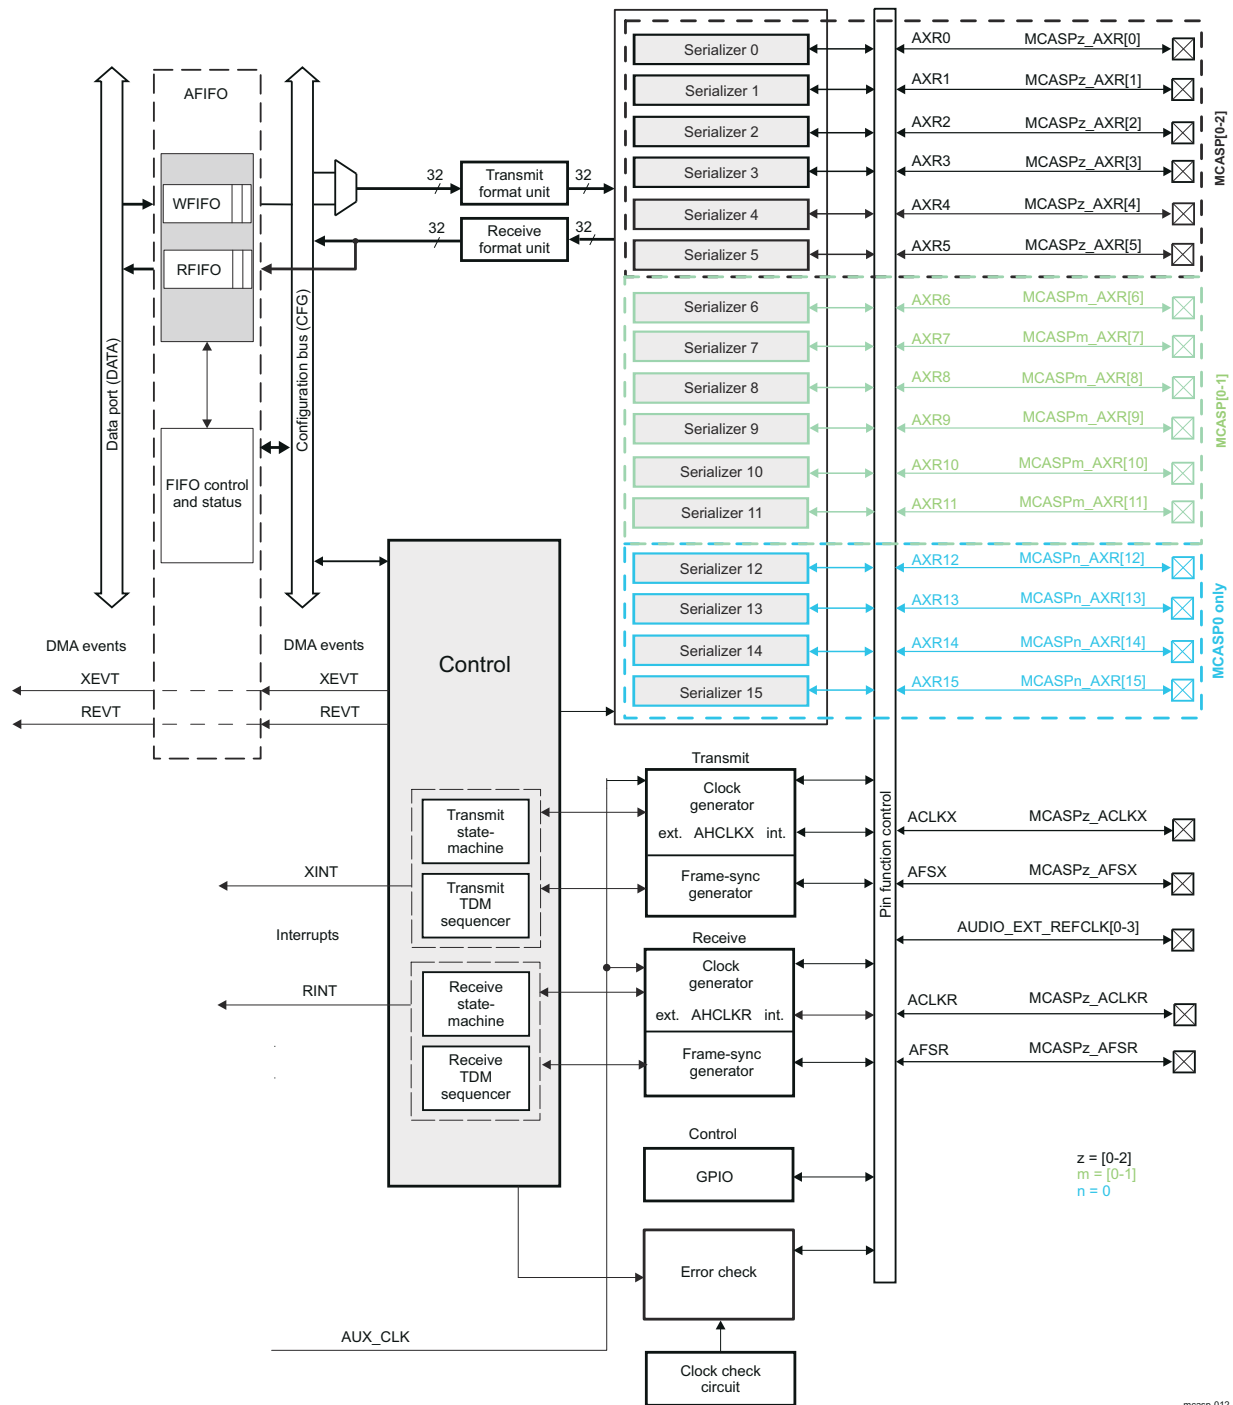

Figure 12-330. MCASP Module Block Diagram

Note

The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

12.5.2.3.2 MCASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the MCASP serializers. The first three scenarios are identical between the Tx and Rx part of the MCASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for MCASP receivers - RCLK is derived from the bit rate clock of the MCASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the MCASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

12.5.2.3.2.1 MCASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- MCASP_ACLKXCTL
- MCASP_AHCLKXCTL

In case, the transmit bit clock, ACLKX, is generated internally, the MCASP_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKXCTL[4-0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in [Section 12.5.2.3.2](#), the MCASP_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKXCTL[11-0] HCLKXDIV bit field) from the MCASP internal clock source AUXCLK.

Internally, the MCASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see [Figure 12-331](#)). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If MCASP_ACLKXCTL[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the MCASP shifts transmit data at the rising edge of ACLKX. If MCASP_ACLKXCTL[7] CLKXP = 1, the CLKXP mux passes the inverted version of ACLKX to XCLK. As a result, the MCASP shifts transmit data at the falling edge of ACLKX.

It can be seen in [Figure 12-331](#) that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between MCASP transmitters and receivers. This is used for example in the MCASP loopback mode.

Note

The polarity of ACLKX can be controlled in the MCASP_ACLKXCTL[7] CLKXP bit, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the MCASP_AHCLKXCTL[14] HCLKXP bit.

Note

In a similar way, the polarity of AHCLKX clock can be controlled in the MCASP_AHCLKXCTL[14] HCLKXP bit, regardless of the AHCLKX signal being internally or externally sourced.

[Figure 12-331](#) presents the block diagram of the transmit clock generator.

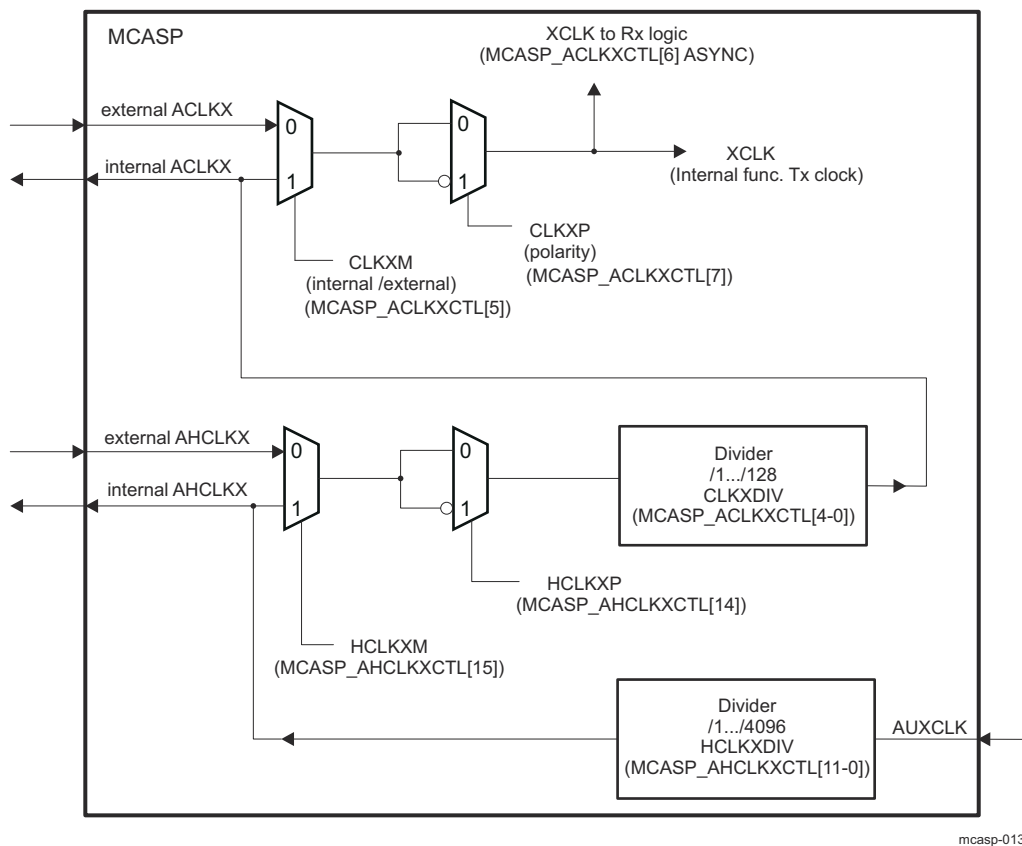

Figure 12-331. Transmit Clock Generator Block Diagram

Note

In this device:

- ACLKX is mapped on the device ball ACLKX
- internal AHCLKX is mapped on the device balls AUDIO_EXT_REFCLK[0-1]
- external AHCLKX is mapped on MCASPi_AHCLKX clock from the Device Configuration

For more information about MCASP integration, see *MCASP Environment* and *MCASP Integration*.

12.5.2.3.2.2 MCASP Receive Clock

The MCASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- MCASP_ACLKRCTL
- MCASP_AHCLKRCTL

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the MCASP_ACLKRCTL[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKRCTL[4-0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in [Section 12.5.2.3.2](#)) and the MCASP_AHCLKRCTL[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKRCTL[11-0] HCLKRDIV bit field) from the MCASP internal clock source AUXCLK.

Note

The polarity of ACLKR can be controlled in the MCASP_ACLKRCTL[7] CLKRP bit, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in the MCASP_AHCLKRCTL[14] HCLKRP bit, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the MCASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see [Figure 12-331](#) and [Figure 12-332](#)) becomes source of the receive clock (RCLK output), when the MCASP_ACLKXCTL[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to [Section 12.5.2.3.2.4](#).

[Figure 12-332](#) presents the block diagram of the receive clock generator.

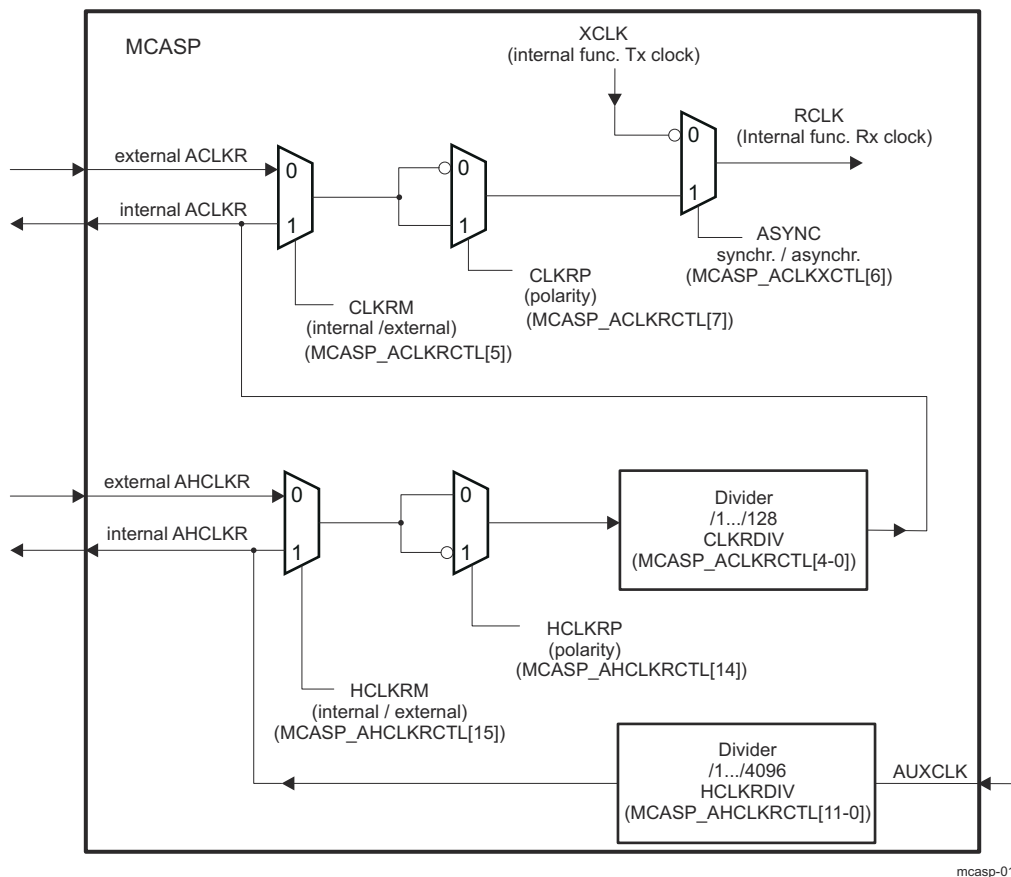

Figure 12-332. Receive Clock Generator Block Diagram

Note

In this device:

- ACLK is mapped on the device ball ACLK
- internal AHCLKX is mapped on the device balls AUDIO_EXT_REFCLK[0-1]
- external AHCLKR is mapped on Device Configuration MCASPi_AHCLKR from Device Configuration

12.5.2.3.2.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The MCASP frame sync generator logic is illustrated in [Figure 12-333](#). The I/O buffers are not part of the MCASP module, and are not shown in the figure.

Figure 12-333. Frame Sync Generator Block Diagram

For the transmit logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring MCASP_AFSXCTL[1] FSXM bit
- Frame-sync polarity: Rising edge or falling edge via configuring MCASP_AFSXCTL[0] FSXP bit
- Frame-sync width: "single bit" or "single word" via configuring MCASP_AFSXCTL[4] FXWID bit
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the MCASP_AFSXCTL[15-7] XMOD bit field, as follows:
 - For DIT mode (384 slots) - MCASP_AFSXCTL[15-7] XMOD = 0x180
 - For I2S mode (2 TDM slots) - MCASP_AFSXCTL[15-7] XMOD = 0x2
 - For TDM mode (from 3 to 32 TDM slots) - MCASP_AFSXCTL[15-7] XMOD bit field set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_XFMT[17-16] XDATDLY bit field

For the receive logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring MCASP_AFSRCTL[1] FSRM bit
- Frame-sync polarity: Rising edge or falling edge via configuring MCASP_AFSRCTL[0] FSRP bit
- Frame-sync width: "single bit" or "single word" via configuring MCASP_AFSRCTL[4] FRWID bit
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the MCASP_AFSRCTL[15-7] RMOD bit field, as follows:
 - For I2S mode (2 TDM slots) - MCASP_AFSRCTL[15-7] RMOD = 0x2
 - For TDM mode (from 3 to 32 TDM slots) - MCASP_AFSRCTL[15-7] RMOD set in range 0x3 - 0x20
 - For the special 384-slot TDM mode - MCASP_AFSRCTL[15-7] RMOD = 0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in the MCASP_RFMT[17-16] RDATDLY bit field

- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to [Section 12.5.2.3.2.4, Synchronous and Asynchronous Transmit and Receive Operations](#).

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

Note

Certain restrictions apply to the receive and transmit logic settings, when the MCASP_ACLKXCTL[6] ASYNC bit is set to 0b0. They are described in [Section 12.5.2.3.2.4](#).

12.5.2.3.2.4 Synchronous and Asynchronous Transmit and Receive Operations

Synchronous Transmit and Receive Operations -

When the MCASP_ACLKXCTL[6] ASYNC bit is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the [Figure 12-332](#), with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When the MCASP_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP_DITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ * RMOD product value must equal XSSZ * XMOD product value)
- The settings in the MCASP_ACLKRCTL register are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

Asynchronous Transmit and Receive Operations -

When the MCASP_ACLKXCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

Note

Synchronous transmit and receive operations are allowed only in the MCASP TDM (I2S) mode (this is, when MCASP_DITCTL[0] DITEN = 0b0).

12.5.2.3.3 MCASP Frame Sync Feedback for Cross Synchronization

The device level requirement is to align frame syncs across McASP that may be feeding DACs with different formats but the same frequency.

The intent of is to provide a mechanism to check for the alignment of frame syncs. This works by feeding the frame sync of McASP into the a receive data pin of McASP. If this serializer is enabled as a receiver, then the frame sync of McASP will appear as receive data for McASP.

To adjust the McASP transmit bit clock, the MCASP_ACLKXCTL[17-16] CLKXADJ register bit field can be used to lengthen (write 0x2) or reduce (write 0x1) the McASP bit clock period in a one-shot fashion. After each adjustment the frame sync should be checked again and the process repeated until the two frame syncs are aligned.

This process is expected to be carried out once, before any audio transfers occur. It is not intended to be used for sample rate conversion but rather initial phase alignment of transmit data across McASP.

12.5.2.3.4 MCASP Serializers

The MCASP serializers shift serial data in (Rx) and out (Tx) of the MCASP. A given serializer n consists of a shift register (XRSRn) with a single-entry data buffer XRBUFn used either for transmitting (write accessible in the MCASP_XBUFn register) or for receiving (read accessible in the MCASP_RBUFn register) data. In addition, each serializer has a dedicated control register (MCASP_SRCTLn) and a serial bidirectional data pin - AXRn. The register MCASP_SRCTLn allows n -th serializer to be configured as a transmitter, receiver, or as inactive. There are transmit and receive data formatting units to support data alignment options of the MCASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSRn shifter configured as a receiver in the MCASP_SRCTLn register, shifts in data through MCASP corresponding device level bidirectional data pad AXRn. A given serializer XRSRn shifter configured as a transmitter in the MCASP_SRCTLn register, shifts out data on MCASP corresponding device level bidirectional data pad AXRn ($n = 0$ to 15).

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for MCASP there are at most a couple of zones, one for transmit and one for receive.

Figure 12-334 shows the serializer block diagram.

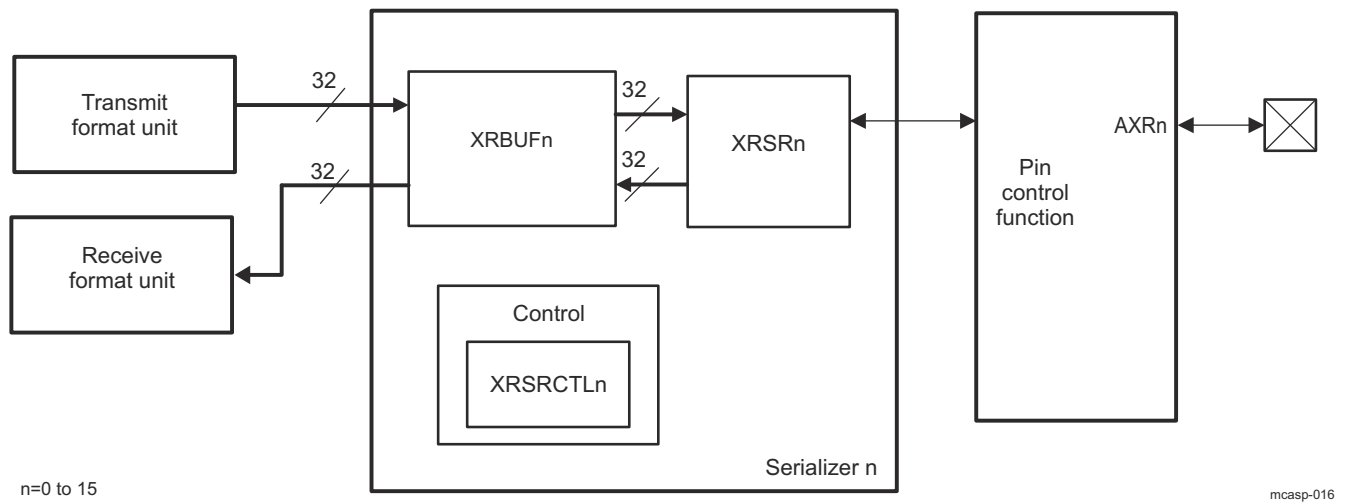

Figure 12-334. Individual Serializer and Connections Within MCASP

Transmission on the n -th serializer is performed as follows:

The MCASP is serviced by writing data into the MCASP_XBUFn register, which is an alias of the serializer data buffer - XRBUFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFn register in the serializer. The data is then copied from the XRBUFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

Reception from the n -th serializer is performed as follows:

The data is shifted into the MCASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFn, and can be accessed in the MCASP_RBUFn register, which is an alias of the serializer data buffer - XRBUFn for receive function. When software reads the data from this register, the MCASP passes the data through the receive format unit, hence it returns the formatted data.

Serializer controls:

A serializer n is configured as inactive via setting MCASP_SRCTLn[1-0] SRMOD bit field to 0x0.

For a transmitting serializer, the MCASP_SRCTLn[3-2] DISMOD bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting MCASP_SRCTLn[1-0] SRMOD bit field to 0x1.

Receive function for the n-th serializer is selected via setting MCASP_SRCTLn[1-0] SRMOD bit field to 0x2 (n = 0 to 15).

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see *S/PDIF Coding Format*.

12.5.2.3.5 MCASP Format Units

The MCASP has one transmit data formatting unit and one receive data formatting unit, shared between the device MCASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the MCASP only supports one transmit format at a time. For example, the MCASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the MCASP only supports one data format at a time, and this format applies to all receiving serializers.

Note

The MCASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP_RFMT/MCASP_XFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the MCASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the MCASP_RFMT/MCASP_XFMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in the MCASP_RFMT/MCASP_XFMT register means that the MCASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

12.5.2.3.5.1 Transmit Format Unit

The MCASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

Figure 12-335 shows the transmit formatting unit.

The MCASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
 - Left aligned = word shifted first, remaining bits are pad
 - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
 - MSB: most-significant bit of word is shifted out first, last bit is LSB

- LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register

- MCASP_XFMT:

- XRVRs: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

mcasp-017

Figure 12-335. Transmit Format Unit

As shown in [Figure 12-335](#), the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_XFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 12.5.2.3.11.1.3, Transfers Through the DATA Port](#), and [Section 12.5.2.3.11.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP_XMASK[31-0] XMASK contents. The masked data is then right-rotated to the MCASP_XFMT[2-0] XROT bit field positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

12.5.2.3.5.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots.

XSSZ should always be programmed to match the slot size of the serial stream.

Note

Note that, TDM word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the XROT field.

The [Table 12-381](#) show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The [Table 12-381](#) assumes that all slot size (SLOT in [Table 12-381](#)) and word size (WORD in [Table 12-381](#)) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter (typically Q31 or integer).

Table 12-381. MCASP TFU TDM Mode Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_XFMT bits	
			XROT ⁽¹⁾	XRVRS
MSB first ⁽²⁾	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first ⁽²⁾	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

12.5.2.3.5.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP_XFMT[17-16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP_XFMT[2-0] XROT =
 - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
 - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
 - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- MCASP_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.
- MCASP_XMASK[32] XMASK = 0xFFFFFFFF00 – 0xFFFFFFFF0000
- MCASP_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP_XFMT[2-0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.

- MCASP_XMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF
- MCASP_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in [Table 12-382](#) should be applied to MCASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the MCASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

Table 12-382. MCASP TFU DIT-Mode Example Settings

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFFF000	0x3
LEFT	24	8	0xFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated on the MCASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the [Table 12-382](#), the user must set XMASK = 0xFFFFF000, and to select a right-rotation to 12 positions (XROT = 0x3).

- After applying 0-s (XPAD = 0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF. Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVR = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the MCASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table MCASP TFU Example Settings, user is supposed to set XMASK = 0x0000FFFF, and to select right-rotation to 0 positions (XROT = 0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

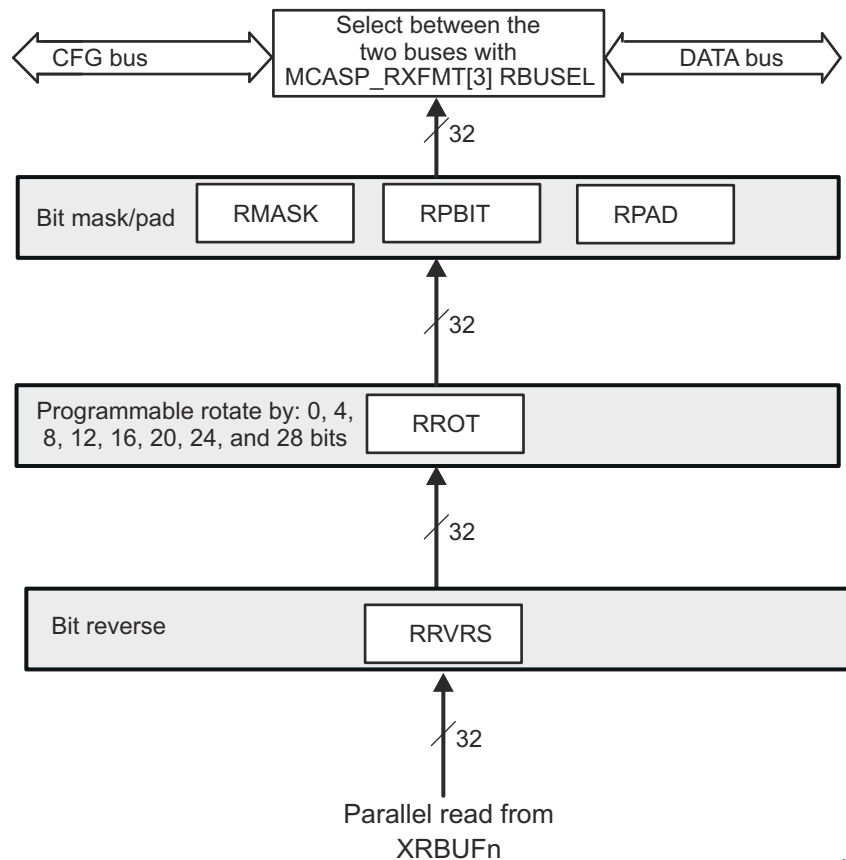

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

12.5.2.3.5.2 Receive Format Unit

The MCASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

[Figure 12-336](#) shows the receive format unit (RFU).

mcasp-018

Figure 12-336. Receive Format Unit

The MCASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
 - Left aligned = word shifted first, remaining bits are pad
 - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
 - MSB: most-significant bit of word is shifted out first, last bit is LSB
 - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - MCASP_RFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on [Figure 12-336](#), the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_RFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 12.5.2.3.11.1.3, Transfers Through the DATA Port](#), and [Section 12.5.2.3.11.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

12.5.2.3.5.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

Note

Note that the word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the RROT field.

Table 12-383 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

Table 12-383. MCASP RFU Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RFMT bits	
			RROT ⁽¹⁾	RRVRS
MSB first ⁽²⁾	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	$(32 - (\text{SLOT} - \text{WORD})) \% 32$	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first ⁽²⁾	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 12-383 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 12-336), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer).

12.5.2.3.6 MCASP State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the MCASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP_XFMT) and it reports the MCASP status and error conditions in the transmitter status register (MCASP_XSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP_RFMT) and it reports the MCASP status and error conditions in the receiver status register (MCASP_RSTAT).

12.5.2.3.7 MCASP TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of the MCASP_RTDM/MCASP_XTDM register and determines if the MCASP should receive/transmit in that time slot.

There are two possibilities for a slot: The MCASP either performs Rx/Tx operations during the time slot (transmit/receive bit is active), or the MCASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control MCASP_SRCTLn[3-2] DISMOD register. Refer also to Section 12.5.2.3.10.2.1, TDM Time Slots

Generation and Processing, for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

In case of a DIT-transmission (S/PDIF transfers): the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP_XBUF_n register during the current time slot (slot 1) is actually shifted out on the next time slot ($n = 0$ to 15).

The transmit TDM sequencer is controlled by the MCASP_XTDM register and reports the current transmit slot to the MCASP_XTDM_SLOT[9-0] XSLOT_CNT bit field.

12.5.2.3.8 MCASP Software Reset

The MCASP can be put into reset through the global transmit and receive control register (MCASP_GBLCTL). A valid serial clock must be supplied to the MCASP to assert the software reset bits in the MCASP_GBLCTL register.

12.5.2.3.9 MCASP Power Management

Table 12-384 describes power-management features available to the MCASP.

Table 12-384. Local Power-Management Features

Feature	Registers	Description
Slave clock stop modes	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	Force-clock stop, no-clock stop, and smart-clock stop modes are available.

CAUTION

No wakeup schema is supported for the MCASP. To ensure a correct behavior after enabling MCASP at device Device Configuration level, the user software is strongly recommended to choose *No Idle* mode, setting MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE bit field to 0x1. Before disabling MCASP at device Device Configuration level, user software is strongly recommended to choose a *Smart-Idle* mode, setting MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE bit field to 0x2.

12.5.2.3.10 MCASP Transfer Modes

12.5.2.3.10.1 Burst Transfer Mode

The MCASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

When operating in burst frame sync mode (see Figure 12-337), as specified for transmit (MCASP_AFSXCTL[15-7] = 0) and receive (MCASP_AFSRCTL[15-7] RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (MCASP_AFSRCTL[4] FRWID = 0, MCASP_AFSXCTL[4] FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF_n (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF_n (for every serializer set to operate as a receiver) has been read.

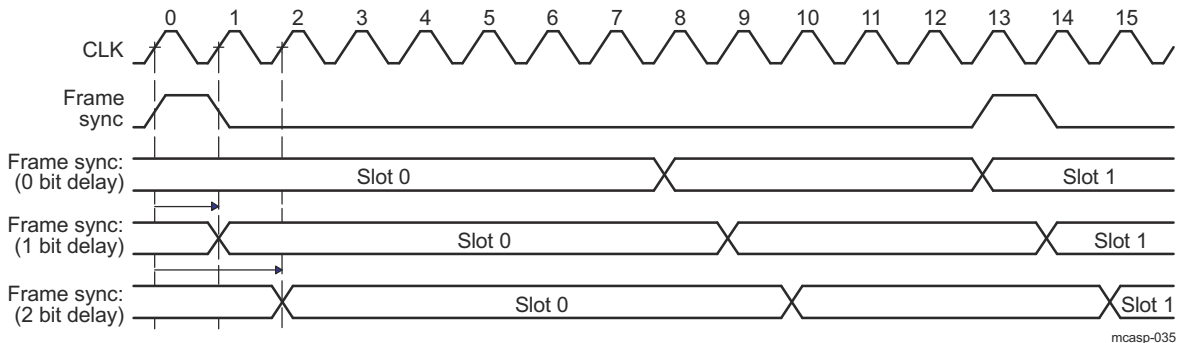

Figure 12-337. Burst Frame Sync Mode

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- MCASP_PFUNC: The clock, frame, data pins must be configured for MCASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_GBLCTL: Follow the initialization sequence in *MCASP Global Initialization*, to configure this register.
- MCASP_AMUTE: Not applicable. Leave at default.
- MCASP_DLBCTL: If loopback mode is desired, configure this register according to [Section 12.5.2.3.15, MCASP Loopback Modes](#), otherwise leave this register at default.
- MCASP_DITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- MCASP_RMASK/MCASP_XMASK: Mask desired bits according to [Section 12.5.2.3.5, MCASP Format Units](#).
- MCASP_RFMT/MCASP_XFMT: Program all fields according to data format desired. See [Section 12.5.2.3.5, MCASP Format Units](#).
- MCASP_RFMT/MCASP_XFMT: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. See [Section 12.5.2.3.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. See [Section 12.5.2.3.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP_RTDM/MCASP_XTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- MCASP_RINTCTL/MCASP_XINTCTL: Program all fields according to interrupts desired.
- MCASP_RCLKCHK/MCASP_XCLKCHK: Not applicable. Leave at default.
- MCASP_SRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default (n = 0 to 15).
- MCASP_DITCSRAi, MCASP_DITCSRBi, MCASP_DITUDRAi, MCASP_DITUDRBi: Not applicable. Leave at default (i = 0 to 5).

12.5.2.3.10.2 Time-Division Multiplexed (TDM) Transfer Mode

The MCASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in *TDM Format*.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to transmit

For more details on MCASP transmitting serializers clock and frame sync options, refer to the [Section 12.5.2.3.2.1, Transmit Clock](#), and [Section 12.5.2.3.2.3, Frame-Sync Generator](#).

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on MCASP receiving serializers clock and frame sync options, refer to [Section 12.5.2.3.2.2, Receive Clock](#), and [Section 12.5.2.3.2.3, Frame-Sync Generator](#).

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- MCASP_PFUNC: The clock, frame, data pins must be configured for MCASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_GBLCTL: Follow the initialization sequence is described in the [Section 12.5.2.4.1, MCASP Operational Modes Configuration](#).
- MCASP_AMUTE: Leave this register at default state.
- MCASP_DLBCTL: If loopback mode is desired, configure this register according to [Section 12.5.2.3.15](#), otherwise leave this register at default.
- MCASP_DITCTL: DITEN must be left at default 0 to select TDM mode (transmitters only).
- MCASP_RMASK/MCASP_XMASK: Mask desired bits according to [Section 12.5.2.3.5, MCASP Format Units](#).
- MCASP_RFMT/MCASP_XFMT: Program all fields according to data format desired. See the [Section 12.5.2.3.5, MCASP Format Units](#).
- MCASP_AFSRCTL/MCASP_AFSXCTL: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by MCASP. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. For more information, refer to [Section 12.5.2.3.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. For more details, refer to [Section 12.5.2.3.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP_RTDM/MCASP_XTDM: Program all fields according to the time slot characteristics desired.
- MCASP_XINTCTL: Program all fields according to transmit interrupts desired.
- MCASP_RCLKCHK/MCASP_XCLKCHK: Program all fields according to clock checking desired.
- MCASP_SRCTLn: Program all fields according to serializer operation desired (n = 0 to 15).

Note

The MCASP_DITCSRAi, MCASP_DITCSRBi, MCASP_DITUDRAi, MCASP_DITUDRBi (i = 0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

12.5.2.3.10.2.1 TDM Time Slots Generation and Processing

TDM mode on the MCASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the MCASP may be configured to participate or to be inactive by configuring MCASP_XTDM and/or MCASP_RTDM registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either MCASP_XTDM or MCASP_RTDM register to determine if the MCASP transmits/receives in that time slot.

Note

If a MCASP_XTDM/MCASP_RTDM bit defines an active slot (number of slot matches the bit position), the MCASP functions normally during that time slot; otherwise, the MCASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. MCASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP_SRCTLn[3-2] DISMOD (n = 0 to 15).

[Figure 12-338](#) shows when the transmit DMA event - XINT is generated. See [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#) for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUFFn to XRSRn generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

mcasp-019

Figure 12-338. Transmit DMA Event (XINT) Generation in TDM Time Slots

12.5.2.3.10.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The MCASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to MCASP frame) size is 384 samples. The receive TDM time slot register (MCASP_RTDm) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXRn, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set MCASP_AFSRCTL[15-7] RMOD bit field to 384 (0x180) to receive 384 time slots

12.5.2.3.10.3 DIT Transfer Mode

The DIT transfer mode of the MCASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see *S/PDIF Coding Format*.

12.5.2.3.10.3.1 Transmit DIT Encoding

When the MCASP operates in DIT mode, the data transmitted is output as a biphasemark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the MCASP. The MCASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

Note

The transmit TDM time slot register (MCASP_XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see [Section 12.5.2.3.5.1.2, DIT Mode Transmission Data Alignment Settings](#).

If the MCASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

12.5.2.3.10.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP_AFSXCTL):
 - Internally generated transmit frame sync, FSXM = 1
 - Rising-edge frame sync, FSXP = 0
 - Bit-width frame sync, FXWID = 0
 - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP_XFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- MCASP_PFUNC: The data pin - AXRn must be configured for MCASP function. If AHCLKX is used, it must also be configured for MCASP function. Other pins can be configured to function as GPIOs, if desired.
- MCASP_PDIR: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- MCASP_GBLCTL: Global initialization
- MCASP_AMUTE: Leave this register at default state.
- MCASP_DITCTL: The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as desired.
- MCASP_XMASK: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- MCASP_XFMT: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the [Section 12.5.2.3.5.1.2](#).
- MCASP_AFSXCTL: Configure the bits according to former discussions.
- MCASP_ACLKXCTL: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- MCASP_AHCLKXCTL: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- MCASP_XTDM: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP_XINTCTL: Program all fields according to the interrupts desired.
- MCASP_XCLKCHK: Program all fields according to the clock checking desired.
- MCASP_SRCTLn: Set SRMOD = 1 (transmitter) for the DIT pins (n = 0 to 15).
- MCASP_DITCSRAi and MCASP_DITCSRBi: Program the channel status bits as desired (i = 0 to 5).
- MCASP_DITUDRAi and MCASP_DITUDRBi: Program the user data bits as desired (i = 0 to 5).

Note

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphasic Mark Encoded Data - see *Biphase-Mark Code*).

12.5.2.3.10.3.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP_DITCSRAi and MCASP_DITCSRBi) and user data registers (MCASP_DITUDRAi and MCASP_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used (i = 0 to 5).

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP_DITCSRA0 to MCASP_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP_DITCSRB0 to MCASP_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP_DITUDRA0 to MCASP_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP_DITUDRB0 to MCASP_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in *S/PDIF Frame Format*. There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 12-385](#).

12.5.2.3.11 MCASP Data Transmission and Reception

The MCASP is serviced by writing data to the MCASP_XBUF_n registers for transmit operations, and by reading data from the MCASP_RBUF_n registers for receive operations. The MCASP sets status flags and notifies the software whenever data is ready to be serviced. The [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#), discusses data-ready status in details (n = 0 to 15).

The MCASP transmit/receive XRBUF_n buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA initiated data transfers on the device for MCASP transmit (Tx) purposes.
- Configuration bus (CFG): The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

[Section 12.5.2.3.11.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 12.5.2.3.11.1.4, Transfers Through the Configuration Bus \(CFG\)](#), discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in [Section 12.5.2.3.11.1.5, Using the device CPUs for MCASP Servicing](#), and [Section 12.5.2.3.11.1.6, Using the DMA for MCASP Servicing](#), respectively.

MCASP DATA port allows DMAs to access the MCASP transmit buffer more efficiently on the CBASS0, using burst transfers. The physical addresses to access these registers are listed in *DMA Registers*.

12.5.2.3.11.1 Data Ready Status and Event/Interrupt Generation

12.5.2.3.11.1.1 Transmit Data Ready

The transmit data ready flag - XDATA in the MCASP_XSTAT register reflects the data ready status of XRBUF_n buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUF_n to its corresponding XRSR_n shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUF_n is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in

its corresponding control register MCASP_SRCTLn[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP_XBUF_n is written to by the host, the MCASP_SRCTLn[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the MCASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_XBUF_n register has to be currently written. Once all requested MCASP_XBUF_n are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP_XSTAT[5] XDATA bit is written to 0b1, or once MCASP_XBUF_n registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the XINT event is automatically generated on MCASP[0-2]_XMIT_DMA_EVT line (if enabled in the MCASP_XEVTCTL register) to notify the DMA of the MCASP_XBUF_n empty status. An interrupt - MCASP[0-2]_XMIT_INTR_PEND can be also generated if the XDATA interrupt is enabled in the MCASP_XINTCTL register (for details, see [Section 12.5.2.3.13.1, Transmit Data Ready Interrupt](#)).

For DMA requests, the MCASP does not require that MCASP_XSTAT register be read between DMA events. This means that, even if MCASP_XSTAT register already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

[Figure 12-339](#) shows the timing details of when XINT is generated at the MCASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the MCASP sets the XDATA flag and generates an XINT event. However, it takes up to five MCASP interface clocks (XINT latency) before XINT is active at the MCASP boundary. Upon XINT, the CPU can begin servicing the MCASP by writing word C into the MCASP_XBUF_n (service time). The CPU must write word C into the MCASP_XBUF_n within the setup time required by the MCASP (setup time) ($n = 0$ to 15).

The maximum service time (see [Figure 12-339](#)) can be calculated as:

Service Time = Time Slot – XINT Latency – Setup Time

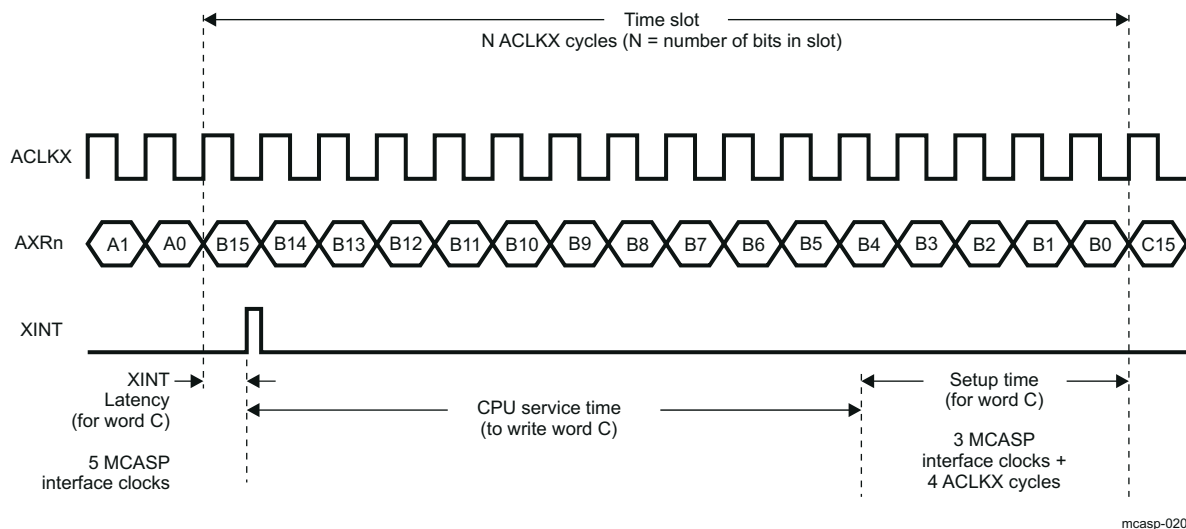

Figure 12-339. Service Time Upon Transmit DMA Event (XINT)

12.5.2.3.11.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the MCASP_RSTAT register reflects the data ready status of XRBUF_n buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSR_n to its corresponding XRBUF_n data buffer. Thus, the RDATA bit

indicates the global event that some of the receivers data buffer - RXBUF_n already contains received data (this is, a buffer is full) and is ready to transfer it to the host. The receive data ready event is individually indicated per serializer in its corresponding control register MCASP_SRCTL_n [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP_RBUF_n register is read from the host, the MCASP_SRCTL_n [5] RRDY bit is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the MCASP host (RDATA = 0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_RBUF_n register has to be currently read. Once all requested MCASP_RBUF_n registers are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

The global RDATA flag can be cleared when the MCASP_RSTAT[5] RDATA bit is written to 0b1, or once MCASP_RBUF_n registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA flag is set, the RINT event is automatically generated on MCASP[0-2]_REC_DMA_EVT line (if enabled in the MCASP_PIDTCTL register) to notify the DMA of the MCASP_RBUF_n full status. An interrupt - MCASP[0-2]_REC_INTR_PEND can be also generated if the RDATA interrupt is enabled in the MCASP_RINTCTL register (for details, see [Section 12.5.2.3.13.1, Receive Data Ready Interrupt](#)).

[Figure 12-340](#) shows the timing details of when RINT event is generated at the MCASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the MCASP sets the RDATA flag and generates an RINT event. However, it takes up to five MCASP interface clocks (RINT Latency) before RINT is active at the MCASP boundary. Upon RINT, the CPU can begin servicing the MCASP by reading Word A from the MCASP_RBUF_n (service time). The CPU must read Word A from the MCASP_RBUF_n register no later than the setup time required by the MCASP (Setup Time) ($n = 0$ to 15).

The maximum service time (see [Figure 12-340](#)) can be calculated as:

Service Time = Time Slot - RINT Latency - Setup Time

Figure 12-340. CPU Service Time Upon Receive Event (RINT)

12.5.2.3.11.1.3 Transfers Through the Data Port (DATA)

CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the MCASP_XFMT/MCASP_RFMT register, respectively. Failure to do so may result in software malfunction.

In a typical MCASP transfer scenario, the DMA Controller write accesses the XRBUF_n transmit buffer through the MCASP data port (DATA) on CBASS0 Interconnect. CPU hosts can access both XRBUF_n transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the MCASP Tx buffer through Interconnect DATA port location. Refer to *DMA Registers*. Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in [Section 12.5.2.3.12](#).

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in *DMA Registers*, the same physical DATA port address is used regardless of a read or write access is performed. The MCASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

Note

DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the MCASP configuration registers addressing their corresponding MCASP DATA port.

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port address) to service all of the active slot transmitting serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See *DMA Registers*).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

Note

For write transfers through MCASP DATA port it is preferable to use DMA on corresponding Interconnect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port address) to service all of the active slot receiving serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See *DMA Registers*).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the CPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0, 1 and 3 in this exact order, upon each receive data ready event.

Note

To service a serializer for a transmit or receive operation through the MCASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to *DMA Registers*), respectively.

Note

When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in MCASP_XTDM) and *transmit* (Tx enabled in MCASP_SRCTLn) within each time slot. Failure to do so results in a buffer underrun condition (see [Section 12.5.2.3.16.1, Buffer Underrun Error - Transmitter](#)). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in MCASP_RTDM) and *receive* (Rx enabled in MCASP_SRCTLn) within each time slot. Failure to do so results in a buffer overrun condition (see [Section 12.5.2.3.16.2, Buffer Overrun Error - Receiver](#)) (n = 0 to 15).

12.5.2.3.11.4 Transfers Through the Configuration Bus (CFG)**CAUTION**

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the MCASP_XFMT/MCASP_RFMT registers, respectively. Failure to do so may result in software malfunction.

Note

MCASP[0-2] whose data ports are accessible directly via CBASS0 do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In this method, the CPU accesses the XRBUF_n transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUF_n transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of MCASP CFG port actual for CBASS0 accesses. The XRBUF_n buffer of the n-th serializer configured as a transmitter is aliased - MCASP_XBUF_n in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the MCASP_XBUF2 register. Similarly, the XRBUF_n buffer of the n-th serializer configured as a receiver is aliased - MCASP_RBUF_n in the CFG port address space. For example, the XRBUF3 receive buffer is mapped as the MCASP_RBUF3 register.

Accessing the XRBUF through the DATA port (see [Section 12.5.2.3.11.1.3](#)) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index, while accessing through the peripheral configuration port - CFG, the CPU must provide the exact MCASP_XBUF_n or MCASP_RBUF_n address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP_XBUF_n and MCASP_RBUF_n addresses corresponding to MCASP CFG port, see *CFG Registers* (n = 0 to 15).

12.5.2.3.11.1.5 Using a Device CPU for MCASP Servicing

The device CPUs can be used to service the MCASP transmit channels through interrupts (upon MCASP[0-2]_XMIT_INTR_PEND and MCASP[0-2]_REC_INTR_PEND interrupts). Because these interrupt events are connected to device COMPUTE_CLUSTER0, PRU_ICSSG0/1, MAIN2MCU_LVL_INTRTR0, R5FSS0/1_INTRTR0, C66SS0/1_INTRTR0, R5FSS0/1 modules, they could be software mapped to input interrupt lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP_XSTAT register and RDATA bit in the MCASP_RSTAT register can be performed by device CPUs, respectively. As discussed in [Section 12.5.2.3.11.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 12.5.2.3.11.1.4, Transfers Through the Configuration Bus \(CFG\)](#), the device CPUs can access MCASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the MCASP through interrupts, the XDATA/RDATA bit must be enabled in the respective MCASP_XINTCTL/MCASP_RINTCTL registers, to generate interrupts MCASP[0-2]_XMIT_INTR_PEND/MCASP[0-2]_REC_INTR_PEND to the device CPUs upon data ready

12.5.2.3.11.1.6 Using the DMA for MCASP Servicing

Note

The associated static Transfer Request (TR) operations of PDMA0, located in front of MCASP, must be configured to match the MCASP configuration. For more information, refer to *DMA Controllers*.

The typical scenario is to use the DMA to service the MCASP transmit and receive logic through the DATA port. The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see [Figure 12-330](#)). The data transfer is managed by the AFIFO according to generated transmit and receive events in the MCASP and data is fed to transmit buffers and fetched from receive buffers as described in [Section 12.5.2.3.12, MCASP Audio FIFO \(AFIFO\)](#). The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from MCASP module, these events are collected in AFIFO and on specific AFIFO conditions described in [Section 12.5.2.3.12, MCASP Audio FIFO \(AFIFO\)](#) the requests (transmit or receive) are forwarded to a DMA controller via MCASP[0-2]_XMIT_DMA_EVT and MCASP[0-2]_REC_DMA_EVT outputs. If the AFIFO is disabled (default state) it is transparent for the MCASP module and all request are directly sent to the DMA controller.

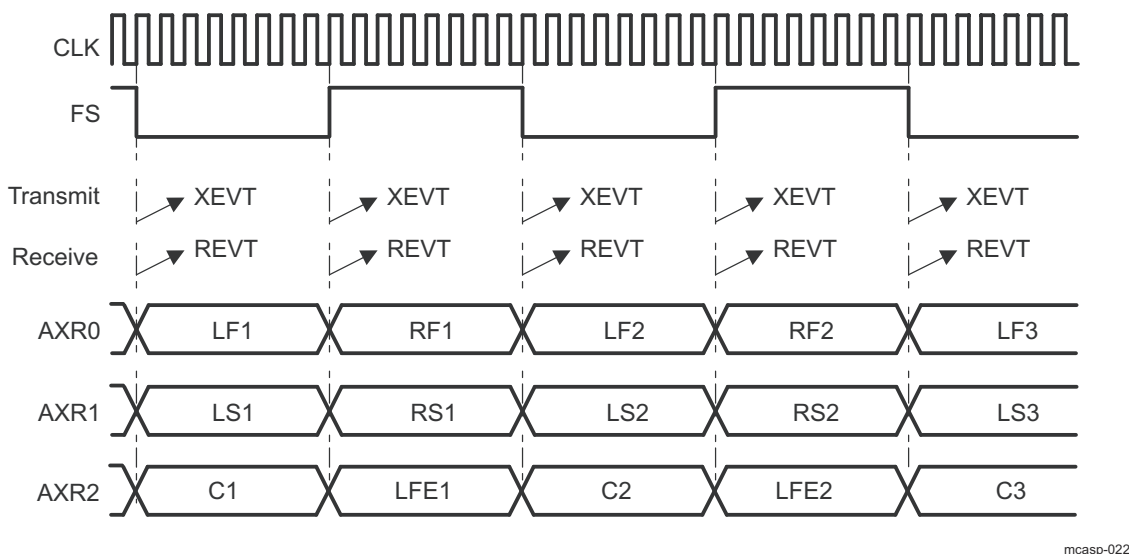

Figure 12-341. DMA Transmit and Receive Event in an Audio Example – One Event

In transmit mode, the DMA event - XINT (MCASP[0-2]_XMIT_DMA_EVT output), which is triggered upon each XDATA transition from 0 to 1, is used to service the MCASP TXBUF_n transmit buffers. In receive mode, the DMA event RINT (MCASP[0-2]_REC_DMA_EVT output) which is triggered upon each RDATA transition from 0 to 1, is used to service the MCASP RXBUF_n receive buffers.

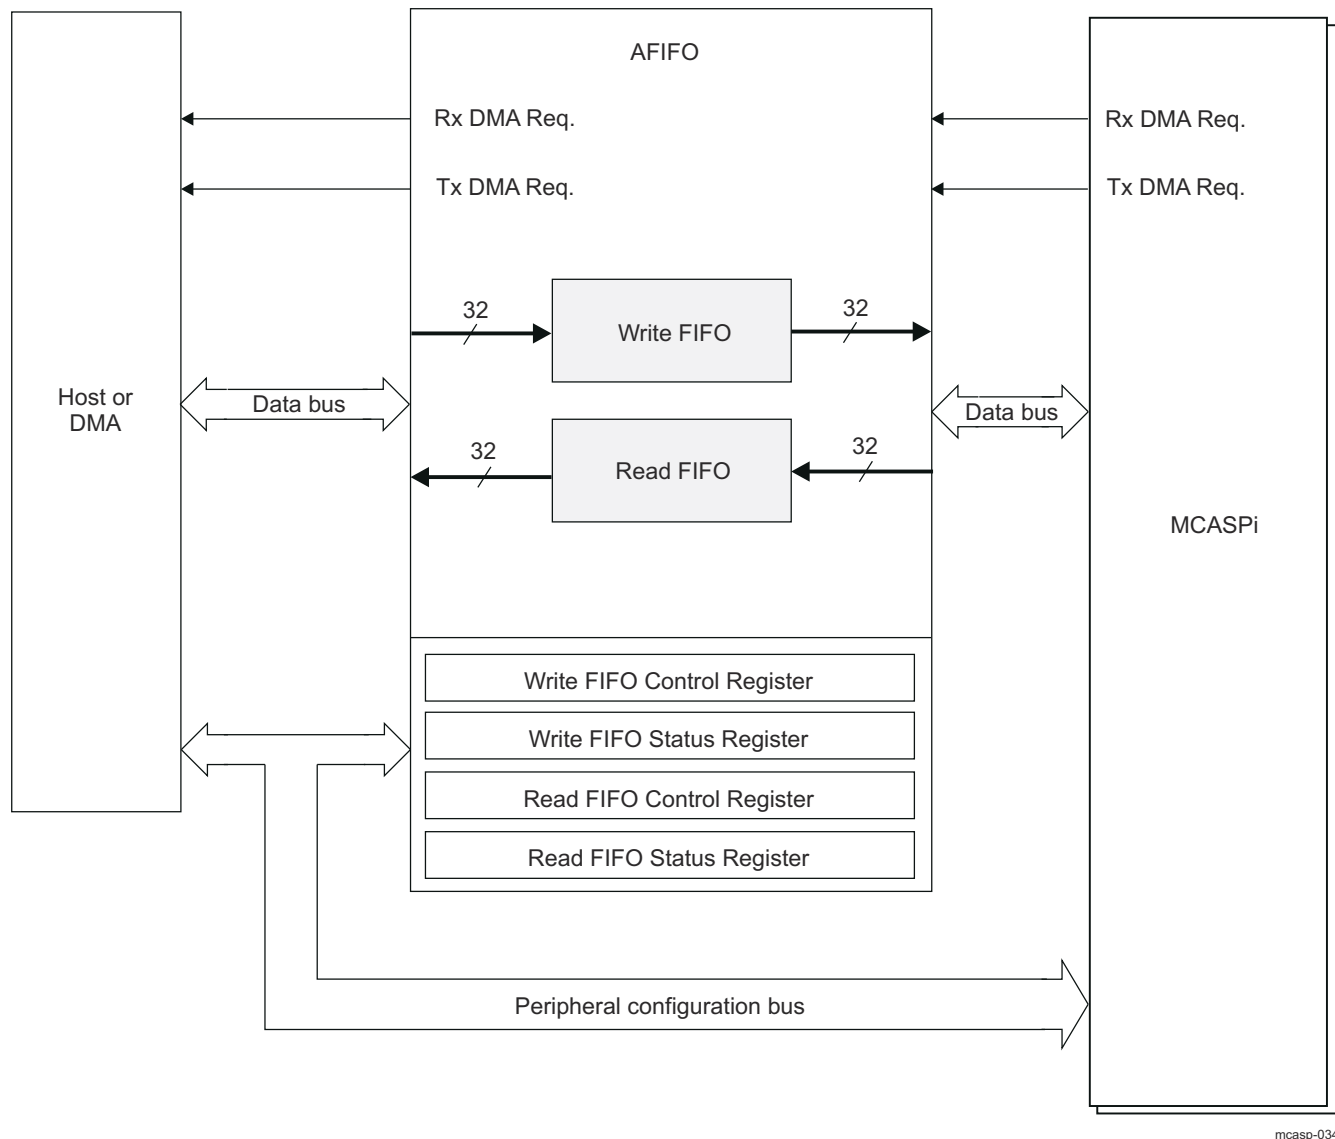

[Figure 12-341](#) is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the MCASP signals - AXR0, AXR1 and AXR2. It shows the points at which events XINT/RINT are triggered.

In [Figure 12-341](#), a Tx DMA event XINT is triggered on each time slot. In the example, XINT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP_XEVTCTL register. Similarly, Rx DMA event RINT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP_PIDTCTL register.

12.5.2.3.12 MCASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See [Figure 12-342](#) for a high-level block diagram of the AFIFO.

The AFIFO may be enabled/disabled and configured via the MCASP_WFIFOCTL and MCASP_RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the MCASP.

mcasep-034

Figure 12-342. MCASP Audio FIFO (AFIFO) Block Diagram

12.5.2.3.12.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the MCASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the MCASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the MCASP. When the Write FIFO is enabled, transmit DMA requests from the MCASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the MCASP, the WFIFO writes WNUMDMA 32-bit words to the MCASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the MCASP (see description for the MCASP_WFIFOCTL[7-0] WNUMDMA). If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

12.5.2.3.12.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, MCASP_WFIFOCTL[15-8] WNUMEVT bit field should be set to a non-zero integer multiple of the value in MCASP_WFIFOCTL[7-0] WNUMDMA bit field. If transmit DMA event pacing is not desired, then the value in MCASP_WFIFOCTL[15-8] WNUMEVT bit field should be set equal to the value in MCASP_WFIFOCTL[7-0] WNUMDMA bit field.

12.5.2.3.12.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from MCASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the MCASP generates receive DMA requests as needed; the AFIFO is “invisible” to the MCASP. When the Read FIFO is enabled, receive DMA requests from the MCASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the MCASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the MCASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the MCASP (see description for the MCASP_RFIFOCTL[7-0] RNUMDMA). If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than RNUMEVT words, those words will be read correctly, emptying the FIFO.

12.5.2.3.12.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least RNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once RNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another RNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, MCASP_RFIFOCTL[15-8] RNUMEVT bit field should be set to a non-zero integer multiple of the value in MCASP_RFIFOCTL[7-0] RNUMDMA bit field. If receive DMA event pacing is not desired, then the value in MCASP_RFIFOCTL[15-8] RNUMEVT bit field should be set equal to the value in MCASP_RFIFOCTL[7-0] RNUMDMA bit field.

12.5.2.3.12.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

12.5.2.3.13 MCASP Events and Interrupt Requests

[Table 12-386](#) lists all the transmit event flags. [Table 12-387](#) lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any MCASP serializer configured as transmitter or receiver respectively.

Table 12-386. TX Events

Event Mask ⁽¹⁾	Event Flag	Map to ⁽¹⁾	Description
MCASP_XINTCTL[0] XUNDRN	MCASP_XSTAT[0] XUNDRN	MCASP[0-2]_XMIT_INTR_PEND	Transmit buffer underrun
MCASP_XINTCTL[1] XSYNCERR	MCASP_XSTAT[1] XSYNCERR	MCASP[0-2]_XMIT_INTR_PEND	Unexpected transmit frame sync

Table 12-386. TX Events (continued)

Event Mask ⁽¹⁾	Event Flag	Map to ⁽¹⁾	Description
MCASP_XINTCTL[2] XCKFAIL	MCASP_XSTAT[2] XCKFAIL	MCASP[0-2]_XMIT_INTR_PEND	Transmit clock failure
MCASP_XINTCTL[3] XDMAERR	MCASP_XSTAT[7] XDMAERR	MCASP[0-2]_XMIT_INTR_PEND	DATA port transmit error
MCASP_XINTCTL[4] XLAST	MCASP_XSTAT[4] XLAST	MCASP[0-2]_XMIT_INTR_PEND	Transmit last slot interrupt
MCASP_XINTCTL[5] XDATA	MCASP_XSTAT[5] XDATA	MCASP[0-2]_XMIT_INTR_PEND	Transmit data-ready interrupt
MCASP_XINTCTL[7] XSTAFRM	MCASP_XSTAT[6] XSTAFRM	MCASP[0-2]_XMIT_INTR_PEND	Transmit start of frame interrupt
n.a.	MCASP_XSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR XCKFAIL XUNDRN XSYNCERR). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_XSTAT[3] XTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every MCASP module generates separate interrupt event.

Table 12-387. RX Events

Event Mask ⁽¹⁾	Event Flag	Map to ⁽¹⁾	Description
MCASP_RINTCTL[0] ROVRN	MCASP_RSTAT[0] ROVRN	MCASP[0-2]_REC_INTR_PEND	Receive buffer overrun
MCASP_RINTCTL[1] RSYNCERR	MCASP_RSTAT[1] RSYNCERR	MCASP[0-2]_REC_INTR_PEND	Unexpected receive frame sync
MCASP_RINTCTL[2] RCKFAIL	MCASP_RSTAT[2] RCKFAIL	MCASP[0-2]_REC_INTR_PEND	Receive clock failure
MCASP_RINTCTL[3] RDMAERR	MCASP_RSTAT[7] RDMAERR	MCASP[0-2]_REC_INTR_PEND	DATA port receive error
MCASP_RINTCTL[4] RLAST	MCASP_RSTAT[4] RLAST	MCASP[0-2]_REC_INTR_PEND	Receive last slot
MCASP_RINTCTL[5] RDATA	MCASP_RSTAT[5] RDATA	MCASP[0-2]_REC_INTR_PEND	Receive data-ready
MCASP_RINTCTL[7] RSTAFRM	MCASP_RSTAT[6] RSTAFRM	MCASP[0-2]_REC_INTR_PEND	Receive start of frame
n.a.	MCASP_RSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR RCKFAIL ROVRN RSYNCERR). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RSTAT[3] RTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every MCASP module generates separate interrupt event.

Software has to read the MCASP_XSTAT/MCASP_RSTAT register to determine which event occurs at a global level for MCASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the MCASP_SRCTLn registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASP[0-2]_XMIT_INTR_PEND) is asserted (active high) when one of the MCASP_XSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_XINTCTL bit. Similarly, a Rx interrupt line (MCASP[0-2]_REC_INTR_PEND) is asserted (active high) when one of MCASP_RSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_RINTCTL bit. See also [Section 12.5.2.3.13.4, Multiple Interrupts](#) and the [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#) (n = 0 to 15).

12.5.2.3.13.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if the MCASP_XSTAT[5] XDATA bit is 1 and MCASP_XINTCTL[5] XDATA bit is enabled. The [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when XDATA is set in the MCASP_XSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

12.5.2.3.13.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if the MCASP_RSTAT[5] RDATA bit is 1 and MCASP_RINTCTL[5] RDATA bit is enabled. The [Section 12.5.2.3.11.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when the MCASP_RSTAT[5] RDATA bit is set.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

12.5.2.3.13.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP_XSTAT):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP_XINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP_RSTAT) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (MCASP_RINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_RSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

12.5.2.3.13.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in MCASP_XSTAT is set and the interrupt is enabled in MCASP_XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the MCASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP_XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in MCASP_XSTAT/MCASP_RSTAT and the interrupt enabled in MCASP_XINTCTL/MCASP_RINTCTL generates a request on the MCASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the MCASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the MCASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to MCASP_XSTAT/MCASP_RSTAT. If any interrupt requests are active after the write, a new request is generated on the MCASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

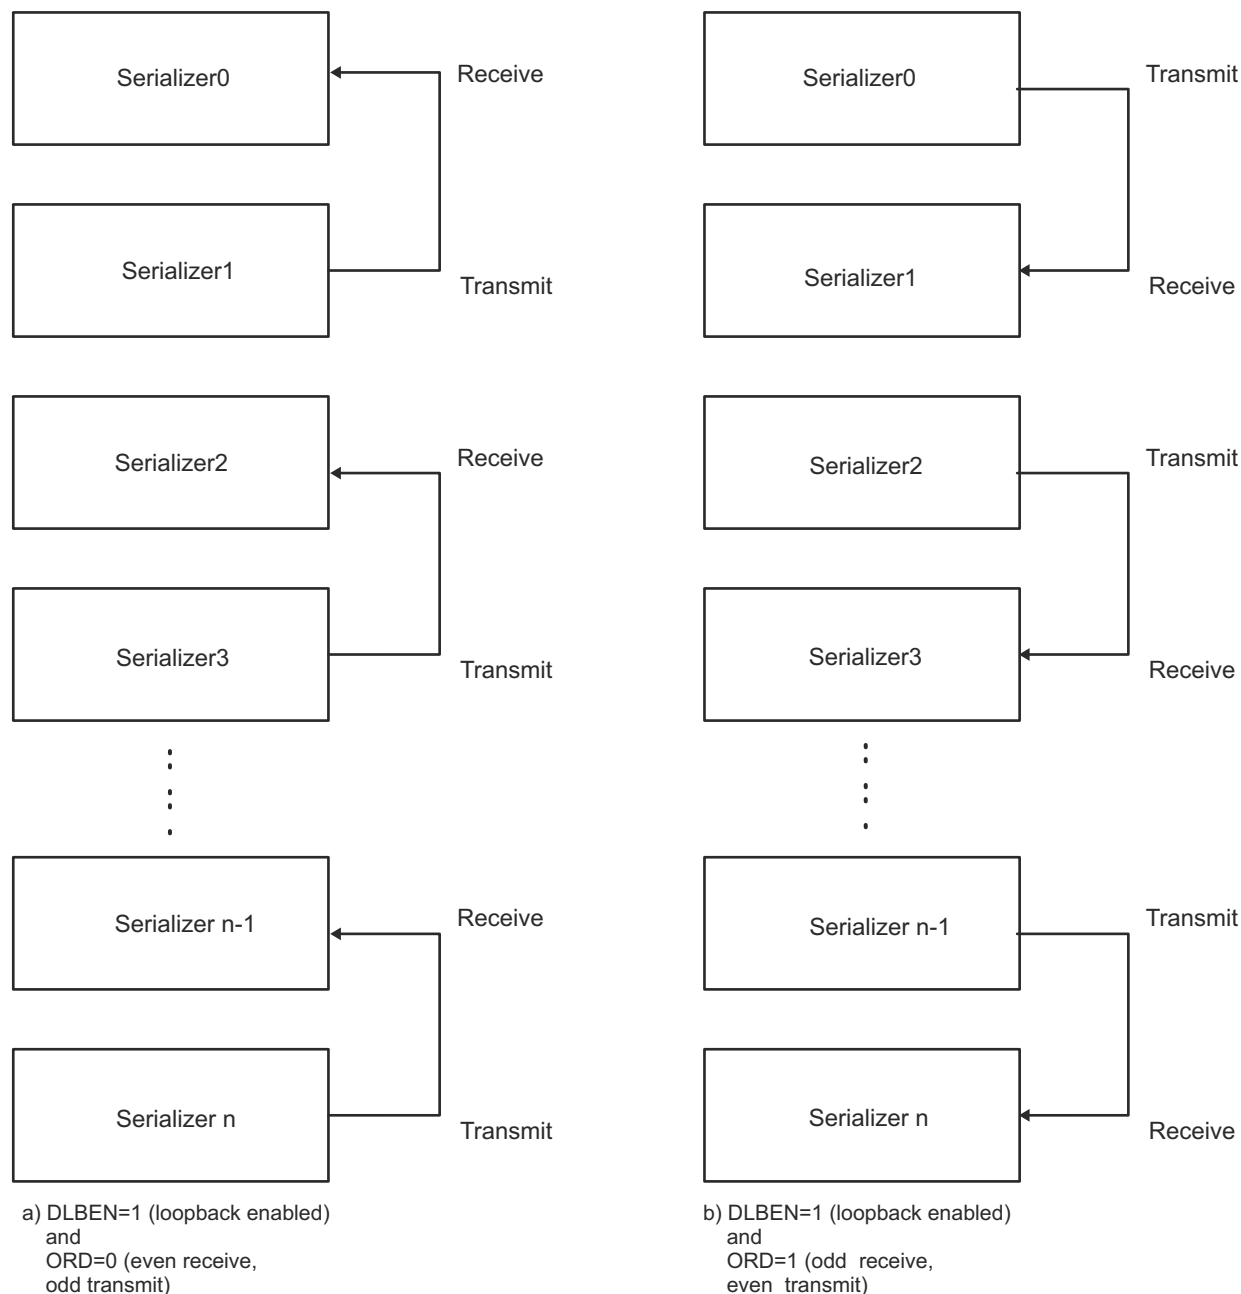

12.5.2.3.14 MCASP DMA Requests

The MCASP can generate one DMA request to the DMA controller to transmit (MCASP[0-2]_XMIT_DMA_EVT) or receive (MCASP[0-2]_REC_DMA_EVT) data. A DMA request to transmit data is generated if the MCASP_XEVTCTL[0] XDATDMA bit is cleared. A DMA request to receive data is generated if the MCASP_PIDTCTL[0] RDATDMA bit is cleared.

12.5.2.3.15 MCASP Loopback Modes

The MCASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between MCASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the MCASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

[Figure 12-343](#) shows the basic logical connection of the serializers in loopback mode.

mcasp-023

Figure 12-343. MCASP Serializers Operation in Loopback Mode

Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - MCASP_DLBCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (the MCASP_DLBCTL[4] IOLBEN bit) between a MCASP module internal loopback and a device I/O level loopback.

When a **MCASP internal loopback** is selected (MCASP_DLBCTL[4] IOLBEN = 0b0), it is NOT necessary to configure MCASP_PFUNC and MCASP_PDIR registers for MCASP pin settings. Nevertheless, data can be

optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a MCASP output pin by setting the corresponding MCASP_PFUNC bit to 0 (this is, to function as MCASP, not GPIO) and MCASP_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP_DLBCTL[4] IOLBEN = 0b1), the MCASP_PFUNC and MCASP_PDIR registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (this is, reaching device I/O buffers).

When in loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the MCASP. The transmit and receive sections operate synchronously. This is achieved by setting the MCASP_DLBCTL[3-2] MODE bit field to 0x1 and the MCASP_ACLKXCTL[6] ASYNC bit to 0b0.

12.5.2.3.15.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The MCASP_DLBCTL[0] DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal MCASP operation.
- The MCASP_DLBCTL[4] IOLBEN bit must be set to select between internal (MCASP local) loopback mode or device I/O level loopback mode.
- The MCASP_DLBCTL[3-2] MODE bit field must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP_DLBCTL[1] ORD bit must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The MCASP_ACLKXCTL[6] ASYNC bit must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The MCASP_AFSRCTL[15-7] RMOD bit field and MCASP_AFSXCTL[15-7] XMOD bit field must be set within range (0x2 - 0x20) to indicate TDM mode.

Note

Loopback mode does not apply to DIT or burst mode, because MCASP receivers do NOT natively support DIR - reception.

12.5.2.3.16 MCASP Error Reporting

The MCASP includes error-checking capability for the serial protocol and data underrun. In addition, the MCASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

12.5.2.3.16.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUF_n buffer to XRSR_n shift register, but the corresponding (MCASP_XBUF_n) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP_XSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it (n = 0 to 15).

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the MCASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the MCASP and start again with the proper initialization.

12.5.2.3.16.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding MCASP_RBUN register has not yet been read since the last time the transfer occurred. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting (n = 0 to 15).

An overrun is checked only once per time slot. The MCASP_RSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

12.5.2.3.16.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the MCASP_XSTAT[7] XDMAERR bit, occurs when the DMA or device CPU writes more words to the DATA port of the MCASP than it should.

The MCASP_XSTAT[7] XDMAERR = 0b1 indicates that the DMA or device CPU wrote too many words to the MCASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting the MCASP_XSTAT[0] XUNDRN bit.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the DMA or device CPU. The MCASP transmitter and the DMA must be reinitialized to resynchronize them.

12.5.2.3.16.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the MCASP_RSTAT[7] RDMAERR bit, occurs when the DMA or device CPU reads more words from the DATA port of the MCASP than it should.

The MCASP_RSTAT[7] RDMAERR bit indicates that the DMA or device CPU read too many words from the MCASP DATA port for a given receive RINT event. Reading too few words results in a receiver overrun error setting the MCASP_RSTAT[0] ROVRN bit.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the DMA or device CPU. The MCASP receiver and the DMA must be reinitialized to resynchronize them.

12.5.2.3.16.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the MCASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
 - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
 - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):

- Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
- Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

12.5.2.3.16.6 Clock Failure Detection

12.5.2.3.16.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP_XCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP_XSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
 - a. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP_XINTCTL)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP_RCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP_RSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
 - a. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register (MCASP_RINTCTL)

12.5.2.3.16.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see [Figure 12-344](#)) works off the internal MCASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (MCASP_XCLKCHK) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (the MCASP_XSTAT[2] XCKFAIL bit) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the MCASP_XSTAT[2] XCKFAIL transmit clock failure flag is set. This causes an interrupt if the MCASP_XINTCTL[2] XCKFAIL transmit clock failure interrupt enable bit is set.

mcaspl-024

Figure 12-344. Transmit Clock Failure Detection Circuit Block Diagram

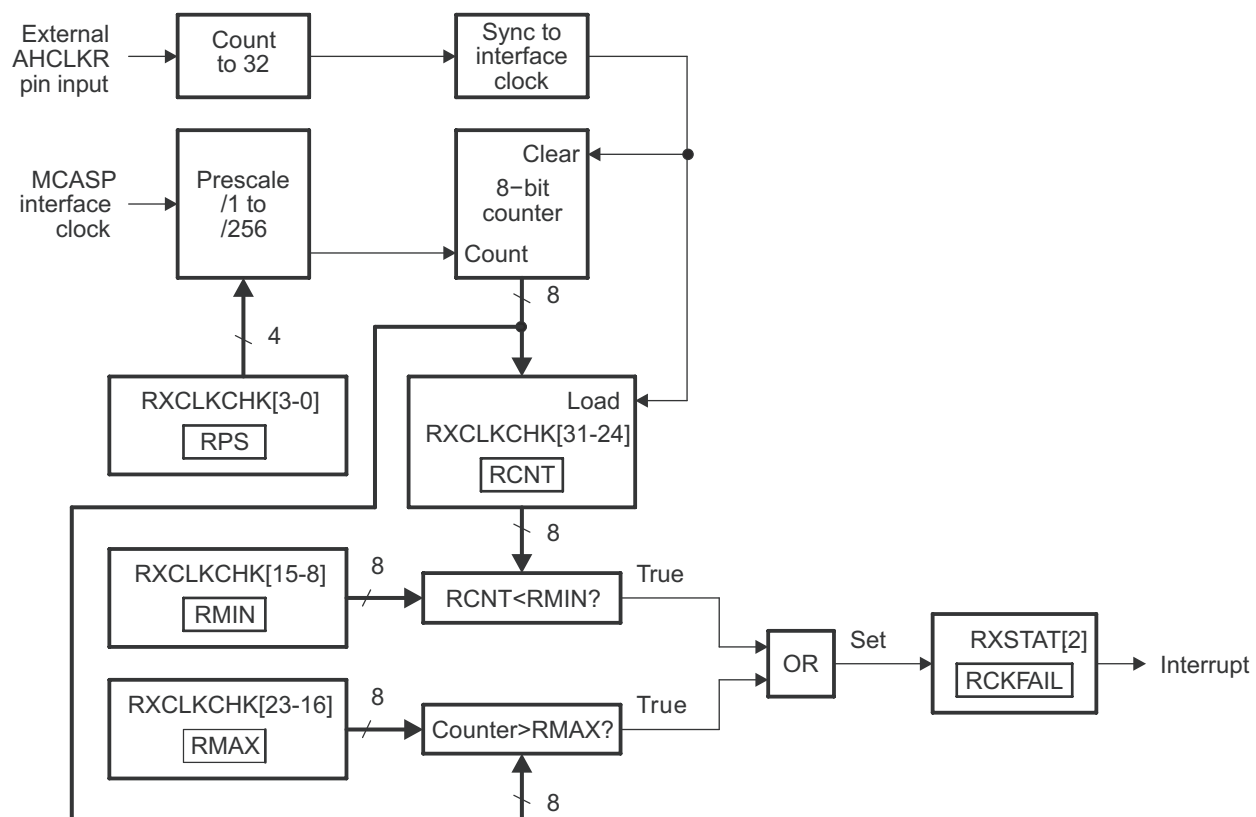

12.5.2.3.16.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (see [Figure 12-345](#)) works off both the internal MCASP interface clock and the external high-frequency serial clock (AHCLKR). It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP_RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (the MCASP_RSTAT[2] RCKFAIL bit) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

12.5.2.4 MCASP Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the MCASP module.

12.5.2.4.1 MCASP Operational Modes Configuration

12.5.2.4.1.1 MCASP Transmission Modes

12.5.2.4.1.1.1 Main Sequence – MCASP DIT- /TDM- Polling Transmission Method

Figure 12-346 shows the MCASP DIT-/TDM- polling method.

Figure 12-346. MCASP DIT- /TDM- Transmission Polling Method

These registers are for MCASP DIT-/TDM- transmission polling method: MCASP_XEVTCTL, MCASP_XSTAT, MCASP_GBLCTL, MCASP_XTDM, MCASP_XBUFn, MCASP_SRCTLn, MCASP_DITUDRAi, MCASP_DITUDRBi, MCASP_DITCSRAi, MCASP_DITCSRBi (n = 0 to 15 and i = 0 to 5).

Table 12-388 summarizes the subprocess call for the DIT-/TDM- transmission polling mode.

Table 12-388. Subprocess Call Summary for Main Sequence – MCASP DIT-/TDM- Transmission Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 12-352

12.5.2.4.1.1.2 Main Sequence – MCASP DIT- /TDM - Interrupt Transmission Method

[Figure 12-347](#) shows the initial setup for interrupt-based transmission.

Table 12-389 shows the configuration of the MCASP using an interrupt method for DIT-/TDM- transmission.

Table 12-389. MCASP DIT-/TDM- Interrupt Transmission Model

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_XINTCTL[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_XINTCTL[2] XCKFAIL	0x1
	MCASP_XINTCTL[1] XSYNCERR	0x1
	MCASP_XINTCTL[0] XUNDRN	0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update).	MCASP_XINTCTL[7] XSTAFRM	0x1
	MCASP_XINTCTL[4] XLAST	0x1
IF write transfer is through the MCASP DATA port (MCASP_XFMT[3] XBUSEL is set to 0b0).		
Software test condition (setting is done in step4 of the MCASP Transmitters Global Initialization - see MCASP Transmitters Global Initialization for DIT-Mode Operation)		
Enable the DATA port error based interrupt.	MCASP_XINTCTL[3] XDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_XINTCTL[3] XDMAERR	0x0
ENDIF		
DIT/TDM - Transmission Startup Procedure	See Figure 12-347 .	

These registers are for MCASP DIT-/TDM- transmission startup procedure: MCASP_GBLCTL, MCASP_XSTAT.

12.5.2.4.1.1.3 Main Sequence –MCASP DIT- /TDM - Mode DMA Transmission Method

[Table 12-390](#) shows the configuration of the ↓ using the DMA method for transmission. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the MCASP DATA port.

Table 12-390. MCASP DMA Transmission Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_XFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of MCASP DATA port usage.	MCASP_XINTCTL[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_XINTCTL[2] XCKFAIL	0x1
	MCASP_XINTCTL[1] XSYNCERR	0x1
	MCASP_XINTCTL[0] XUNDRN	0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_XINTCTL[7] XSTAFRM	0x1
	MCASP_XINTCTL[4] XLAST	0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_XINTCTL[5] XDATA	0x0
DMA startup transmission procedure. This procedure is identical than the one shown in Figure 12-347 . The only difference is that DMA automatically services all the XINT events raised by the MCASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 12-350 .	See Figure 12-347 .	

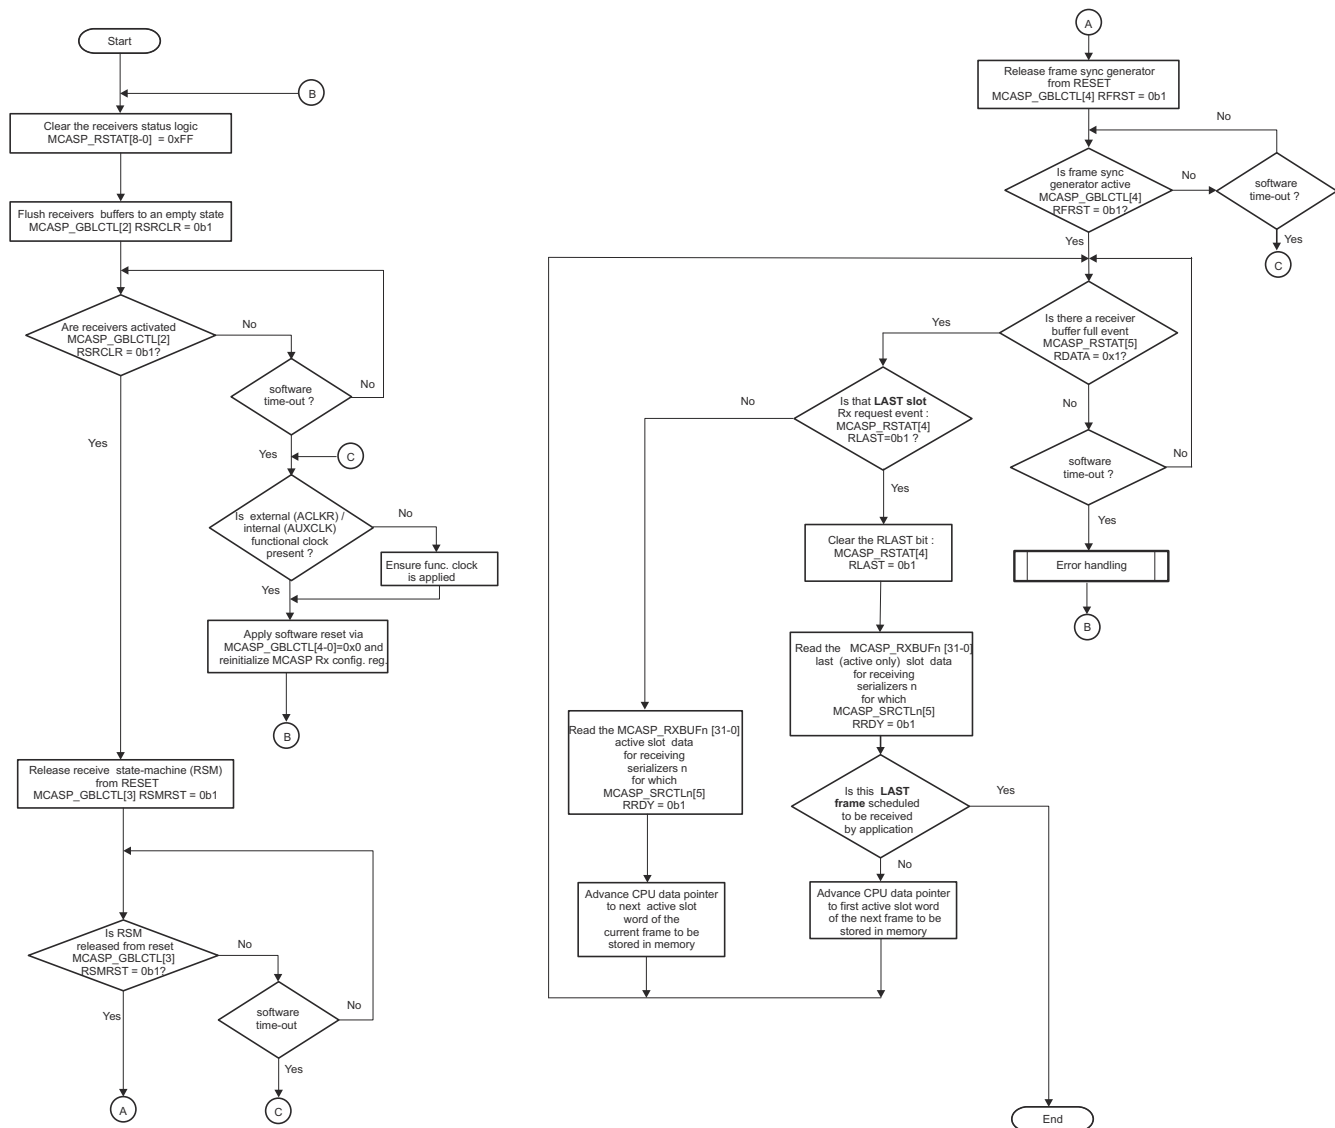

12.5.2.4.1.2 MCASP Reception Modes

12.5.2.4.1.2.1 Main Sequence – MCASP Polling Reception Method

[Figure 12-348](#) shows the MCASP polling reception method.

Note

The MCASP polling reception model considers the device CPUs as the accessor of audio data from the MCASP receive buffers.

mcasp-028

Figure 12-348. MCASP Polling Reception Method

These registers are for MCASP reception polling method: MCASP_RSTAT, MCASP_XGBLCTL, MCASP_RBUF_n, MCASP_SRCTL_n (n = 0 to 15).

[Table 12-391](#) summarizes the subprocess call for the polling mode.

Table 12-391. Subprocess Call Summary for Main Sequence – MCASP Reception Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 12-353

12.5.2.4.1.2.2 Main Sequence – MCASP TDM - Interrupt Reception Method

[Figure 12-349](#) shows the initial setup for interrupt-based reception.

Table 12-392 shows the configuration of the MCASP using an interrupt method for TDM- reception.

Table 12-392. MCASP TDM- Interrupt Reception Model

Step	Register/Bit Field/Programming Model	Value
Disable Rx DMA requests generation.	MCASP_PIDTCTL[0] RDATDMA	0x1
Enable the data ready event receive interrupt.	MCASP_RINTCTL[5] RDATA	0x1
Optional: Enable the receive error event interrupts.	MCASP_RINTCTL[2] RCKFAIL	0x1
	MCASP_RINTCTL[1] RSYNCERR	0x1
	MCASP_RINTCTL[0] ROVRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_RINTCTL[7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt	MCASP_RINTCTL[4] RLAST	0x1
IF read transfer is through the MCASP DATA port (MCASP_RFMT[3] RBUSEL is set to 0b0).		
Software test condition (setting is done in step4 of the <i>MCASP Receivers Global Initialization for TDM-Mode Operation</i> - see <i>MCASP Receivers Global Initialization for TDM-Mode Operation</i>)		
Enable the DATA port error based interrupt.	MCASP_RINTCTL[3] RDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_RINTCTL[3] RDMAERR	0x0
ENDIF		
TDM - Transmission Startup Procedure	See Figure 12-349 .	

These registers are for MCASP TDM- interrupt reception model: MCASP_XGBLCTL, MCASP_RSTAT.

12.5.2.4.1.2.3 Main Sequence – MCASP TDM - Mode DMA Reception Method

[Table 12-393](#) shows the configuration of the MCASP using the DMA method for reception. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the MCASP DATA port.

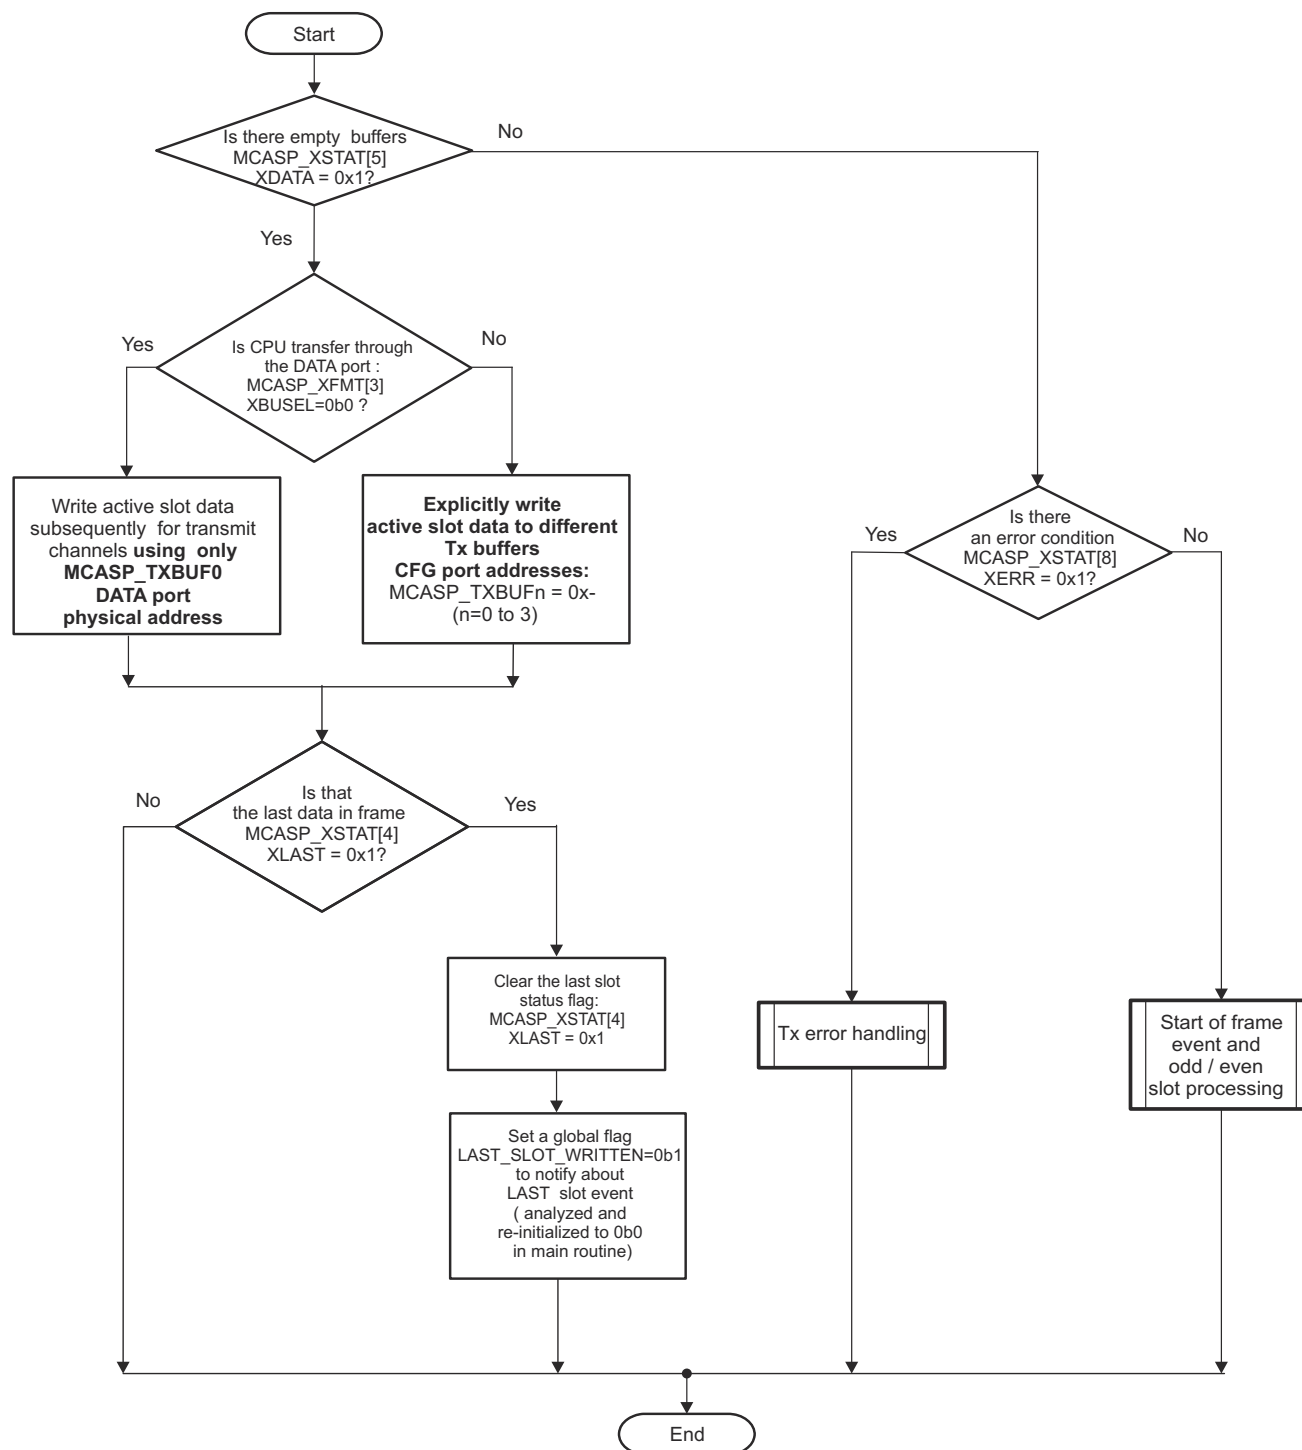

Table 12-393. MCASP DMA Reception Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_RFMT[3] RBUSEL	0x0
Enable the Rx DMA requests generation.	MCASP_PIDTCTL[0] RDATDMA	0x0
Enable the Rx DMA error event, because of MCASP DATA port usage.	MCASP_RINTCTL[3] RDMAERR	0x1
Optional: Enable the receive error event interrupts.	MCASP_RINTCTL[2] RCKFAIL	0x1
	MCASP_RINTCTL[1] RSYNCERR	0x1
	MCASP_RINTCTL[0] ROVRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_RINTCTL[7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt.	MCASP_RINTCTL[4] RLAST	0x1
Disable the data ready event receive interrupt, as DMA is used to service this request.	MCASP_RINTCTL[5] RDATA	0x0
DMA startup reception procedure. This procedure is identical than the one shown in Figure 12-349 . The only difference is that DMA automatically services all the RINT events raised by the MCASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 12-351 .	See Figure 12-349 .	

12.5.2.4.1.3 MCASP Event Servicing

12.5.2.4.1.3.1 MCASP DIT-/TDM- Transmit Interrupt Events Servicing

[Figure 12-350](#) shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the MCASP module.

mcasp-029

Figure 12-350. MCASP Transmit Interrupt Events Servicing

12.5.2.4.1.3.2 MCASP TDM- Receive Interrupt Events Servicing

12.6 Display Subsystem (DSS) and Peripherals

This section describes the Display Subsystem (DSS) in the device, integrated together with display peripherals, such as the MIPI Display Serial Interface (DSI) transmitter host controller with associated MIPI DSI (Physical Layer) D-PHY module (DPHY_TX), and the Embedded Display Port (eDP) transmitter with associated SerDes and auxiliary complex I/O (eDP AUXPHY) modules.

12.6.1 DSS Overview

The DSS is a flexible composition-enabled display subsystem, that supports multiple high resolution display outputs. It consists of a Display Controller (DISPC) and a Frame Buffer Decompression Core (FBDC). The DISPC supports a multi-layer blending and transparency for each of its display outputs. The DISPC also supports a write-back pipeline with scaling to enable memory-to-memory composition and/or to capture a display output for Ethernet video encoding. The DISPC supports gamma correction and programmable color control in both source and destination pipelines for enhanced color space control and video output quality. The DISPC video outputs connect to various display interface controllers, integrated at the SoC level, to drive specific displays in the end application. The DSS also includes freeze frame detection and data signature check capabilities for each display output path.

The MIPI DSI v1.3.1 Controller (DSITX) implements the stream arbitration and low-level protocol layer functionalities required by MIPI DSI 1.3 standard. It supports up to 4 x 2.5 Gbps D-PHY data lanes in a single-link configuration and handles the byte lane mapping per use case (1, 2, 3, or 4-lanes). The accompanying DSI (Physical Layer) D-PHY module (DPHY_TX) provides the video output interfacing by implementing a four-lane MIPI D-PHY transmitter.

The VESA DP1.4/eDP1.4 Compliant Transmitter Host Controller (EDP) can output up to 4 video streams (through Multiple Stream Transport / MST) and one audio stream through the 4-lane accompanying SerDes module. It provides up to 25.92 Gbps of application bandwidth. An additional auxiliary PHY (AUXPHY) module implements a doubly-terminated differential pair required for 1 Mbps data rates over a long (15m) cable. This is a half duplex, Manchester II encoded connection, used by the EDP to configure the link. The AUX channel is used to access the Display Port Configuration Data (DPCD) memory area in the sink device and to implement VESA Enhanced Extended Display Identification Data (EDID) function.

12.6.1.1 DSS Features

The Display Controller (DISPC) supports:

- An embedded DMA Controller with the following features:
 - Support for 1D-only DMA transfers
 - Support for 48b addressable memory space
 - Support for memory fragmentation through external PAT (Page Address Translation) table at SoC level
 - Integrated shared buffer management for pipelines within the same DMA controller group
 - Support for up to 8K-pixels wide frame buffer for 8/16/32/64 bits per pixel (total buffer space requirement not exceeding the total DMA buffer size of the DISPC)
 - Programmable DMA request management
 - Programmable buffer thresholds for request priority
 - Bandwidth limiter on write requests (insertion on idle cycles between requests)
 - Self-refresh using the DMA buffers
 - Arbitration between normal/low priority pipelines
 - Support for source image flip along X and Y-axis
 - Support for secure access to firewall protected frame buffer in DDR memory
- Two input display processing Video Pipelines, each supporting:
 - Input RGB source pixel formats:
 - Bitmap-1, Bitmap-2, Bitmap-4, Bitmap-8
 - ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555
 - RGB16-565/BGR16-565 with a separate A8 plane
 - RGB24-888, BGR24-888

- ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, ARGB32-2101010, ABGR32-2101010
- ARGB64-16161616, RGBA64-16161616
- Additionally, equivalent RGBx, xRGB, xBGR, and BGRx pixel formats defined, considering that A component of RGBA, ARGB, ABGR, BGRA pixel formats is ignored by HW (for example, ARGB → xRGB); ("A" can be ignored by not selecting Alpha pixel)
- Pre-multiplied ARGB/RGBA formats
- Input YUV source pixel formats:
 - Packed: YUV422-UYVY, YUV422-YUV2
 - 2-plane: YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21
 - 8-bit per component support for all YUV formats
 - 10-bit IMG pack-format and 12-bit TI fully packed format support for 420/422 (internally processed as 10-bit component data)
 - 16-bit unpacked source format (internally processed as 10-bit component data)
- Programmable poly-phase filter (scaler):
 - Independent horizontal and vertical re-sampling: up-sampling (up to x16) and down-sampling (down to x0.25)
 - Maximum input width of 2048 pixels using ARGB pixels and 5-tap, 4096 pixels using YUV pixels and 5-tap, and 4096 pixels using ARGB pixels and 3-tap. No limitation on the input height.
 - Alpha blending factor is re-scaled like the R, G and B color components
 - Implementation with 16 phases with symmetrical coefficients
- Programmable color space conversion from YUV422/YUV420 (chroma upsampled to YUV444 using the scaler) into ARGB48-12121212
- Programmable VC1 range mapping
- Programmable Brightness/Contrast/Hue/Saturation
- Programmable Gamma Correction LUT
- Luma Key generation
- 10-bit processing pipeline
- Two input display processing Video Lite Pipelines, each supporting:
 - Input RGB source pixel formats:
 - Bitmap-1, Bitmap-2, Bitmap-4, Bitmap-8
 - ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555
 - RGB16-565/BGR16-565 with a separate A8 plane
 - RGB24-888, BGR24-888
 - ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, ARGB32-2101010, ABGR32-2101010
 - ARGB64-16161616, RGBA64-16161616
 - Additionally, equivalent RGBx, xRGB, xBGR, and BGRx pixel formats defined, considering that A component of RGBA, ARGB, ABGR, BGRA pixel formats is ignored by HW (for example, ARGB → xRGB); ("A" can be ignored by not selecting Alpha pixel)
 - Pre-multiplied ARGB/RGBA formats
 - Input YUV source pixel formats:
 - Packed: YUV422-UYVY, YUV422-YUV2
 - 2-plane: YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21
 - 8-bit per component support for all YUV formats
 - 10-bit IMG pack-format and 12-bit TI fully packed format support for 420/422 (internally processed as 10-bit component data)
 - 16-bit unpacked source format (internally processed as 10-bit component data)
 - YUV420 to YUV422 chroma upsampling using an average filter
 - YUV422 to YUV444 chroma upsampling using a 4-tap filter based on Catmull-Rom algorithm
 - Programmable color space conversion from YUV422/YUV420 into ARGB48-12121212
 - Programmable VC1 range mapping
 - Programmable Brightness/Contrast/Hue/Saturation
 - Programmable Gamma Correction LUT
 - Luma Key generation

- 10-bit processing pipeline
- One Write-back (WB) pipeline, supporting:
 - Destination RGB pixel formats:
 - ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555
 - RGB24-888 (no support for BGR24-888)
 - RGB16-565/BGR16-565 with a separate A8 plane
 - ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, ARGB32-2101010, ABGR32-2101010
 - ARGB64-16161616, RGBA64-16161616
 - Destination YUV pixel formats:
 - Packed: YUV422-UYVY, YUV422-YUV2
 - 2-plane: YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21
 - Only 8-bit output support for YUV formats
 - Programmable poly-phase filter (scaler):
 - Independent horizontal and vertical re-sampling: up-sampling (up to x16) and down-sampling (down to x0.25). When the output format of the WB pipeline includes a format change RGB/YUV422 → YUV420, the maximum downscaling provided by the WB scaler is x0.5.
 - Maximum input width of 2048 pixels using ARGB pixels and 5-tap, 4096 pixels using YUV pixels and 5-tap, and 4096 pixels using ARGB pixels and 3-tap. No limitation on the input height.
 - Alpha blending factor is re-scaled like the R, G and B color components
 - Implementation with 16 phases with symmetrical coefficients
 - Operation modes:
 - Output capture mode (to save one of the display outputs)
 - Memory-to-memory (M2M) mode (to save a M2M composition/conversion operation result)
- Four Overlay Managers (OVR), each supporting:
 - Input pixel format: ARGB48-12121212
 - Output pixel format: ARGB48-12121212 ("A" component data is only used for the Write-back path)
 - Overlay of the input pipelines (fully mapped to all input pipelines)
 - Up to 4 input layers blending, plus background layer
 - Transparency color key (source and destination)
 - Alpha blending support: Embedded pixel alpha (ARGB and RGBA), global pixel, and combination of global pixel and pixel alpha
 - Z-order programmable (full flexibility)
 - Color bar test pattern insertion
 - Any overlay output can be selected to drive the Write-back pipeline
- Four Video Port (VP) display outputs, each supporting:
 - 36-bit per pixel on the RGB output interface (12-bits per component)
 - Independent programmable timing generator, supporting up to 600 MHz pixel clock video formats (actual support limited by the maximum pixel clock provided to DSS at SoC level)
 - Independent programmable 10-bit gamma correction
 - Independent programmable multiple cycles output format on 8/9/12/16-bit interface (TDM)
 - Selection between RGB and YUV422 output pixel format (YUV422 only available when BT.656/BT.1120 output is enabled)
 - Configurable VP output mode: progressive mode only on RGB output, or progressive/interlaced mode on BT.656/BT.1120 output
- Internal data check diagnostic features:
 - Supports up to 4 programmable (position/size) check regions on the DISPC video port display outputs
 - Support for 1 check region on each input video pipeline output
 - MISR (Multiple Input Signature Register) used on each check region to perform data correctness check and/or freeze frame detection
- Local power management features:
 - Low power saving modes
 - Capability to associate all buffers with a single pipeline for a display self-refresh
- System interconnect ports:

- Two 128-bit VBUSM master interfaces for data read/write
- One 32-bit VBUSP slave interfaces for configuration

MIPI Display Serial Interface (DSI) transmitter host controller supports:

- Compliance with MIPI DSI v1.3.1 protocol specification and previous specifications
- Compliance with MIPI Stereoscopic Display Formats (MIPI SDF v1.0) specification
- Video and command operational modes
- Both burst and non-burst modes for video mode data transmission (with either sync pulses or sync events)
- Up to 4 virtual channels via command mode
 - Supports data interleaving support for one synchronous stream (video mode) from the display controller, and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
 - Supports data interleaving for up to four interleaved asynchronous streams (virtual channels in command mode) from the interconnect
- Bi-directional communication and escape mode (only on Lane-0)
- Pixel clock rate range 25-330 MHz (10-bit/component, 4MPix @60fps performance). Actual performance is limited by the maximum pixel clock provided to the DSI controller at SoC level.
- Programmable display resolutions with maximum clock rate not exceeding the total available bandwidth over 4MPix @60fps (10-bit/component RGB)
- 16/18/24/30/36-bit RGB input data formats for video mode
- RGB16, RGB18 packed, and RGB24 input data formats for command mode
- All generic data types defined by MIPI
- Display Command Set (DCS): transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral
- ECC on the APB interface
- Data splitter for 2-, 3-, or 4-data lane configuration
- Connection to a single MIPI D-PHY complex I/O through an 8-bit Protocol Peripheral Interface (PPI)
- Bus contention recovery
- Video mode pattern generator: color bar pattern image and D-PHY BET testing pattern
- APB slave interface with 32-bit data and address for configuration

MIPI DSI (Physical Layer) D-PHY module supports:

- Compliance with MIPI D-PHY 1.2 physical layer interface specification and features
- 1, 2 or 4 data lanes, in addition to clock signaling
- Maximum data rate up to 2.5 Gbps per data lane
- Protocol Peripheral Interface (PPI)
- HS continuous and burst mode
- LP (Low-Power), ULPM (Ultra-Lower Power Mode), and Shutdown modes
- Forward direction and reverse direction escape modes (only on Lane-0)
- Automatic termination control in both high-speed and low-power modes
- DSI D-PHY IO pad signals work at/with electrical specification specified by requested standards
- Single 32-bit VBUSP slave interface

The Embedded Display Port (eDP) transmitter host controller supports:

- Compliance with VESA Display Port (DP) 1.3 (with 1.4 DSC/FEC support) specification
- Compliance with VESA embedded Display Port (eDP) 1.4 specification
- Static configuration of either DP or eDP mode
- Link rates up to HBR3 (maximum application bandwidth up to 25.92Gbps)
- Pixel clock rate range 25-600 MHz (10-bit/component, 8MPix@60fps performance).
- Transceiver AUX CH (1 MHz Manchester II coding mode) for access of DPCD and EDID
- 8, 10, and 12 bpc (bits per component), in RGB/YCbCr444 colorimetry formats (CEA-861 compliant) and YCbCr422 (via simple decimation)
- Data splitter for 1-, 2-, or 4-data lane configuration
- SST (Single Stream Transport)
- MST (Multiple Stream Transport):
 - Up to 4 video and up to 1 audio sources

- Support for up to 25 Gbps throughput (equivalent to approximately 4K + 2x4K streams) use case
- HDCP support on one video source
- DSC (Display Stream Compression) support on one 4K or 2x2.5K streams
- HDCP 1.4 and HDCP 2.2 with True Random Number Generator (TRNG with 8 FRO)
- DSC (Display Stream Compression) encoded stream data transport via an embedded DSC core:
 - Supports VESA DSC 1.1 compliant video compression at 2x~3x compression ratios
 - Supports all DSC 1.1 mandatory encoding mechanisms (MMAP, BP, MPP and ICH)
 - Supports configurable maximum display resolution up to 8Mpix @60fps including (but not limited to) 4K@60 (4096x2160), and up to 8K wide-aspect-ratio resolution displays
 - Supports two hard encoder slices (peak pixel ratio <= 340MP/s on each slice)
 - Supports 8 and 10 bits per video component
 - Supports RGB/YCbCr4:4:4 video input format (Native Encoding) only
 - Supports Dual pixel streams or Split panel input streams
 - Supports dual or single transport link
- Forward Error Correction (FEC) encoder with/without DSC enabled in DP mode
- Various eDP specific features:
 - eDP DPCD registers
 - Full and Fast Link Training
 - (Regional) backlights and multi-touch command over AUX channel
 - Alternate Scrambler Reset
- Audio transport features:
 - I2S (LPCM/IEC60948/619376) audio input stream
 - Audio transport of uncompressed multichannel (up to eight channels) via SDP (Secondary-data Packet)
- Metadata transport via MSA (Main Stream Attribute) packet or via SDP
- Display Port transmitter functionalities:
 - Scrambler
 - 8/10-bit Encoder (in the DPTX core)
 - Inter Lane Skew Insertion
 - Training Pattern Generation – TPS1,2,3,4 PRBS7 and 80-bit custom training pattern generation (bypassing the scrambler and encoder)
- PAPB Interface:
 - The primary APB slave port controls the HD Display controller from the host processor
 - During the boot, the primary APB slave port enables access to the I-MEM and D-MEM, and to the full address space for debugging purposes
 - After the boot, the primary APB slave port enables direct register access to designated HW modules and enables communication with uCPU through a mailbox channel
- SAPB Interface
 - For configuring the embedded HDCP, this bus is considered as a secured APB to carry secured commands over the mailbox channel
- Internal diagnostic features:
 - ECC on the critical memories
 - Parity check on the configuration interface
 - Encoder self-check diagnostics support in the DSC core
 - Corrected/Uncorrected error interrupt generation
 - Injection of ECC and parity errors

The DP (Physical Layer) SERDES and Aux PHY modules support:

- DP1.3 HBR3 and eDP1.4a HBR3 throughput
- 1, 2, or 4 lanes at 1.62 Gbps, 2.7 Gbps, 5.4 Gbps, and 8.1 Gbps per lane
- Additional link rates (2.16, 2.43, 3.24, 4.32 Gbps) per lane in eDP mode
- Reduced differential voltage swing (0.2/0.25/0.30/0.35/0.40/0.45) in eDP mode
- Hot Plug Detect (HPD) for connection detection and interrupt from sink
- Integrated Low Jitter, Fixed Bandwidth PLL
- 1 Mbps AUX PHY for link training, DPCD register access, HDCP authentication and EDID access.

12.6.2 DSS Environment

This section describes the interfaces handled by the Display Subsystem.

The DSS is capable of driving multiple displays in parallel, through a combination of interfaces:

- Two DPI parallel interfaces, directly delivered on SoC pads from DISPC Video Port (VP) outputs
- One MIPI Display Serial Interface (DSI)
- One Embedded DisplayPort (DP/eDP) interface

The pixel format mapping between the DISPC VP outputs and DPI, eDP, and DSI display peripherals varies depending on the interface used. The pixel bit color mapping for the DISPC VP outputs is as shown in [Figure 12-354](#).

Color Format	Pixel Width	Pixel Interface Mapping																																						
		35	34	33	32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
RGB565	16-bit																					R4				R0		G5					G0		B4					
RGB666	18-bit																				R5					R0		G5					G0		B5					
RGB888	24-bit																				R7						R0		G7					G0		B7				
RGB101010	30-bit																																							
RGB121212	36-bit																																							

dss-007

Figure 12-354. DSS Pixel Mapping on the DISPC Video Port Outputs

The pixel format support at a DISPC VP output when connected to each of the DPI, eDP, and DSI peripherals is as listed in [Table 12-401](#).

Table 12-401. DSS Pixel Format Interoperability between DISPC VP Output and DPI, eDP, and DSI

Pixel Format	DISPC VP Output Pixel Format	DPI Parallel Out	DSI		eDP
	DSS0_VP_CONTROL [10-8] DATALINES Register Field Value		DSI-DPI Interface	DSI-SDI Interface	
RGB565	0x1	Supported	Supported	Supported	Not supported
RGB666	0x2	Supported	Supported	Supported	Not supported
RGB888	0x3	Supported	Supported	Supported	Not supported
RGB101010	0x4	Not supported	Supported	Not supported	Supported
RGB121212	0x5	Not supported	Supported	Not supported	Supported

Note

The DISPC VP outputs are connected to the display peripherals through the Merge-Split-Sync (MSS) block. For more details, see *DISPC VP Merge-Split-Sync (MSS) Module*.

12.6.2.1 DISPC Environment

Figure 12-355 shows the DSS DPI parallel interface signals. The output data bus of the DISPC video ports is 36 bits wide. The DSS DPI parallel interface uses up to the 24 LSB bits [23:0] of the data bus.

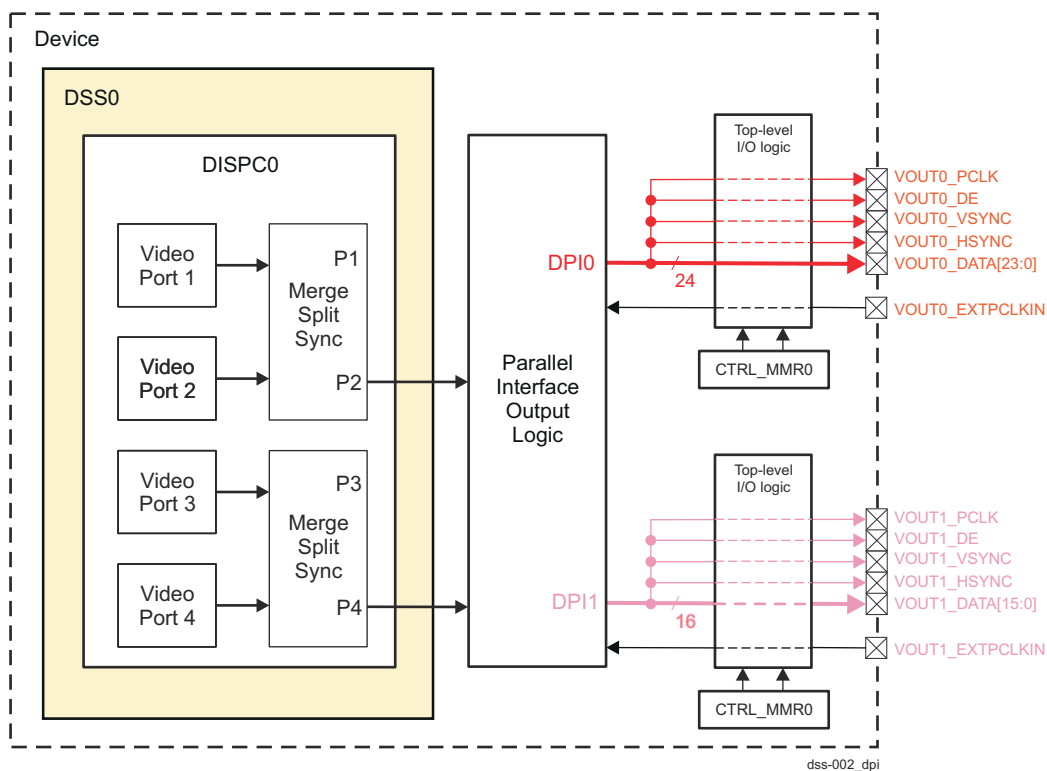

Figure 12-355. DSS DPI Parallel Interface Signals

Each DISPC video port in Figure 12-355 can be connected to any DPI output via the parallel interface output logic.

The [3-0] DPI_0_CONN and [7-4] DPI_1_CONN fields in the DSS0_COMMON_DISPC_CONNECTIONS register define the DISPC VP connections to DPI0 and DPI1 outputs, respectively.

The DISPC video ports output the required data and control signals to device pads to support one of the following display interface modes:

- Parallel MIPI DPI 2.0 (Digital Pixel Interface): RGB 16/18/24-bit output with separate sync signals.
- BT.656/BT.1120 interface: YUV422 output (8/10-bit modes) with embedded syncs.
- BT.601 interface: YUV422 output with discrete syncs. For more details, see *VSYNC/HSYNC/DE Signal Export to SoC Boundary*.

12.6.2.2 DSI Environment

Figure 12-356 shows the DSI interface signals.

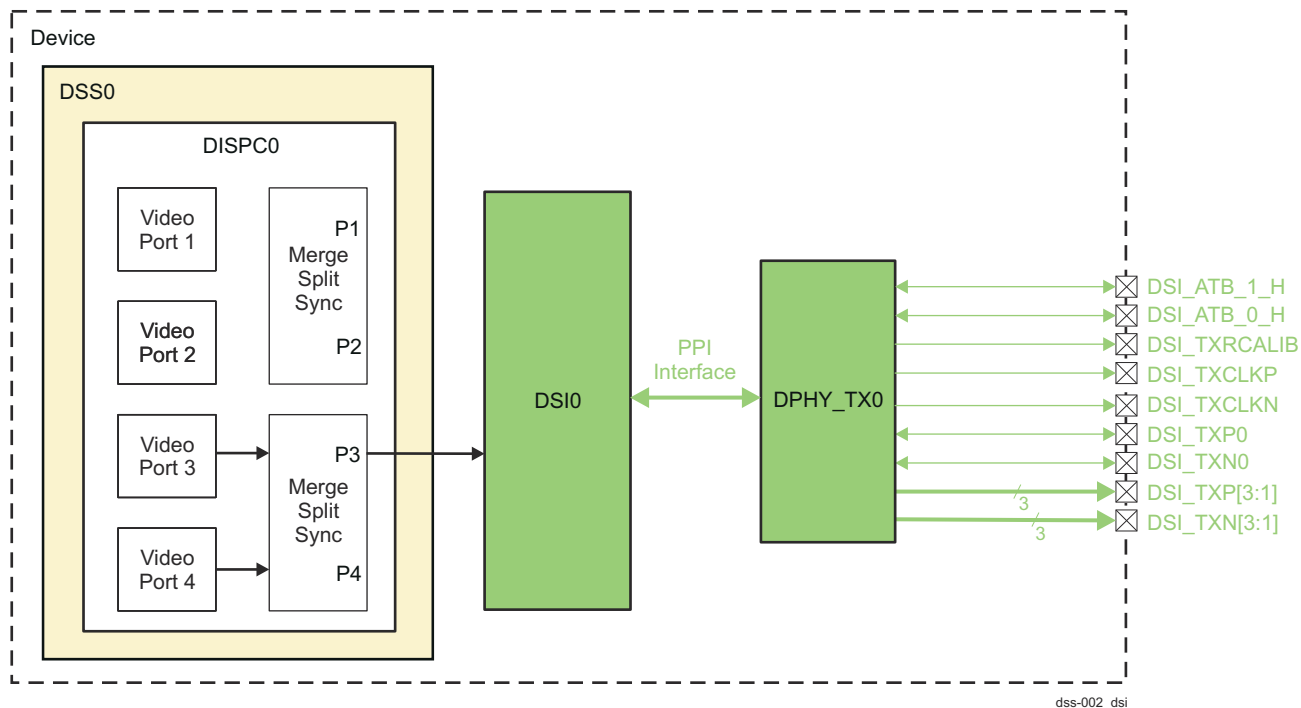

Figure 12-356. DSI Interface Signals

12.6.2.3 EDP Environment

Figure 12-357 shows the EDP interface signals.

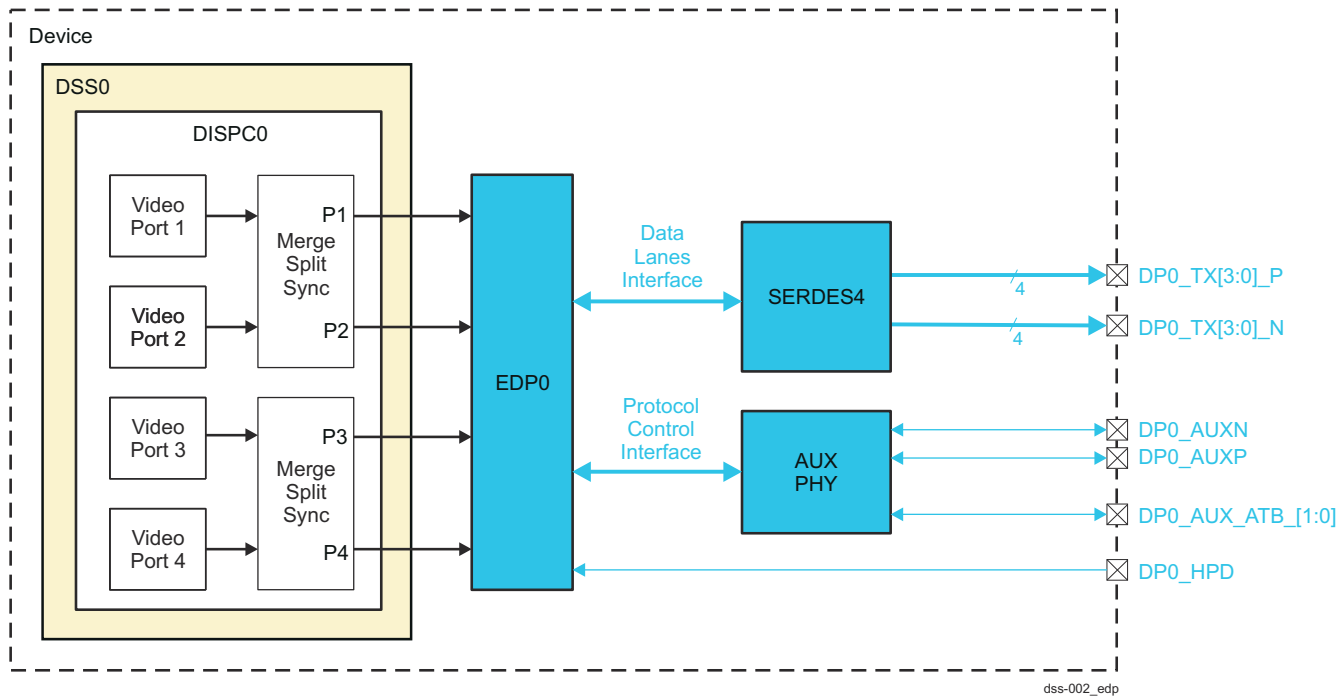

Figure 12-357. DP/eDP Interface Signals

12.6.3 Display Subsystem Controller (DISPC) with Frame Buffer Decompression Core (FBDC)

12.6.3.1 DISPC Overview

Figure 12-358 is a simplified block diagram of DISPC.

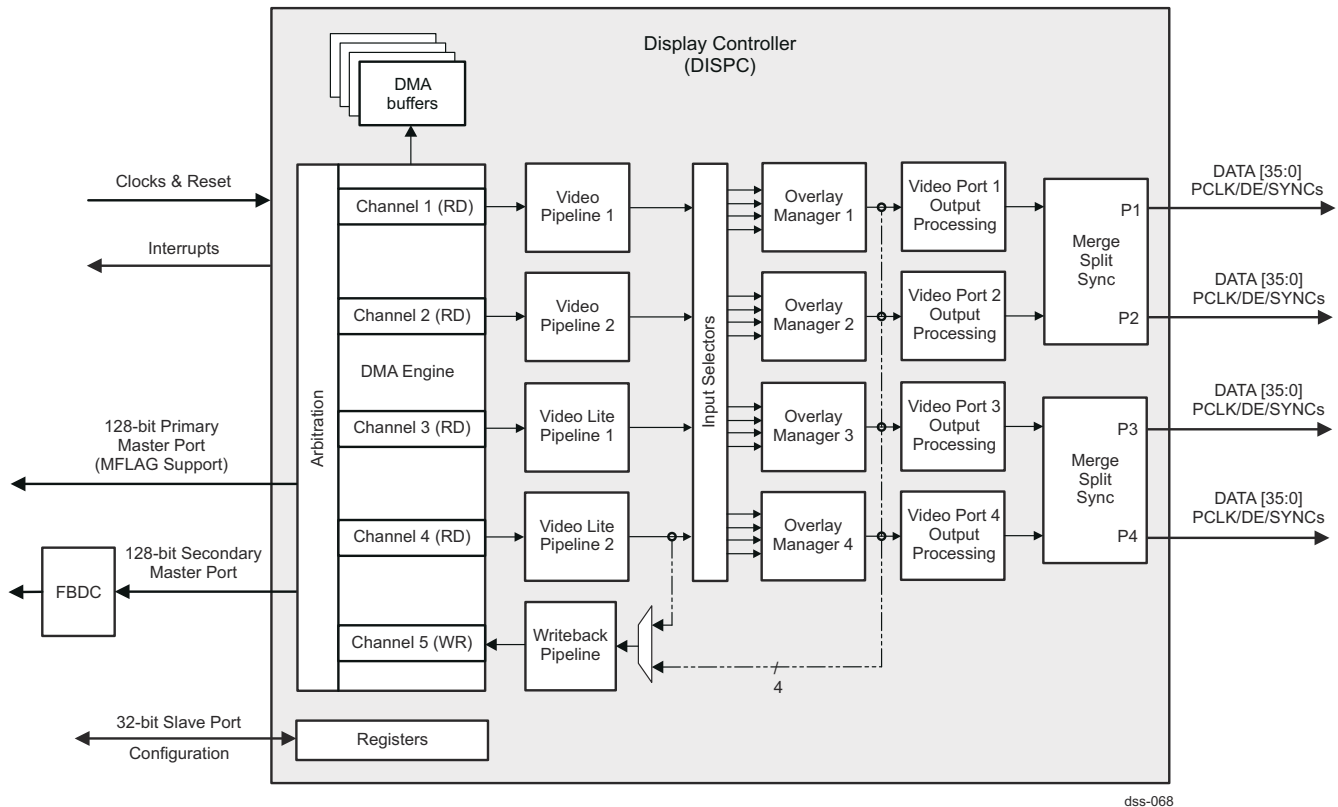

Figure 12-358. DISPC Architecture Overview

The DISPC integrated within DSS is capable of fetching pixel data from the device system memory through its dual master ports, performing various pixel processing, and then providing the processed pixels to an external display panel. The internal DMA engine tightly coupled to the DISPC is used for the pixel data transfer from system memory (frame buffer). The DISPC DMA engine is in charge of scheduling the memory requests. Several processes are configurable in order to manage the video pipeline features (color space conversion, up-sampling, down-sampling) and overlay features. The internal timing generator logic generates the video port output signals based on VESA DMT and CEA-861 standards. The DISPC video port outputs can be connected to display panels either directly (for MIPI DPI 2.0 or BT.656/BT.1120 support), or through either MIPI DSI or DisplayPort (DP/eDP) interfaces.

Note

The DISPC does not support any tiled frame buffer. The DISPC has no internal capability to support rotation of the frame buffer. The support for a compressed frame buffer is provided via the Frame Buffer Decompression (FBDC) module connected to the DISPC secondary master port.

Note

The display resolution is programmable and can be any width in the range [1:4096] pixels. The following limitations apply, related to the type of display or the processing done:

- Active Matrix screen + dithering forces a width multiple of 2 pixels
- Active Matrix + TDM may force a width multiple of 2 pixels

The display buffers in the system memory must consist of contiguous pixels.

12.6.3.2 DISPC Clocks

The DISPC has one clock domain for its internal logic and separate domains for each video port output.

The DISPC functional clock (DSS_FUNC_CLK) serves as the internal logic clock and also acts as the interface clock for the DISPC master and slave ports to system interconnect. There is no internal divider on this clock.

The DISPC pixel clocks (DSS_DPI_p_PCLK and DSS_DPI_p_DIV_PCLK, where $p = 0$ to 3) serve as the clocks for the output display interface. The DSS_DPI_p_PCLK clock is the 2x version of the DSS_DPI_p_DIV_PCLK clock. There are no internal dividers on the pixel clocks.

The relationship between the outgoing pixel clock and the input pixel clocks is as shown in [Section 12.6.3.11.9.1, MSS Clocking Scheme](#).

The frequency of the display controller logic clock (DSS_FUNC_CLK) has to be greater than the frequency of the DSS_DPI_p_PCLK clocks, in order to get the DISPC internal logic to function properly. The frequency of the DSS_DPI_p_PCLK and DSS_DPI_p_DIV_PCLK clocks depend on the required output display resolution and frame rate. For information on the maximum supported frequency ratings, see the device-specific Datasheet.

The DSS_FUNC_CLK is asynchronous to DSS_DPI_p_PCLK and DSS_DPI_p_DIV_PCLK clocks. They can be generated by different sources.

The DSS_DPI_p_PCLK and DSS_DPI_p_DIV_PCLK clocks are synchronous to one another (for the same value of p).

The DSS0_COMMON_DSS_SYSCONFIG[0] AUTOCLKGATING register bit is set by default to allow the auto-gating of the interface and functional clocks. The AUTOCLKGATING bit can be reset to disable the auto-gating of the clocks, if required.

The DISPC provides also a clock-gating control on sub-module level, via configuration of the appropriate DSS0_COMMON_DISPC_CLKGATING_DISABLE register fields.

12.6.3.3 DISPC Resets

DISPC receives a single hardware reset signal. For more information, see *DSS Integration*.

To perform a software reset on the DISPC, set the DSS0_COMMON_DSS_SYSCONFIG[1] SOFTRESET bit to 0x1. The DSS0_COMMON_DSS_SYSSTATUS[0] DISPC_FUNC_RESETDONE bit indicates that the software reset is complete (for the DISPC internal logic) when its value is 0x1. When the software reset completes, the DSS0_COMMON_DSS_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing DISPC operations.

The completion of the software reset for the video ports logic is indicated in the DSS0_COMMON_DSS_SYSSTATUS[3-1] DISPC_VP_RESETDONE register bit-field.

12.6.3.4 DISPC Power Management

DISPC supports a power management protocol with the device Power Sleep Controller (PSC).

The (software) sequence, while performing a *clkstop_req* to DISPC, is as follows:

1. Disable DISPC by programming the [0] ENABLE bit of DSS0_VP_CONTROL register to 0.
2. DISPC hardware completes the output of the current frame. Then hardware sets the DSS0_COMMON_DSS_SYSSTATUS[9] DISPC_IDLE_STATUS register bit to 1.
3. Poll the DSS_IDLE_STATUS bit to ensure that DISPC is in idle mode.
4. PSC initiates *clkstop_req* to DISPC.
5. DISPC hardware acknowledges with *clkstop_ack* immediately.

12.6.3.5 DISPC Interrupt Requests

The DISPC supports twelve interrupt output lines. The DISPC interrupt events are classified into functional, internal diagnostic error, and secure interrupt sub-categories, and then mapped to the respective sub-category interrupt line. Multiple sets of IRQ aggregation registers and IRQ generators enable fully independent monitoring and control of the interrupt events by up to 4 processor hosts at SoC level, as shown in [Figure 12-359](#). For more details on the mapping of the interrupt lines to SoC-level resources, see *DISPC Integration*.

- The 4 functional interrupt (FUNC_IRQ) lines are DISPC_FUNC_IRQ_PROC0_0 through DISPC_FUNC_IRQ_PROC3_0.
- The 4 internal diagnostic error interrupt (SAFETY_ERROR_IRQ) lines are DISPC_SAFETY_ERROR_IRQ_PROC0_0 through DISPC_SAFETY_ERROR_IRQ_PROC3_0.
- The 4 secure interrupt (SECURE_IRQ) lines are DISPC_SECURE_IRQ_PROC0_0 through DISPC_SECURE_IRQ_PROC3_0.

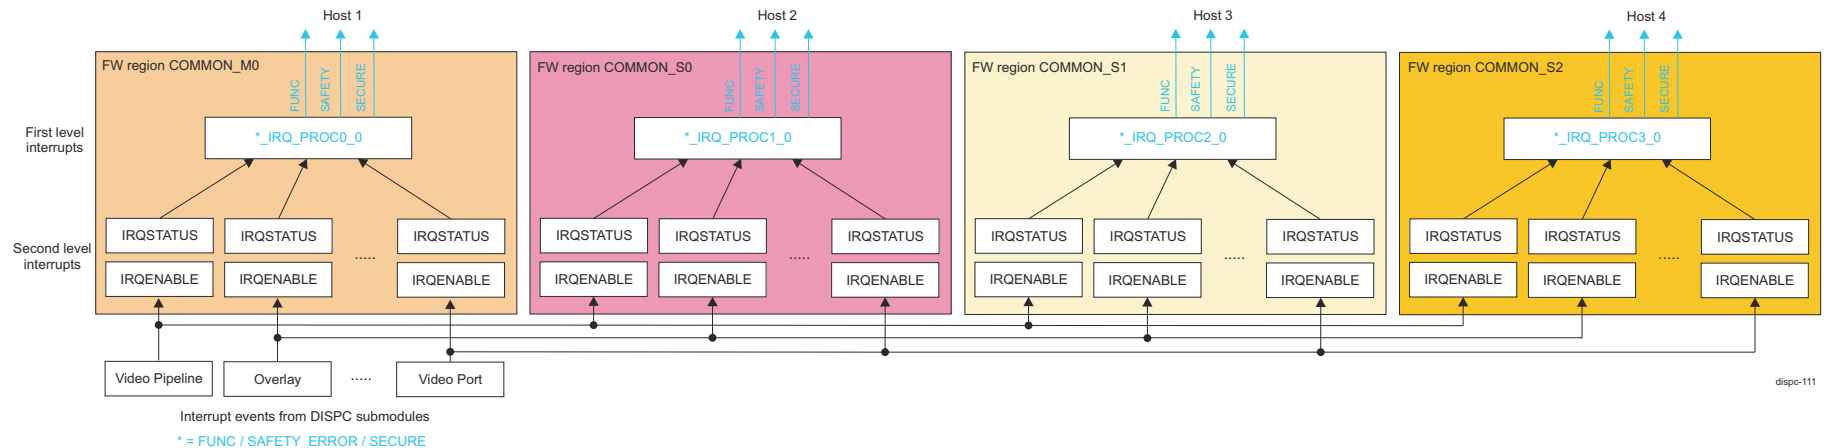

Figure 12-359. DISPC Interrupts Generation

Each of the interrupt signals indicates that one or more interrupt events are detected by the hardware. Each event is independently maskable for each interrupt output.

There are two level of interrupt events, as shown in [Figure 12-359](#). The first level is used to indicate common events and is also source for the second level of interrupts. The second level of interrupt events consists of status and enable interrupt registers for each video pipeline and each video port.

[Table 12-402](#) describes the first level of interrupt events with associated mask and status register fields. Each interrupt event is captured in an interrupt status register. Equivalent DSS0_COMMON_DISPC_IRQSTATUS_RAW register exist, which is updated even if interrupts are not enabled. This allows software to get access to updated status for all interrupt events.

Table 12-402. DISPC Interrupts - First Level

Interrupt Name	Set Interrupt Enable Register DSS0_COMMON_DISPC_IRQENA BLE_SET	Clear Interrupt Enable Register DSS0_COMMON_DISPC_IRQENA BLE_CLR	Interrupt Status Register DSS0_COMMON_DISPC_IRQSTAT US	Description
VID1_IRQ	[4] SET_VID_IRQ	[4] CLR_VID_IRQ	[4] VID_IRQ	At least one event of the VID1 pipeline interrupt events has occurred. See Table 12-403 for more details.

Table 12-402. DISPC Interrupts - First Level (continued)

Interrupt Name	Set Interrupt Enable Register DSS0_COMMON_DISPC_IRQENA BLE_SET	Clear Interrupt Enable Register DSS0_COMMON_DISPC_IRQENA BLE_CLR	Interrupt Status Register DSS0_COMMON_DISPC_IRQSTAT US	Description
VIDL1_IRQ	[5] SET_VID_IRQ	[5] CLR_VID_IRQ	[5] VID_IRQ	At least one event of the VIDL1 pipeline interrupt events has occurred. See Table 12-404 for more details.
VID2_IRQ	[6] SET_VID_IRQ	[6] CLR_VID_IRQ	[6] VID_IRQ	At least one event of the VID2 pipeline interrupt events has occurred.
VIDL2_IRQ	[7] SET_VID_IRQ	[7] CLR_VID_IRQ	[7] VID_IRQ	At least one event of the VID2L pipeline interrupt events has occurred.
VP1_IRQ	[0] SET_VP_IRQ	[0] CLR_VP_IRQ	[0] VP_IRQ	At least one event of the VP1 interrupt events has occurred. See Table 12-406 for more details.
VP2_IRQ	[1] SET_VP_IRQ	[1] CLR_VP_IRQ	[1] VP_IRQ	At least one event of the VP2 interrupt events has occurred. See Table 12-407 for more details.
VP3_IRQ	[2] SET_VP_IRQ	[2] CLR_VP_IRQ	[2] VP_IRQ	At least one event of the VP3 interrupt events has occurred.
VP4_IRQ	[3] SET_VP_IRQ	[3] CLR_VP_IRQ	[3] VP_IRQ	At least one event of the VP4 interrupt events has occurred.
WB_IRQ	[14] SET_WB_IRQ	[14] CLR_WB_IRQ	[14] WB_IRQ	At least one event of the WB pipeline interrupt events has occurred.

[Table 12-403](#) describes the second level of interrupts for VID1 and VID2 pipelines with associated mask and status register bits.

Table 12-403. DISPC Interrupts - Second Level - VID1 and VID2 Pipeline

The MISR signature generated does not match the expected signature, or the VP output frame freeze detection has triggered.

12.6.3.6 DISPC DMA Controller

The DISPC DMA controller is based on a 5-channel DMA engine that:

- Requests and supplies data from system memory to the VID and VIDL pipelines (up to 4 input layers) through the SoC system interconnect, based on the configuration of the pipeline settings.
- Stores the composed frames back into system memory by using the WB pipeline.
- Is fully programmable and fetches pixel data via 128-bit requests using 1D burst.

The DISPC DMA engine has an additional (secondary) 128-bit master port. By default, all transactions from every channel go through the primary 128-bit master port. If compression is enabled for a particular channel (by using the FBDC module), then all the transactions of that channel go through the secondary master port. It is also possible to force transactions from a particular channel to the secondary master port (even without compression) by setting the DSS0_VID_ATTRIBUTES2[25] MPORTSEL register bit to 0x1. This is possible only when compression through the FBDC is completely disabled (that is, none of the read channels are fetching compressed data).

Each pipeline has a dedicated DMA buffer and channel with independent settings. If a pipeline is disabled (that is, not used), then its DMA buffer can be assigned to another pipeline by configuring the DSS0_COMMON_DISPC_GLOBAL_BUFFER register. For example, unused buffers for a VIDL pipeline can be used by a VID pipeline.

Each DMA channel supports a total of 8 line buffers, each of which can store 2048 32-bit pixels.

- The size of each DMA buffer associated to the VID, VIDL and WB pipelines is 8x512x128-bit.

The DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration has been programmed for the video layer), that is, when the video window is present and the video pipeline is active.

12.6.3.6.1 DISPC DMA Addressing and Bursts

For each line to be fetched, the DMA engine address generator:

- Calculates the pixel address
- Aligns the address
- Determines byte enable pattern
- Determines 1D burst length

The meaning of the address bits is as follows:

- Bits [31-0]: system (DDR) memory address (pixel address)
- Bits [47-32]: 32 bits + address extension

The address extension bits are defined by the programmable parameter DSS0_VID_BA_EXT_0/DSS0_VID_BA_EXT_1 and DSS0_VID_BA_UV_EXT_0/DSS0_VID_BA_UV_EXT_1 registers, optionally used to extend the BA memory addressing to 48-bit addressed external memory space (that is, to extend DISPC address space into 4GB+ space).

The DDR scan pixel addresses are generated by the DMA engine in order to read data from the system memory. The base address defines the start address of the first pixel, and then the address is incremented based on the number of pixels per line, offset between two consecutive lines and number of lines. The DSS0_VID_ROW_INC register allow the access to a frame using 1D bursts (but as a two-dimensional block) by adding a fixed address offset at the end of a line. The ROW_INC can also be used to skip lines from the input frame.

The byte address of each pixel in the frame buffer located in the system memory is determined by:

Pixel address = base_address + x × (bpp/8) + y × (width × (bpp/8) + increment), where:

- "base_address" corresponds to the base address defined by:
 - DSS0_VID_BA_0/DSS0_VID_BA_1[31-0] BA register bit-fields for all formats, and Y frame buffer in case of YUV-NV12 format. Optional extension bits in DSS0_VID_BA_EXT_0/DSS0_VID_BA_EXT_1 registers.
 - DSS0_VID_BA_UV_0/DSS0_VID_BA_UV_1[31-0] BA register bit-fields for UV frame buffer in case of YUV-NV12 format. Optional extension bits in DSS0_VID_BA_UV_EXT_0/DSS0_VID_BA_UV_EXT_1 registers.

- "bpp" corresponds to the number of bits per pixel defined by the DSS0_VID_ATTRIBUTES[6-1] FORMAT register bit-field.
- "width" corresponds to the number of pixels per line defined by the DSS0_VID_PICTURE_SIZE[11-0] MEMSIZEX + 1 register bit-field.
- "increment" corresponds to the number of bytes to skip between two contiguous lines defined by the DSS0_VID_ROW_INC [31-0] ROWINC – 1 register bit-field.
- "x" corresponds to the pixel position on the x-axis.
- "y" corresponds to the pixel position on the y-axis.

In cases where the DMA controller is doing a flip/mirror (see [Section 12.6.3.6.4, DISPC Flip/Mirror Support](#)) or fetching a compressed frame buffer (see [DISPC Compressed Data Format Support](#)), the above equation for pixel byte address needs to be modified according to those features.

Note

Since the base address is aligned on pixel size boundary the horizontal resolution is one pixel. In case of YUV422 formats, the resolution is 4 bytes (2 pixels). In case of RGB24 packed format the resolution is 4 pixels. In case of Y frame buffer (YUV-NV12 format) the resolution is one byte. The vertical resolution is one line.

In case of YUV422 non-planar format, the number of pixels per line shall be a multiple of 2 pixels and the size of a pixel shall be considered as 2 bytes. In case of YUV planar format (YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21), the Y buffer shall be considered as an 8-bit frame buffer, and the CbCr shall be considered as a 16-bit frame buffer. The pixel size is 1 byte and 2 bytes respectively for Y and CbCr.

For two-plane pixel formats (YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21, RGB565-A8), the pixel values are defined in two separate buffers (Y and UV buffers). The first buffer consists of Y values (8 bits for each Y sample) or 16-bit RGB value. The second buffer consists of CbCr values (16 bits for each pair of CbCr samples) or 8-bit Alpha value. The base address, the number of bytes to skip between pixels and between lines of each buffer are defined by separate registers:

- The DSS0_VID_BA_0/DSS0_VID_BA_1, DSS0_VID_PIXEL_INC and DSS0_VID_ROW_INC registers define the values to use for the first buffer
- The DSS0_VID_BA_UV_0/DSS0_VID_BA_UV_1 and DSS0_VID_ROW_INC_UV define the values to use for the second buffer
- Internal to the DMA controller, the two planes use the same shared memory space, which is allocated to the relevant pipeline which has the two-plane pixel format set

In case of interlaced mode, DSS0_VID_BA_0 and DSS0_VID_BA_UV_0 registers define the base address of the even field, and DSS0_VID_BA_1 and DSS0_VID_BA_UV_1 registers define the base address of the odd field.

[Table 12-408](#) summarizes the register settings for a simple access of a picture in the system memory.

Table 12-408. DISPC Register Settings for Accessing Image in Internal Memory

Pipeline Registers	Value
DSS0_VID_BA_0 ⁽¹⁾ and DSS0_VID_BA_1 ⁽²⁾ / DSS0_WB_BA_0 and DSS0_WB_BA_1	The physical base address (PBA) of image in the memory for all formats and Y buffer.
DSS0_VID_BA_EXT_0 and DSS0_VID_BA_EXT_1 / DSS0_WB_BA_EXT_0 and DSS0_WB_BA_EXT_1	Address extension bits of PBA for all formats and Y buffer.
DSS0_VID_BA_UV_0 ⁽¹⁾ and DSS0_VID_BA_UV_1 ⁽²⁾ / DSS0_WB_BA_UV_0 and DSS0_WB_BA_UV_1	The physical base address (PBA) of UV buffers image in the memory.
DSS0_VID_BA_UV_EXT_0 and DSS0_VID_BA_UV_EXT_1 / DSS0_WB_BA_UV_EXT_0 and DSS0_WB_BA_UV_EXT_1	Address extension bits of PBA for UV buffers.
DSS0_VID_PIXEL_INC / DSS0_WB_PIXEL_INC	1 or other in pixel incremental value.
DSS0_VID_ROW_INC / DSS0_WB_ROW_INC	1 or other in row incremental value. Used for Y buffer.

Table 12-408. DISPC Register Settings for Accessing Image in Internal Memory (continued)

Pipeline Registers	Value
DSS0_VID_ROW_INC_UV / DSS0_WB_ROW_INC_UV	1 or other in row incremental value. Used for UV buffer.

- (1) The BA_0 and BA_UV_0 registers define the base address of even field, in case of interlaced mode.
- (2) The BA_1 and BA_UV_1 registers define the base address of odd field, in case of interlaced mode.

An interconnect request (128 bits) corresponds to one or several pixels, depending on the bits per pixel. Therefore, the DMA engine determines the appropriate burst sequence to optimize the fetching of each new line. The DMA engine must prevent a single burst from crossing two lines. The DMA engine supports only 1D burst. 1D burst is used, if the fetch data is linear in memory. The size of the burst can be one of the following values:

- 1x128-bit, 2x128-bit, 4x128-bit: Only during start of the row and end of the row, if there is a misaligned address
- 8x128-bit: Steady state burst size
- 16x128-bit: Only while accessing a compressed frame buffer

The DMA controller supports the start address of a row of pixels to be aligned to any arbitrary boundary in memory (with the restriction that a 32-bit format is aligned to 32-bit boundary, a 16-bit format is aligned to a 16-bit boundary, a 8-bit format is aligned to a 8-bit boundary, etc.). However, it operates most efficiently when the start address of a row is aligned to the max burst boundary of 8x128-bit. For all other cases of unaligned rows the DMA will need to go through non-optimal transactions at the start and end of each row, till it can issue a max burst of 8x128.

While accessing a compressed frame buffer (through the FBDC module), the base-address needs to be aligned to 256 bytes. In this case, the DMA will always issue a burst of 16x128-bit.

12.6.3.6.2 DISPC Read DMA Buffers

The read DMA buffers are used by the VID and VIDL pipelines.

When the vertical front porch (VFP) period starts after the last horizontal front porch (HFP) of the last line, the DMA buffers are flushed according to the video port output associated with the particular video pipeline. The DMA engine restarts fetching new frame data from the memory through the DISPC master port. Enabling or disabling the DISPC also flushes the DMA buffers.

Programmable high and low thresholds, independent for each DMA buffer, are used by the DMA engine to start and stop requesting data through the master port.

- When low threshold (set in the DSS0_VID_BUF_THRESHOLD [15-0] BUFLOWTHRESHOLD register bit-field) is reached, the DMA engine starts a request on the device interconnect to fill the DMA buffer.
- When high threshold (set in the DSS0_VID_BUF_THRESHOLD [31-16] BUFHIGHTHRESHOLD register bit-field) is reached, the DMA engine stops requesting encoded pixels.

Note

The configuration of thresholds for optimal performance can be defined using the DSS0_VID_BUF_SIZE_STATUS[15-0] BUFSIZE register field value, as follows:

- For high threshold: BUFSIZE (in number of 128-bit words) – 1
- For low threshold: BUFSIZE (in number of 128-bit words) – burst size (in number of 128-bit words)

The following limitations for BUFLOWTHRESHOLD values must be also considered:

- If the scaler in VID pipeline is disabled, BUFLOWTHRESHOLD can be programmed as low as interconnect latency and pixel output rate allow it.
- If the scaler in VID pipeline is enabled, BUFLOWTHRESHOLD must be programmed to guarantee that at least four full lines can be stored.

To avoid underflow at the beginning of a frame and have sufficient encoded pixel data to start some processing, a preloading of the DMA buffer is configurable between a fixed value of bytes and the high threshold value. When the preload value is reached, the associated channel will start pulling pixels out of the DMA buffer. To enable the preload based on the value entered in the DSS0_VID_PRELOAD[11-0] PRELOAD register bit-field, the DSS0_VID_ATTRIBUTES[19] BUFPRELOAD register bit must be set to 0x0.

The vertical blanking between two frames must be long enough to allow fetching the number of pixels defined by the DSS0_VID_PRELOAD register and preloading the whole video pipeline. If the value set in the preload register is greater than some overflow conditions detected by the hardware, then data will start to be read from the video DMA buffer before the preload value is reached. If SYNCLOST_IRQ event occurs the video buffer needs to be increased (buffer merge). Preload value must be greater or equal to low threshold, and smaller or equal to high threshold value.

Note

When self-refresh mode is selected (which means that the data in the DMA buffer are used for multiple frames) the DMA buffers are not flushed at the end of each frame. Each DMA buffer has an independent control for selecting the self-refresh mode. For more information, see [Section 12.6.3.6.10, DISPC DMA Ultra-Low Power Mode](#).

12.6.3.6.3 DISPC Write DMA Buffer

The write DMA buffer is used by the WB pipeline.

Two modes for filling the DMA buffer are supported by the WB channel, selectable through the DSS0_WB_ATTRIBUTES[19] WRITEBACKMODE bit:

- Capture mode, WRITEBACKMODE bit set to 0: One of the overlay outputs connected to an external interface is captured at the same time the data are sent on the output. The WB timings are controlled by the VP timings.
- Memory-to-memory mode, WRITEBACKMODE bit set to 1: One of the overlay outputs or one of the pipelines is captured to perform a memory-to-memory transfer, with some processing by the DISPC (rescaling, overlaying, color space conversion, etc.).

In capture mode: Transfer is synchronous (that is, tightly coupled) to one of the display outputs. In this mode, the write back buffer starts receiving data after DSS0_WB_ATTRIBUTES[0] ENABLE register bit has been set and the associated output vertical sync has triggered the start of the transfer (VFP). In addition, the WB ENABLE bit shall be set prior to the enable of the captured channel output in order to capture the first frame.

In memory-to-memory mode: The data transfer is not synchronous to any of the display outputs. In this mode, the write back buffer starts receiving data after the DSS0_WB_ATTRIBUTES[0] ENABLE has been set. The WB ENABLE bit also is triggering the update of the shadow register in the WB pipeline.

Programmable high and low thresholds are used by the DMA engine to start and stop sending data to the system interconnect.

- When high threshold (set in the DSS0_WB_BUF_THRESHOLD[31:16] BUFHIGHTHRESHOLD bit field) is reached, and there are enough data for at least one burst of pixels in the DMA buffer ready for transfer, the DMA engine generates a request to the arbitration logic. The size of the burst is defined by the user.
- When low threshold (set in the DSS0_WB_BUF_THRESHOLD[15:0] BUFLOWTHRESHOLD bit field) is reached, the DMA engine stops sending encoded pixels.

At the end of the frame, to completely drain the DMA buffer, some smaller bursts (even single requests) may have to be issued. To limit the number of interconnect requests from the DISPC (that is, to limit the throughput of the write-back channel to the memory), a number of IDLE cycles between requests can be inserted. IDLE cycles can be inserted only when WB is used in memory-to-memory mode. It is ignored when WB is in capture mode.

The number of IDLE cycles between requests can be activated and determined by:

- Setting the DSS0_WB_ATTRIBUTES[27] IDLESIZE bit to 0x0 (default value) and entering the number of idles between requests in the DSS0_WB_ATTRIBUTES[31:28] IDLENUMBER bit field. Idle numbers vary from 0 to 15.
- Setting the DSS0_WB_ATTRIBUTES[27] IDLESIZE bit to 0x1, which considers the size of the burst (the DSS0_WB_ATTRIBUTES[15:14] BURSTSIZE bit field) to determine the number of IDLE cycles.
 - If BURSTSIZE = 0x0, then the number of IDLE cycles equals IDLENUMBER (0 to 15).
 - If BURSTSIZE = 0x1, then the number of IDLE cycles equals IDLENUMBER × 4 (0 to 60).
 - If BURSTSIZE = 0x2, then the number of IDLE cycles equals IDLENUMBER × 8 (0 to 120).

12.6.3.6.4 DISPC Flip/Mirror Support

The DISPC supports on-the-fly source image flip along the x/y-axis for 8-bit/component formats (ARGB or YUV) to create a mirror effect on the source data. The DMA engine reads the source frame from right to left by requesting burst transfers for each line in negative address increments while performing each burst transfer as a linear incremental burst. The read data is repacked and stored in the line buffer incrementally - effectively storing the frame as a flipped image for the processing pipeline. The configuration of the flip/mirror operation is explained in [Table 12-409](#).

Table 12-409. DISPC Flip/Mirror Configuration

Flip Direction	FLIP Bit	Base Address	Byte Increment
Along Y-axis (vertical mirror)	1	Start of window	1
Along X-axis (horizontal mirror)	0	Start of last line of the window	$-(2 * (\text{width of the line in bytes}))$
Along both X-axis and Y-axis (horizontal and vertical mirror)	1	Start of last line of the window	$-(2 * (\text{width of the line in bytes}))$

In [Table 12-409](#):

- The FLIP bit is located in DSS0_VID_ATTRIBUTES register.
- The base address of the video buffer must be configured as explained in [Section 12.6.3.6.1, DISPC DMA Addressing and Bursts](#).
- The the number of bytes to increment at the end of the row in the video buffer can be configured through DSS0_VID_ROW_INC and DSS0_VID_ROW_INC_UV registers. For more information, see [Section 12.6.3.6.1, DISPC DMA Addressing and Bursts](#), and [Section 12.6.3.6.5, DISPC DMA Predecimation](#).

The flip/mirror feature is not supported for compressed data formats (when the DMA engine receives data from the FBDC module).

12.6.3.6.5 DISPC DMA Predecimation

The predecimation process consists of downscaling an image by fetching only the necessary pixels out of the memory. Vertical and horizontal predecimation are possible:

- Vertical predecimation: The picture stored in memory can be predecimated vertically by skipping lines. Burst mode is used to fetch the data when skipping lines. Only the lines that will be used by the DISPC are fetched from memory; the other lines are skipped. The DMA engine sends requests only for the useful lines using 1D burst. The base address indicates the first valid pixel to fetch from memory. The number of lines to skip is set in the ROW_INC and ROW_INC_UV registers (see [Section 12.6.3.6.1, DISPC DMA Addressing and Bursts](#)).
- Horizontal predecimation: When fetching data from memory, it is possible to skip 1 out of 2 pixels, up to 1 out of 2047 pixels, by setting the PIXEL_INC register (see [Section 12.6.3.6.1, DISPC DMA Addressing and Bursts](#)) to the number of pixels to skip (n), multiplied by the size of a pixel (in bytes), +1. The condition to generate a burst is that there is at least one useful pixel per 128-bit OCP request. Therefore, when the pixels are 16/32-bit, the maximum number of pixels that can be skipped is 8/4. If $\text{PixelWidthInBytes} + \text{BytesToSkip}$ is greater than 16, then the programmed burst is changed into single request.

No decimation is supported when the input format is 1, 2, 4, or 8-bit BITMAP.

For RGB and YUV420 data formats, each pixel data container in memory holds 1 pixel. Thus, when configuring the PIXEL_INC register, the value of n equals the number of pixels to skip:

- For RGB format, one pixel data container = 32 bits = 1 pixel
- For YUV format:
 - One Y pixel data container = 8 bits = 1 pixel
 - One UV pixel data container = 16 bits = 1 pixel

For YUV422 format, each 32-bit pixel data container holds the Luma components for 2 pixels, and the Chrominance component of 1 pixel (see [Figure 12-360](#)). Therefore, for the valid values of the PIXELINC bit field in the case of the following YUV422 format, caution must be taken because n equals the number of pixel data containers to skip, and not the number of pixels:

- For n = 1, PIXELINC = 5
- For n = 2, PIXELINC = 9

- For $n = 3$, PIXELINC = 13
- For $n = 4$, PIXELINC = 17, etc.

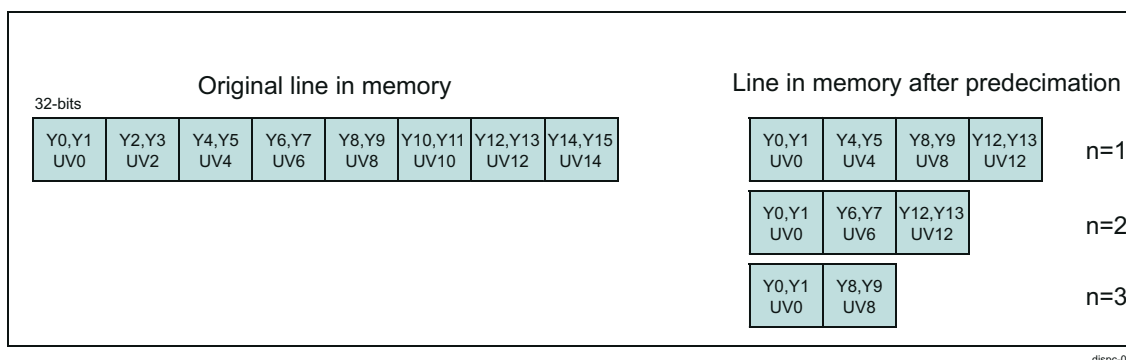

Figure 12-360. DISPC YUV422 Predecimation

12.6.3.6.6 DISPC DMA Buffer Sharing

The DISPC DMA controller supports dynamic re-partition of the memory among the different channels.

At reset, each channel in DMA is allocated a uniform buffer size of 64KB. This 64KB is further partitioned into four 16KB blocks as shown in [Figure 12-361](#). A 64KB buffer is enough to support ping-pong mode for resolutions up to 4K for YUV420/YUV422 formats and up to 2K for ARGB32 formats.

Figure 12-361. DISPC DMA Channel Memory Allocation at Reset

To support resolutions larger than 4K YUV or 2K ARGB (with ping-pong configuration), the default buffer size of 64KB per read channel is not sufficient. In such cases, the DISPC allows dynamic repartition of the allocated buffers across the different read channels. In this way each read channel can have a variable buffer size allocated to it, starting from a minimum of 16KB to a maximum of 256KB, in 16KB increments. The WB channel buffers cannot be re-allocated and remain fixed. This is the case even when WB channel is disabled. A particular configuration (for a specific example use-case) is as shown in [Figure 12-362](#).

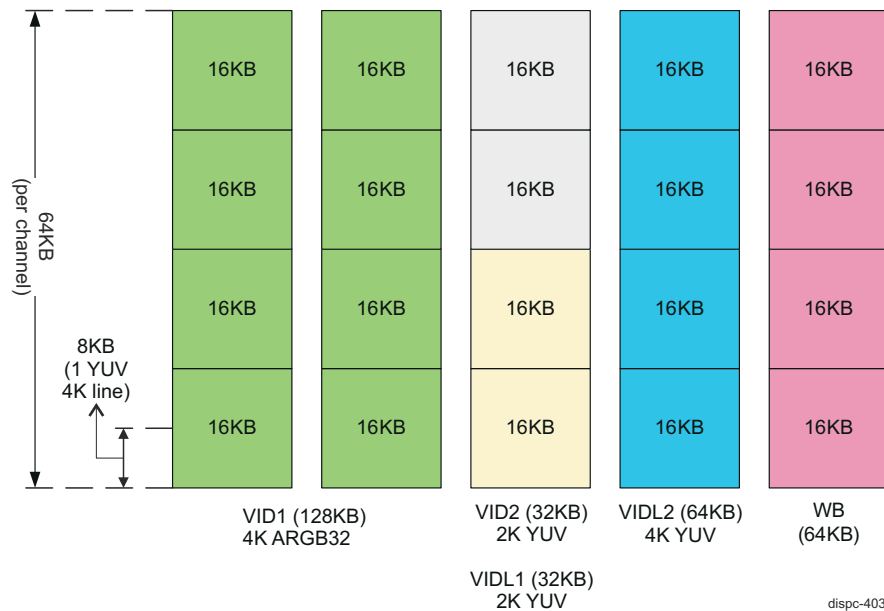

Figure 12-362. DISPC Dynamic Buffer Repartition between DMA Read Channels

When the size of the buffer is changed, the thresholds shall be re-programmed by the user to reflect the new DMA buffer configuration.

The activity on a read channel is controlled by the timing of the Overlay/VP to which the channel is connected (or to the WB, if the channel is connected to WB in M2M mode). Due to this, the DISPC HW ensures that any change in a channel buffer setting is synchronized with regard to the Overlay/VP or WB (M2M mode) to which the channel is connected. In addition, the software also must follow the following programming sequences:

- Initialization sequence (before enabling any pipe or VP or WB):
 1. Allocate the total available memory among the different threads (configurable through the DSS0_COMMON_GLOBAL_DMA_THREADSIZE[19-0] VP#nTHREADSIZE and [24-20] WBTHREADSIZE register bit-fields).
 2. Wait for the DISPC HW to sync to the programmed THREADSIZE (read the value from DSS0_COMMON_GLOBAL_DMA_THREADSIZESIZESTATUS[19-0] VP#nTHREADSIZE and [24-20] WBTHREADSIZE register bit-fields).
 3. Allocate a buffer for each of the (active) read channels (configurable through the DSS0_VID_DMA_BUFSIZE[4-0] BUFSIZE register field). Software needs to ensure that the total size allocated to all the channels in a thread does not surpass the total size allocated to the thread.
 4. Enable the read channels as well as the VP output.
- Intra thread re-allocation sequence. Within the thread the re-allocation always happens at the next VSYNC. There is no handshake needed on the part of software.
 1. Allocate the new buffer size (configurable through the DSS0_VID_DMA_BUFSIZE[4-0] BUFSIZE register field).
- Inter thread re-allocation sequence. The synchronization events (VSYNC) between two threads will be different. Therefore, any re-allocation between two threads needs to go through a software managed handshake sequence as follows:
 1. Free the required amount of memory from Thread-#n (configurable through the DSS0_COMMON_GLOBAL_DMA_THREADSIZE register).
 2. Wait till the synchronization event of Thread-#n (achieved by looking at the status reflected in the DSS0_COMMON_GLOBAL_DMA_THREADSIZESIZESTATUS register).
 3. Allocate the freed buffer space to a different thread, Thread-#m (configurable through the DSS0_COMMON_GLOBAL_DMA_THREADSIZE register).
 4. Further allocate this space to the different read channels of Thread-#m (configurable through the DSS0_COMMON_GLOBAL_DMA_THREADSIZESIZESTATUS register).

5. Further allocate the new buffer size to the read channels in Thread-#m (configurable through DSS0_VID_DMA_BUFSIZE register).

Note

In a case where a channel is connected to multiple Overlay/VP (multi-cast use-case), then the channel belongs to the thread corresponding to the first (lowest numbered) Overlay/VP to which it is connected.

12.6.3.6.7 DISPC DMA MFLAG Mechanism

The MFLAG mechanism allows a dynamic increase of the priority of DISPC real-time traffic, when required, based on the fullness of the DISPC DMA read buffers.

The MFLAG mechanism is used when fullness of the DMA buffers is critical (close to underflow). The mechanism is implemented for all DMA buffers of the video pipelines.

Programmable buffer thresholds (forming hysteresis) are used to configure when a local MFLAG signal is generated. The 1-bit MFLAG signal is generated on DISPC master port in order to inform the system that the outstanding requests from DISPC shall be considered with higher priority in order to get faster interconnect responses. The MFLAG signal is asynchronous to any ongoing interconnect transaction.

Each pipeline maintains its own MFLAG bit. The MFLAG bit is asserted depending on the fullness of the DMA buffers associated with the pipeline and depending on the thresholds programmed by software. All MFLAG signals are OR-ed together to generate the single 1-bit MFLAG for the master port connected to the DISPC DMA engine.

The threshold for video pipelines corresponds to the fullness of the associated DMA buffer, and is defined by two threshold parameters:

- HT_MFLAG: High threshold.
 - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
 - This threshold can be programmed in the DSS0_VID_MFLAG_THRESHOLD [31-16] HT_MFLAG register field.
- LT_MFLAG: Low threshold.
 - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
 - This threshold can be programmed in the DSS0_VID_MFLAG_THRESHOLD [15-0] LT_MFLAG register field.

Summary of the MFLAG value, based on DMA read buffer fullness:

- If DMA read buffer fullness < LT_MFLAG, then MFLAG signal = 1
- If LT_MFLAG < DMA read buffer fullness < HT_MFLAG, then MFLAG signal = 1
- If DMA read buffer fullness > HT_MFLAG, then MFLAG signal = 0

Similarly, the MFLAG is set based on fullness and the transition history on the out bound writeback pipeline. There is no pre-fetch state for out bound DMA controller. The MFLAG is set when the buffer fullness rises above the HT_MFLAG bit-field value. The MFLAG is cleared only when the buffer fullness falls back below the LT_MFLAG bit-field value. In between these two fullness states, the MFLAG bit keeps the previous value.

By default, the MFLAG mechanism is disabled (DSS0_COMMON_DISPC_GLOBAL_MFLAG_ATTRIBUTE[1-0] MFLAG_CTRL register field = 0x0), and the MFLAG signal is low (de-asserted). The arbitration scheme for the pipelines is the same as described in [Section 12.6.3.6.9, DISPC DMA Arbitration](#). That is, round-robin either between high-priority pipelines, or between normal-priority pipelines (if all pipelines are of normal priority).

When the MFLAG_CTRL register field is set to 0x2, the MFLAG mechanism is enabled, and the MFLAG signal is dynamically set to 0 or 1, depending on DMA buffer fullness and programmed threshold levels, as explained previously in this section. In this case, the arbitration scheme for the pipelines is round-robin between those high-priority pipelines, which have asserted their local MFLAG signals. If there are no high-priority pipelines with

their local MFLAG signals asserted, then the arbitration scheme is the same as described in [Section 12.6.3.6.9, DISPC DMA Arbitration](#).

The DSS0_COMMON_DISPC_GLOBAL_MFLAG_ATTRIBUTE[6] MFLAG_START bit defines the following additional rules for the MFLAG mechanism:

- If the MFLAG_START bit is set to 0x0 (default value), then when the DMA buffer is empty at the beginning of the frame, the MFLAG signal of each pipeline is kept at 0 until PRELOAD is reached (for more information on preloading, see [Section 12.6.3.6.2, DISPC Read DMA Buffers](#)). Then, based on the setting of the DSS0_COMMON_DISPC_GLOBAL_MFLAG_ATTRIBUTE[1-0] MFLAG_CTRL register field, the MFLAG signal is generated and DISPC internal logic is arbitrating between pipeline requests.
- If the MFLAG_START bit is set to 0x1, then even in the beginning of the frame when the DMA buffer is empty, the configuration of DSS0_COMMON_DISPC_GLOBAL_MFLAG_ATTRIBUTE[1-0] MFLAG_CTRL register field determines the generation of the MFLAG signal.

12.6.3.6.8 DISPC DMA Priority Requests Control

The DSS0_COMMON_DSS_CBA_CFG register controls the priority level for DMA requests going out to the memory through the system interconnect.

As explained in [Section 12.6.3.6.7, DISPC DMA MFLAG Mechanism](#), the DISPC master port generates a 1-bit MFLAG output signal to raise the priority of all requests made on that port, if any of its DMA buffers runs critically low (determined by a set of user programmable threshold values for each buffer).

DSS uses the MFLAG signal from DISPC to set a 3-bit priority level output (*Mpriority*) for the master port to either a low or high value (configurable in DSS0_COMMON_DSS_CBA_CFG[2-0] PRI_LO and [5-3] PRI_HI register fields with optional values of 0~7) as follows:

- When MFLAG = 0, the PRI_LO register field determines the value of the Mpriority output for the normal transactions.
- When MFLAG = 1, the PRI_HI register field determines the value of the Mpriority output for the high-priority transactions.

This Mpriority output directly drives the respective input of the system interconnect port, which corresponds to the DISPC DMA master port.

CAUTION

Upon a hardware reset, DSS0_COMMON_DSS_CBA_CFG[2-0] PRI_LO and [5-3] PRI_HI register fields are set by default to 4 and 1, respectively. Afterwards, these priority level register fields can only be modified by a secure host.

12.6.3.6.9 DISPC DMA Arbitration

The read requests sent to the system interconnect are pipelined and arbitrated in a round-robin scheme. The default arbitration scheme can be modified by setting the priority attribute of each pipeline as defined in the DSS0_VID_ATTRIBUTES[23] ARBITRATION register bit.

By default, all pipelines have the same priority (normal priority), which means all pipeline requests are treated in a round-robin order manner. If one or more pipelines require a higher number of requests going to the system interconnect, its priority can be moved up to high priority. In this case, the high-priority pipeline is granted access before any pipeline in normal priority. If more than one active pipeline is in high priority, then the behavior is the same as all active pipelines in normal priority. Normal active pipelines are not treated until all high active pipelines are finished. The ARBITRATION bit cannot be modified during the entire frame.

In addition to the priority bit-field, the MFLAG mechanism can also result in a higher priority for a pipeline. An MFLAG priority level is set, for all pipelines for which MFLAG bit is set, which is defined as the highest priority level for arbitration. For more details on MFLAG mechanism, see [Section 12.6.3.6.7, DISPC DMA MFLAG Mechanism](#). [Figure 12-363](#) shows the transition between the different priority levels.

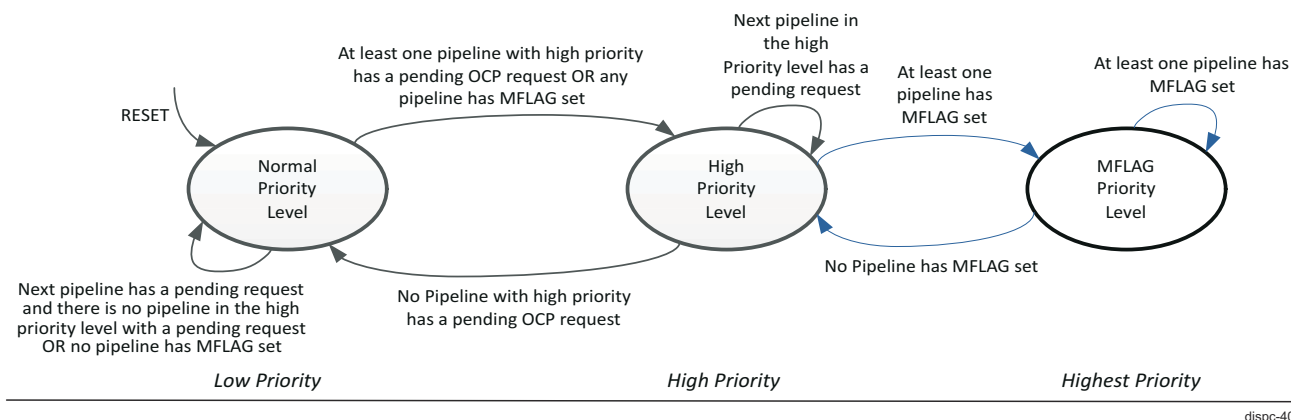

Figure 12-363. DISPC DMA High/Low Priority Arbitration

12.6.3.6.10 DISPC DMA Ultra-Low Power Mode

In ultra-low power mode, the system interconnect is used to fill up the DMA buffers to store all the data required to display a full frame. Then, the system interconnect is not used anymore to fetch new pixels for the consequent frames. The data are fetched once into the DMA buffer and then the following frames re-use the DMA buffer to display on the screen.

The programming of the ultra-low power mode is independent for each pipeline and is achieved via the DSS0_VID_ATTRIBUTES[24] SELFREFRESH register bit. One pipeline may have all frame pixels into the DMA buffer and other pipeline may have to refill the DMA buffers along the display scan, because the frame buffer is too big to be stored in the DMA buffer.

The DMA buffers can be merged in order to optimize the system interconnect OFF time. Each DMA buffer dedicated to one pipeline can be split into two buffers. The merge of the DMA buffers into a single one can be used at the same time to improve the Ultra-Low Power mode.

Two ultra-low power modes can be entered, manual or automatic mode:

- **Manual self-refresh mode:** Starting self-refresh mode is done manually by setting the SELFREFRESH bit to 0x1 after capturing a frame in the DMA buffers. Self-refresh mode is stopped by setting the SELFREFRESH bit to 0x0. Software must first disable the SELFREFRESH bit during at least one frame in order to capture the data (by setting the GOBIT register bit of the video port the pipeline is associated with). Once the DSS0_VP_CONTROL[5] GOBIT bit has been set, the software must read the GOBIT bit to ensure that the frame has been loaded into the buffer, then it can set the SELFREFRESH bit to 1. Once SELFREFRESH is enabled, the fetch of data from the system memory is stopped for the following frames. The software needs to reset the SELFREFRESH bit in order to restart fetching data from system memory.
- **Automatic self-refresh mode:** By setting the DSS0_VID_ATTRIBUTES[17] SELFREFRESHAUTO bit to 0x1, the transition from disabled to enabled for self-refresh mode is controlled by hardware. This allows the software to reset the SELFREFRESH bit to "disabled", and then automatically after the fetch of the first frame the hardware switches back SELFREFRESH bit to "enabled". The SELFREFRESH must be disabled during at least one frame in order to capture the data, so software must reset the bit to 0 every time the data in the DMA buffer needs to be updated. The hardware reads the data inside the DMA buffer without accessing the interconnect and system memory during the frame, then modifies the SELFREFRESH bit to reflect the current state of the self-refresh mode by setting the bit to 0x1.

12.6.3.6.11 DISPC Compressed Data Format Support

The DISPC is capable of reading a compressed frame buffer through the FBDC block. The FBDC is a Frame Buffer Decompression module that is compatible with the lossless compression module (FBC) in the GPU in the SoC. The FBDC performs the lossless decompression of the compressed images on a tile-by-tile basis. The size of the tiles is 16 pixels by 4 lines or 32 pixels by 2 lines. The FBDC is enabled by setting the DSS0_VID_FBDC_ATTRIBUTES[0] ENABLE register bit.

12.6.3.6.11.1 FBDC Tile Request

Since the compression/decompression is tile based, the DMA engine generates a 256-byte (16x128-bit) 1D burst request for each tile (a tile is a 16x4 or 32x2 2D structure of 32-bit elements) to FBDC which handles the DMA transfer and decompression of the requested tile. The de-compression phases are transparent to the DISPC hardware. Only ordering of the pixels from a returned tile is taken care by the DISPC DMA engine using 1D burst. The data returned from the FBDC, for a single tile over different OCP data-phases (DP), is as shown in Figure 12-364.

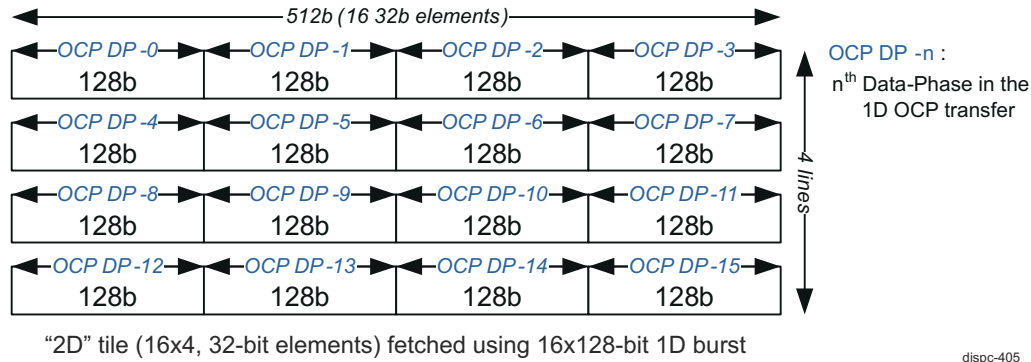

Figure 12-364. DISPC FBDC Tile Request (16x4 Tile)

Note

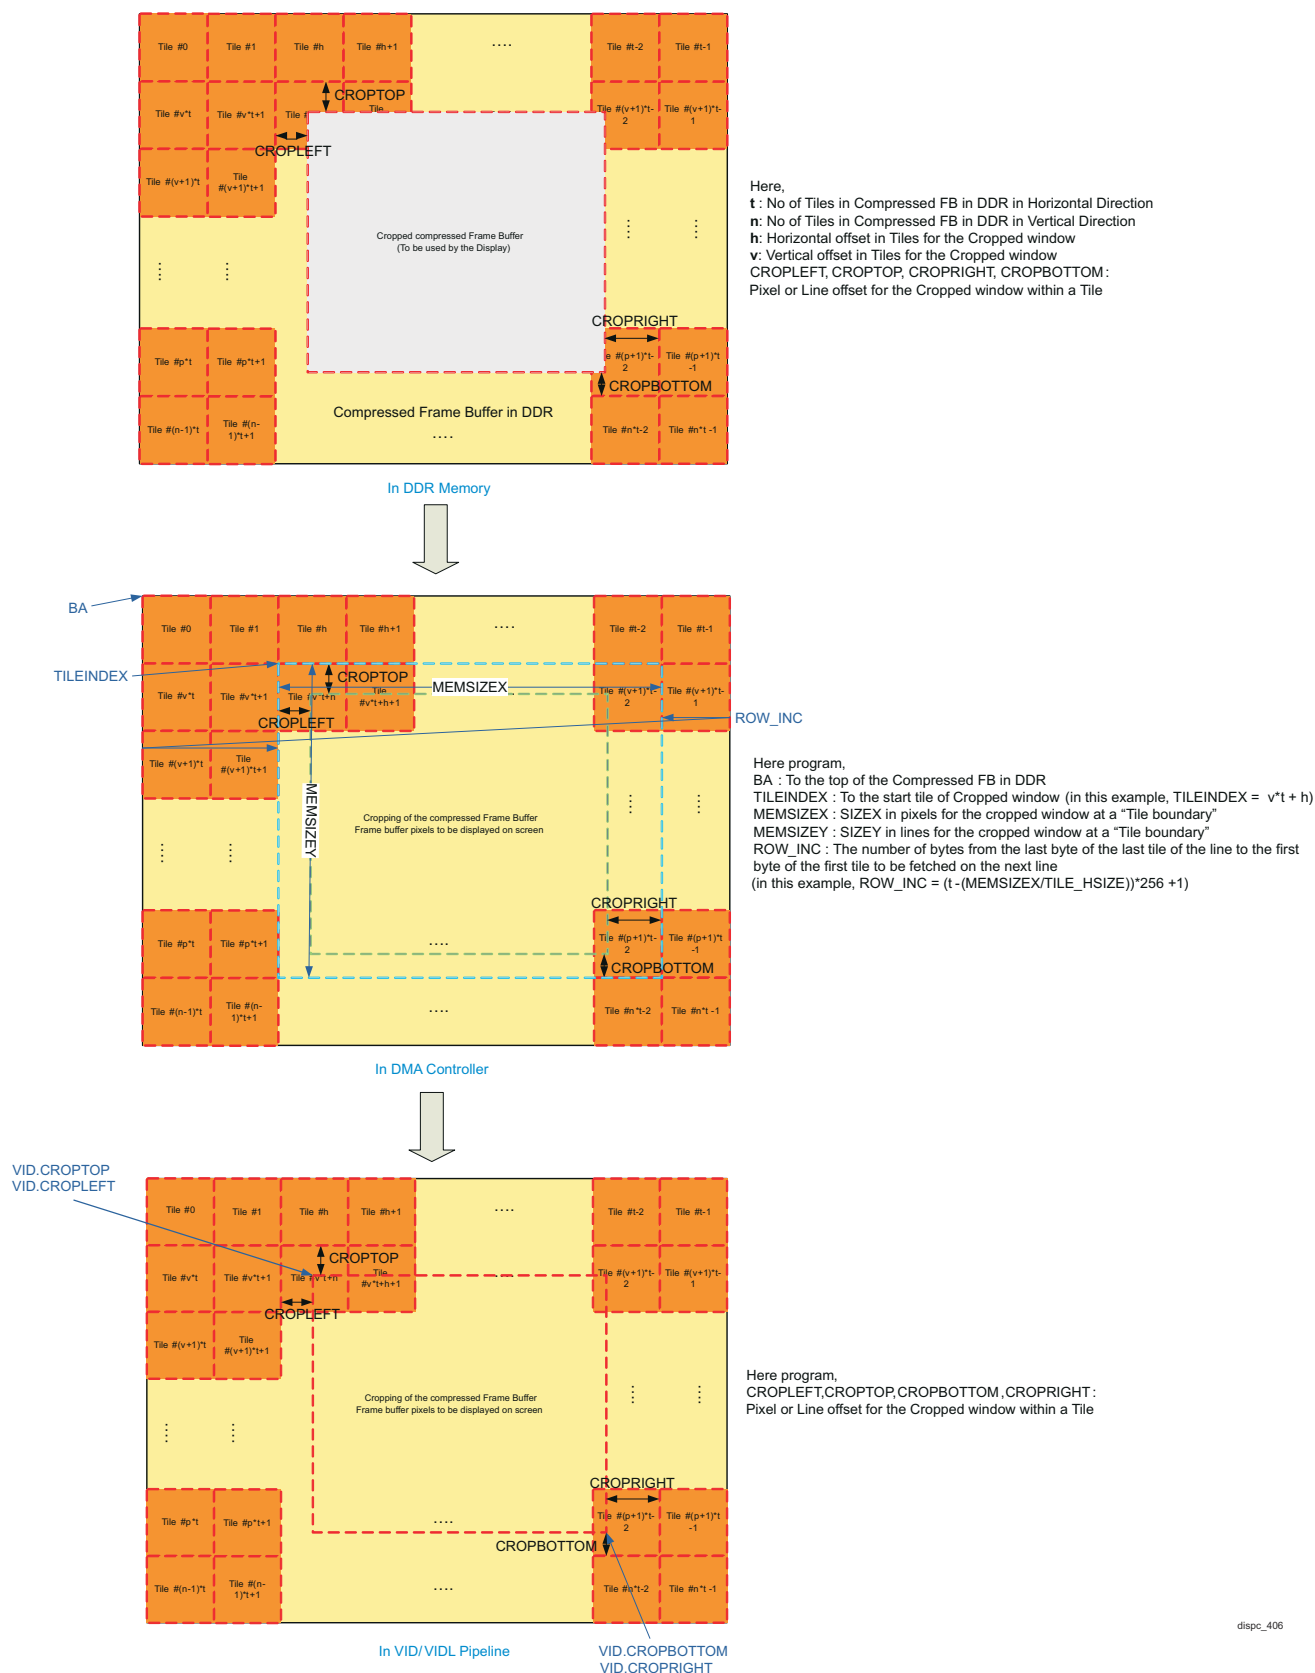

Due to the tile nature of the data, the following DMA features are not available with compressed data formats:

- Flip/Mirror support
- ROW_INC on a line basis (that is, ROW_INC cannot be used to skip lines). It can only be specified in such a way as to skip entire tile rows.

12.6.3.6.11.2 FBDC Source Cropping

The FBDC supports a source cropping of the compressed frame buffer. The source cropping is achieved as a two-step process.

- Cropping at a tile boundary is achieved by the DMA controller.
- Cropping within a tile (to a pixel or a line) is achieved by the VID/VIDL pipeline. That is a regular crop feature in the VID/VIDL pipeline which is useful for non-compressed frames as well.

dispc_406

Figure 12-365. DISPC FBDC Example of a Frame Buffer Source Cropping (Decompression)

The necessary programming for cropping at a tile boundary within the DMA Controller (based on [Figure 12-365](#)) is as follows:

- BA must be programmed to the top of the compressed frame buffer in DDR.
- TILEINDEX must be programmed to the start tile of the cropped window in the DSS0_VID_TILE[22-0] TILEINDEX register field. In this example, $TILEINDEX = v \cdot t + h$.
- MEMSIZE_X is the SIZE_X in pixels for the cropped window at a "Tile boundary".
- MEMSIZE_Y is the SIZE_Y in lines for the cropped window at a "Tile boundary".
- ROW_INC is the number of bytes from the last byte of the last tile of the line to the first byte of the first tile to be fetched on the next line. In this example, $ROW_INC = (t - (MEMSIZE_X / TILE_H_SIZE)) \cdot 256 + 1$, where $TILE_H_SIZE = 16$ or 32 depending on whether 16x4 tile-type is used or a 32x2 tile-type is used. The tile type must be programmed in the DSS0_VID_FBDC_ATTRIBUTES[9-8] TILETYPE register field.

For details on the register programming for the crop feature in the VID/VIDL pipeline, see [Section 12.6.3.8.9, DISPC VID Cropping Support](#).

12.6.3.7 DISPC Pixel Data Formats

The DISPC pipelines support various types of memory formats, as listed in [Table 12-410](#).

For BITMAP formats the nibble mode (pixels in each byte are packed in reverse order) can be enabled by setting the DSS0_VID_ATTRIBUTES[10] NIBBLEMODE register bit to 0x1. The nibble mode is supported only for the VID/VIDL pipelines, but not for the WB pipeline.

The pixel data format can be selected by loading the corresponding value from [Table 12-410](#) in the DSS0_VID_ATTRIBUTES/DSS0_WB_ATTRIBUTES[6-1] FORMAT register bit-field.

Table 12-410. DISPC Supported Pixel Data Formats

FORMAT Register Field Value		Pixel Format ⁽⁴⁾		Component Bit Depth

NA	0x3C	YUV422-NV12	YUV422-NV12	8/10/12 ⁽³⁾
NA	0x3D	YUV420-NV12	YUV420-NV12	8/10/12 ⁽³⁾
NA	See ⁽²⁾	YUV420-NV21 YUV422-NV21	YUV420-NV21 YUV422-NV21	8/10/12

- (1) The video and writeback pipelines support an optional 8-bit Alpha plane (separate buffer), if the pixel format of the source/destination buffer is either RGB16-565 or BGR16-565.
- (2) NV21 formats for YUV420/YUV422 are indirectly supported through chroma swapping during the color space conversion.
- (3) The 10-bit/12-bit versions of these YUV formats are also supported in both packed and unpacked (in 16-bit container) formats. For unpacked formats, both LSB or MSB alignments are supported. These configurations are set using a separate configuration registers: DSS0_VID_ATTRIBUTES2 and DSS0_WB_ATTRIBUTES2. The default is an 8-bit packed format support.
- (4) All RGB formats with alpha component include both pre/non-pre-multiplied data support. Also, alpha can be disabled to work as X (can be replaced with global alpha value).
- (5) The writeback path supports only 8-bit and 10-bit YUV data formats.

Figure 12-366 shows the pixel data memory organization for the bitmap pixel formats.

dispc-306

Figure 12-372 shows the pixel data memory organization for the RGB 64-bit pixel formats.

Figure 12-373 and Figure 12-374 show the pixel data memory organization for the YUV 8-bit pixel formats, together with some specific register settings.

Figure 12-378 through Figure 12-380 show the pixel data memory organization for the YUV 10-bit/12-bit unpacked pixel formats in 16-bit container, together with some specific register settings.

YUV 10-bit/12-bit unpacked formats have the same component packing order as 8-bit formats except that each component is stored in a 16-bit container (with MSB or LSB bits within the 16-bit container not used depending on the MSB/LSB alignment).

ATTRIBUTES2.YUV_SIZE = 1 or 2 (10b or 12b)

ATTRIBUTES2.YUV_MODE = 1 (Unpacked)

ATTRIBUTES2.YUV_ALIGN = 0 or 1 (LSB or MSB aligned)

dispc-315

12.6.3.8 DISPC Video Pipeline

The DISPC includes two types of input video pipelines:

- Video pipeline (VID1 and VID2)
- Video lite pipeline (VIDL1 and VIDL2)

The video pipeline (VID) consists of:

- VC-1 range mapping unit for YUV422/YUV420 input formats;
- Replication logic for ARGB input formats;
- One 256 x 24-bit entries Color Look-up Table (CLUT);
- Polyphase-filter based resizer unit (scaler) supporting chroma upsampling;
- Luma-key support;
- Color Space Conversion (CSC) unit (YUV to RGB), which can be used also for programmable BCHS (Brightness/Contrast/Hue/Saturation) control;

The video lite pipeline (VIDL) is identical to the video pipeline (VID), except for:

- Polyphase-filter based resizer (scaler) is not included;
- Chroma upsampling is done using dedicated YUV420-to-422 and YUV422-to-444 upsamplers (instead of using the scaler);

Each pipeline processing block can be independently bypassed.

Note

The DISPC input video pipelines, VID and VID1L, will be commonly referred to as *video pipeline (VID)* in the following sections. Any differences in their functionality will be highlighted.

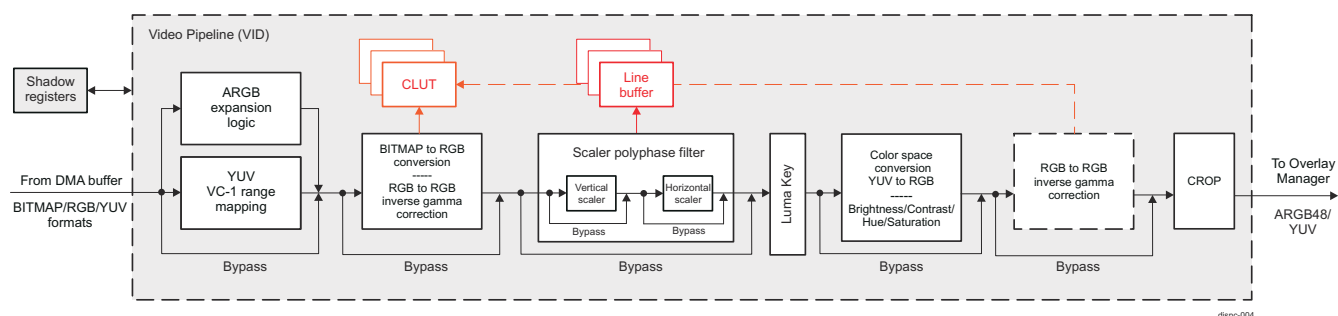

Figure 12-381. DISPC Video Pipeline Configuration

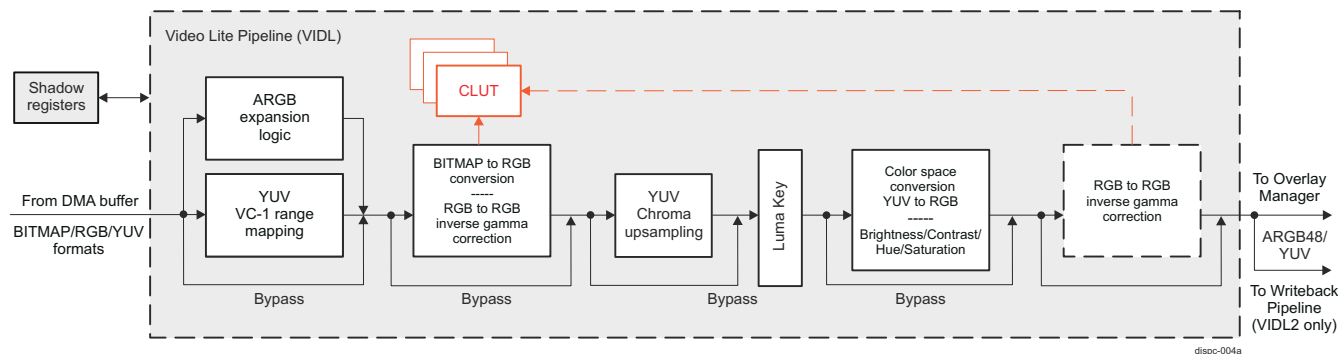

Figure 12-382. DISPC Video Lite Pipeline Configuration

The input of the VID pipeline is connected to the video DMA buffer controller. The pixel output of the VID pipeline is connected to the overlay managers. The VID pipeline configuration supports various BITMAP, RGB (ARGB and RGBA), and YUV formats, as listed in [Table 12-410, DISPC Pixel Data Formats](#).

The 256-entry CLUT is either used to convert BITMAP (1, 2, 4, or 8-bit indexed formats) into RGB format, or for RGB to RGB inverse gamma correction. For a BITMAP format data, scaling is not supported. Scaling and

color look-up table features are mutually exclusive. If the color look-up feature is enabled, then the video pipeline scaler has to be disabled.

For chroma sub-sampled YUV formats (YUV422 and YUV420-NV12/NV21):

- VID pipeline: the scaler unit upsamples the chrominance data using both vertical and horizontal polyphase filters;
- VIDL pipeline: dedicated YUV420 to YUV422 and YUV422 to YUV444 chroma upsamplers are used;

For ARGB source data with less than/equal to 10-bit component data size the replication logic (ARGB expansion) converts the data to ARGB48 by replicating the MSBs into the LSBs:

- When scaling is disabled (or no scaler supported), the resulting ARGB48 data is directly provided to the pipeline output;
- When vertical scaling is engaged, the resulting ARGB48 data is first truncated to ARGB8888, and then converted to ARGB10101010 (by MSBs replication into LSBs), before being fed to the vertical scaler input;
- When vertical scaling is disabled, but horizontal scaling is engaged, the resulting ARGB48 data is directly provided to the horizontal scaler input;

Note

There are limitations on using the inverse gamma (InvGamma) operation along with scaling. If the scaler is enabled, the InvGamma operation must always take place after the scaler in the data-path (as shown in [Figure 12-381](#)). This position of the InvGamma operation is controllable through the DSS0_VID_ATTRIBUTES2[29] GAMMAINVERSIONPOS register field.

All the memories (line buffers attached to the scaler, LUT and chroma upsamplers) are sized to support 10-bit per color component. This allows full 10-bit support inside the video pipeline.

The VID pipeline can be enabled by setting the DSS0_VID_ATTRIBUTES[0] ENABLE register bit. If the video pipeline is disabled, the video window does not exist on the screen and the whole video pipeline and its DMA are inactive. Prior to enabling the video layer a valid configuration has to be set by the user.

12.6.3.8.1 DISPC VID Replication Logic

The replication logic (ARGB expansion) converts ARGB pixel formats into ARGB48 format by replicating the MSBs into the LSBs. The logic is always enabled.

[Table 12-411](#) shows how some of the ARGB formats supported by VID are remapped into ARGB48 by default.

Table 12-411. DISPC VID Replication: ARGB Pixel Formats Remapping into ARGB48-12121212

ARGB32-8888	A[7:0]A[7:4]	R[7:0]R[7:4]	G[7:0]G[7:4]	B[7:0]B[7:4]

12.6.3.8.2 DISPC VID VC-1 Range Mapping Unit

The VC-1 range mapping unit is used when the video frame picture is decoded using a VC-1 codec by the video accelerator. It remaps the Y, Cb, and Cr components to the full range (from the reduced data range) before displaying. The unit is used primarily for YUV420-NV12 (NV21) pixel format, but also can be applied to YUV422 pixel formats (YUV2 and UYVY).

The VC-1 range mapping unit is enabled by setting the DSS0_VID_ATTRIBUTES2[0] VC1ENABLE bit to 0x1. The VC-1 range mapping must be enabled only for 8 bits/component YUV input data.

The DSS0_VID_ATTRIBUTES2[3:1] VC1_RANGE_Y and [6:4]VC1_RANGE_CBCR register bitfields are two 3-bit values programmed by the user.

The equations for the mapping process are:

$$Y_{out} = \text{CLIP}((((Y_{int} - 128) \times (\text{VC1_RANGE_Y} + 9) + 4) / 8) + 128)$$

$$C_b = \text{CLIP}((((C_b - 128) \times (\text{VC1_RANGE_CBCR} + 9) + 4) / 8) + 128)$$

$$C_r = \text{CLIP}((((C_r - 128) \times (\text{VC1_RANGE_CBCR} + 9) + 4) / 8) + 128)$$

Note

The input and output pixel values are unsigned (Y, Cr, and Cb).

The function CLIP() clips to 0 or 255 when minimum or maximum, respectively, is reached. Otherwise, the resulting output remains identical.

12.6.3.8.3 DISPC VID Color Look-Up Table (CLUT)

The video pipeline supports a look up table to perform either of the following operations:

- Conversions of BITMAP formats (1, 2, 4, or 8-bit indexed) into RGB format (CLUT mode), or
- Inverse gamma correction on non-linear RGB source data (gamma mode)

The look-up table consists of 3 separate 1024 x 10-bit memories and is indexed either by the source BITMAP data or by R/G/B component data. The table is loaded through direct register access by writing to the CLUT registers.

The sequence to load the table is:

1. SW writes (only writes are supported) 32-bit values for both color and monochrome mode using single access, or burst access in linear increment burst mode, into the DSS0_VID_CLUT_0 through DSS0_VID_CLUT_15 registers. The LSB 30 bits [29:0] are used for the value and the MSB 1 bit [31] is used to reset the index of the table for the color mode, while the LSB 8 bits are used for the value and the MSB 1 bit to reset the index of the table for monochrome mode. [Figure 12-383](#) describes the format of one of the palette value in the memory.
2. Loop to Step 1, if there is a new access to the CLUT registers. Software can access other registers between two accesses to the CLUT registers.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the look-up table in CLUT mode is activated when a BITMAP format is selected in the DSS0_VID_ATTRIBUTES[6:1] FORMAT register bit-field.

The usage of the look-up table for RGB inverse gamma correction can be enabled by setting DSS0_VID_ATTRIBUTES[30] GAMMAINVERSION register bit.

Figure 12-383. DISPC VID CLUT/Gamma Data Memory Organization

Note

Scaling and color look-up table features are mutually exclusive. If color look-up feature is enabled, then video pipeline scaler has to be disabled.

12.6.3.8.4 DISPC VID Chrominance Resampling

12.6.3.8.4.1 Chrominance Resampling for VID Pipeline

The chrominance resampling from 8-bpc or 10-bpc to 12-bit color components is always performed using filtering (the scaler unit filter). Chrominance resampling and rescaling can be combined to support native rescaling of YUV formats.

The usage of the scaler unit for resampling the chrominance of YUV420 and YUV422 is shown in [Figure 12-384](#) and [Figure 12-385](#), respectively. The settings of the scaler unit to perform chrominance resampling are described in [Section 12.6.3.8.5, DISPC VID Scaler Unit](#).

Figure 12-384. DISPC VID YUV420 to ARGB48 Using Scaler Unit for Resampling Chrominance

Figure 12-385. DISPC VID YUV422 to ARGB48 Using Scaler Unit for Resampling Chrominance

The vertical scaler is not a mandatory block for resampling the chrominance of YUV422 data, as shown in [Figure 12-385](#).

Using the filter it is possible to re-sample the chrominance from either MPEG1 or MPEG2 sub-sampled chroma source.

12.6.3.8.4.2 Chrominance Resampling for VIDL Pipeline

The VIDL pipeline does not include a scaler unit. Chroma upsampling is done using dedicated YUV420 to YUV422, and YUV422 to YUV444 chroma upsamplers.

The VIDL pipeline converts YUV420 (Chroma) data to YUV422 (Chroma) using a simple vertical average filter (average of two adjacent chroma lines to generate a missing line except for the very bottom line which is generated by repeating the previous chroma line). If the video image is a sub-image of a larger video frame data, then the vertical Luma line offset from the top should be an even number.

The VIDL pipeline converts YUV422 data to YUV444 format using a 4-tap filter (implementing the Catmull-Rom algorithm) to generate missing chroma data as follows:

$$\text{Cout}[2*i] = \text{Cin}[i]$$

$$\text{Cout}[2*i+1] = \text{CLIP} \left(-1/16 * \text{Cin}[i-1] + 9/16 * \text{Cin}[i] + 9/16 * \text{Cin}[i+1] - 1/16 * \text{Cin}[i+2] \right)$$

The missing chroma data is generated as a simple weighted average of the surrounding 4 chroma values, which is equivalent to a 4x1 filter kernel with values: $[-1/16, 9/16, 9/16, -1/16]$. In this algorithm, edge effects are treated by repeating the first and last pixel.

12.6.3.8.5 DISPC VID Scaler Unit

Note

Only VID pipeline includes a resizer unit (scaler). The VIDL pipeline does not include a scaler.

The programmable scaler filter works with all supported video formats, including formats with alpha channel. The alpha channel is scaled with the same parameters as the RGB color components. For the YUV formats,

Y and Cb/Cr are processed independently. A RGB 64-bit source (16 bits per component) is truncated to 8-bit/component, if the scaler is enabled. Otherwise, it will be truncated to ARGB48 format in the scaler bypass mode. A 10-bit/12-bit YUV source is also truncated to 8-bit, since the scaler is enabled to either upsample the chroma component and/or resize the YUV frame data directly (for memory-to-memory operation with YUV format as the memory destination type).

The filter is based on a finite impulse response (FIR) filter with 16 phases. The filter is a 5-tap for horizontal filtering, and can be configured for 3 or 5 taps for vertical filtering. The filtering can be used for various processing:

- Up-sampling of the picture
- Down-sampling of the picture
- Anti-aliasing reduction
- Chrominance resampling in case of YUV data formats

The following limitations must be considered:

- The up-sampling ratio is up to x16.
- The down-sampling ratio using 3-tap configuration is down to x0.5 for RGB format.
- The down-sampling ratio using 5-tap configuration is down to x0.25 for RGB format.

Note

The user must set the correct size and position of the original video before resize in order for the up-sampled/down-sampled video to be displayed inside the screen boundaries.

Figure 12-386 shows an example of video up-sampling, with corresponding video window attributes.

Figure 12-386. DISPC Video Window Attributes

The video window attributes can be configured in the following register bit-fields:

- Source data format (input to the scaler unit) in DSS0_VID_ATTRIBUTES[6-1] FORMAT bit-field
- Video picture width in system memory (frame buffer) in DSS0_VID_PICTURE_SIZE[13-0] MEMSIZEX bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed except for YUV422 formats. In case of YUV422 and UYVY422 formats the width has to be a multiple of 2 pixels.
- Video picture height in system memory (frame buffer) in DSS0_VID_PICTURE_SIZE[29-16] MEMSIZEY bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed.

- Video window width at pipeline output (after resizing) in DSS0_VID_SIZE[13-0] SIZE_X bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen width minus the horizontal start location of the window on the screen.
- Video window height at pipeline output (after resizing) in DSS0_VID_SIZE[29-16] SIZE_Y bit-field. The window height is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen height minus the vertical start location of the window on the screen.
- Video window overlay X-position in DSS0_OVR_ATTRIBUTES2_0 through DSS0_OVR_ATTRIBUTES2_4[13-0] POS_X bit-field. See [Section 12.6.3.10, DISPC Overlay Managers](#).
- Video window overlay Y-position in DSS0_OVR_ATTRIBUTES2_0 through DSS0_OVR_ATTRIBUTES2_4[29-16] POS_Y bit-field. See [Section 12.6.3.10, DISPC Overlay Managers](#).
- For configuration of LPP and PPL video port output display parameters, see [Section 12.6.3.11.8, DISPC VP Timing Generator and Display Panel Settings](#).

For vertical up-sampling and down-sampling in a 3-tap configuration, the equations are:

For RGB formats	For YUV formats
$A_{out}(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times A_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $R_{out}(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $G_{out}(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times G_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $B_{out}(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times B_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$	$Y_{out}(n) = \left(\sum_{i=-1}^{i=1} C_{yi}(\Phi_y) \times Y_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cb_{out}(n) = \left(\sum_{i=-1}^{i=1} C_{ci}(\Phi_c) \times Cb_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cr_{out}(n) = \left(\sum_{i=-1}^{i=1} C_{ci}(\Phi_c) \times Cr_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-012

(23)

For vertical and horizontal up-sampling and down-sampling in a 5-tap configuration, the equations are:

For RGB formats	For YUV formats
$A_{out}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times A_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $R_{out}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $G_{out}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times G_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $B_{out}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times B_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$	$Y_{out}(n) = \left(\sum_{i=-2}^{i=2} C_{yi}(\Phi_y) \times Y_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cb_{out}(n) = \left(\sum_{i=-2}^{i=2} C_{ci}(\Phi_c) \times Cb_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cr_{out}(n) = \left(\sum_{i=-2}^{i=2} C_{ci}(\Phi_c) \times Cr_{in}(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-012

(24)

Note

The pixel (n + 1) is the previous pixel with respect to pixel (n). The line (n + 1) is the previous line with respect to line (n).

The coefficients C_i() depend on the phase between input and output pixels.

The coefficients are different for Y and Cr/Cb filtering because the calculations are independent due to the chrominance resampling for YUV422 and YUV420.

First, the vertical filter is applied to the encoded input pixel data, and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. The vertical input of the filter consists of:

- Six lines of 2048 × 32 bits for 5-tap configuration
- Three lines of 4096 × 32 bits for 3-tap configuration

Table 12-412 lists some of the scaler supported configurations.

Table 12-412. DISPC VID Line Buffer Width for Scaler Unit

Pixel Format	Maximum Input Width (Pixels) for 5-tap	Maximum Input Width (Pixels) for 3-tap
32 bits per pixel (ARGB32-8888, ARGB-2101010, etc.)	2048 pixels wide ⁽¹⁾	4096 pixels wide
YUV420, YUV422	4096 pixels wide	4096 pixels wide

- (1) For the 5-tap configuration, the 6th video line is used on the output of the horizontal scaler in order to start the next output line generation while the video pipeline output is being stalled by the overlay manager (either due to display in blanking period and/or in background pixel period). The 6th line buffer is actually 48-bit wide to allow storage of ARGB48 format pixel data.

At the beginning of frame scaling processing, the first line may be duplicated multiple times depending on the initial vertical phase programmed for the poly-phase filter.

At the end of frame scaling processing the last line is duplicated, if the scaling logic requires loading more lines and the last line has been reached.

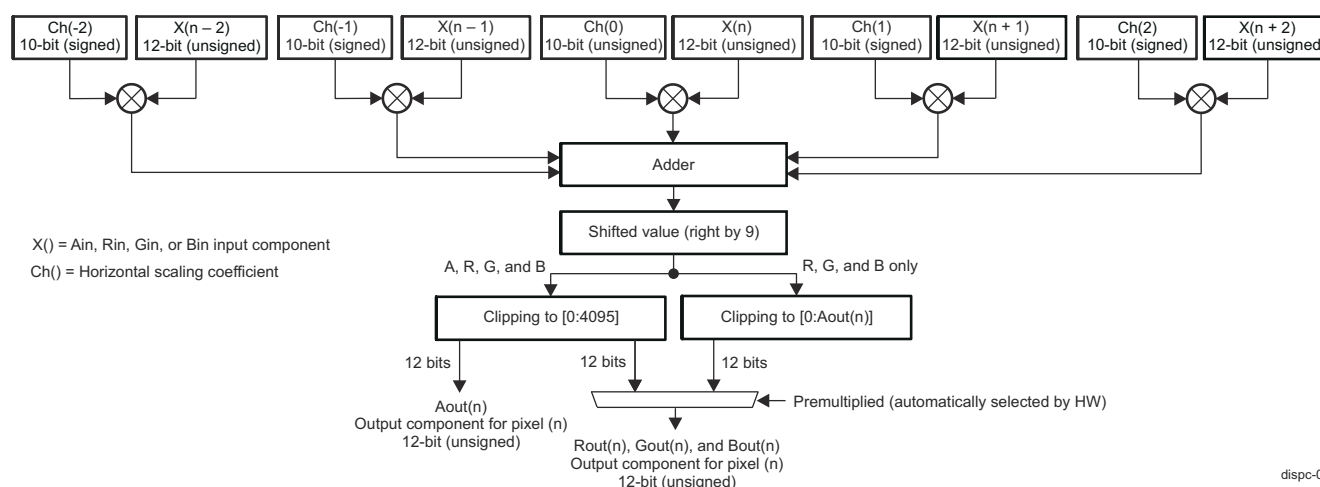

Similarly, the first pixel may be duplicated multiple times depending on the initial horizontal phase programmed for the poly-phase filter. The last pixel is duplicated, if the scaling logic requires loading more pixels and the last pixel has been reached.

The programmable coefficients of the polyphase filters are signed 10-bit values (except for the central coefficient, which is unsigned). The vertical video scaler has an 10-bit input and a 12-bit output. The horizontal scaling stage takes the resulting 12-bit input and produces 12-bit output.

Figure 12-387 and Figure 12-388 show the scaler macro-architecture for components A, R, G, and B. Figure 12-389 and Figure 12-390 show the scaler macro-architecture for components Y, Cr, and Cb.

Note

The scaling and CSC clipping is set by the same bit, DSS0_VID_ATTRIBUTES[11] FULLRANGE.

Note

In Table 12-413, the cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DSS0_VID_FIR_COEF_V0_0 to DSS0_VID_FIR_COEF_V0_8, and DSS0_VID_FIR_COEF_V12_0 to DSS0_VID_FIR_COEF_V12_15 are used).

Similar table approach applies to the coefficients for Cb/Cr filtering in case of YUV format (registers DSS0_VID_FIR_COEF_H0_C_0 to DSS0_VID_FIR_COEF_H0_C_8, and DSS0_VID_FIR_COEF_H12_C_0 to DSS0_VID_FIR_COEF_H12_C_15, and DSS0_VID_FIR_COEF_V0_C_0 to DSS0_VID_FIR_COEF_V0_C_8 and DSS0_VID_FIR_COEF_V12_C_0 to DSS0_VID_FIR_COEF_V12_C_15 are used).

The VID scaler unit vertical and/or horizontal sampling is selected by configuring the DSS0_VID_ATTRIBUTES[8-7] RESIZEENABLE bit field.

Prior to enabling the video up/down-sampling block a valid configuration has to be set by the user. After configuring the required VID registers change the DSS0_VP_CONTROL[5] GOBIT register bit of the video port the video pipeline is associated with. The software has to wait before setting the GO bit that the hardware has reset the bit. The software reset is not recommended since the application cannot guarantee to be able to reset it before the HW.

The following fields define the configuration of the video up-sampling/down-sampling block in the VID pipeline for ARGB and YUV formats:

- Vertical upsampling and downsampling increment value in the [23-0] FIRVINC bit field of DSS0_VID_FIRV (for ARGB and Y) and DSS0_VID_FIRV2 (for CbCr) registers. The unsigned integer value range is 2^{23} . Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left(\frac{MEMSIZEY+1}{SIZEY+1} \right)$$

dispc-066

- Horizontal upsampling and downsampling increment value in the [23-0] FIRHINC bit field of the DSS0_VID_FIRH (for ARGB and Y) and DSS0_VID_FIRH2 (for CbCr) registers. The unsigned integer value range is [1:16384]. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left(\frac{MEMSIZEH+1}{SIZEH+1} \right)$$

dispc-067

- Vertical up/downsampling accumulator value in the [23-0] VERTICALACCU bit field of the DSS0_VID_ACCUV_0 and DSS0_VID_ACCUV_1 (for ARGB and Y), and DSS0_VID_ACCUV2_0 and DSS0_VID_ACCUV2_1 (for CbCr) registers. The accumulator value indicates on which phase the vertical filtering starts. The DSS0_VID_ACCUV_0 register is used for progressive output, while for interlace output both DSS0_VID_ACCUV_0 and DSS0_VID_ACCUV_1 registers are used. The DSS0_VID_ACCUV2_0 and DSS0_VID_ACCUV2_1 registers are used in the same manner for progressive or interlace output.
- Vertical upsampling and downsampling line buffer configuration via the DSS0_VID_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value in the [23-0] HORIZONTALACCU bit field of the DSS0_VID_ACCUH_0 and DSS0_VID_ACCUH_1 (for ARGB and Y), and DSS0_VID_ACCUH2_0 and DSS0_VID_ACCUH2_1 (for CbCr) registers. The accumulator value indicates on which phase the horizontal filtering starts. The register DSS0_VID_ACCUH_0 is used for progressive output, while for interlace output both DSS0_VID_ACCUH_0 and DSS0_VID_ACCUH_1 registers are used. The DSS0_VID_ACCUH2_0 and DSS0_VID_ACCUH2_1 are used in the same manner for progressive or interlace output.

Table 12-414 lists the scaler vertical and horizontal accumulator values and phases.

Table 12-414. DISPC VID Scaler Vertical and Horizontal Accumulator Phases

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8

Table 12-414. DISPC VID Scaler Vertical and Horizontal Accumulator Phases (continued)

Accumulator Value (MSB bits)	Phases f
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
 - For ARGB and Y, the vertical upsampling and downsampling central coefficients are defined in the DSS0_VID_FIR_COEF_V0_0 to DSS0_VID_FIR_COEF_V0_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
 - Four CbCr, the vertical upsampling and downsampling central coefficients are set in DSS0_VID_FIR_COEF_V0_C_0 to DSS0_VID_FIR_COEF_V0_C_8 registers.
- Vertical upsampling and downsampling coefficients:
 - For ARGB and Y, the vertical upsampling and downsampling coefficients are defined in the DSS0_VID_FIR_COEF_V12_0 to DSS0_VID_FIR_COEF_V12_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.
 - Four CbCr, the vertical upsampling and downsampling coefficients are set in DSS0_VID_FIR_COEF_V12_C_0 to DSS0_VID_FIR_COEF_V12_C_15 registers.
- Horizontal upsampling and downsampling central coefficients:
 - For ARGB and Y, the horizontal upsampling and downsampling central coefficients are defined in the DSS0_VID_FIR_COEF_H0_0 to DSS0_VID_FIR_COEF_H0_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
 - Four CbCr, the horizontal upsampling and downsampling central coefficients are set in DSS0_VID_FIR_COEF_H0_C_0 to DSS0_VID_FIR_COEF_H0_C_8 registers.
- Horizontal upsampling and downsampling coefficients:
 - For ARGB and Y, the horizontal upsampling and downsampling coefficients are defined in the DSS0_VID_FIR_COEF_H12_0 to DSS0_VID_FIR_COEF_H12_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
 - Four CbCr, the horizontal upsampling and downsampling coefficients are set in DSS0_VID_FIR_COEF_H12_C_0 to DSS0_VID_FIR_COEF_H12_C_15 registers.

The YUV filtering is based on the equations of the ARGB filtering. In addition to the registers used for ARGB filtering configuration, a second set of registers for filtering is used. The first set of registers is used for Y configuration (instead of ARGB configuration) and the second set of registers is used for CbCr filtering configuration. The two sets of registers can be the same when the YUV format is not converted to RGB after filtering. When the RGB conversion is required after filtering, then the chrominance needs to be re-sampled with a different filtering configuration because:

- Chrominance samples are offset to the luminance samples. That is, DSS0_VID_FIRH2 and DSS0_VID_FIRV2, and DSS0_VID_ACCUV2_0/DSS0_VID_ACCUV2_1 and DSS0_VID_ACCUH2_0/DSS0_VID_ACCUH2_1 registers need to be configured differently than DSS0_VID_FIRH and DSS0_VID_FIRV, and DSS0_VID_ACCUH_0/DSS0_VID_ACCUH_1 and DSS0_VID_ACCUV_0/DSS0_VID_ACCUV_1 registers used for the luminance filtering.
- Chrominance is sub-sampled by two horizontally only in case of YUV422, and horizontally and vertically in case of YUV420. The coefficients for the vertical chrominance re-sampling are identical to the coefficients for

vertical luminance filtering in case of YUV422. The coefficients for the horizontal and vertical chrominance re-sampling are different than the ones for luminance filtering in case of YUV420.

12.6.3.8.6 DISPC VID Color Space Conversion YUV to RGB

The Color Space Conversion (CSC) unit converts the video-encoded pixel values from YUV444 format into ARGB48 format (12-bit value per component A, R, G, and B, with A fixed at 0xFFFF).

In case of YUV420 or YUV422 formats, a chrominance resampling to YUV444 is performed before converting the YUV into RGB values (see [Section 12.6.3.8.4, DISPC VID Chrominance Resampling](#)). The YUV422/YUV420 to YUV444 chrominance resampling is a pre-processing to the color space conversion.

[Figure 12-391](#) and [Figure 12-392](#) show the 3×3 11-bit coefficients used to convert from YUV444 into ARGB48. The value of A component is fixed at 0xFFFF in the output. The coefficients are set according to the standard used to encode the pixel data in YUV color space. [Table 12-415](#) summarizes the coefficients with their respective register bit fields.

Table 12-415. DISPC VID CSC - YUV to RGB Register Settings

Coefficients	Register Fields
R_Y	DSS0_VID_CSC_COEF0[10-0] C00
R_{Cr}	DSS0_VID_CSC_COEF0[26-16] C01
R_{Cb}	DSS0_VID_CSC_COEF1[10-0] C02
G_Y	DSS0_VID_CSC_COEF1[26-16] C10
G_{Cr}	DSS0_VID_CSC_COEF2[10-0] C11
G_{Cb}	DSS0_VID_CSC_COEF2[26-16] C12
B_Y	DSS0_VID_CSC_COEF3[10-0] C20
B_{Cr}	DSS0_VID_CSC_COEF3[26-16] C21
B_{Cb}	DSS0_VID_CSC_COEF4[10-0] C22
Y offset	DSS0_VID_CSC_COEF5[15-3] PREOFFSET1
Cr offset	DSS0_VID_CSC_COEF5[31-19] PREOFFSET2
Cb offset	DSS0_VID_CSC_COEF6[15-3] PREOFFSET3

- Limited data range conversion (video data range)

If the active range for the luminance samples (Y) is [256:3760] and for the chrominance samples (Cb and Cr) is [256:3840], the following equation in [Figure 12-391](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the DSS0_VID_ATTRIBUTES[11] FULLRANGE bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{Cr} & R_{Cb} \\ G_Y & G_{Cr} & G_{Cb} \\ B_Y & B_{Cr} & B_{Cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 256 \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-005

Figure 12-391. DISPC VID CSC YCbCr to RGB Equation (Limited Data Range), 12-Bit Outputs

In [Figure 12-391](#), the offset values (-256, -2048, -2048) are also programmed via corresponding register bit-fields shown in [Table 12-415, DISPC VID CSC - YUV to RGB Register Settings](#).

- Full data range conversion (graphics data range)

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], the following equation in [Figure 12-392](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the DSS0_VID_ATTRIBUTES[11] FULLRANGE bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{Cr} & R_{Cb} \\ G_Y & G_{Cr} & G_{Cb} \\ B_Y & B_{Cr} & B_{Cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-006

Figure 12-392. DISPC VID CSC YCbCr to RGB Equation (Full Data Range), 12-Bit Outputs

In [Figure 12-391](#) and [Figure 12-392](#), the offset values (0, -256, -2048) can be programmed via the corresponding register bit-fields shown in [Table 12-415](#), *DISPC VID CSC - YUV to RGB Register Settings*.

Note

In case of YUV420/YUV422-NV21 data, the coefficients for Cr and Cb must be swapped in order to correctly support YUV420/YUV422-NV21 format.

The scaling and CSC clipping is set by the same bit, DSS0_VID_ATTRIBUTES[11] FULLRANGE.

Output Clipping

It is possible for the output results to be larger (overflow) than the maximum or smaller (underflow) than the minimum value the output representation supports. The Color Space Conversion module clips the overflow/underflow result to the maximum/minimum value as follows:

- FULLRANGE = 1 (Graphics range)
 - Maximum: 4095
 - Minimum : 0
- FULLRANGE = 0 (Video range)
 - Maximum: 3760 for Luma, 3840 for Chroma
 - Minimum: 256 for both Luma and Chroma

The FULLRANGE = 0 setting should only be used when the CSC logic is used to convert RGB to YCrCb and the output needs to be in the video data range.

For YCrCb to RGB conversion and other RGB to RGB processing, the FULLRANGE bit should be set to 1 to enable full data range in the output.

12.6.3.8.7 DISPC VID Brightness/Contrast/Saturation/Hue Control

The brightness/contrast/saturation controls are implemented in the same Color Space Conversion (CSC) block by making adjustments to the conversion coefficients and input/output offset values as shown in [Figure 12-393](#):

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * B0 & m * k * C0 \\ m * A1 & m * k * B1 & m * k * C1 \\ m * A2 & m * k * B2 & m * k * C2 \end{bmatrix} \begin{bmatrix} Y + Y_offset_adj \\ Cr + Cr_offset \\ Cb + Cb_offset \end{bmatrix} + \begin{bmatrix} R_offset \\ G_offset \\ B_offset \end{bmatrix}$$

dispc-101

Figure 12-393. DISPC VID Brightness/Contrast/Saturation Equation for YUV to RGB

In [Figure 12-393](#) the following terminology is used:

- A/B/C coefficients and the offset parameters are for YUV to RGB conversion. See [Table 12-416](#) below for coefficients and offsets mapping to register fields.
- The gain term (m) is used for contrast control. The allowed range is: 0 < m ≤ 2.0 (where m=1 means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is: 0 < k ≤ 2.0 (where k=1 means saturation bypass).
- The brightness offset (b) is added to Y_offset_adj. The allowed range (for 8-bit example) is: -128 ≤ b ≤ +127 (where b=0 means brightness bypass).

The hue adjustment can also be built into the above equation ([Figure 12-393](#)) to comprehend the following Cb/Cr hue angle adjustments:

$$Cb_hue_adj = (Cb \cdot \cos \emptyset + Cr \cdot \sin \emptyset)$$

$Cr_hue_adj = (Cr \cdot \cos \emptyset - Cb \cdot \sin \emptyset)$, where \emptyset is the desired hue angle (with $\emptyset=0$ meaning hue adjustment bypass)

The final combined matrix equation for controlling brightness/contrast/saturation/hue (BCSH) during YUV to RGB conversion is shown in [Figure 12-394](#)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m \cdot A0 & m \cdot k \cdot [B0 \cdot \cos(Hue) + C0 \cdot \sin(Hue)] & m \cdot k \cdot [C0 \cdot \cos(Hue) - B0 \cdot \sin(Hue)] \\ m \cdot A1 & m \cdot k \cdot [B1 \cdot \cos(Hue) + C1 \cdot \sin(Hue)] & m \cdot k \cdot [C1 \cdot \cos(Hue) - B1 \cdot \sin(Hue)] \\ m \cdot A2 & m \cdot k \cdot [B2 \cdot \cos(Hue) + C2 \cdot \sin(Hue)] & m \cdot k \cdot [C2 \cdot \cos(Hue) - B2 \cdot \sin(Hue)] \end{bmatrix} \begin{bmatrix} Y + Y_offset_adj \\ Cr + Cr_offset \\ Cb + Cb_offset \end{bmatrix} + \begin{bmatrix} R_offset \\ G_offset \\ B_offset \end{bmatrix}$$

dispc-102

Figure 12-394. DISPC VID Brightness/Contrast/Saturation/Hue Equation for YUV to RGB

Gain and offset terms in the above equation ([Figure 12-394](#)) are programmed in the hardware registers as adjusted CSC coefficients (11-bit signed) and offset values (13-bit signed) to control the brightness, contrast, saturation and hue. Mapping of the coefficients and offsets to register fields is provided in [Table 12-416](#). Outputs are clipped to keep the output values in the proper range.

Table 12-416. DISPC VID BCSH Register Settings for YUV to RGB

Coefficients	Register Fields
A0	DSS0_VID_CSC_COEF0[10-0] C00
B0	DSS0_VID_CSC_COEF0[26-16] C01
C0	DSS0_VID_CSC_COEF1[10-0] C02
A1	DSS0_VID_CSC_COEF1[26-16] C10
B1	DSS0_VID_CSC_COEF2[10-0] C11
C1	DSS0_VID_CSC_COEF2[26-16] C12
A2	DSS0_VID_CSC_COEF3[10-0] C20
B2	DSS0_VID_CSC_COEF3[26-16] C21
C2	DSS0_VID_CSC_COEF4[10-0] C22
Y offset	DSS0_VID_CSC_COEF5[15-3] PREOFFSET1
Cr offset	DSS0_VID_CSC_COEF5[31-19] PREOFFSET2
Cb offset	DSS0_VID_CSC_COEF6[15-3] PREOFFSET3
R offset	DSS0_VID_CSC_COEF6[31-19] POSTOFFSET1
G offset	DSS0_VID_CSC_COEF7[15-3] POSTOFFSET2
B offset	DSS0_VID_CSC_COEF7[31-19] POSTOFFSET3

For RGB input formats, the same CSC block can be used to adjust contrast, brightness, saturation, and hue using the matrix equation from [Figure 12-395](#).

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \begin{bmatrix} m \cdot A0 & m \cdot k \cdot [B0 \cdot \cos(Hue) + C0 \cdot \sin(Hue)] & m \cdot k \cdot [C0 \cdot \cos(Hue) - B0 \cdot \sin(Hue)] \\ m \cdot A1 & m \cdot k \cdot [B1 \cdot \cos(Hue) + C1 \cdot \sin(Hue)] & m \cdot k \cdot [C1 \cdot \cos(Hue) - B1 \cdot \sin(Hue)] \\ m \cdot A2 & m \cdot k \cdot [B2 \cdot \cos(Hue) + C2 \cdot \sin(Hue)] & m \cdot k \cdot [C2 \cdot \cos(Hue) - B2 \cdot \sin(Hue)] \end{bmatrix} \begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} + \begin{bmatrix} R_offset \\ G_offset \\ B_offset \end{bmatrix}$$

Coefficients a/b/c are related to A/B/C (for RGB to YUV and YUV to RGB conversions) as follows:

$$\begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} = \begin{bmatrix} A0 & B0 & C0 \\ A1 & B1 & C1 \\ A2 & B2 & C2 \end{bmatrix}^{-1}$$

dispc-103

Figure 12-395. DISPC VID Brightness/Contrast/Saturation/Hue Equation for RGB Input

In [Figure 12-395](#) the following specifics apply:

- A/B/C coefficients and the RGB offset parameters mapping to register fields is provided in [Table 12-416](#).

- The gain term (m) is used for contrast control. The allowed range is: $0 < m \leq 2.0$ (where $m=1$ means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is: $0 < k \leq 2.0$ (where $k=1$ means saturation bypass).
- The brightness is controlled by the RGB offset values.
- The Hue angle is used to adjust hue. Hue $\emptyset=0$ means hue adjustment bypass.

Outputs are clipped to keep the output values in the proper range.

12.6.3.8.8 DISPC VID Luma Key Support

The video pipeline supports Luma key transparency for Blue-ray video layer composition. When enabled, Y value of each pixel will be checked against luma key range values. The range values are defined in DSS0_VID_LUMAKEY register fields, as follows: $[11-0] \text{ LUMAKEYMIN} < Y < [27-16] \text{ LUMAKEYMAX}$. If this condition is true, then the pixel alpha value will be forced to zero (transparent) to make the pixel transparent during the blending process in the overlay manager.

12.6.3.8.9 DISPC VID Cropping Support

At the output of the video pipeline a final crop stage is added which allows further cropping of the video window to the required dimensions. The crop feature is enabled by DSS0_VID_ATTRIBUTES[13] CROP register field and the cropping dimensions are further set by DSS0_VID_CROP[...] CROPLEFT/CROPTOP/CROPBOTTOM/CROPRIGHT register fields. Cropping of up to 31 pixels/lines is supported in every direction.

The crop feature is especially useful while dealing with the compressed frame buffer using the FBDC module, as explained in [Section 12.6.3.6.11, DISPC Compressed Data Format Support](#).

12.6.3.9 DISPC Write-Back Pipeline

The write-back (WB) pipeline is used to store in the system memory the capture of the overlay output or the output of one of the pipelines. The WB pipeline consists of a CSC unit, a scaler unit, and an RGB truncation logic. The format from the overlay managers is always ARGB48. The format from the output of the VID pipeline can be YUV422, YUV420 or ARGB48. Because the overlay works on ARGB48 format and the video accelerator works on YUV format, the color space conversion from RGB to YUV is used to directly output to memory the format that can be encoded with no extra processing.

The write-back pipeline can be connected either to the VID pipeline output or to the output of one of the overlay managers, either in M2M (memory-to-memory) or Capture mode (see [Section 12.6.3.6.3, DISPC Write DMA Buffer](#)), by configuring the DSS0_COMMON_DISPC_CONNECTIONS[20-16] WB_CONN register field.

- In M2M mode, the pipeline or overlay manager connected to WB must not be connected to any VP.
- In Capture mode, the pipeline or overlay manager connected to WB must be connected to at least one VP.

The capture frame rate can be set in the DSS0_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field.

The write-back pipeline also supports input source cropping to allow a sub-frame capture.

The ARGB48 format is truncated (LSB drop) or expanded to match the output color depth formats. No dithering on the output is supported. When there is no alpha field mentioned by x in the pixel format description, 0's shall be used. For example, for RGB12 pixel format the upper 4 bits are 0's since RGB value is only 12 bits inside a 16-bit container.

The WB pipeline is enabled by setting the DSS0_WB_ATTRIBUTES[0] ENABLE bit to 0x1.

[Figure 12-396](#) shows the WB pipeline.

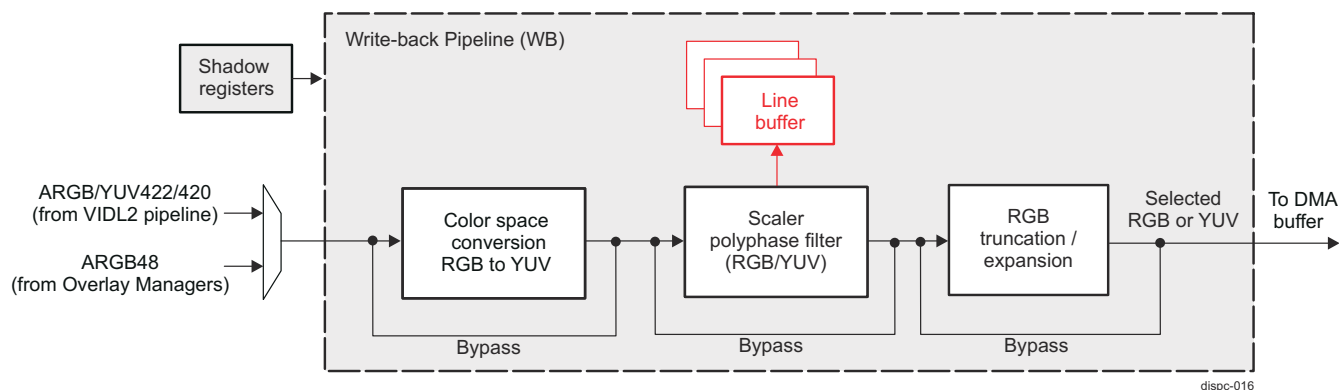

Figure 12-396. DISPC Write-Back Pipeline

12.6.3.9.1 DISPC WB Color Space Conversion RGB to YUV

The WB CSC unit converts the encoded pixel values from RGB48 into YUV444 format. For YUV420 or YUV422 as output formats, a chrominance subsampling (YUV444 to YUV422, and YUV422 to YUV420) is performed in the WB scaler block after the CSC operation.

Figure 12-397 and Figure 12-398 show the 3×3 11-bit coefficients used for the CSC operation. The user sets the coefficients according to the standard used to encode the pixel data in YUV color space. Table 12-417 lists the coefficients with their respective bit fields, together with the post offsets (that are 13-bit signed integer numbers).

Table 12-417. DISPC WB CSC - RGB to YUV Register Settings

Coefficients	Register Bit Fields
Y_R	DSS0_WB_CSC_COEF0[10:0] C00
Y_G	DSS0_WB_CSC_COEF0[26:16] C01
Y_B	DSS0_WB_CSC_COEF1[10:0] C02
Cr_R	DSS0_WB_CSC_COEF1[26:16] C10
Cr_G	DSS0_WB_CSC_COEF2[10:0] C11
Cr_B	DSS0_WB_CSC_COEF2[26:16] C12
Cb_R	DSS0_WB_CSC_COEF3[10:0] C20
Cb_G	DSS0_WB_CSC_COEF3[26:16] C21
Cb_B	DSS0_WB_CSC_COEF4[10:0] C22
$R_{POSTOFFSET}$	DSS0_WB_CSC_COEF6[31:19] POSTOFFSET1
$G_{POSTOFFSET}$	DSS0_WB_CSC_COEF7[15:3] POSTOFFSET2
$B_{POSTOFFSET}$	DSS0_WB_CSC_COEF7[31:19] POSTOFFSET3

Limited data range conversion (video data range)

If the active range for the 12-bit output luminance samples (Y) is to be [256:3760] and for the output chrominance samples (Cb and Cr) is to be [256:3840], then Figure 12-397 gives the equation (based on 11-bit coefficients) to convert the RGB to YUV. The range selection is done by setting the DSS0_WB_ATTRIBUTES[11] FULLRANGE bit to 0x0. The [256, 2048, 2048] offset values are programmable through the registers from Table 12-417.

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 256 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-017

Figure 12-397. DISPC WB CSC RGB to YCbCr Equation (Limited Data Range), 12-bit Outputs

Full data range conversion (graphics data range)

If the active range for the output luminance samples (Y) and or the chrominance samples (Cb and Cr) is [0:4095], then [Figure 12-398](#) gives the equation (based on 11-bit coefficients) to convert the RGB to YUV. The [0, 2048, 2048] offset values are programmable through the registers from [Table 12-417](#).

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-018

Figure 12-398. DISPC WB CSC RGB to YCbCr Equation (Full Data Range), 12-bit Outputs

12.6.3.9.2 DISPC WB Scaler Unit

The functional aspect of the WB pipeline scaler unit is identical to the VID pipeline scaler unit (see [Section 12.6.3.8.5, DISPC VID Scaler Unit](#)), except that the WB scaler is 8-bit only and takes only the 8 most significant bits of the data fed through. The WB scaler, similarly to the one in the video pipeline, can perform scaling in the native ARGB, YUV422, or YUV420 formats. The support for scaling in YUV formats allows a YUV source to be scaled through video and write-back scalers without chroma up and downsampling, if the output is to remain in the same format. In addition, the scaling capability of VID and WB pipelines can be combined to double the maximum rescaling factor (applicable for memory-to-memory operations only).

The downscaling capability is further reduced, if the pipeline is doing a format conversion where downsampling is inherent. When doing RGB/YUV422-to-YUV420 conversion in WB pipeline, the downsampling capability of WB scaler is reduced to:

- If 5 taps is selected, then the downsampling is limited to 0.5 in RGB
- If 3 taps is selected, then no down-scaling is available

The write-back window attributes of the WB pipeline can be configured in the following register bit-fields:

- Source data format for write-back (input to the scaler unit) in DSS0_WB_ATTRIBUTES[6-1] FORMAT bit-field
- Start position (offset) of the window on the overlay which WB will capture in DSS0_WB_POSITION[29-16] POSY and [13-0] POSX register field. Only applicable when the WB pipeline is operating in capture_mode.
- Write-back picture width in system memory (frame buffer) in DSS0_WB_PICTURE_SIZE[13-0] MEMSIZE_X bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed in the case of RGB16 and RGB24 video data. In the case of YUV2422 and UYVY422 formats the width has to be a multiple of 2 pixels.
- Write-back picture height in system memory (frame buffer) in DSS0_WB_PICTURE_SIZE[29-16] MEMSIZE_Y bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed. In the case of YUV420 the height has to be a multiple of 2 lines.
- Write-back window width at pipeline input (before resizing) in DSS0_WB_SIZE[13-0] SIZE_X bit-field. The window width is from 1 up to 4096 pixels. The width of the image sent to the write back pipe has to be a multiple of 2 pixels, if its format (input) is YUV420/YUV422.
- Write-back window height at pipeline input (before resizing) in DSS0_WB_SIZE[29-16] SIZE_Y bit-field. The window height is from 1 up to 4096 pixels. The width of the image sent to the write back pipe has to be a multiple of 2 lines, if its format (input) is YUV420.

Note

The WB pipeline supports input source cropping to allow a sub-frame capture by specifying the offset position and the size of the sub-frame. With the offset position parameters (POSY, POSX) set to (0,0) and the size parameters (SIZEY, SIZEX) set to the full size, no clipping should be applied. The software must make sure that the clipping parameters are set up correctly to avoid going over the WB input frame boundaries. Otherwise, the pipeline may lock up.

[Table 12-418](#) list the register fields in the function of the coefficients for the VID horizontal scaler in the DSS0_WB_FIR_COEF_H0_0 to DSS0_WB_FIR_COEF_H0_8, and DSS0_WB_FIR_COEF_H12_0 to DSS0_WB_FIR_COEF_H12_15 registers.

Table 12-418. DISPC Register Fields Associated to Coefficients for ARGB and Y Configuration in WB Horizontal Scaler

Phases	Ch(2)	Ch(1)	Ch(0)	Ch(-1)	Ch(-2)
	Signed coefficient [29-20] FIRHC2 bitfield	Signed coefficient [19-10] FIRHC1 bitfield	Unsigned central coefficient [9-0] FIRHC0 bitfield	Signed coefficient [19-10] FIRHC1 bitfield	Signed coefficient [29-20] FIRHC2 bitfield

15	DSS0_WB_FIR_COEF_F_H12_15	DSS0_WB_FIR_COEF_F_H12_15	DSS0_WB_FIR_COEF_F_H0_1	DSS0_WB_FIR_COEF_F_H12_1	DSS0_WB_FIR_COEF_F_H12_1

Note

In [Table 12-418](#), the cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DSS0_WB_FIR_COEF_V0_0 to DSS0_WB_FIR_COEF_V0_8, and DSS0_WB_FIR_COEF_V12_0 to DSS0_WB_FIR_COEF_V12_15 are used).

Similar table approach applies to the coefficients for Cb/Cr filtering in case of YUV format (registers DSS0_WB_FIR_COEF_H0_C_0 to DSS0_WB_FIR_COEF_H0_C_8, and DSS0_WB_FIR_COEF_H12_C_0 to DSS0_WB_FIR_COEF_H12_C_15, and DSS0_WB_FIR_COEF_V0_C_0 to DSS0_WB_FIR_COEF_V0_C_8 and DSS0_WB_FIR_COEF_V12_C_0 to DSS0_WB_FIR_COEF_V12_C_15 are used).

The WB scaler unit vertical and/or horizontal sampling is selected by configuring the DSS0_WB_ATTRIBUTES[8-7] RESIZEENABLE register bit field.

Prior to enabling the WB scaler a valid configuration has to be set by the user.

In case of capturing data of one of the output channels, the corresponding DSS0_VP_CONTROL[5] GOBIT bit has to be set to update the configuration depending to which VP output the write-back pipeline is associated with. Refers also to [Section 12.6.3.15, DISPC Shadow Mechanism for Registers](#) when write back channel is active. The SW has to wait before setting the GOBIT bit that the HW has reset the same bit. The DSS0_WB_ATTRIBUTES[0] ENABLE bit can be set to update those registers, if it has been previously disabled.

The following register fields define the configuration of the video up/downsampling block in the WB pipeline:

- Vertical up/downsampling increment value in the[23-0] FIRVINC bit field of DSS0_WB_FIRV (for ARGB and Y) and DSS0_WB_FIRV2 (for CbCr) registers. Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left(\frac{SIZEY+1}{MEMSIZEY+1} \right) \quad \text{dispc-066} \quad (25)$$

- Horizontal up/downsampling increment value in the [23-0] FIRHINC bit field of the DSS0_WB_FIRH (for ARGB and Y) and DSS0_WB_FIRH2 (for CbCr) registers. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left(\frac{SIZEX+1}{MEMSIZEX+1} \right) \quad \text{dispc-067} \quad (26)$$

- Vertical up/downsampling accumulator value in the [23-0] VERTICALACCU bit field of the DSS0_WB_ACCUV_0 and DSS0_WB_ACCUV_1 (for ARGB and Y), and DSS0_WB_ACCUV2_0 and DSS0_WB_ACCUV2_1 (for CbCr) registers. The accumulator value indicates on which phase the vertical filtering starts.
- Vertical upsampling and downsampling line buffer configuration via the DSS0_WB_ATTRIBUTES[21] VERTICALTAPS bit. The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value in the [23-0] HORIZONTALACCU bit field of the DSS0_WB_ACCUH_0 and DSS0_WB_ACCUH_1 (for ARGB and Y), and DSS0_WB_ACCUH2_0 and DSS0_WB_ACCUH2_1 (for CbCr) registers. The accumulator value indicates on which phase the horizontal filtering starts.

[Table 12-419](#) lists the DISPC vertical and horizontal accumulator values and phases. Other accumulator values are also supported. The HW determines the nearest phase value in order to load the corresponding one.

Table 12-419. DISPC WB Scaler Vertical and Horizontal Accumulator Phases

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14

Table 12-419. DISPC WB Scaler Vertical and Horizontal Accumulator Phases (continued)

Accumulator Value (MSB bits)	Phases f
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
 - For ARGB and Y, the vertical upsampling and downsampling central coefficients are defined in the DSS0_WB_FIR_COEF_V0_0 to DSS0_WB_FIR_COEF_V0_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
 - Four CbCr, the vertical upsampling and downsampling central coefficients are set in DSS0_WB_FIR_COEF_V0_C_0 to DSS0_WB_FIR_COEF_V0_C_8 registers.
- Vertical upsampling and downsampling coefficients:
 - For ARGB and Y, the vertical upsampling and downsampling coefficients are defined in the DSS0_WB_FIR_COEF_V12_0 to DSS0_WB_FIR_COEF_V12_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.
 - Four CbCr, the vertical upsampling and downsampling coefficients are set in DSS0_WB_FIR_COEF_V12_C_0 to DSS0_WB_FIR_COEF_V12_C_15 registers.
- Horizontal upsampling and downsampling central coefficients:
 - For ARGB and Y, the horizontal upsampling and downsampling central coefficients are defined in the DSS0_WB_FIR_COEF_H0_0 to DSS0_WB_FIR_COEF_H0_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
 - Four CbCr, the horizontal upsampling and downsampling central coefficients are set in DSS0_WB_FIR_COEF_H0_C_0 to DSS0_WB_FIR_COEF_H0_C_8 registers.
- Horizontal upsampling and downsampling coefficients:
 - For ARGB and Y, the horizontal upsampling and downsampling coefficients are defined in the DSS0_WB_FIR_COEF_H12_0 to DSS0_WB_FIR_COEF_H12_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
 - Four CbCr, the horizontal upsampling and downsampling coefficients are set in DSS0_WB_FIR_COEF_H12_C_0 to DSS0_WB_FIR_COEF_H12_C_15 registers.

The YUV filtering is based on the equations of the ARGB filtering. In addition to the registers used for ARGB filtering configuration, a second set of registers for filtering is used. The first set of registers is used for Y configuration (instead of ARGB configuration) and the second set of registers is used for CbCr filtering configuration. The two sets of registers can be the same when the YUV format is not converted to RGB after filtering. When the RGB conversion is required after filtering, then the chrominance needs to be re-sampled with a different filtering configuration because:

- Chrominance samples are offset to the luminance samples. That is, DSS0_WB_FIRH2 and DSS0_WB_FIRV2, and DSS0_WB_ACCUV2_0/DSS0_WB_ACCUV2_1 and DSS0_WB_ACCUH2_0/DSS0_WB_ACCUH2_1 registers need to be configured differently than DSS0_WB_FIRH and DSS0_WB_FIRV, and DSS0_WB_ACCUH_0/DSS0_WB_ACCUH_1 and DSS0_WB_ACCUV_0/DSS0_WB_ACCUV_1 registers used for the luminance filtering.
- Chrominance is sub-sampled by two horizontally only in case of YUV422, and horizontally and vertically in case of YUV420. The coefficients for the vertical chrominance re-sampling are identical to the coefficients for vertical luminance filtering in case of YUV422. The coefficients for the horizontal and vertical chrominance re-sampling are different than the ones for luminance filtering in case of YUV420.

12.6.3.10 DISPC Overlay Manager

The overlay manager (OVR) is responsible for compositing selected input layers together to generate the final display output frame. The DISPC implements four identical overlay managers, one for each display output (see [Figure 12-358, DISPC Architecture Overview](#)). Any of these overlay managers can be used to source also the Write-back pipeline.

- OVR1 is connected to Video Port 1 (VP1).
- OVR2 is connected to Video Port 2 (VP2).
- OVR3 is connected to Video Port 3 (VP3).
- OVR4 is connected to Video Port 4 (VP4).

Each OVR is preceded by a programmable input pipeline selector which re-maps the output of the selected input pipelines according to the overlay manager Z-order configuration.

Figure 12-399. DISPC Overlay Manager and Input Selector

Note

The DISPC overlay managers, OVR1 through OVR4, will be commonly referred to as *overlay manager (OVR)* in the following sections.

12.6.3.10.1 DISPC Overlay Input Selector

The overlay input selector before the overlay manager is a n-input to n-output crossbar switch. As such, any input can be connected to any output in the selector. The selection is based on the Z-order layer selection in the overlay configuration through the following register fields:

- DSS0_OVR_ATTRIBUTES_0[4-1] CHANNELIN field for layer 0, Z-order 0
- DSS0_OVR_ATTRIBUTES_1[4-1] CHANNELIN field for layer 1, Z-order 1
- DSS0_OVR_ATTRIBUTES_2[4-1] CHANNELIN field for layer 2, Z-order 2
- DSS0_OVR_ATTRIBUTES_3[4-1] CHANNELIN field for layer 3, Z-order 3
- DSS0_OVR_ATTRIBUTES_4[4-1] CHANNELIN field for layer 4, Z-order 4

The z-order determines the order in which the selected layers are blended together to generate the final output by the overlay manager:

- The lowest enabled order input is the bottom-most layer, just above the background color
- The highest enabled order input is the top-most layer

The OVR input selector also passes the following attributes from the selected input pipeline to the corresponding selector output port (*zsel*):

- Source pipeline size attributes:
 - Number of pixels per line (from DSS0_VID_SIZE[13-0] SIZEX register field)
 - Number of lines (from DSS0_VID_SIZE[29-16] SIZEY register field)
- Source pipeline global blending level (from DSS0_VID_GLOBAL_ALPHA register)

Then, the overlay manager uses the above listed attributes as input layer attributes along with POSX and POSY overlay manager configuration parameters. The POSX and POSY can be configured in the [13-0] POSX and [29-16] POSY fields of the following registers:

- For layer 0, Z-order 0, in DSS0_OVR_ATTRIBUTES2_0 register
- For layer 1, Z-order 1, in DSS0_OVR_ATTRIBUTES2_1 register
- For layer 2, Z-order 2, in DSS0_OVR_ATTRIBUTES2_2 register
- For layer 3, Z-order 3, in DSS0_OVR_ATTRIBUTES2_3 register
- For layer 4, Z-order 4, in DSS0_OVR_ATTRIBUTES2_4 register

Note

The output of an input pipeline can be mapped to more than one overlay manager simultaneously, if and only if the following conditions are true:

- All video port timing generators controlling the overlay managers are identically programmed (same frame width/height with same blanking parameters running at same frame rate) and clocked by the same pixel clock source, AND ...
- The pipeline output is positioned on each display output at the same frame position, OR ...
- One of the overlay managers is connected to the write-back path only.

The software is responsible for managing the pipeline assignment and setting up the video port timing generators properly in order to avoid any resource conflicts that may cause the DISPC to lock up (sync loss).

12.6.3.10.2 DISPC Overlay Mechanism

The overlay mechanism consists of displaying more than one input layer (graphics and/or video layers) using:

- A priority rule based on the display Z-order (selected by configuring the overlay input selector, as described in [Section 12.6.3.10.1](#))
- Transparency color keys configuration (destination and source transparency)
- Alpha blending values (using the alpha component of each pixel or a global alpha value set by the user)
- Size and position attributes of the source window data, as described in [Section 12.6.3.10.1](#)

The overlay manager is configured by using the Z-order parameter. The Z-order value defined for each pipeline indicates the visibility order of the window on the screen. If the Z-order value of window A is lower than the Z-order of layer B, then layer A is displayed below layer B. The transparency color keys and the alpha blending factors are then used to blend the layers together (see [Section 12.6.3.10.2.1, Overlay Alpha Blender](#), and [Section 12.6.3.10.2.2, Overlay Transparency Color Keys](#)).

[Figure 12-400](#) gives an simplified example of how two input pipeline frame outputs are merged together to generate the final display output.

Figure 12-400. DISPC Overlay Example and Display Attributes

As shown in [Figure 12-400](#), each input pipeline generates one rectangular sub-frame output in ARGB48 format. The overlay is responsible for positioning the sub-frame in the display output frame (specified by DSS0_VP_SIZE_SCREEN[13-0] PPL and [29-16] LPP video port register fields), using the overlay window position parameters (specified by the [13-0] POSX and [29-16] POSY overlay fields in the DSS0_OVR_ATTRIBUTES2_0 through DSS0_OVR_ATTRIBUTES2_4 registers), and the window size parameters (specified by the [13-0] SIZEX and [29-16] SIZEY input pipeline fields in the DSS0_VID_SIZE registers). When the overlay manager does not require the input pipeline data (either because it is currently outputting the background color pixel or it is being stalled by the VP output module), the overlay manager stalls the input pipeline.

When there are no video-encoded pixels at a specific position, the programmable solid background color appears. The solid background color can be set in the DSS0_OVR_DEFAULT_COLOR and DSS0_OVR_DEFAULT_COLOR2 registers.

The entire pixels of the video window have to be inside the display screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width must be adjusted by software to limit the right edge of the window inside the display screen. The same is also true for the video layer height in the input pipe line configuration.

12.6.3.10.2.1 Overlay Alpha Blender

The overlay manager can blend as many as four input pipelines using three cascaded stages of basically the same alpha-blending logic. Alpha output generation is supported only for the write-back path.

The alpha blending value is defined by:

- The component value A when using an ARGB or RGBA pixel format (alpha in the source pixel data is converted to 8-bit alpha value in the input pipeline logic):
 - For ARGB-1555, the alpha blending is defined using a 1-bit value. It is converted into an 8-bit value by duplicating the 1-bit value (see [Table 12-420](#)).
 - For ARGB-4444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value (see [Table 12-420](#)).
 - If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF, and if alpha is equal to 0xFF, there is no multiplication.
 - For BITMAP or YUV formats, there is no alpha blending factor associated with each pixel value. Only the global alpha blending factor associated with the window displaying the BITMAP or YUV format is used.
- The global alpha blending value can be set in the DSS0_VID_GLOBAL_ALPHA register of the input pipeline, and is updated in synch with the selected output channel.
- The modulated alpha blending value (that is, a total alpha blending value, when a combination of the pixel alpha blending value A and a global alpha blending ia present) is determined as: $\text{Alpha} = (\text{Pixel_Alpha} \times \text{Global_Alpha}) / 256$.

[Table 12-420](#) shows the remapping and the percentage of alpha blending achieved.

Table 12-420. DISPC Overlay Alpha Blending – ARGB

Alpha Blending 1-Bit Value (ARGB16-1555)	Alpha Blending 4-Bit Value (ARGB16-4444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x0	0x00	100% (transparent)
N/A	0x1	0x11	93.33%
N/A	0x2	0x22	86.6%
N/A
N/A	0xE	0xEE	6.6%
0x1	0xF	0xFF	0% (opaque)

Premultiplied Alpha and Alpha Output Generation

The source image in ARGB format may have its RGB component already premultiplied with the alpha (AR'G'B') where:

- $R' = A * R$
- $G' = A * G$
- $B' = A * B$

In that case, the processing is as follows:

- Color components of premultiplied layers are multiplied with the global alpha, if Global_Alpha is not equal to 0.
- Color components of the composed underlying layer are multiplied with $(1 - A * \text{Global_Alpha})$.

The premultiplied alpha option is accessible through the DSS0_VID_ATTRIBUTES[28] PREMULIPLYALPHA register bit of the input pipeline. The following settings are available:

- PREMULIPLYALPHA bit = 0: Source is not premultiplied with alpha. Full blending is done in the overlay manager.
- PREMULIPLYALPHA bit = 1: Source is premultiplied with alpha. Partial blending is done.

When the write-back channel copies back to memory the premultiplied color component, the the alpha value is computed as follows:

$$A(\text{dst}) = A(\text{src}) + (1 - A(\text{src}))A(\text{dst})$$

When the DSS0_WB_ATTRIBUTES[9] ALPHAENABLE register bit is cleared or when the overlay channel is not selected for write-back, the computation of the A(dst) is disabled.

Note

There is no alpha blending between the background and the next layer (layer-0) above it.

Layer-0 cannot be pre-multiplied, if the overlay output is driving the display, since that layer (or the background color) defines the bottom most layer. In this case, layer-0 alpha is 1 always.

Layer-0 can have an alpha value other than 1 when the overlay output is only used to generate an intermediate layer composition result in a memory-to-memory operation (through the WB pipeline). But, if alpha is not 1, the resulting data will be "pre-multiplied". If a non-premultiplied data is required, the resulting overlay output must be fed through a Porter-Duff compositing engine to have the result divided by the overlay alpha output.

12.6.3.10.2.2 Overlay Transparency Color Keys

The overlay manager supports two color transparency modes - source and destination. These modes cannot be active at the same time.

The source transparency is tied to the top most layer, so the layer to have this transparency applied to has to be mapped to the highest Z-ordered input (layer-4) of the overlay manager. The destination transparency is tied to the bottom most layer, so the layer to have this transparency applied to has to be mapped to the lowest Z-ordered input (layer-0) of the overlay manager.

The source and destination transparencies are defined as following:

- Source color transparency: Top layer pixel that meets the source transparency color check is made transparent.
- Destination color transparency: Top layer pixel is made transparent, only if the bottom layer pixel does not meet the destination transparency color check.

The transparency color key is enabled via the DSS0_OVR_CONFIG[10] TCKLCDENABLE register bit.

The minimum transparency color values are specified in the TRANSCOLORKEY field of the DSS0_OVR_TRANS_COLOR_MIN and DSS0_OVR_TRANS_COLOR_MIN2 registers.

The maximum transparency color values are specified in the TRANSCOLORKEY field of the DSS0_OVR_TRANS_COLOR_MAX and DSS0_OVR_TRANS_COLOR_MAX2 registers.

The transparency color key values defined in the registers are compared with the pixel values. If each color component (R, G, and B) is in the range defined by MIN and MAX, then there is a match. If at least one of the color component is not in the range, then there is no match.

• Source transparency color key

The values of the source transparency color key define the range of encoded pixel data considered as a transparent pixel. The encoded pixel values with the source color key value inside the valid range are not visible, and the encoded pixel values of the under layers or solid background color are visible.

The source transparency color key can be used with YUV and RGB formats (ARGB, RGB, RGBA, xRGB, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care, since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison, in case the original format is YUV.

The scaler can be enabled as a preprocessor in the video pipelines. The pixel scaling processing can be considered in order to define the color key value to be used after the rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the DSS0_OVR_CONFIG[11] TCKLCDSELECTION register bit to 0x1.

Figure 12-401 shows an example of source transparency color key usage. The pixels with the transparency color key are not displayed. Instead, pixels of the resulting layer underneath are shown.

Figure 12-401. DISPC Overlay Source Transparency Color Key Example

- **Destination transparency color key**

The destination transparency color key values define the range of the encoded pixels in layer-0 (bottom layer), which are not going to be displayed. That is, the encoded pixel values matching the destination color key value range are pixels not visible on the screen. Pixels at the same position in the layers above layer-0 are visible. The destination transparency color key is applicable in the layer in the background position only when there is an overlap between the layer in background position and the layer just above it, otherwise, the destination transparency color key is ignored. See [Section 12.6.3.10.2, DISPC Overlay Mechanism](#), for details on layer position depending on the Z-order parameter.

The destination transparency color key can be used only with RGB formats (ARGB, RGB, xRGB, RGBA, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison in case the original format is YUV.

The scaler can be enabled as a preprocessor in the pipelines. The pixel scaling processing must be considered in order to define the color key value to be used after rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the DSS0_OVR_CONFIG[11] TCKLCDSELECTION register bit to 0x0.

[Figure 12-402](#) shows an example of the destination color key usage. The pixels from layer-0 (bottom layer) equal to the transparency color key are not displayed and are replaced by the pixels from layer-1 (top layer). All other layer-0 pixels, different from the transparency color key, are displayed over layer-1.

Figure 12-402. DISPC Overlay Destination Transparency Color Key Example

12.6.3.10.3 Overlay 3D Support

In order to support S3D (Stereoscopic 3D) by combining in hardware left and right frames into the same output frame, the following configurations (defined by HDMI 1.4b standard specification) can be used:

- Separate pipeline mode: Left/Right or Top/Bottom. One layer is used for left/top and another layer is used for right/bottom.

12.6.3.10.4 Overlay Color Bar Insertion

Each overlay manager supports a simple internal color bar insertion in each display output path to enable testing of display output interface without using the frame buffer data from the memory.

The colors are: White, Yellow, Cyan, Green, Magenta, Red, Blue, Black, as shown in below. These make three primary colors, three secondary colors, white, and black.

Figure 12-403. DISPC Overlay Internal Color Bar

When the DSS0_OVR_CONFIG[1] COLORBAREN register bit is set to 1, the overlay output data is replaced by the predefined ARGB48 color bar data.

When color bar mode is used, the color space conversion matrix should be appropriately programmed, so that it can convert the full-range RGB to the desired color format.

Table 12-421. DISPC Overlay Color Bar Table

Color	G	B	R
White	0xFFF	0xFFF	0xFFF
Yellow	0xFFF	0	0xFFF
Cyan	0xFFF	0xFFF	0
Green	0xFFF	0	0
Magenta	0	0xFFF	0xFFF
Red	0	0	0xFFF
Blue	0	0xFFF	0
Black	0	0	0

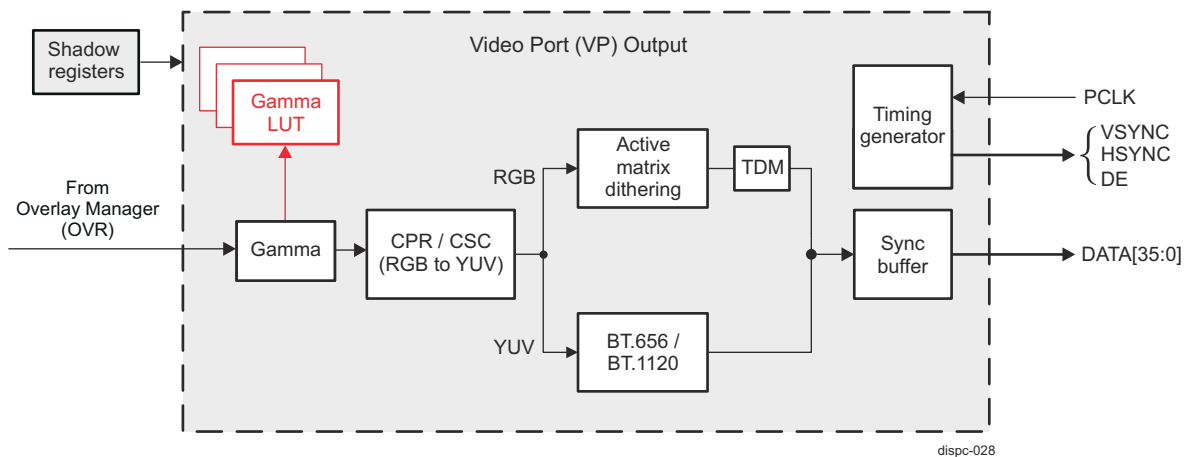

12.6.3.11 DISPC Video Port Output

The DISPC implements four identical Video Port (VP) outputs:

- VP1 processes data received from Overlay Manager 1 (OVR1)
- VP2 processes data received from Overlay Manager 2 (OVR2)
- VP3 processes data received from Overlay Manager 3 (OVR3)
- VP4 processes data received from Overlay Manager 4 (OVR4)

The VP output path consists of several processing blocks (see [Figure 12-404](#)):

- Gamma correction unit
- Color phase rotation (CPR) unit, also used for RGB to YUV color space conversion (CSC)
- Active matrix dithering with TDM (multiple cycle output format)
- BT.656/BT.1120 block
- Timing generator
- Async buffer

**Figure 12-404. DISPC VP Output Architecture**

The CSC processing can be configured to occur either before or after the gamma correction in the VP output module via the DSS0_VP_CONFIG[26] COLORCONVPOS register bit. For RGB to YUV color space conversion, the conversion must be done after the gamma correction. For other RGB output applications, the conversion must be done before the final gamma correction.

Note

The DISPC video port (VP) outputs, VP1 through VP4, will be commonly referred to as *video port (VP)* in the following sections.

12.6.3.11.1 DISPC VP Gamma Correction Unit

The VP supports a look up table to perform the gamma correction on the display output. The look up table consists of 3 separate 1024x10-bit memories, which are indexed by the R/G/B component data.

When performing gamma correction, the selected encoded pixel values from the video pipeline path are sent by the overlay manager to the gamma curve table. Each R/G/B component of the encoded pixel value is used as a pointer to index 1 out of 1024x30-bit gamma curve entries in the table. Each 10-bit component is replaced with the 10-bit table value corresponding to R, G, or B component. The table is loaded by software via the DSS0_VP_GAMMA_TABLE_0 through DSS0_VP_GAMMA_TABLE_15 registers. It is possible to load only part of the table.

The sequence to load the gamma table is:

1. SW writes (only writes are supported) 32-bit gamma correction values using single access, or burst access in linear increment burst mode, into the 64-byte region strating at DSS0_VP_GAMMA_TABLE_0 register address. The LSB 30 bits [29:0] are used for the value, and the MSB 1 bit [31] is used for resetting the index into the table at the end.
2. Loop to step #1, if there is a new access to the gamma table register. The software can access other registers between two accesses to the gamma table register.

Software needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the gamma table is activated by setting DSS0_VP_CONFIG[2] GAMMAENABLE register bit.

Figure 12-405 describes the format of one of the gamma curve values in the memory.

Figure 12-405. DISPC VP Output Gamma Table Write Data Format

12.6.3.11.2 DISPC VP Color Phase Rotation Unit

If required, a color phase rotation (CPR) processing can be applied on the "gamma" data before the spatial/temporal dithering.

The CPR can be selected to correct the non-pure white backlight of the display panel by using a programmable matrix to convert the 36-bit RGB pixel value into a new 36-bit RGB pixel value. The matrix is programmed through a set of nine 11-bit signed coefficients. The output of the calculation is clipped to [0:4095]. The CPR is enabled by setting the DSS0_VP_CONFIG[15] CPR bit to 0x1.

The CPR processing is expressed by the equation shown in Figure 12-406. Table 12-422 lists all coefficients with their respective register bitfields for configuration.

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_r & R_g & R_b \\ G_r & G_g & G_b \\ B_r & B_g & B_b \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dispc-023

DSS0_VP_CSC_COEF7[31-19] POSTOFFSET3	-	B offset

12.6.3.11.3 DISPC VP Color Space Conversion - RGB to YUV

The RGB to YUV color space conversion (CSC) in the video port is done by using the same programmable logic used for CPR. If CPR is also required, then the process can be combined with the CSC processing by adjusting matrix coefficients. Table 12-422 lists the associated coefficients with their respective register bit-fields. The CSC processing is enabled by setting the DSS0_VP_CONFIG[24] COLORCONVENABLE register bit.

The color space conversion can be selected in order to convert from 36-bit RGB to YUV444. The conversion matrix is programmed through a set of nine 11-bit signed coefficients. The result is clipped to [256:3760] for the luminance and [256:3840] for the chrominance, when a full-range YUV output is not desired (equivalent to clipping to [16..235] and [16..240] in 8-bit video). In this case the DSS0_VP_CONFIG[25] FULLRANGE register bit must be set to 0x0.

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 256 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-098

Figure 12-407. DISPC VP CSC RGB to YUV Equation (FULLRANGE=0)

If the programmed active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], then the values Y, Cb, and Cr are clipped to the range [0:4095]. The following equation gives the 11-bit coefficients of the RGB to YUV color space conversion, for full range (when DSS0_VP_CONFIG[25] FULLRANGE = 0x1).

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-099

Figure 12-408. DISPC VP CSC RGB to YUV Equation (FULLRANGE=1)

In order to provide YUV422 data to the BT.656 / BT.1120 block, the YUV444 format is further converted to YUV422 by sub-sampling the chrominance values. The hardware does this by averaging two-by-two the chrominance samples. The conversion from YUV444 to YUV422 is performed when the color space conversion in the VP is enabled.

12.6.3.11.4 DISPC VP BT.656 and BT.1120 Modes

Each VP output can be configured in BT.656 or BT.1120 mode. The following standards are not supported in BT.656 mode:

- BT.470 (Support for conventional Analog TV Systems)
- BT.803 (The avoidance of interference generated by digital television studio equipment)
- BT.1364 (Format of ancillary data signals carried in digital component studio interfaces)
- BT.601 (Studio encoding parameters for digital TV standards for standard 4:3 and wide 16:9 aspect ratios)

Unsupported formats when BT.1120 mode is used:

- BT.1364 (Support for Ancillary Data during blanking period)
- BT.709 (Square pixel support)

BT.656/BT.1120 modes use embedded EAV/SAV syncs.

Enabling BT.656 or BT.1120 format for a VP output is done by setting DSS0_VP_CONFIG[20] BT656ENABLE or [21] BT1120ENABLE register bit, respectively

Note

It is not possible to enable BT.656 and BT.1120 modes simultaneously on the same VP output.

12.6.3.11.4.1 DISPC BT Mode Blanking

During the transmission of the video signal, the portion of the stream in-between active video data segments is known as the horizontal blanking interval.

Strictly speaking this entire region is the blanking interval, but this interval also includes the EAV and SAV codes. The remaining bytes of information in a digital blanking interval are filled with values corresponding to the blanking levels of the Cb, Y and Cr signals respectively, and in accordance with the standard multiplex sequence for the stream (CbYCrY...). The blanking levels are as follows:

- Cb = 80h
- Y = 10h
- Cr = 80h.

The sequence in the BLANKING region of the data stream is therefore: 80h, 10h, 80h, 10h.....80h, 10h

For more details on setting the blanking timing values for BT.1120 and/or BT.656 mode, see [Section 12.6.3.11.8, DISPC VP Timing Generator and Display Panel Settings](#).

12.6.3.11.4.2 DISPC BT Mode EAV and SAV

The End of Active Video (EAV) and Start of Active Video (SAV) parts of the stream are timing codes. Their function can be summarized as follows:

- EAV – marks the end of the active video data within the current line and therefore also the start of the subsequent line.
- SAV – heralds the start of the active video data within the current line.

These codes are embedded within the BT.656 video data stream, thereby eliminating the need for additional timing signals (HSYNC, VSYNC) to be included as part of the interface.

Both EAV and SAV codes are comprised of a sequence of four bytes (FFh – 00h – 00h - XY). The first three bytes in the sequence constitute a fixed preamble. The fourth byte, contains information about the field being transmitted (Field 1 or Field 2 in an interlaced video signal), the state of field blanking (Vertical) and the state of line blanking (Horizontal). The bit assignment for this byte of the code is shown in [Figure 12-409](#), with the function of each bit described in [Table 12-423](#).

MSB							LSB
1	F	V	H	P3	P2	P1	P0

Figure 12-409. DISPC BT Mode Bit-Assignment for the Fourth Byte of EAV/SAV Codes

Table 12-423. DISPC BT Mode Bit Function

Bit	Symbol	Function
7	1	Always set to '1'.
6	F	Field bit. 0 – Field 1 1 – Field 2
5	V	Vertical Blanking Status bit. This bit goes High during a vertical field blanking interval, otherwise it remains Low.
4	H	Horizontal Blanking Status bit. 0 – byte is part of SAV code (i.e. stream is entering an active video data region for the current line) 1 – byte is part of EAV code (i.e. stream has entered a horizontal blanking interval - start of a new line)
3	P3	Protection bit 3
2	P2	Protection bit 2
1	P1	Protection bit 1
0	P0	Protection bit 0

The protection bits allow for detection and correction of 1-bit errors and the detection of 2-bit errors. The status of P3, P2, P1 and P0 depend on the states of bits F, V, and H. This dependency is shown in [Table 12-424](#).

Table 12-424. DISPC BT Mode Status of Protection Bits in Function of F, V, and H

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

12.6.3.11.5 DISPC VP Spatial/Temporal Dithering

The active spatial/temporal dithering logic can be enabled to minimize the color banding when displaying the data on a LCD panel with color depth lower than 24-bit. The dithering logic is integrated after the color/gamma conversion blocks and before the TDM (Time Division Multiplexing) block. The spatial/temporal dithering algorithm is based on the (x,y) pixel position and frame rate control (the value of removed bits and the frame number). The dithering logic can process the pixels over one frame, two frames, or four frames. The number of frames is selected by setting the DSS0_VP_CONTROL[31-30] SPATIALTEMPORALDITHERINGFRAMES register field. In the case of a single frame, only spatial processing is applied. In case of multiple frames, both spatial and temporal processing are applied to the pixels. The number of frame is initialized before enabling the spatial/temporal dithering logic. It must be never changed by the software while the spatial/temporal logic is enabled. The spatial/temporal dithering logic is enabled by setting the DSS0_VP_CONTROL[7] STDITHERENABLE bit to 0x1.

Note

- If the interface data bus is smaller than the pixel format size and the spatial/temporal dithering is not enabled, the MSBs of the pixel color components are output on the interface data bus.
- If the interface data bus is larger than the pixel format size, then by programming the pixel components replication active/inactive the MSB is replicated to the LSB of the interface data bus.

12.6.3.11.6 DISPC VP Multiple Cycle Output Format (TDM)

The pixels (only RGB components) after the active matrix dithering unit are formatted on one or multiple cycles (from 1 to 3 cycles). On three cycles, two pixels can concatenate and send to the panel. The cycle format is

selected through the DSS0_VP_CONTROL[24-23] TDMCYCLEFORMAT bit field. The number of bits for each cycle is set in the DSS0_VP_DATA_CYCLE_0 register for the first cycle, the DSS0_VP_DATA_CYCLE1 register for the second cycle, and the DSS0_VP_DATA_CYCLE2 register for the third cycle. The output interface data bus width, when TDM mode is enabled (DSS0_VP_CONTROL[20] TDMENABLE register bit = 1), can be 8, 9, 12, or 16 bits, configurable through the DSS0_VP_CONTROL[22-21] TDMPARALLELMODE register field.

When the TDM is disabled (DSS0_VP_CONTROL[20] TDMENABLE = 0), the video port output interface data bus width is configured through the DSS0_VP_CONTROL[10-8] DATALINES register field.

When using TDM mode, only up to 24 bits per pixel can be output on the interface. For higher color depth, only the upper bits are kept before converting each pixel into TDM output.

Figure 12-410 through Figure 12-413 show various examples of TDM settings in the function of pixel data formats and the interface data bus width.

Figure 12-413. DISPC VP TDM 16-Bit Interface Settings

12.6.3.11.7 DISPC VP Stall Mode

The VP output can be programmed to operate in Stall Mode, where there is a stall handshake mechanism (back-pressure) with the display peripheral to which the VP is connected. No sync signals (HS, VS) are generated in Stall Mode of operation. Data and Enable (DE) signals are provided only when the stall signal is de-asserted (1'b0) by the peripheral. The Stall Mode can be enabled via the DSS0_VP_CONTROL[11] STALLMODE register bit.

Note

In this SoC, the Stall Mode of operation is supported only on the VP outputs connected to the DSI peripheral module.

There are two types of data transfer, if Stall Mode is enabled, that can be selected by the DSS0_VP_CONTROL[12] STALLMODETYPE register bit:

- In DSI Video Mode, multiple frames are sent out on VP until the VP is disabled. A FRAMEDONE_IRQ interrupt is generated at the end of each frame. No VSYNC_IRQ interrupt is generated.
- In DSI Command Mode, a single frame is sent out on VP and the VP is auto disabled. A FRAMEDONE_IRQ interrupt is generated at the end of frame. To transfer another frame in Command Mode, the user needs to re-enable the VP. No VSYNC_IRQ interrupt is generated.

12.6.3.11.8 DISPC VP Timing Generator and Display Panel Settings

Each video port output has a dedicated timing generator supporting progressive and interlaced modes. It is clocked using the pixel clock and is configured to generate the video data and sync signals to match the desired video display standard timings.

Two-level configuration for enabling the video ports exists:

- Via the individual DSS0_VP_CONTROL[0] ENABLE register bit for each VP. It allows each VP to be independently controlled by two different hosts.
- Via the common DSS0_COMMON_DISPC_GLOBAL_OUTPUT_ENABLE[2-0] VP_ENABLE register field. It allows two or more VP timing generators to be in sync by enabling them simultaneously with a single register write.

Both ENABLE and VP_ENABLE register fields must be set in order for a VP (timing generator) to start.

Figure 12-414 shows the timing generator display parameters.

Figure 12-414. DISPC VP Display Timing Parameters

The width of VP output data bus is configured in the DSS0_VP_CONTROL[10-8] DATALINES register field, when TDM feature is disabled. When TDM is enabled, the width of the output data bus is defined according to Section 12.6.3.11.6, DISPC VP Multiple Cycle Output Format (TDM).

The size of the display panel is defined by:

- Number of lines per frame, DSS0_VP_SIZE_SCREEN[29-16] LPP bit field
- Number of pixels per line, DSS0_VP_SIZE_SCREEN[13-0] PPL bit field

Standard HSYNC/VSYNC timing generation is programmable as follows:

- Horizontal front porch is set in the DSS0_VP_TIMING_H[19-8] HFP bit field.
- Horizontal back porch is set in the DSS0_VP_TIMING_H[31-20] HBP bit field.
- Horizontal synchronization pulse width is set in the DSS0_VP_TIMING_H[7-0] HSW bit field.
- Vertical front porch is set in the DSS0_VP_TIMING_V[19-8] VFP bit field.
- Vertical back porch is set in the DSS0_VP_TIMING_V[31-20] VBP bit field.
- Vertical synchronization pulse width is set in the DSS0_VP_TIMING_V[7-0] VSW bit field.

When the output is in BT.1120 or BT.656 mode, the following timing constants are mapped onto the DSS0_VP_TIMING_H and DSS0_VP_TIMING_V registers:

- Progressive mode:
 - Horizontal blanking (12 bits) is set in the {DSS0_VP_TIMING_V[3-0] VSW, DSS0_VP_TIMING_H[7-0] HSW} register fields (up to 2048 bytes of horizontal blanking supported).
 - Vertical frame blanking No 1 is set in the DSS0_VP_TIMING_V[19-8] VFP bit field.
 - Vertical frame blanking No 2 is set in the DSS0_VP_TIMING_V[31-20] VBP bit field.
 - Number of lines per frame is set in the DSS0_VP_SIZE_SCREEN[29-16] LPP bit field.
 - Number of pixels per line is set in the DSS0_VP_SIZE_SCREEN[13-0] PPL bit field.
- Interlaced mode:
 - Horizontal blanking (12 bits) is set in the {DSS0_VP_TIMING_V[3-0] VSW, DSS0_VP_TIMING_H[7-0] HSW} register fields (up to 2048 bytes of horizontal blanking supported).
 - Vertical field blanking No.1 for Even Field is set in the DSS0_VP_TIMING_H[19-8] HFP bit field.
 - Vertical field blanking No.2 for Even Field is set in the DSS0_VP_TIMING_H[31-20] HBP bit field.
 - Vertical field blanking No.1 for Odd Field is set in the DSS0_VP_TIMING_V[19-8] VFP bit field.
 - Vertical field blanking No.2 for Odd Field is set in the DSS0_VP_TIMING_V[31-20] VBP bit field.
 - Number of lines per field (even) is set in the DSS0_VP_SIZE_SCREEN[29-16] LPP bit field.
 - Delta number of odd field compared to even field (in a single line) is set in the DSS0_VP_SIZE_SCREEN[15-14] DELTA_LPP bit field. The DELTA_LPP field only controls the output channel and not the size of the field fetched from the frame buffer in memory. This field must be set to zero for YUV420 format.
 - Number of pixels per line is set in the DSS0_VP_SIZE_SCREEN[13-0] PPL bit field.

Horizontal/vertical synchronization and output enable signals polarity are programmable by setting the DSS0_VP_POL_FREQ[12] IVS, [13] IHS, and [15] IEO register bits. These signals can be gated by setting the DSS0_VP_CONFIG[7] VSYNCGATED and [6] HSYNCGATED register bits. In addition, the alignment between VSYNC and HSYNC signals can be programmed via the DSS0_VP_POL_FREQ[18] ALIGN register bit.

The latch of data can be driven on the rising or falling edge of the pixel clock by setting the DSS0_VP_POL_FREQ[14] IPC register bit. The drive of the SYNC and VSYNC signals in the function of the pixel clock is done by setting the DSS0_VP_POL_FREQ[16] RF bit.

Each VP output can be configured in progressive output mode or interlaced output mode. The selection is done by writing into the bit-field DSS0_VP_CONFIG[22] OUTPUTMODEENABLE register bit. The default setting is for progressive mode. The selection can be changed only when the corresponding VP output is disabled. The configuration is independent for each VP output. It is possible to change the configuration of one of the VP outputs while the other VP is enabled.

The pixel clock for each VP output can be gated by setting the DSS0_VP_CONFIG[5] PIXELCLOCKGATED register bit.

The hold time of the pixels on the data bus is determined in clock cycles by the DSS0_VP_CONTROL[16-14] HT register field.

12.6.3.11.9 DISPC VP Merge-Split-Sync (MSS) Module

In order to interface with peripherals which can support a different data rate than the VP output, a Merge-Split-Sync (MSS) module is introduced between the VP outputs and DISPC final output. When interfacing with a peripheral which can support a higher data rate than the VP, two VP outputs can be merged to generate one

high data rate stream on the DISPC output (MERGE mode). When interfacing with a peripheral which requires dual physical links to support a high resolution video, one VP output can be split into two half data rate pixel streams on two separate DISPC outputs (SPLIT mode).

Both left/right (L/R) or odd/even (O/E) pixel selection types are supported.

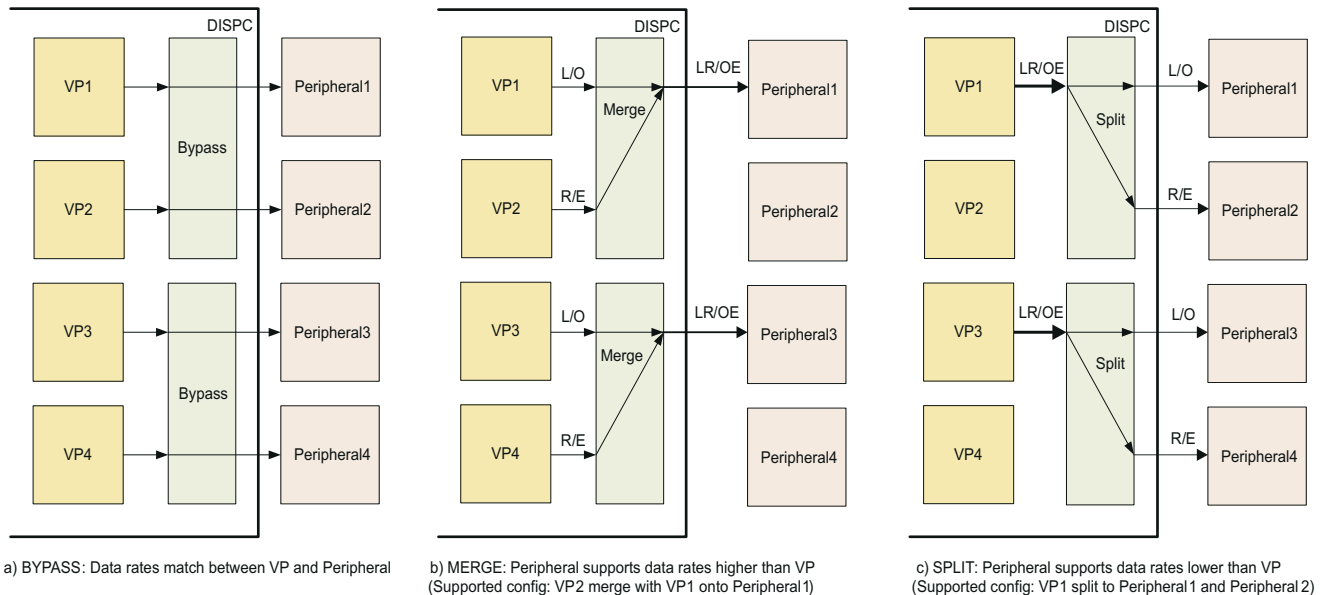

Figure 12-415. DISPC VP Merge-Split Scheme

Additionally, the MSS module can also operate in a SYNC mode where two VP outputs get the same source pixel clock. The SYNC mode only affects the clock muxing and does not manipulate the data going out of each VP output.

Only the following configurations, as shown in [Figure 12-415](#), are supported:

- MERGE Mode
 - VP2 (Right/Even stream) merged with VP1 (Left/Odd stream) output onto Peripheral #1 (P1)
 - VP4 (Right/Even stream) merged with VP3 (Left/Odd stream) output onto Peripheral #3 (P3)
- SPLIT Mode
 - VP1 split into Peripheral #1 (P1)(Left/Odd stream) and Peripheral #2 (P2)(Right/Even stream)
 - VP3 split into Peripheral #3 (P3)(Left/Odd stream) and Peripheral #4 (P4)(Right/Even stream)
- SYNC Mode
 - VP1 and VP2 in sync and get the same pixel clock
 - VP3 and VP4 in sync and get the same pixel clock

The DSS0_COMMON_DISPC_MSS_VP1 and DSS0_COMMON_DISPC_MSS_VP3 registers control the MSS operation.

The MSS line buffers are sized to support up to 6K RGB30 video data. Therefore, in MERGE use-case, two 3K VP outputs can be merged to create a 6K output at DISPC. In SPLIT use-case, one 6K output can be split into two 3K outputs.

In both, MERGE and SPLIT use-cases, all the control signals (VS, HS, DE) are re-generated so as to match with the timing of the new merged frame or split frames.

Note

For Merge-Split-Sync mode of operation, the VP outputs need to be programmed to be active-high for the different signals (DE, VS, HS). For SPLIT mode of operation, it is required that the total number of pixels in a line is a multiple of 2. For both SPLIT mode and SYNC mode of operation, both the VP blocks need to be enabled at the same cycle. This is achieved by making a single write to the global enable register (DSS0_COMMON_DISPC_GLOBAL_OUTPUT_ENABLE[3-0] VP_ENABLE field).

When the DISPC is interfaced with the DP/eDP peripheral, the SPLIT mode corresponds to the Split (single stream transport) mode of operation of the DSC (Digital Stream Compression) sub-module within the EDP module. In this case, the two streams at half the pixel clock rate are first provided to DSC_ENC0 and DSC_ENC1 within the EDP. Then, the combined encoded stream is provided to the EDP MHDPTX Controller VIF0 port. The SYNC mode corresponds to the Dual (multi stream transport) mode of operation of the EDP module. In this case, the two streams at full pixel clock rate are provided to the EDP VIF0 and VIF1 ports (the EDP DSC has to be bypassed in this mode). For more details, see the EDP [Section 12.6.5.2.1](#), *Video Stream Clock/Data Muxing*.

12.6.3.11.9.1 MSS Clocking Scheme

The pixel clocks going to the VPn as well as the pixel clocks going to the peripherals (Pn) will be different under different cases, depending on whether the output is in BYPASS, SYNC, MERGE or SPLIT mode. The different combinations of the clocks are as shown in [Figure 12-416](#) and [Figure 12-417](#).

Figure 12-416. DISPC VP Clocking Scheme for MSS BYPASS and SYNC Modes

Figure 12-417. DISPC VP Clocking Scheme for MSS MERGE and SPLIT Modes

Figure 12-417 show VP1 and VP2. Same clock scheme is applicable to VP3 and VP4.

For all cases in Figure 12-416 and Figure 12-417 there is no async interaction between P1_PCLKs and P2_PCLKs.

12.6.3.11.9.2 MSS Merge with Scaling

Merge operation with scaling enabled in the VID pipelines can result in visual artifacts at the merged boundary. The artifacts can be avoided by scaling each half to a larger window size and then using the crop feature of the VID pipelines to get to the required size for each half.

12.6.3.12 DISPC Internal Diagnostic Features

The DSS supports the following internal diagnostic features in DISPC hardware:

- Data correctness check: To verify intended data is shown correctly on the display.
- Freeze frame detection: To notify a possible frame freeze, when there is no change in the display frame over a multiple frame periods.

These features are implemented by collecting signatures from user-defined regions within each pipeline output frame and the final display output frame, and comparing them to reference signatures provided by the user (software) and/or to previously saved signatures. The signature from each region is generated by using a MISR (Multiple Input Signature Register) module.

12.6.3.12.1 Internal Diagnostic Check Regions

The DSS supports the following internal diagnostic check regions:

- Video pipelines: One internal diagnostic check region at the output of each video pipeline.
- Video port outputs: Up to eight internal diagnostic sub-regions within the active video output area of the final display output of each video port.

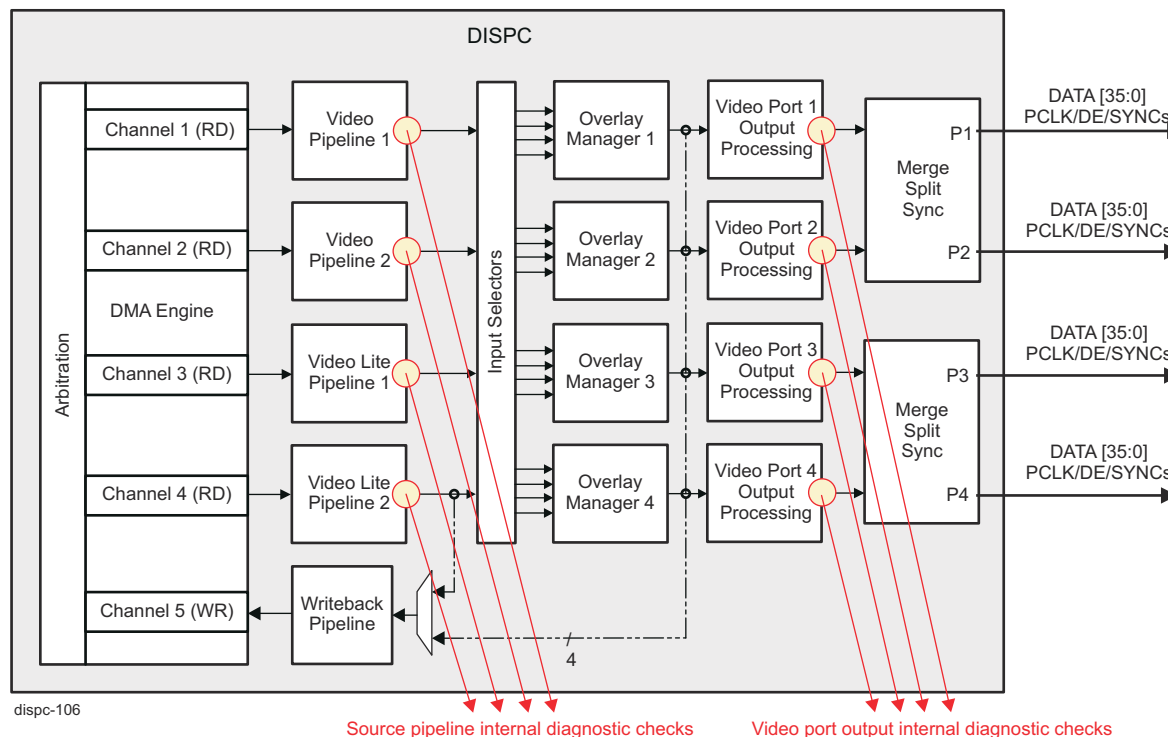

Figure 12-418. DISPC Internal Diagnostic Check Regions

Table 12-425 lists the parameters supported by each of the internal diagnostic check regions, together with the associated register control fields.

Table 12-425. DISPC Internal Diagnostic Check Regions Parameters

Internal Diagnostic Region Parameter	Video Pipeline Control Register	Video Port Sub-region m (m = 0 to 7) Control Register
X position	DSS0_VID_SAFETY_POSITION[11-0] POSX	DSS0_VP_SAFETY_POSITION_m[11-0] POSX
Y position	DSS0_VID_SAFETY_POSITION[27-16] POSY	DSS0_VP_SAFETY_POSITION_m[27-16] POSY
Width	DSS0_VID_SAFETY_SIZE[11-0] SIZEX	DSS0_VP_SAFETY_SIZE_m[11-0] SIZEX
Height	DSS0_VID_SAFETY_SIZE[27-16] SIZEY	DSS0_VP_SAFETY_SIZE_m[27-16] SIZEY

Table 12-425. DISPC Internal Diagnostic Check Regions Parameters (continued)

Internal Diagnostic Region Parameter	Video Pipeline Control Register	Video Port Sub-region m (m = 0 to 7) Control Register
Data Correctness Check Mode Enable	DSS0_VID_SAFETY_ATTRIBUTES[1] CAPTUREMODE	DSS0_VP_SAFETY_ATTRIBUTES_m[1] CAPTUREMODE
Freeze Frame Detection Mode Enable	DSS0_VID_SAFETY_ATTRIBUTES[1] CAPTUREMODE	DSS0_VP_SAFETY_ATTRIBUTES_m[1] CAPTUREMODE
Region Internal Diagnostic Check Enable	DSS0_VID_SAFETY_ATTRIBUTES[0] ENABLE	DSS0_VP_SAFETY_ATTRIBUTES_m[0] ENABLE
Freeze Frame Detection Threshold	DSS0_VID_SAFETY_ATTRIBUTES[10-3] THRESHOLD	DSS0_VP_SAFETY_ATTRIBUTES_m[10-3] THRESHOLD
Frames to Skip	DSS0_VID_SAFETY_ATTRIBUTES[12-11] FRAMESKIP	DSS0_VP_SAFETY_ATTRIBUTES_m[12-11] FRAMESKIP
Reference Signature	DSS0_VID_SAFETY_REF_SIGNATURE[31-0] SIGNATURE	DSS0_VP_SAFETY_REF_SIGNATURE_m[31-0] SIGNATURE
MISR Seed	DSS0_VID_SAFETY_LFSR_SEED[31-0] SEED	DSS0_VP_SAFETY_LFSR_SEED[31-0] SEED
MISR Seed Selection	DSS0_VID_SAFETY_ATTRIBUTES[2] SEEDSELECT	DSS0_VP_SAFETY_ATTRIBUTES_m[2] SEEDSELECT
MISR Captured Signature	DSS0_VID_SAFETY_CAPT_SIGNATURE[31-0] SIGNATURE	DSS0_VP_SAFETY_CAPT_SIGNATURE_m[31-0] SIGNATURE

Figure 12-419 shows examples of one internal diagnostic region in the video pipeline output stage and up to 8 possible regions in the final video port output stage.

Figure 12-419. DISPC Internal Diagnostic Check Region Examples

The internal diagnostic region in the video pipeline captures data, only if the embedded alpha data is not equal to 0 (that is, non-transparent pixels). The internal diagnostic regions in the display video port output captures all active video pixels within the region boundary. The regions (up to eight) in the display output should be typically non-overlapping areas of the screen, but the hardware does not restrict them to be non-overlapping.

Figure 12-420 shows the locations within DISPC data path where the data is analyzed.

Figure 12-420. DISPC Internal Diagnostic Check Locations

12.6.3.12.2 Internal Diagnostic Signature Generator Using MISR

A 32-bit multiple input signature register (MISR) with 32-bit Galois LFSR polynomial, $P(x)=X^{32}+X^{22}+X^2+x+1$, is used to capture a signature of active video pixel data (the 10 MSB bits of each color component) for each internal diagnostic region, as shown in Figure 12-421 and the algorithm below it.

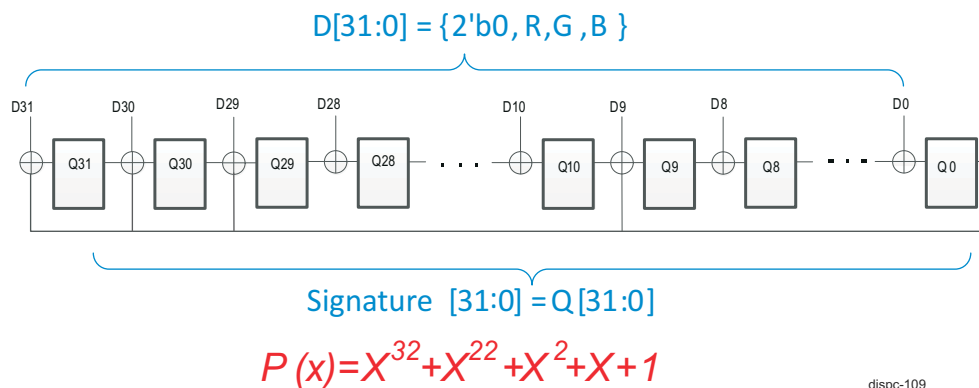

Figure 12-421. DISPC Internal Diagnostic 32-bit MISR Implementation

The MISR (32-bit Galois LFSR based) signature generation algorithm is as follows:

```
Tap_polynomial = 32'hE000_0200
```

```
lfsr_q = seed // initial LFSR value - any non zero value should work
```

```
For each (pixel data in the internal diagnostic region) {
```

```
data_in[31:0] = { 2'b0, r,g,b } // 10 MSB bits of R,G,B components
```

```
lfsr_d = (data_in(lfsr_q >> 1))
```

```
If (lfsr_q[0]) lfsr_d = lfsr_d ^ Tap_polynomial
```

```
lfsr_q = lfsr_d
```

```
}
```

```
signature = lfsr_q
```

All MISRs are initialized at the beginning of each frame with a non-zero "seed" value either with the default constant value (0xFFFF_FFFF) or with the programmable seed configuration value in SAFETY_LFSR_SEED register for each group of regions (refer to Table 12-425, *DISPC Internal Diagnostic Check Regions Parameters*). Note that a same seed must be used to compare signatures between two frames. If different than the default seed value is desired, then a SEEDSELECT parameter must be set before the corresponding SAFETY_LFSR_SEED register is configured with the customer seed value.

All captured signatures from the internal diagnostic regions are memory mapped to read-only SAFETY_CAPT_SIGNATURE registers for each video port (refer to Table 12-425, *DISPC Internal Diagnostic Check Regions Parameters*). A SAFETY_CAPT_SIGNATURE register is updated with the signature from each sub-region at the end of every frame. This register returns the signature of the last frame data when the MISR is enabled. When MISR is disabled, this register is cleared.

The MISR aliasing (faulty signature matches fault-free signature) probability is:

$$(2^{(L-n)}-1)/(2^L-1) \approx 2^{(L-n)}/2^L = 2^{-n} \text{ for large } L, \text{ where}$$

n = length of signature register

L = length of input sequence

Using the above approximation, the result is:

$n=4$, aliasing probability = 6.25%

n=16, aliasing probability = 0.0015%

...

n=32 (as in DISPC MISR), aliasing probability is $\sim 2^{-32}$ (negligible)

12.6.3.12.3 Internal Diagnostic Checks

If the data correctness check is enabled (see [Table 12-425](#), *DISPC Internal Diagnostic Check Regions Parameters*):

- When a new signature is generated, it is compared against the reference signature provided by the software. A SAFETY_REF_SIGNATURE register must be configured with a reference signature data, see [Table 12-425](#), *DISPC Internal Diagnostic Check Regions Parameters*.
- If signatures do not match, an interrupt event is generated to indicate data mismatch.

If the freeze frame detection is enabled (see [Table 12-425](#), *DISPC Internal Diagnostic Check Regions Parameters*):

- When a new signature is generated, it is first compared against the saved signature (from previous frame).
 - There exists a capability within the frame freeze detection logic to skip alternate frames during comparison. This feature is useful while handling ping-pong buffers or interlaced input video. This feature is controlled via the [12-11] FRAMESKIP field within a SAFETY_ATTRIBUTES register.
- If signatures match, an internal counter used to keep track of the number of frames with no data change (for the region) is incremented.
- If signatures do not match, the counter is cleared.
- If the counter value is greater than the user programmed freeze frame detection threshold value (see [Table 12-425](#), *DISPC Internal Diagnostic Check Regions Parameters*), an interrupt event (VIDSAFETYREGION_IRQ or VPSAFETYREGION_IRQ, see [Section 12.6.3.5](#), *DISPC Interrupt Requests*) is generated to indicate a possible freeze frame detection. The threshold value must be configured with the maximum number of identical successive frames allowed before an interrupt is generated.
- After the comparison, the signature is saved as the previous signature.
- The counter is cleared when the interrupt event is generated or when freeze frame detection check is disabled.

This frame freeze is different from the display getting frozen due to pipeline lock up. In that case, the DISPC will generate an SYNCLOST_IRQ and/or DMA VIDBUFFERUNDERFLOW_IRQ interrupt. The freeze frame detection is for source data getting frozen while the DSS is working normally.

The two internal diagnostic checks are continuously performed over multiple frames as long as their mode enable register bits are set.

12.6.3.12.4 Internal Diagnostic Check Limitations

The internal diagnostic check is only be available when the DISPC is outputting RGB/YUV component data with separate sync signals. The internal diagnostic functions are not available for the following output modes:

- YUV422 embedded sync modes (BT.656 and BT.1120)
- RGB TDM (Time Division Multiplex) mode

12.6.3.13 DISPC Security Management

12.6.3.13.1 Security Implementation

DSS supports the following security features:

- Secure mode configuration
- Illegal connection prevention

Secure Mode

The DISPC supports secure mode configuration registers (DSS0_VID_SECURE, DSS0_WB_SECURE, DSS0_OVR_SECURE and DSS0_VP_SECURE) which defines the "secure mode" attribute of each pipeline, overlay manager, and video port instance in DISPC. These registers can only be modified by a host with an appropriate secure privilege (MReqSecure=1). When the SECURE bit corresponding to an instance is set by a secure host, the instance is deemed to be in "secure mode" and the DISPC hardware prevents the output of the

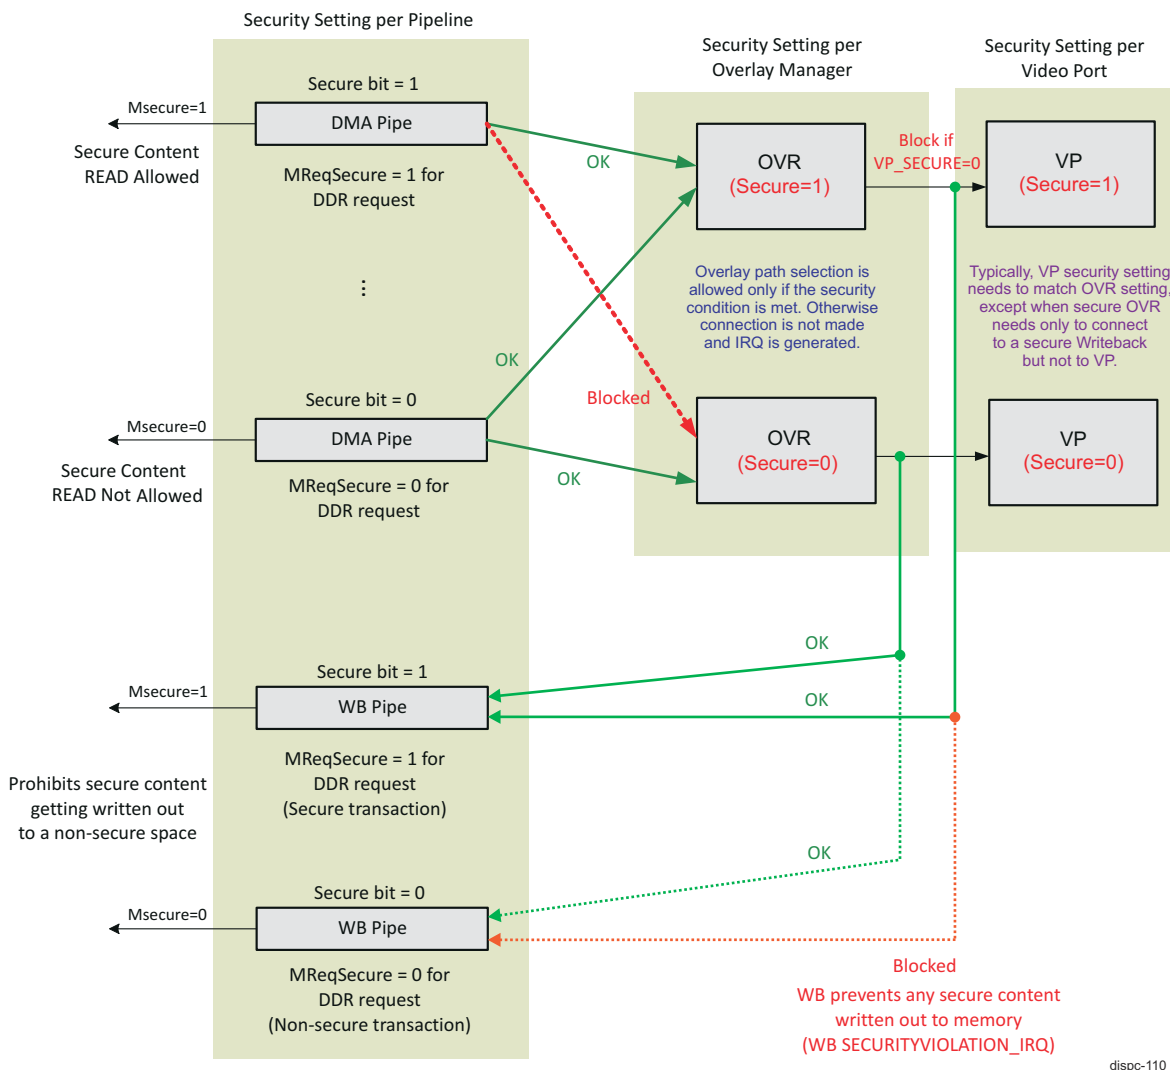

instance getting connected to a non-secure downstream module. Also, any DMA transfer initiated by a secure pipeline will have its OCP in-band signal MReqSecure set to HIGH to indicate that is a secure mode transaction request.

By default, all pipelines, overlay managers, and video ports are in a "non-secure mode". The corresponding SECURE bits in the DSS0_VID_SECURE, DSS0_WB_SECURE, DSS0_OVR_SECURE and DSS0_VP_SECURE registers are active, only when the DSS0_COMMON_DISPC_SECURE_DISABLE[0] SECURE_DISABLE register bit is configured properly to 0x0. When the SECURE_DISABLE bit is set to 0x1, the SECURE register bits are non-active and DISPC will behave as non-secure module.

Illegal Connection Prevention

The DISPC hardware enforces the following rules to prevent an illegal connection:

- Secure input pipeline can only connect to a secure overlay manager: If any host (secure or non-secure) configures an overlay manager input selection to connect a secure input pipeline to a non-secure overlay manager, then the DISPC hardware will block the connection and issue a "security violation" interrupt (SECURITYVIOLATION_IRQ) to alert the host.
- Non-Secure WB pipeline can take its input only from a non-secure input pipeline or a non-secure overlay manager output. Otherwise, the DISPC hardware will block the data transfer through WB and issue a "security violation" interrupt to alert the host.
- Non-Secure video port can only display data from a non-secure overlay manager output. Otherwise, the DISPC hardware will block the data display on the video port and issue a "security violation" interrupt to alert the host.

dispc-110

Figure 12-422. DISPC Secure Bit Setting and Illegal Connection Block

12.6.3.13.2 Secure Mode Configuration

The SECURE bit in DSS0_VID_SECURE, DSS0_WB_SECURE, DSS0_OVR_SECURE and DSS0_VP_SECURE registers is set/reset by a secure transaction. When the SECURE bit has been set, the software in "secure mode" is responsible for checking the DISPC configuration. The SECURE bit is propagated by DISPC to the system Interconnect in order to qualify all DISPC requests as secure or non-secure requests, based on the secure bits defined in the control register.

When DISPC accesses the frame buffer, in the case the SECURE bit has been reset and the frame buffer has been set secure, the DISPC will receive an "error" in response of non-secure requests.

12.6.3.14 DISPC Resources Sharing

For resource sharing of sub-components across different hosts processors or virtual machines, the DISPC implements the following features:

- Register region in memory per sub-component
- Interrupt duplication
- Independent context update for pipelines
- CHANNELID support

12.6.3.14.1 Register Region per Sub-component

The DISPC register regions in memory are partitioned such that each DISPC sub-component has its own region as shown in [Table 12-426](#). This allows the SoC infrastructure to firewall the register memory regions in such a way that a particular processor host or virtual machine can only access the sub-component(s) allocated to it.

Table 12-426. DISPC Register Memory Region Partitioning

Region Name	Description	Byte Offset
DISPC_0_COMMON_M	COMMON Region for Master Host (Control Processor)	0x0
DISPC_0_COMMON_S0	COMMON Region for Slave Host-0	0x10000
VIDL1	Video Lite 1 Pipeline	0x20000
VIDL2	Video Lite 2 Pipeline	0x30000
VID1	Video 1 Pipeline	0x50000
VID2	Video 2 Pipeline	0x60000
OVR1	Overlay 1	0x70000
VP1	Video Port 1	0x80000
OVR2	Overlay 2	0x90000
VP2	Video Port 2	0xA0000
OVR3	Overlay 3	0xB0000
VP3	Video Port 3	0xC0000
OVR4	Overlay 4	0xD0000
VP4	Video Port 4	0xE0000
WB	Write-Back Pipeline	0xF0000
DISPC_0_COMMON_S1	COMMON Region for Slave Host-1	0x100000
DISPC_0_COMMON_S2	COMMON Region for Slave Host-2	0x110000

12.6.3.14.2 Interrupt Duplication

The DISPC supports multiple interrupt outputs, each of which can be set up independently of the other. There are also separate interrupt lines for different category of events such as functional, internal diagnostic error, and secure. This allows fully independent monitoring/control of the interrupt events by multiple hosts (up to 4). For more details on interrupts, see [Section 12.6.3.5, DISPC Interrupt Requests](#).

12.6.3.14.3 Independent Context Update for Pipelines

The DISPC supports use-cases where portions of a single display (driven out of single OVR and VP) are controlled by multiple host processors (or virtual machines). In such a case, having a single GO bit per VP (display output) would result in partial updates of a particular pipeline register configuration on a frame boundary. The DISPC provides the additional capability to sync register configurations of each pipeline independently to a chosen frame boundary. This is achieved by setting the <PIPE> GO bit.

When the DSS0_COMMON_GLOBAL_GOBITMODE[0] MODE register bit is set, the individual pipeline register configurations are synced (shadow to work copy) only on frame boundaries where the DSS0_VID_PIPE_GO[0] GOBIT register bit of each used pipeline is set. The scheme is as shown in [Figure 12-423](#).

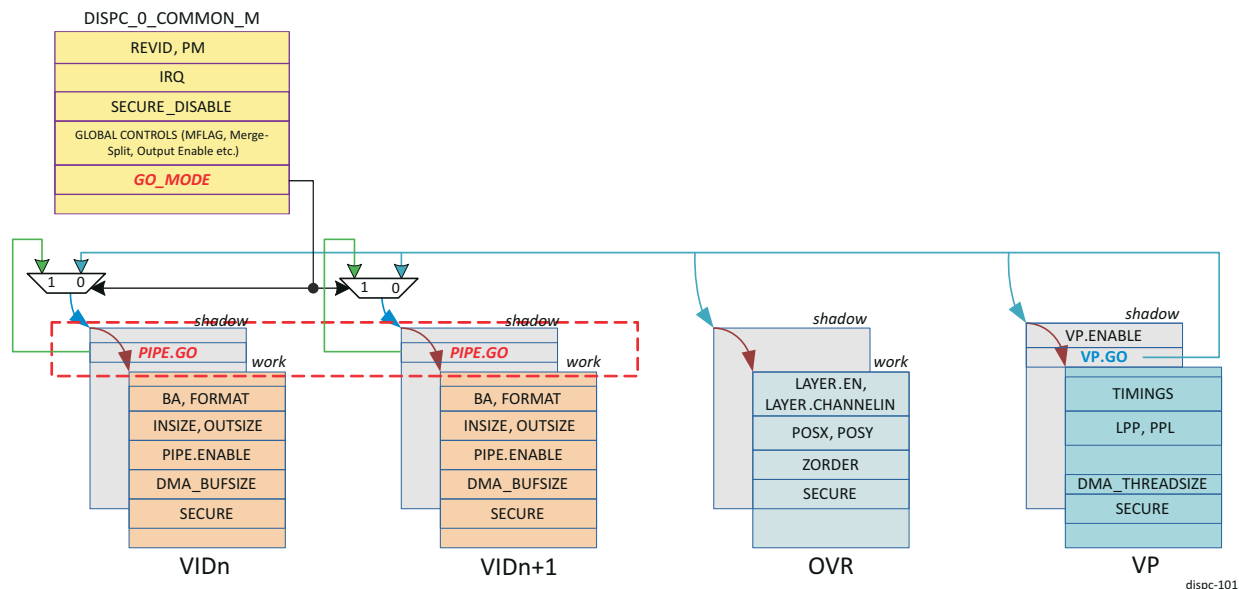

Figure 12-423. DISPC PIPE GO Bit Implementation

12.6.3.14.4 CHANNELID Support

In order to support IO virtualization that allows control of different DISPC pipes by different hosts, the DISPC pipelines must be identifiable on the SoC system interconnect with different channel IDs. To achieve this, every read and write transaction out of the DISPC DMA is tagged with a CHANNELID. The SoC infrastructure then uses the CHANNELID to set the various parameters (address translation, priority, security, etc.) on a per-channel basis.

The LSB bit of the CHANNELID (that is, CHANNELID[0]) is always used to differentiate between the two planes when a pipe is fetching a 2-plane pixel format (for example, YUV420-NV12). When the pipeline is fetching a 1-plane pixel format, the LSB bit is always '0'. The mapping of the MSB bits of the CHANNELID is as shown in Table 12-427.

Table 12-427. DISPC CHANNELID Mapping

CHANNELID[m:1]	Pipeline Mapping
0	VID1
1	VIDL1
2	VID2
3	VIDL2
4	WB

12.6.3.15 DISPC Shadow Mechanism for Registers

Some DISPC registers are termed *shadow registers*. The shadow registers allow the software to modify them at any time, without direct effect on the DISPC hardware configuration. When all the values for a given configuration are written into the shadow registers, software must set only one register bit to validate the configuration. When the hardware reaches the end of the current frame and sees that the bit has been set by software, the new configuration is now the configuration used by the hardware.

The DSS0_VP_CONTROL[5] GOBIT bit enables the hardware to use the new configuration, for all shadow registers associated with each VP output.

The registers are statically associated to a particular output (for example, timing registers) or dynamically associated to one output at a time (for example, video registers).

12.6.4 MIPI Display Serial Interface (DSI) Controller

12.6.4.1 DSI Block Diagram

The MIPI DSI v1.3.1 Transmitter Controller (DSITX) provides an interface that receives data and control from the host processor display system using either the DPI or SDI input bus interfaces. The DSITX will translate the incoming pixel information and control signals into an internal packed byte format, in the case of DPI, or pass in the prepacked SDI byte format, before the internal byte format data is packetized and sent to the MIPI DSI Compatible display via the MIPI D-PHY physical interface. It supports video and command mode displays and can work in multi-display mode using virtual channel identification on the packets.

The DSITX controller provides two interfaces for connection to a display panel. Normal operation for a panel supporting DCS commands can be done using either SDI interface, or using the APB (Advanced Peripheral Bus) access to DIRECT_CMD registers. Video streaming applications can only use the SDI or DPI interface. The DSI controller supports flow control using the SDI video interface.

The DSITX implements the stream arbitration and low-level protocol layer functionalities required by MIPI DSI specification v1.3. It supports up to 4 x 2.5 Gbps D-PHY data lanes in a single-link configuration and handles the byte lane mapping per use case (1, 2, 3, or 4-lanes).

The DSITX controller block diagram is illustrated in [Figure 12-424](#).

Figure 12-424. DSITX Controller Block Architecture

12.6.4.2 DSI Clocking

The DSI receives all the clocks from DISPC or DPHY_TX modules. There are no other dedicated PLLs. For more details on DSI clocks mapping at DSS and SoC level, see *DSI Integration*.

The DSI requires multiple clocks running asynchronously, that are shown in [Table 12-428](#).

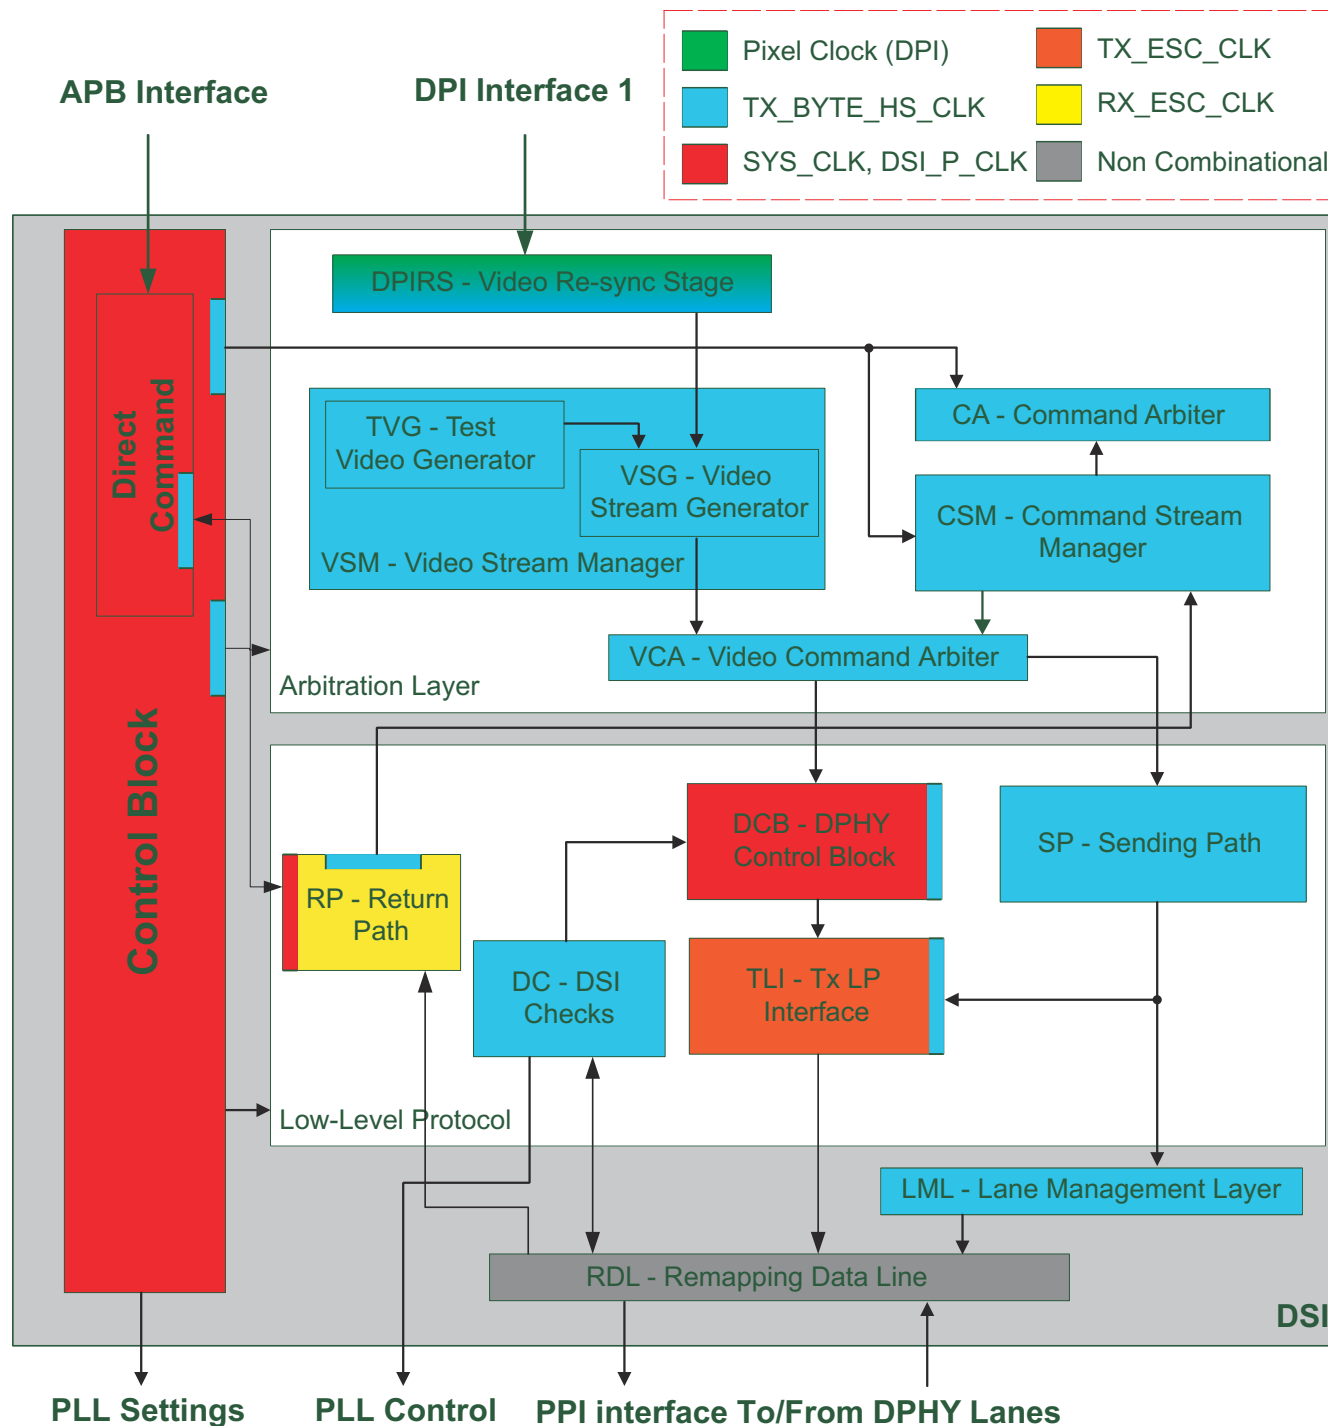

Table 12-428. DSI Clocking

Clock	Direction	Min	Max	Constraints	Description
dpi_0_clk (Async to all other clocks)	Input	7 MHz	425 MHz	$F_{\text{pixel_clk}} = F_{\text{tx_byte_hs_clk}} \times \text{active_lanes} \times 8 / (\text{bits_per_pixel})$	Used for DPI interface only. Frequency range depends on expected data rate with respect of number of data lanes, data lane frequency and frame rate

Table 12-428. DSI Clocking (continued)

Clock	Direction	Min	Max	Constraints	Description
sys_clk (Async to all other clocks)	Input	7 MHz	250 MHz	1. Cannot be slower than $tx_byte_hs_clk \times datapath_size / if_datasize$ (risk of underrun) in SDI mode. 2. Must be greater than: $rx_esc_clk \times 8$. 3. Speed should be sufficient to provide enough data in SDI operation. 4. Must be faster than the $tx_byte_hs_clk$ for Direct command operation.	Main functional clock Also used for the VBUS/APB interface
dphy_0_tx_byte_hs_clk (Async to all other clocks)	Input	10 MHz	312.5 MHz	The max value in SDI interface operation depends on sys_clk: can't exceed sys_clk freq x if_datasize datapath_size Otherwise 312.5 MHz to match the 2.5Gbps limit on DPHY v1.3 specification	DPHY PPI Byte Clock Frequency set by the DPHY and its High Speed input clock ($tx_byte_hs_clk = dphy \text{ bit rate } / 8$) Maximum limit due to risk of underrun
dphy_0_tx_esc_clk (Async to all other clocks)	Input	1 MHz	20 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 20 MHz	TX Escape Clock
dphy_0_rx_esc_clk (Async to all other clocks)	Input	1 MHz	10 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 10 MHz	RX Escape Clock

Figure 12-425 describes the clock scheme and domains of the DSI_TX.

dsi_spruij7-057

Figure 12-425. DSITX Clock Scheme and Domains

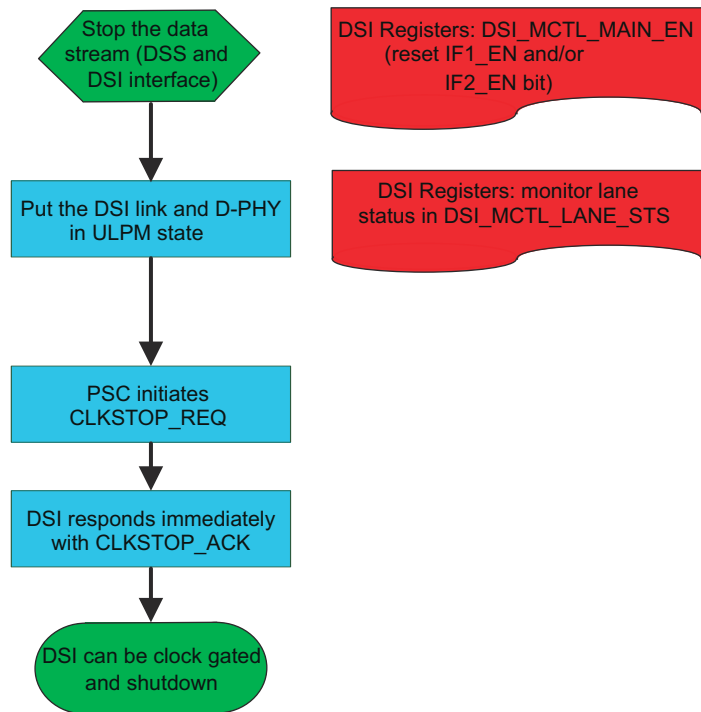

12.6.4.3 DSI Reset

The DSI has one active low reset input. The entire internal logic is reset by this reset. Internal resets (synchronous and asynchronous) for different clock domains are generated internally (synchronized to the respective clock domain).

12.6.4.4 DSI Power Management

The DSI implements a power management protocol to interface to a PSC (Power and Sleep Controller) module SoC level.

Figure 12-426 shows the expected sequence from SW while performing a *clkstop_req* to the DSI.

dsi_spruij7-058

Figure 12-426. DSI Clock Gate / Power Off Procedure

12.6.4.5 DSI Interrupts

Table 12-429 shows the interrupts that are generated by the DSI module.

Table 12-429. DSI Interrupts

Interrupt (n = 0)	Description	Source Module	Source Signal Name
dsi_#n_func_intr	DSI-#n Func Interrupt	DSI Controller	dsi_irq_n
dsi_#n_safety_error_fatal_intr	DSI #n Internal Diagnostic Fatal interrupt	DSI Controller	asf_int_fatal
dsi_#n_safety_error_nonfatal_intr	DSI #n Internal Diagnostic Non-fatal interrupt	DSI Controller	asf_int_nonfatal
ecc_intr_uncorr_level_sys_intr	ECC aggr uncorrectable error	-	-

12.6.4.6 DSI Internal Interfaces

12.6.4.6.1 Video Input Interfaces

DSITX supports following video streaming interfaces:

- DPI (Uncompressed video stream)
- SDI (Serial Display Interface)

The DSI does not require DSI sub-link support. Therefore, only one video mode source is supported.

12.6.4.6.1.1 Pixel Mapping

The pixel bit color mapping for the DSITX input interfaces are as shown in Figure 12-427. This matches with the pixel bit mapping on the output of DISPC for the supported formats.

Figure 12-427. DSI Pixel Mapping On The DSI-DPI Interface

Table 12-430. DSI Pixel Format Interoperability between DISPC and DSITX

DSITX DPI Pixel Format	DISPC VPOUT Pixel Format ⁽¹⁾ DSS0_VP_CONTROL[10-8] DATALINES Register Field Setting	DPI Interface Support	SDI Interface Support
RGB565	16-bit (DATALINES = 0x1)	Supported	Supported
RGB666	18-bit (DATALINES = 0x2)	Supported	Supported
RGB666p	N/A	Not Supported	Not Supported
RGB888	24-bit (DATALINES = 0x3)	Supported	Supported
RGB10	30-bit (DATALINES = 0x4)	Supported	Not Supported
RGB12	36-bit (DATALINES = 0x5)	Supported	Not Supported
YcbCr422 8-bit	N/A	Not Supported	Not Supported
YCbCr420 12-bit	N/A	Not Supported	Not Supported

(1) Output aligned on the LSB of the pixel data interface.

12.6.4.6.2 DPI (Pixel Stream Interface)

- One uncompressed video stream input
- CEA-861 signaling/timing compatible interface
- Pixel clock rate range from 7 MHz - 425 MHz
- Frame Resolution – 4MPix@60fps equivalent frame size – supporting various frame resolutions and aspect ratios (with pixel clock freq < MAX_dsi_pixel rate = 425 MHz)
- Progressive video timing only
- Maximum Width - 8K (should only be constrained by the throughput)
- RGB format only –color space conversion or chroma up-sampling NOT supported

12.6.4.6.2.1 Signals

DPI interface supports the following set of DPI standard signals:

- VSYNC – Video Vertical Blanking indication signal as defined in the above standards
- HSYNC - Video Horizontal Blanking indication signal as defined in the above standards
- DATA ENABLE – Video data enable indication signal as defined in the above standards
- DATA - 36 bits of data for supporting up to 12bpp
- Clock – As defined for each format from 7 MHz - 425 MHz

12.6.4.6.3 SDI (Serial Data Interface)

DSITX uses a SDI interface (32-bit) to receive active video data from an internal frame memory using a DMA or other data pull mechanism. The interface uses req/ready handshake signaling to control the data flow.

The DSITX SDI Interface supports one of the following modes:

- Command-only

SDI-DSI Interface requires following signals:

- dsi_if_valid
- dsi_if_stall
- dsi_if_start (Line Start)
- dsi_if_frame_sync (frame_sync)
- dsi_if_data

The SDI interface of DSI_TX receives data directly from DSS VP output and is functional when the user configures the DSS to operate in COMMAND_STALLMODE (DSS0_VP_CONTROL[11] STALLMODE = '1' and DSS0_VP_CONTROL[12] STALLMODETYPE = '0').

12.6.4.6.3.1 Secure Display Support

Only secure peripherals can be connected to a secure DPI (VP) output of DSS. In order to support this requirement, the DSS exports a secure qualifier to the DSI_TX. Inside the DSI a SECURE register is implemented (DSI_WRAP_DPI_SECURE), which contains SECURE bits, [0] DPI_0_SECURE and [1] DPI_0_SECURE_VIOLATION, corresponding to the DPI port. These SECURE bits can only be set or reset by a secure host (vbusp transactions with secure qualifier set).

The behavior of DSI module for different settings of SECURE register bit and SECURE qualifier from DSS is as shown below:

Table 12-431. Secure Display Support

SECURE Register Bit (DSI)	SECURE mqualifier (DSS)	Security Violation Status	Comments
0	0	0	Data is passed (non-secure DSS data through non-secure DSI)
1	0	0	Data is passed (non-secure DSS data through secure DSI)
1	1	0	Data is passed (secure DSS data through secure DSI)
0	1	1	Security Violation. Data is blocked (secure DSS data through non-secure DSI)

Once a security violation is detected, it is captured in the DSI_WRAP_DPI_SECURE[1] DPI_0_SECURE_VIOLATION register status bit.

12.6.4.7 DSI Programming Guide

This section describes the programming guidelines for the DSI Controller and D-PHY.

The goal of this section is to present more in detail how the DSI link should be used at application level plus some scenarios of use of the DSI link (start-up, display switch on/off, dual-display).

12.6.4.7.1 Application Guidelines

The purpose of this section is to provide guidelines on how to drive the DSI host controller, provide general sequence of operations and some typical application notes.

12.6.4.7.1.1 Overview of a Display Subsystem

Figure 12-428 shows an overview of a display subsystem. It covers the point to point interfaces between the DPI/SDI and DSI blocks. Other blocks and interfaces are included to give a better understanding of the environment for this interface.

A DSI interface is made up from one DSI controller and one D-PHY block. D-PHY is the physical layer of the DSI interface. The DSI block handles protocol. The DSI interfaces support displays that comply with the MIPI DSI standard.

The displays can be of either command mode type or video mode type. Command mode displays have a frame memory that can hold the entire image. The display is refreshed from this memory and only changes of the display content are sent over the display interface. Video mode displays do not have this memory and thus all data for every refresh must be transferred in real time.

The SDI block can support one display in command mode. By using command mode displays and rerouting of connections, between display updates, more than two displays can be connected and active.

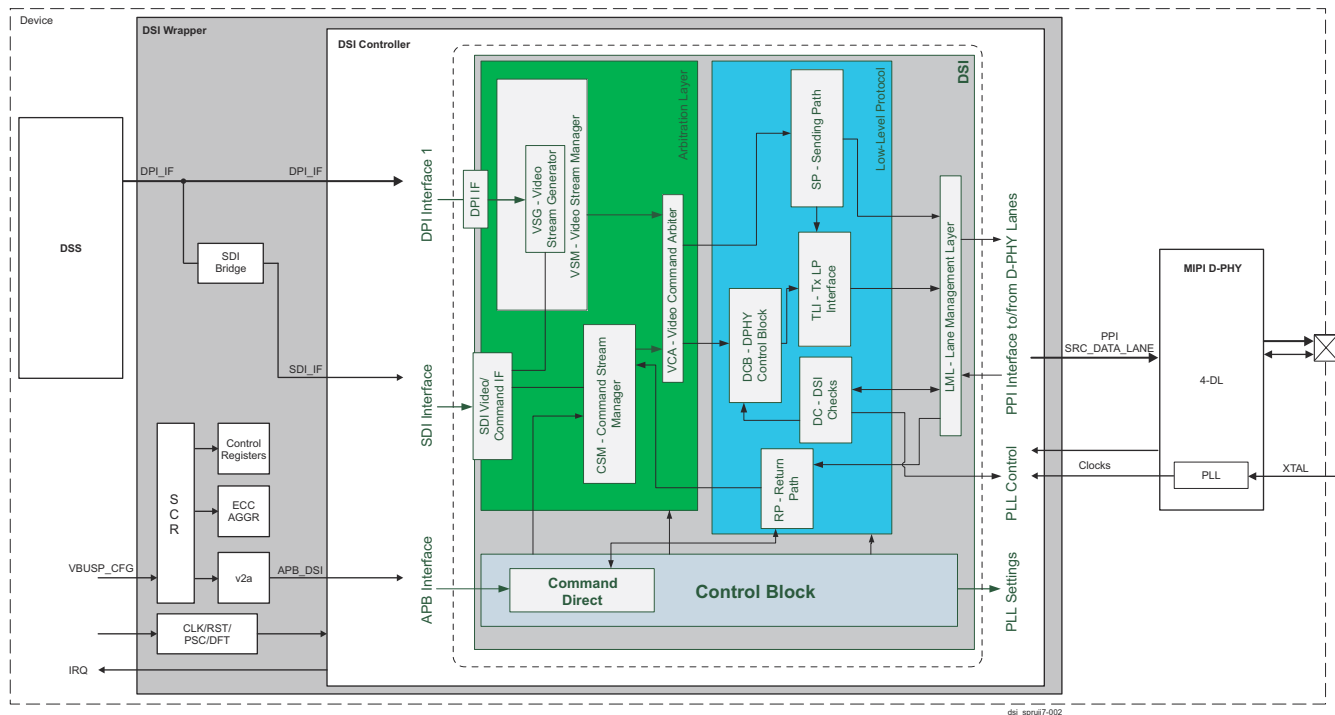

Figure 12-428. Example Display Subsystem Showing Controller and PHY Blocks

12.6.4.7.1.2 D-PHY And DSI Configuration

The DPHY and DSI controller must be configured before any panel video display can be used. All accesses to the DPHY to configure it for use with the DSI Controller should be performed through the DPHY own APB interface .

12.6.4.7.1.3 DSI Controller Initialization

The DSI controller will always require the DPHY and data path configuration to be set after power up and any hard reset. The minimum sequence should define the data path lane configuration; mappings, available lanes, DPHY power, resets and lane swap. All these register values should be set before the DSI controller is enabled for functional operation.

The DSI registers are accessed through the APB interface. The programming sequence for command, video and controller configuration must follow a sequence of accesses to ensure the clock gate control updates the internal nodes before the link is enabled.

All DSI_VID_xxx registers must be programmed, if required, before the write to the DSI_VID_MAIN_CTL register.

All DSI_MCTL_DPHY_xxx registers must be programmed, if required, before the write to the DSI_MCTL_MAIN_DATA_CTL register to set the [0] LINK_EN bit.

12.6.4.7.1.4 Panel Configuration Using Command Mode

The DSI controller can provide DCS command access using either the SDI interface or through the APB interface control of the DIRECT COMMAND registers (see [Table 12-432](#)). The panel registers will be programmed using the LP mode before the high-speed video is enabled. Commands can either be sent using the command interface or though the Command FIFO using the APB registers.

The command FIFO access is done though the APB Command mode registers by forming packets of DCS commands. The DCS commands can be found in the MIPI DCS specification or the display panel data sheet.

DCS commands are essentially register write or read transfers to panel registers. The initialization of a panel will require APB register writes to fill the FIFO with the DCS commands. The commands can be grouped into a long packet by sending the packet split into 4 bytes to fill the FIFO using a write to the DSI_DIRECT_CMD_WRDAT register.

Table 12-432. DSI Direct Command Mode Registers

DSI Register	Description
DSI_DIRECT_CMD_SEND	Direct Command - trigger the direct command sending - write only
DSI_DIRECT_CMD_MAIN_SETTINGS	Direct Command - main settings
DSI_DIRECT_CMD_STS	Direct Command - status - read only
DSI_DIRECT_CMD_RD_INIT	Direct Command - stop read operation
DSI_DIRECT_CMD_WRDAT	Direct Command - data to write byte 0 to 3
DSI_DIRECT_CMD_FIFO_RST	Direct Command- reset the write FIFO pointer

Each DCS command packet to be sent can be built by first selecting the packet configuration using the DSI_DIRECT_CMD_MAIN_SETTINGS. The DCS Command data types are defined in the DSI specification based on the number of parameters that are expected to be sent. Configuration of a panel display will normally use DCS write data types.

Table 12-433 shows the DSI_DIRECT_CMD_MAIN_SETTINGS register bit description.

Table 12-433. DSI Main Settings Register Description

DSI_DIRECT_CMD_MAIN_SETTINGS Register Bit	Description			
[24] CMD_LP_EN	Enables LP sending for the command request.			
[23:16] CMD_SIZE	Size of the command in case of write command - when written value is bigger than 0x10, the value is rounded to 0x10 for write - when size is bigger to 0x2 for read it is rounded to 0x2.			
[15:14] CMD_ID	In case of read/write command, Virtual Channel of the command.			
[13:8] CMD_HEAD	In case of read/write command, data type of the command:			
	0x05	DCS Write	0 parameters	Short Packet
	0x15	DCS Write	1 parameter	Short packet
	0x39	DCS Long Write	N parameters	Long Packet
[3] CMD_LONGNOTSHORT	This bit must be tied to one.			
[2:0] CMD_NAT	Nature of the direct command: 000: write command.			

Once the packet is loaded, issue a DIRECT_CMD_SEND (via the DSI_DIRECT_CMD_SEND register) and the data will be sent in LP mode.

12.6.4.7.1.5 VIDEO Interface Configuration

The DSI video operation requires the configuration of the VSG and TVG registers to match the panel configuration. The two video interface options will also require careful selection of the clock and registers to achieve error free video streaming.

The DSITX controller supports the mechanism for initial skew calibration for D-PHY data rates greater than 1.5 Gbps.

DPI Video Interface Operation

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. If this is the case, then the blanking and active data periods must be matched up. The DSI controller will slave its frame timing to the incoming DPI **VSYNC**, if it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered.

The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So, programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

Program the DSI vertical size registers as follows:

- $VSA = DPI_VSI$ (lines, minimum of 2)
- $VBP = DPI_VBP$ (lines, minimum of 0)
- $VACT = DPI_VACT$ (lines)
- $VFP < DPI_VFP$ (minimum of 1)

The timing should also be matched per line, therefore the blanking and active periods should match. DPI horizontal timing is measured in pixels, whereas the DSI controller uses bytes. If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure the FIFO depth and vsync_delay is suitable.

The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. Additionally, the PPI short packets and packet headers that are inserted by the controller must be accounted for. HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and footer (4 + 2 bytes) and the HSE short packet (4 bytes). HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (6 bytes). HFP should be reduced by 6 bytes to account for the long packet header and footer. Finally, for lines with no active data, the BLKLINE_PULSE_PCK is the total size minus 20 bytes (14 for HSA, 6 for the remaining blanking which is all combined into a single packet).

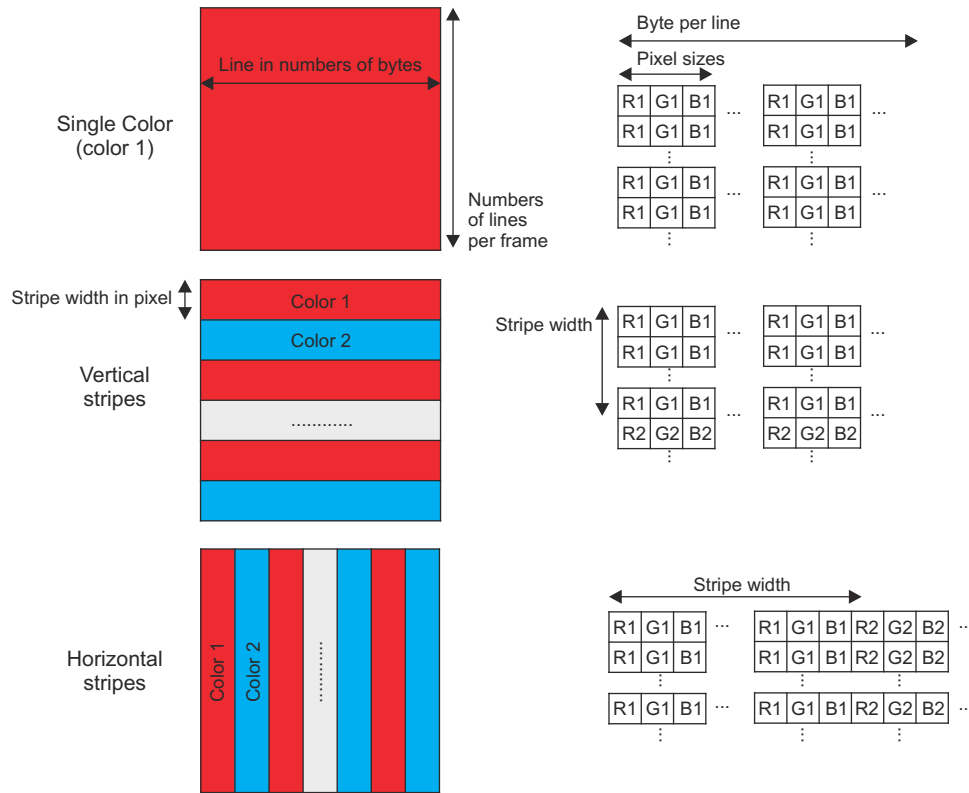

Program the DSI horizontal size registers as follows:

- $HSA = (DPI_HSA \times \text{bpp}/8) - 14$
- $HBP = (DPI_HBP \times \text{bpp}/8) - 12$
- $HACT = (DPI_HACT \times \text{bpp}/8)$ NOTE: $(DPI_HACT \times \text{bpp}/32)$ must be an integer.
- $HFP = (DPI_HFP \times \text{bpp}/8) - 6$
- $BLKLINE_PULSE_PCK = ((DPI_HSA + DPI_HBP + DPI_HACT + DPI_HFP) \times \text{bpp}/8) - 20;$

TVG Generator

The TVG oversees generating dummy data (to display something even if there is no video stream running). It is also able to ease verification or validation of the DSI without having a complete environment (application or verification test bench). The controller has a Test Video Generator that can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

[Figure 12-429](#) presents TVG MODE patterns.

dsi_spruij7-003

Figure 12-429. TVG MODE Patterns

The TVG generates a data stream in the same format than the one specified for the normal functional video stream (as set in VSG register). The content of that flow is specified by registers. Those registers specify the following information: Image size: Number of bytes per line (see TVG_LINE_SIZE[14:0] register) and number of lines per frame (TVG_NBLINE[12:0]).

Image kind: Single color, vertical stripes or horizontal stripes (see TVG_MODE[1:0] register). Stripe width: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128 (see TVG_STRIPE_SIZE[2:0] register).

Pixel kind: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB (see VID_PIXEL_MODE[3:0] register).

Color one: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered (see COL1_GREEN[11:0], COL1_RED[11:0], COL1_BLUE[11:0] registers).

Color two: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered. (see COL2_GREEN[11:0], COL2_RED[11:0], COL2_BLUE[11:0] registers). Start pulse and stop handshake (+ stop mode) (see TVG_CTL register).

An example of the sequence is as follows:

- Select TVG for video stream generation instead of SDI 1 interface:
 - IF1_EN bit to 0 (stall signal at 1) in MCTL_MAIN_EN.
- Select video mode for interface 1 in MCTL_MAIN_DATA_CTL:
 - TVG_SEL bit to 1 in MCTL_MAIN_DATA_CTL register to select stream from TVG.
- Select generated frame format in TVG_CTL register:
 - Image format (single color, H stripes, V stripes) in TVG_MODE field.
 - Image color selection in TVG_COLOR1, TVG_COLOR1_BIS, TVG_COLOR2, VG_COLOR2_BIS.
 - Stripes size in TVG_STRIPE_SIZE field.

- Image size in TVG_IMG_SIZE register.

Note: The number of lines per frame and number of bytes per line. It is required that TVG settings on active area match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG_STOPMODE field of TVG_CTL:
 - TVG video stream generation start/stop controlled by the TVG_RUN bit in TVG_CTL register. Polling TVG run status from the TVG_RUNNING bit in TVG_STS register is useful when setting TVG_RUN to 0. TVG video stream generation does not stop instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

12.6.4.7.2 Application Considerations

The following sections outline the normal operation of the DSITX controller and the programming and sequences require to operate the DSITX controller for normal video and command operation.

12.6.4.7.2.1 D-PHY Timings Control

Several DPHY timing constraints must be respected by the system, which are described in this section. When a switch in ULP is requested, the application should be aware that the D-PHY needs 1 ms to leave this state (this timing is guaranteed by the DSI itself). It makes no sense to start an ULP request if the expected time in ULP is short.

When PLL power down is asserted, the system should continue to assert for a specific minimum period of time (PLL internal requirement – please refer to DPHY documentation). Please note that shutting down the PLL implies that no clock is present on tx_byte_hs_clk input and thus the DSI link is stopped; even if the system-side interface clocks remain active, no more HS transfers can be done.

Force_stop, ppi_c_force_tx_stop (clock lane) and ppi_d_force_tx_stop (1 per data lane), can be useful to resolve certain deadlock situations, for example: DSI slave does not give back control to master, or critical DPHY error. When a 'force stop mode' is issued by the application, the system should maintain this state on the bus to ensure the request is correctly considered by the D-PHY cells and the **stop_state** is asserted and direction signal is deasserted.

reg_wait_burst_time (for the LML) must be programmed to ensure that two HS bursts are separated by at least 100 ns. The value will be based on the period of the tx_byte_clk cycle.

VCA: When trying to interleave commands to video stream, it is assumed that only write/read commands and BTA request are sent (no TE). The reason is that such transfers are slow and difficult to predict in term of duration. They could take longer than the slots available for video. The read commands are unpredictable and may cause some break in the video stream, however, they can still be used, if an appropriate response time can be guaranteed. It is the responsibility of the system integrator and the application to plan and implement recovery procedures when the video stream is stalled due to a read that takes too long.

12.6.4.7.2.2 Control Block

Most of the register contents must be resynchronized against a DSI internal clock (tx_hs_byte_clk). This means there is a certain time to pass data from one clock domain to the other. If two writes in the same register are too close, the register itself is updated but the synchronization may fail.

The formula to calculate the number of system clock periods between two writes is:.

$$\text{nb_cycle}(\text{dsi_p_clk}) = 6 * (\text{f}_{\text{dsi_p_clk}} / \text{f}_{\text{tx_byte_hs_clk}} + 1)$$

The application must respect a period of TX ns between two write accesses to the same register (there is no issue writing different registers back-to-back).

Table 12-434 shows an example of required time between two write accesses.

Table 12-434. Example of Required Time between Two Write Accesses

$\text{f}_{\text{dsi_p_clk}}$	$\text{f}_{\text{tx_byte_hs_clk}}$	TX minimum time between 2 writes accesses
200 MHz	106 MHz	~ 90 ns
160 MHz	10 MHz	~ 650 ns

Table 12-434. Example of Required Time between Two Write Accesses (continued)

$f_{\text{dsi_p_clk}}$	$f_{\text{tx_byte_hs_clk}}$	TX minimum time between 2 writes accesses
200 MHz	10 MHz	~ 650 ns

Another place where asynchronous behaviour may interfere with programming in the CB is the direct command status register `DIRECT_CMD_STS`. Some of the bits of this register are set when a pulse (that lasts one clock period) coming from `tx_hs_byte_clk` domain is observed (after resynchronization on `dsi_p_clk`) and is reset when the clear bit is written. In use case where `tx_byte_hs_clk` is slow (10 MHz range), the bit can be read and a clear attempted before the end of the source pulse. This can result in the re-assertion of the bit immediately after it is cleared. For that reason, it is recommended to wait for a while between reading the bits of the `DIRECT_CMD_STS` register and clearing them.

Application Issues

Some register fields cannot take all the possible values but are restricted to a certain number of combinations (mode control). The DSI controller does not check that all the fields match a valid setup so it is the responsibility of the system integrator and the application to check that the written values are amongst the permitted combinations. Amongst the register fields that fall in to this category are most of the mode settings (stop mode, recovery mode, direct command type, image sizes, etc.)

Programming Coherency

The application level must ensure that the register configurations are valid for the system to operate correctly. There are several possible combinations are possible in the CB registers however should be avoided. A few examples:

- No HS transfer should be enabled when PLL is shut-off.
- TVG should not be run when the video interface is running.
- No access (from interface or from register) should be attempted while TBG is active.
- Prior to shut-down of the DPHY PLL, application should verify that the DSI link is in proper state. If the bit that enables BTA is not set and that any operation implying a BTA is sent, the system is stalled. Then the bit that enables BTA must be aligned with application needs. Moreover, read enable or TE enable cannot be set if `bta_en` is not set (these operations cannot be enabled when BTA is not enabled).
- TE feature must not be enabled in SDI interface.

12.6.4.7.2.3 Video Coherency

In video mode, there are a lot of sizes defined for the video stream generation. This data corresponds to the payload of the various generated packets and not to their duration. However, they are closely linked. It is the responsibility of the system integrator and the application to use correct sizes to ensure the correct video timing and behaviour, because the system may use 1 to 4 active data lanes with a fixed number of bytes for the header/checksum overhead. In the same way, when programming D-PHY time (to switch from LP to HS), the application must consider D-PHY time plus overhead due to LLP and LML crossing time (see [Section 12.6.4.7.7.2, Video stream settings \(VSG\)](#)).

VSG Control

Start and stop sequences can take a long time to be performed. If the requests are not maintained up to the time the status bit are indicating effective start or stop, they can be ignored and the VSG may not have started or stopped as expected by application. It is then up to the application to carefully manage the request and to verify that requests are being processed before changing the state of the VSG.

Test Generator:

The DSITX provides test generator to provide a video data stream. When using TVG, all sources can be used (provided VCA permits it) however the SDI interface must not be programmed to send video data and must be restricted to command mode.

The pixel modes supported are: RGB 16-, 18-, 24-, 30- and 36-bit; YCbCr422 16-bit; and YCbCr420 12-bit (note that additional YCbCr422 20-bit and YCbCr420 24-bit may be supported using SDI interface, but are restricted to command mode only).

The supported display sizes are listed below:

- QQVGA (160 x 120) - 15/20/30/60 fps - RGB 16-18-24 (-30 and 36) bits per pixels
- QCIF (176x144), QCIF + (176x208 and 176x220) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QVGA (320x240) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- CIF (352x288), CIF + (352x416 or 352x440) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- 1/2 VGA (320x480) and 2/3 VGA (640x320) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- VGA (640x480) - 15/20/30/60 fps - RGB 16-18-24(-30 and 36) bits per pixels
- WVGA (800x480 - 848x480 - 854x480 - 852x480) - RGB 15/20/30/60 fps - 16-18 and 24 bits per pixels
- SVGA (800x600) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QHD (960x540) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- XVGA (1024x768) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- Full HD (1920x1080) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- WUXGA(1920x1200) - 15/20/30/60/(120 fps – 16 bpp only) 16, 18 and 24 bits per pixels
- 4Kx4K(4096x4096) - 15/20/30 fps - 16-18 and 24 bits per pixels

12.6.4.7.3 Start-up Procedure

The start-up sequence described in [Figure 12-430](#) assumes that the rest of the chip is ready (all clocks are present except tx_byte_hs_clk, application it is ready...) and that the DSI is ready (reset de-asserted).

The following is the most common start up sequence:

Firstly, application layer programs and enables the PLL, then waits for a period for the PLL to lock (minimum time will be defined by the PHY documentation). At the end of the minimum wait period, the application layer should poll the PLL lock status register periodically to confirm lock status, repeating until confirmed. At the end of this step, it is assumed that a clock is present on the tx_byte_hs_clk input (this step may be replaced by an interrupt-based alternative if available from the selected DPHY or provided in the system integration logic).

During the time taken by the PLL to lock, the application can program the configuration registers and prepare the DSI link. This can also be done after the PLL is locked. It should at least configure enough to be able to use LP mode to send direct commands.

Enable clock and data lane(s) per the needs. This action is only concerned with programming registers that control the D-PHY lane enable signal. The active lane configuration with the DSI_MCTL_MAIN_PHY_CTL and DSI_MCTL_MAIN_EN registers must be programmed to match, i.e. for two data lanes (0 and 1).

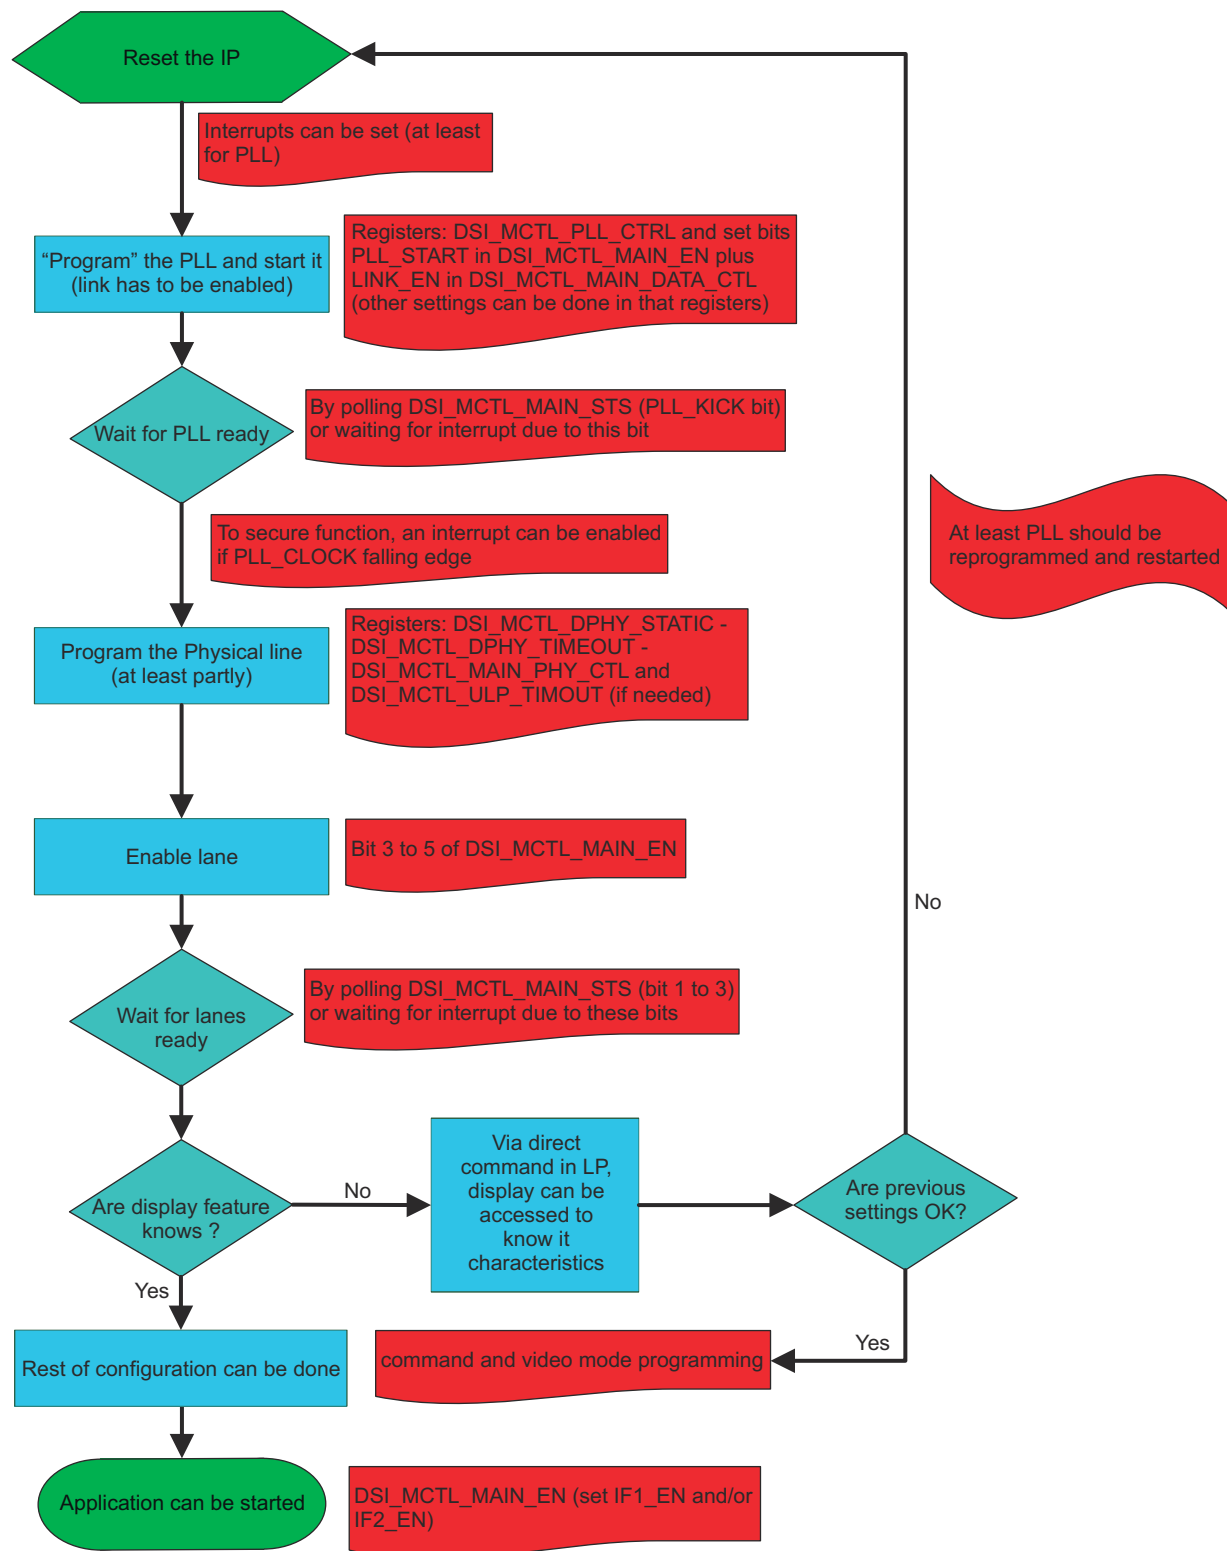

- DSI_MCTL_MAIN_PHY_CTL (0x08) register – LANE3/4_EN - bits[2:1] set to zero to disable lanes 2/3.
- DSI_MCTL_MAIN_EN (0x24) register – DAT3/4_EN fields - bits[6:5] set to zero to disable lanes 2/3.

Start the lane in the DCB. The DCB state machine puts the lanes in the correct state to be ready.

At this step, the DSI link should be able to access to display - at least in LP mode. If the system (DSI link and display) is fully programmed, code to display image can be started. If display characteristics must be read from the display and the system is programmed in LP mode, this is time to read the displays parameters to allow correct programming of the DSI. A new round of programming can then take place to set-up the system, based on the parameters which have been read from the display.

The DSI internal setting is now completed and it is ready to accept data. The application can now enable the interface so that the stall signal is removed and that DSI link can accept data.

When the procedure described above is terminated, it does not imply that display itself is ready. At this stage, the D-PHY and DSI link are ready to send/receive data to/from display and thus application may still need to initialize the display itself.

ds_i_spruij7-005

Figure 12-430. Start-up Procedure Summary**12.6.4.7.4 Interrupt Management**

There are numerous error and status conditions that can be monitored via the interrupt mechanism. The edge on which these conditions are generated is programmable.

Each interrupt source has four associated registers:

1. The status register itself "<sts_reg>"
2. a control register "<sts_reg>_ctl" to control corresponding interrupt behaviour
3. a flag register "<sts_reg>_flag" to observe when interrupt/event has been triggered
4. A clear register "<sts_reg>_clr" to clear the event flag register.

The decision of which status bits (<sts_bit>) can generate interrupt is taken when the corresponding enable bit "<sts_bit>_en" is set in the status control register. In the same register the status bit edge "<sts_bit>_edge" states on which edge of the status bit the interrupt is triggered. When the selected edge is observed, the flag bit "<sts_bit>_flag" is set. The interrupt signal is an OR of all flag bits that are enabled. When the register "<sts_reg>_clr" is written with the bit "<sts_bit>_clr", the "<sts_bit>_flag" is cleared.

12.6.4.7.4.1 Error and Status Registers

The error register bank handles storing all error flags that are identified. It also stores some status bits that must be observable and detectable by the application. These status and error registers can generate an interrupt on the rising or falling edge if this generation is enabled.

This mechanism is different depending on the nature of the status or error bits. For those that are generated in the DSI block (basically all status and error bits except direct command), the status bits cannot be easily controlled and toggle according to the internal status meaning only the current value is observed in the status/error register itself.

If the interrupt generation is enabled with the associated enable bit, a rising edge (associated edge bit set to 0) or a falling edge (associated edge bit set to 1) of that status bit toggles the corresponding flag bit. At the end, all the flag bits are put together with an OR to generate the interrupt signal. The flag register can be reset by writing in the clear register.

The described behavior can be summarized by the following pseudo-HDL. The signal named signal_sts_bit is the bit that is observable by reading status bit.

- reg_sts_q is the status register (accessible via APB)
- reg_flag_sts_q is the flag register
- clear_the_flag is set when the register clear is written
- edge_sts_ctl is the edge bit
- enable_sts_ctl is the enable bit

```
reg_sts_d <= signal_sts_bit;

reg_flag_sts_d <= '0' WHEN clear_the_flag = '1' ELSE
  - '1' WHEN (reg_sts_q = '0' AND reg_sts_d = '1' AND edge_sts_ctl = '0') ELSE -- detect rising
  - '1' WHEN (reg_sts_q = '1' AND reg_sts_d = '0' AND edge_sts_ctl = '1') ELSE -- detect falling
  - reg_flag_sts_q;

irq_n <= NOT (OR_OF_ALL(reg_flag_sts_q AND enable_sts_ctl));
```

The code is slightly different in cases where the observed bit is a generated condition (in the control block), as is the case for the direct command status and error flags. The status/error information is automatically generated but is cleared only when writing in the corresponding clear bit. The interrupt generation behaves similarly to the error condition cases, however, as the status falling edge is observed only when the bit is cleared, it is not possible to use the falling edge detection on flag (however the code is kept as-is to provide a standard implementation method). This leads to the following code:

- reg_sts_d <= '0' WHEN clear_the_flag = '1' ELSE
 - '1' WHEN the_sts_bit (Note 1) = '1' AND reg_sts_q = '0' ELSE -- (see Note)
 - reg_sts_q;
- reg_flag_sts_d <= '0' WHEN clear_the_flag = '1' ELSE
 - '1' WHEN (reg_sts_q = '0' AND reg_sts_d = '1' AND edge_sts_ctl = '0') ELSE -- detect rising
 - '1' WHEN (reg_sts_q = '1' AND reg_sts_d = '0' AND edge_sts_ctl = '1') ELSE -- detect falling
 - reg_flag_sts_q;
- int <= NOT(OR_OF_ALL(reg_flag_sts_q AND enable_sts_ctl));

Note: In some case (pulse generated), the rising edge detection is not done and the code becomes simply '1' WHEN signal_sts_bit = '1' ELSE...

12.6.4.7.4.2 Interrupt Management for Direct Command Registers

The following direct command status bits/registers are only set when error is generated and only cleared when the clear bit is written:

- all the status bits of the register DSI_DIRECT_CMD_RD_STS
- all the status bits of the register DSI_DIRECT_CMD_STS
- all the status bits except bit 0 (cmd_transmission) of the register DSI_DIRECT_CMD_STS

As these registers are reset only when the clear register is written, it is not possible to detect the falling edge on them to generate interrupts. Only the rising edges can generate the interrupt.

Note: There can be issues with detection when using the bits for all the signals that are a pulse generated in the tx_byte_hs_clk domain. When the speed of that clock is slower in relation to dsi_p_clk, it is possible to have the interrupt set, the bit read and the clear attempted before the end of the tx_byte_hs_clk pulse, after the clear, the bit is set again.

12.6.4.7.5 Direct Command Usage

The direct command mechanism is a way to send commands (with a maximum size of direct_cmd_fifodepth bytes) by writing and reading registers. It allows commands to be sent that are not allowed through the SDI-DSI interface (DSI commands, triggers), to perform read operations or to send DCS / generic write / generic read operations when the DSI link is not fully programmed and cannot use the SDI interface for commands.

Figure 12-431 shows direct command management sequence.

Basically, the procedure to do so is as follows:

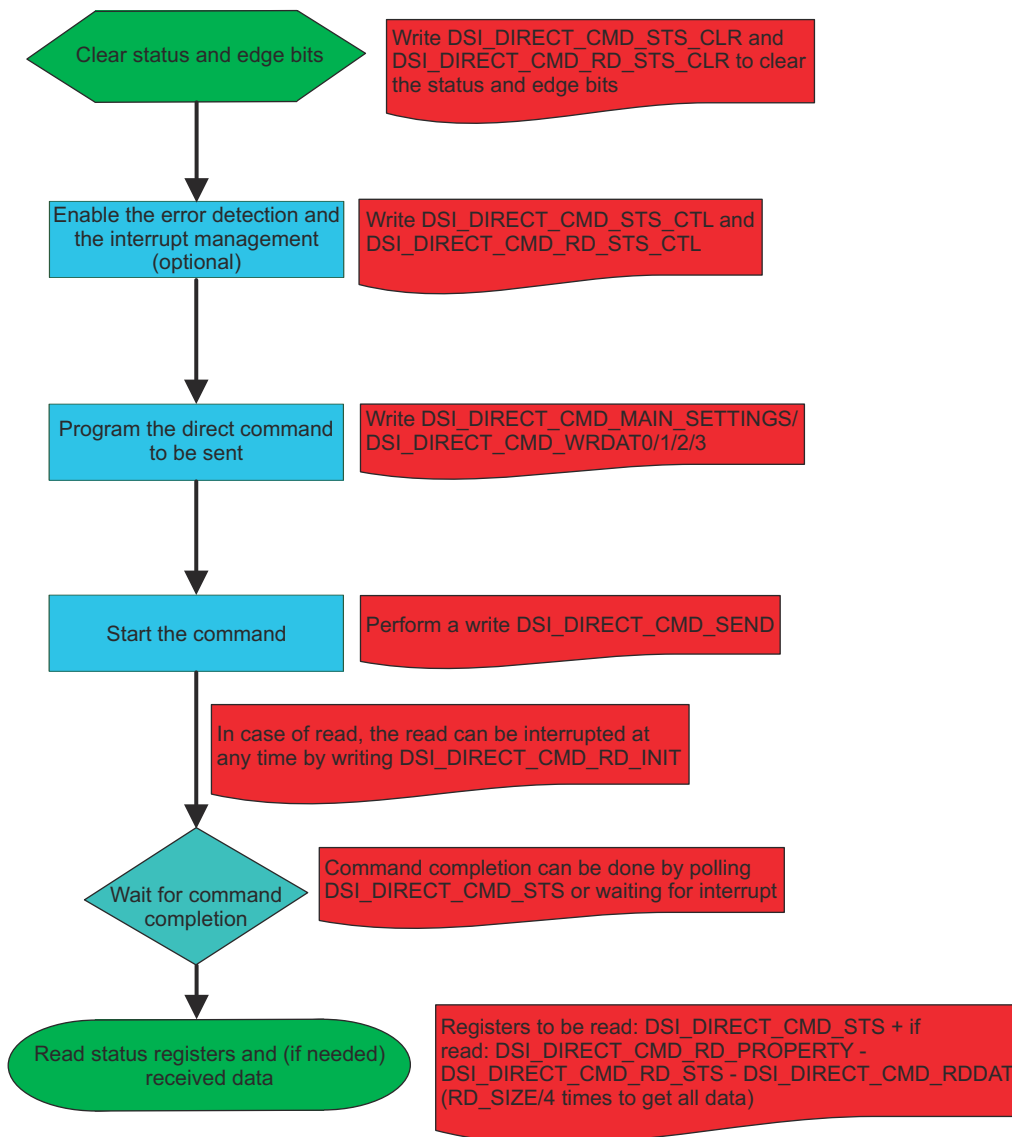

- Clear the status bits (when reading the status bits, only the DSI reads the current access status).
- Program the various registers that define the command to send.
- Write the direct_cmd_send register. Writing in that register (any value) triggers the command sending mechanism.

The command should be started only if the command request is amongst the defined ones for DCS or Generic Write or Read with 0, 1, or more parameters:

- DCS Write codes 0x05, 0x15, 0x39
- DCS Read codes 0x06
- Generic Write codes 0x03, 0x13, 0x23, 0x29
- Generic Read codes 0x04, 0x14, 0x24

Note: The direct_cmd_main_settings register can use other data type values for cmd_head to support future types and no check is performed for invalid types.

- Wait for the assertion of the command_completed bit in the direct_cmd_sts register (or any of the relevant bits that indicate a specific command termination). Instead of polling the registers, it is possible to enable the corresponding interrupts and wait for its detection.
- Read the received data and (if any) the different status bits.

dsi_spruij7-006

Figure 12-431. Direct Command Management

There are several checks performed when sending a direct command to verify that requested command sizes are supported and to check that the requested command exists (otherwise the request to send the command is ignored).

- For Short packets commands the DCS and Generic Read and Write the data size is rounded to maximum of 2.
- For Long packet DCS and Generic Read and Write the data size is rounded to the maximum size of the FIFO.
- No checks are made for the write FIFO having the expected number of bytes programmed into the CMD_SIZE in the dir_cmd_main register. In this case the data written out will loop back through the value in the FIFO.

At completion of a read command, registers can be read (they contain read data and/or errors detected during the communication) and trigger events are sent to the application to announce the request completion (using the status and error register bank).

When a read request is performed, the read data is put in the RP FIFO. If more bytes are sent, they are ignored and errors are set accordingly. The received read can then be accessed by reading several times the register that gives an access to the FIFO.

For every new command, several status bits are present: one signals that a command is being transmitted (cmd_transmission). When the command is complete, several bits can be toggled to signal it (write_completed, trigger_completed, te_received, read_completed and read_completed_with_err).

Some complex commands provide intermediate information. For BTA requests, there is a bit that signals when the BTA request has been sent (BTA_completed) and another one that signals when the DSI is master of the D-PHY interface again (BTA_finished). For commands that imply a BTA, some other bits specify whether specific data has been received (such as trigger, acknowledge with or without error).

12.6.4.7.5.1 Trigger Mapping Information

Triggers are one of the groups of direct commands that can be sent and received using the DPHY in Low Power escape mode. The trigger_val[3:0] bits (in the registers DIRECT_CMD_MAIN_SETTINGS and DIRECT_CMD_STS) are used to define which of the four possible trigger entry codes has to be sent or has been received. The register fields described above are copied in signal ppi_d1_tx_trigger_esc[3:0] (for trigger_val[3:0] of DIRECT_CMD_MAIN_SETTINGS) or are a copy of ppi_d1_rx_trigger_esc[3:0] (for trigger_val[3:0] of DIRECT_CMD_STS). Only one bit out of the four should be set else the D-PHY behavior is not very precisely defined. [Table 12-435](#) gives the trigger mapping in the system.

Table 12-435. Trigger Mapping

Trigger name	Trigger entry code	trigger_val	meaning in TX direction	meaning in RX direction
trigger 0 - reset	01100010	1b0001	Reset	Not affected by DSI spec
trigger 1 - unknown 3	01011101	1b0010	Not affected by DSI spec	TE response ⁽¹⁾
trigger 2- unknown 4	00100001	1b0100	Not affected by DSI spec	Acknowledge with no error ⁽¹⁾
trigger 3 - unknown 5	10100000	1b1000	Not affected by DSI spec	Not affected by DSI spec

(1) These triggers are not observed in the trigger_val field of the direct_cmd_sts register because they are used by the DSI link for a specific purpose.

Trigger Reset – This will request from the display and expects an immediate reset of the DSI command/video mode with all pending requests in TX sending path FIFO for transfer to be discarded.

Acknowledge – This is a response to DSITX controller. The host processor may request a command acknowledge and error information related to any transmission by asserting Bus Turnaround with the transmission. The peripheral shall respond with ACK Trigger Message if there are no errors and with Acknowledge and Error Report packet if any errors were detected in previous transmissions. Appropriate flags shall be set to indicate what errors were detected on the preceding transmissions.

If the transmission was a Read request, the peripheral shall return READ data without issuing additional ACK Trigger Message or an Acknowledge and Error Report packet if no errors were detected. If there was an error in the Read request, the peripheral shall return the appropriate Acknowledge and Error Report unless the error was a single-bit correctable error. In that case, the peripheral shall return the requested READ data packet followed by Acknowledge and Error Report packet with appropriate error bits set.

Tearing Effect - The Tearing effect on the display is avoided by having synchronization information from the display. It is used only in command mode. Users are responsible for selecting the command mode for the VC using the TE feature and selecting the polling or automatic mechanism.

The user is responsible for ensuring that there is a delay after a trigger is issued by the host to the panel, before any other action, message or trigger is performed. When the host issues a reset trigger, the system will expect the controller to stop and re initialise the clock and data links. All other triggers issued by the host will be application specific and are outside the scope of this document.

12.6.4.7.5.2 Command Mode Settings

The command mode is enabled on the SDI interface. This is controlled using the register mctl_main_en. Other settings can be set using the registers: mctl_main_data_ctrl (to decide about TE usage, read enable...); and cmd_mode_ctl (Virtual Channel of the command packets, arbitration between requests of the two interfaces, possibility to use LPDT, TE timer programming and padding value in case of an error).

When programming Direct READ commands, a BTA request is sent automatically following the read transmission, for the peripheral to respond – it is therefore not necessary to explicitly send a BTA request at that time. The system must allow the BTA request to be completed and the bus returned to the host before issuing any new read or write command. The system must either: poll the read_completed (and read_completed_with_err) status bits; or, wait for an interrupt caused by these bits before issuing any new command.

When programming Direct WRITE commands, it is advisable to ensure that each transaction can complete successfully before moving on to a subsequent command. There are two recommended methods to achieve this, either: explicitly request a BTA between write transactions while checking for the associated interrupt or polling the appropriate status flag (this method also provides the added security of an ACK response from the peripheral); or allowing a gap between commands sufficient to allow completion of the first before commencing with the second. The recommended approximate gap time required to ensure that all commands complete successfully is equivalent to 100 TX ESC byte periods. If required (for instance, to minimize the start-up time), it is also possible to calculate the minimum delay time required for each transaction, based on the TX escape clock frequency used in the application and the length of each command (no active video transmission should be enabled at the time – a typical use case would be peripheral parameter configuration). As with read operations, any write operation followed by an explicit BTA request must allow the BTA to be completed and the bus returned to the host before issuing any new read or write command.

For single parameter commands, the upper bytes of the 32-bit value written to the Direct Command write data register (direct_cmd_wrdat) should be masked to zero to comply with the DSI specification requirement that unused parameter locations are set to zero. For zero parameter writes, assuming there have been previous write commands sent, it is necessary to clear the sending path FIFO by writing to the direct_cmd_fifo_rst register to clear the data path, then write a zero value to the direct_cmd_wrdat register to send the zero parameter write command.

Note: Failure to follow these procedures may result in non-zero data in the unused parameter locations; this may or may not affect the peripheral, however it is recommended to use the process described to ensure compliance with the DSI specification in this regard.

If STOP mode is forced during a command mode read or write transaction, all outstanding transactions should be considered lost and all status and error flags should be disregarded and cleared. Similarly, if an LPDT read data operation is stopped by writing to the STOP_READ_OPERATION field of the DIRECT_CMD_RD_INIT register, the status for the aborted read operation should be disregarded and cleared before resuming normal operation.

12.6.4.7.5.3 Bus Turnaround Sequence

The command operation can request a read or an acknowledge response from the panel after a long sequence of packets is sent. The Bus turnaround is also used to control the Tearing Effect control.

When a Bus Turnaround is requested from the command stream manager, the DPHY will be given a turn request. The request will make the DPHY interface perform a sequence of LP states (LP11-10-00-10-00) to indicate that it is releasing control of the DP/DN signals. The DPHY Direction signal will change once it detects the Panel side driving the LP00-10-11 states. The panel will then be able to send any response packets (see section 0) and release the bus by issuing a bus turnaround sequence to the controller DPHY. The DSITX controller DPHY will detect the sequence and change the direction signal once the pattern is sent and LP00 state is valid for 2-3 TX_ESC_CLK cycles.

Figure 12-432 shows Bus turnaround timing sequence from controller to panel and panel to controller.

12.6.4.7.5.5 Tearing Effect Control on Panels with Frame Buffer

Display panels will use command mode sequencing when an on-board frame buffer is used to store the video image rather than using the video streaming and synchronisation packets to control the update of the image information. This means that the host display driver must know when the panel is processing the image and avoid changing pixel information before it is updated. The mechanism is known as the tearing effect. The DSITX controller can support two schemes as outlined in the MIPI DSI specification.

TE control using the Polling Method

For polling to the display module, the host processor shall detect the current scan line information with a DCS command such as **get_scan_line** to avoid Tearing Effects. DSITX controller will issue a READ using this command until it gets to the expected value for the last line.

DCS Command - get_scanline (45h)

Command

Direction H->D

Hex Code 0 1 0 0 0 1 0 1 45h

Parameter 1

Direction D->H

Hex Code N15 N14 N13 N12 N11 N10 N9 N8 XXh

Parameter 2

Direction D->H

Hex Code N7 N6 N5 N4 N3 N2 N1 N0 XXh

Figure 12-433. get_scan_line Command

Description

The display module returns the current scanline, N, used to update the display device. The total number of scanlines on a display device is defined as VSYNC + VBP + VACT + VFP. The first scanline is defined as the first line of V Sync and is denoted as Line 0.

In Sleep Mode, the value returned by **get_scanline** is undefined. See [MIPI-DPI] for definitions of VSYNC, VBP, VACT, and VFP.

- In 2D mode, the scanline value of the display memory and the display panel is the same.
- In 3D Mode, the scanline value of the display memory and the display panel can be different; **get_scanline** shall return the current scanline of the display panel.

Restrictions

None

TE control using the Automatic Method

For TE-reporting from the display module, the TE-reporting function is enabled and disabled by three DCS commands to the display module controller: `set_tear_on`, `set_tear_scanline`, and `set_tear_off`. See [MIPI-DCS] for details.

`set_tear_on` and `set_tear_scanline` are sent to the display module as DSI Data Type 0x15 (DCS Short Write, one parameter) and DSI Data Type 0x39 (DCS Long Write/write_LUT), respectively. The host processor ends the transmission with Bus Turn-Around asserted, giving bus possession to the display module.

Since the display module DSI Protocol layer does not interpret DCS commands, but only passes them through to the display controller, it responds with a normal Acknowledge and returns bus possession to the host processor. In this state, the display module cannot report TE events to the host processor since it does not have bus possession.

To enable TE-reporting, the host processor shall give bus possession to the display module without an accompanying DSI command transmission after TE reporting has been enabled. This is accomplished by the host processor protocol logic asserting (internal) Bus Turn-Around signal to its D-PHY functional block. The PHY layer will then initiate a Bus Turn-Around sequence in LP mode, which gives bus possession to the display module.

Since the timing of a TE event is unknown to the host processor, the host processor shall give bus possession to the display module and then wait for up to one video frame period for the TE response. During this time, the host processor cannot send new commands, or requests to the display module, because it does not have bus possession.

DCS Command - `set_tear_on` (35h)

Command

Direction H->D

Hex Code 35h

Parameter

Direction H->D

Hex Code X X X X X X M XXh

dsi_sprui7-009

Figure 12-434. `set_tear_on` Command - 1

Description

This command turns on the display module Tearing Effect output signal on the TE signal line. The TE signal is not affected by changing `set_address_mode` bit B4. `set_tear_on` has one parameter that describes the Tearing Effect Output Line mode.

If M = 0 (Mode 0):

The Tearing Effect Output line consists of V-Blanking information only.

Figure 12-435. set_tear_on Command - 2

If M = 1 (Mode 1):

The Tearing Effect Output Line consists of both V-Blanking and H-Blanking information.

Figure 12-436. set_tear_on Command - 3

The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI- DPI] for definitions of tvdl, tvdh, thdl and thdh.

Restrictions

This command takes effect on the frame following the current frame. Therefore, if the Tearing Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous set_tear_on, or set_tear_scanline, command until the end of the frame.

DCS Command - set_tear_scanline (44h)

Command

Direction H->D

Hex Code 0 1 0 0 0 1 0 0 44h

Parameter 1

Direction H->D

Hex Code N15 N14 N13 N12 N11 N10 N9 N8 XXh

Parameter 2

Direction H->D

Hex Code N7 N6 N5 N4 N3 N2 N1 N0 XXh

Figure 12-437. set_tear_scanline Command - 1

Description

This command turns on the display module Tearing Effect output signal on the TE signal line when the display module reaches line N. The TE signal is not affected by changing set_address_mode bit B4.

The Tearing Effect Line On has one parameter that describes the Tearing Effect Output Line mode.

After issuing a set_tear_scanline command to the display module, the Tearing Effect output signal, e.g. as in DBI- 2 systems, shall be a delayed version of V-Blanking information as illustrated in [Figure 12-438](#).

Figure 12-438. set_tear_scanline Command - 2

Note that set_tear_scanline with N = 0 is equivalent to set_tear_on with M = 0. The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI-DBI] for definitions of tvdl and tvdh and [MIPI-DSI] for definition of display module line numbers. In 2D mode, the scanline value of the display memory and the display panel is the same.

Restrictions

This command takes effect on the frame following the current frame. Therefore, if the Tear Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous set_tear_on, or set_tear_scanline, command until the end of the frame.

DCS Command - set_tear_off (34h)

Command

Direction H->D

Hex Code 0 0 1 1 0 1 0 0 34h

Parameters None

Description

This command turns off the display module Tearing Effect output signal on the TE signal line.

dsi_sprui7-014

Figure 12-439. set_tear_off Command

Restrictions

This command has no effect when the Tearing Effect output is already off.

12.6.4.7.5.6 Return Path Operation

The DSI Return Path behaves like a slave, by collecting data from the DPHY receive interface when the DPHY is configured to accept a transmission from the peripheral. The RP receives 6 signals from the DPHY (see [Table 12-437](#)).

The data (and trigger) reception is inactive if the DPHY PPI direction signal is at low level. When it is active, data is received using the RX ESC_CLK clock (the clock is transmitted with the data itself - see D-PHY protocol description from MIPI) and may stop if there is a pause in the data transmission but data is generated on clock falling edge. New data is available on rx_data_esc on a rising edge of the clock, if both rx_lpd_t_esc and rx_valid_esc are asserted.

Table 12-437. Interface Between Return Path and DPHY

Signal Name	I/O	From/To	Description
rx_lpd_t_esc	I	DPHY	Escape Low Power data receive mode This active high signal is asserted to indicate that the lane module is in low-power data receive mode. While in this mode, received data bytes are driven onto the rx_data_esc output when rx_valid_esc is active. The lane module remains in this mode with rx_lpd_t_esc asserted until a stop state is detected on the lane interconnect.
rx_trigger_esc(3:0)	I	DPHY	Escape trigger received These signals indicate that an escape trigger command has been received. Only one of these signals will be asserted at any time and the signal will remain asserted until the lane module returns to stop state.
rx_data_esc(7:0)	I	DPHY	Escape receive data For Low Power data receptions, this eight-bit value is driven by the D-PHY and is valid on rising edges of rx_clk_esc with rx_valid_esc asserted. The bit connected to rx_data_esc[0] was received first.
rx_valid_esc	I	DPHY	Escape receive data valid This signal indicates that the lane module is driving data on rx_data_esc and expects the protocol layers to take the data at the current rising edge of rx_clk_esc. There is no "ready" signal to throttle the receive data.
stop_state_dl1	I	DPHY	Lane is in stop state This signal indicates that the lane module is in STOP state. Note that this signal is asynchronous to any clock in the protocol interface.
direction	I	DPHY	Lane direction. When this signal is high, the lane module is in receive mode. When direction is low, the lane module is in transmit mode. (Mnemonic: 1 = Input, 0 = Output.)

The received data messages are identified as one of two possible types:

- Trigger
- Read packet

Trigger messages are passed almost directly to the register (reg_req = reg_trigger = 1 and reg_rd_data<3:0> equals to trigger value during one clock cycle). However, triggers are decoded to see if they are a TE trigger or an acknowledge with no error.

- The TE data is passed separately to the CSM using csm_te_received pin. It needs to be resynchronized with tx_byte_clk byte clock because of the CSM working clock domain.
- The acknowledge is only passed to register using reg_req and reg_ack pins. All other trigger values are passed undecoded to the registers without any processing. It is the responsibility of the application to decode and decide what to do with them.

Read Packet: When data is received, the system waits for the 4 bytes of the **HEADER**, and performs an ECC correction (if it is enabled) and then decodes the packets.

The following cases are considered when the system performs the ECC check:

- If the received command is not in the list of legal display opcodes, (i.e. errors in the packet header), it discards that packet and all further incoming bytes, even if they are legal packets (until the next BTA - i.e. direction change). It sends errors to the register bank (err_undecodable and uncorrectable_err). This may also result in an EOT error being reported as no further bytes have been decoded. But even if ECC correction shows an uncorrected error, decoding is attempted (if the errors are in the ECC byte or in the payload bytes, the opcode can be understood and data correctly recovered). In this case only err_uncorrectable error bit is sent to register and it falls in the situation of regular commands (acknowledge with error or read).
- If "an acknowledge with error", the two status bytes are sent to the registers (reg_req = 1 and reg_ack_err = 1 and reg_rd_data<15:0> contains the correct value).
- If the message type is a short read (either DCS or generic), data is passed to the registers (2 bytes without any specific decoding). Interface signals must be set accordingly and the two bytes are sent to registers (reg_req = reg_start = reg_end = reg_read = 1 with data and dscnotgen set accordingly). Size information is decoded in the first byte of the received packet depending on the data type information and then sent to register using reg_size port.
- If a long read, the size is sent to the register using reg_size. The system goes to **LONG state**. All data received are sent to register using reg_data and are used for checksum detection. If during receive, return packet fifo (in control block) becomes full (rd_data_fifo_full), the error flag err_oversize must be set. All remaining data is used for checksum calculation but are not transferred to registers. When the number of received bytes is equal to the packet size, the system will check the **CHECKSUM**. The two checksum bytes are never transferred to register. They are used to make checksum detection and indicate err_checksum status.
- If the transfer is shorter than the size specified in the header, the error err_wrong_length is issued along with any subsequent errors such as err_missing_eot (if needed). The case where it is longer drives to a tentative checksum decoding that generates an error and by a tentative to decode a new header (that is in fact a part of the previous packet) that drives to an error err_undecodable and the throwing of the rest of the received bytes (with corresponding errors such as err_missing_eot).
- If it is an EoT packet, it is not passed to the control block. The following data is ignored (if any). If the system is waiting for **EoT**, this is the only action. If system is not waiting for EoT packet, the err_eot_with_err is sent.
- If after an "acknowledge with error", the system waits for EoT packet and counts 4 bytes but is not able to decode them, it emits an err_eot_with_err and err_undecodable.
- If direction is removed at a "wrong" time (i.e before the fourth byte of a small packet, the system stops to works but emit errors to the register: err_receive with eventually err_missing_eot.

The DSI is designed to support multi-peripheral integration, the virtual channel of the received packet is also stored in register using reg_vc port.

The application FW layer is responsible of all read actions, it is assumed that once a read is requested, application reads return packets before requesting other read actions. Based on this assumption, the receive FIFO implemented in the register block is cleared each time a read action is started. All data not read before the new read command are lost.

A re-initialization of the return path is also performed using register access on reg_init_rp.

All errors related to short or long received data packets should be captured in the register when the direction changes (to capture all errors at the same time and not generate several errors and possibly several interrupts on the same reverse transaction). As soon as an error is detected on a packet, the error must be recorded and maintained up to the end of the packet transfer.

The maximum packet size supported by the DSI return path is 16 bytes. If a longer packet is received, only the first 16 bytes are available (by register way) for application.

12.6.4.7.5.7 EoT Packet Management

The DSI protocol states that, in the sending path, only the HS transmission requires use of EoT packet. For transfer from display to host, it is not recommended to use EoT but it is possible. The host needs to be able to detect the EoT packet and then behaves accordingly.

In case the display makes use of the EoT packet, the bit disp_eot_gen must be set to one. In that case, if after the ECC correction, the packet header is 0x08, we've detected an EoT packet and all bytes that may arrive between this packet and the direction change must be ignored.

If additional data is received between the EOT packet and the next BTA (end of read process), or if an unwanted EOT packet is detected, the unwanted bytes must be rejected and err_receive is asserted.

If the EoT packet is not detected although it should be present, the error err_missing_eot is set. If after an "acknowledge with error", 4 bytes are received before BTA but are not identified as EoT (because of errors), it is assumed these 4 bytes are the EoT. In that case, the error err_eot_with_err has to be set with err_undecodable.

12.6.4.7.5.8 ECC Correction

The DSITX controller uses the packet header ECC information to detect and correct one error, and can detect two or more errors without correction.

12.6.4.7.5.9 LP Transmission and BTA

The DSI host may send a command sequence and then request an acknowledge message from the panel. The host will send the command and release the bus by performing a BTA sequence. The panel will then respond with an acknowledge message (or error response) followed by a BTA to return the bus to the host. This sequence is illustrated in Overview of a Display Subsystem.

Overview of a Display Subsystem.

Figure 12-440 shows LP transmission timing diagram.

ds1_spruij7-015

Figure 12-440. LP Transmission Timing Diagram for Host Read and Trigger ACK

The Host will not be able to transmit any other packets once the BTA is sent to the panel and will expect either an ACK trigger or response LPDT message with a payload. The system must ensure there is sufficient time to send any command and issue the BTA, receive the response (Trigger, Short or long packet) and accept the BTA from the panel, if this request is made in the line blanking intervals.

Figure 12-441 presents panel read response sequences.

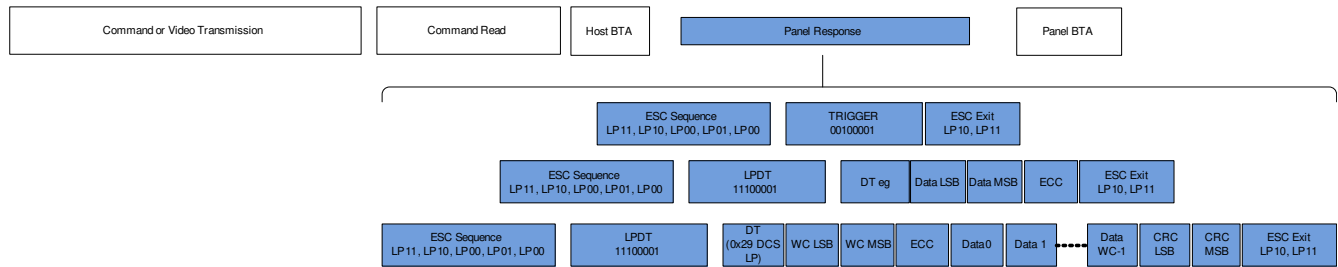

Figure 12-441. Panel Read Response Sequences

The panel response time will be based on the tx_esc_clk used inside the panel and the expected number of bytes for the payload. The expected responses are illustrated in the blocks in the MIPI DSI standard.

12.6.4.7.6 Low-power Management

There are several low-power scenarios which consist of switching off various parts of the design:

1. Switch D-PHY cells in ULP mode when there is no data to be sent (bits clk_lane_ulpm_en, dat1_ulpm_en, dat2_ulpm_en, dat3_ulpm_en and dat4_ulpm_en in register mctl_main_en set to one with ULP mode enabled in register mctl_main_phy_ctl). Please, note that the time to leave ULP state is 1 ms and needs to be set in clock cycles in the register mctl_ulpout_time.
2. Switch the DPHY byte/bit clock PLL off (refer to DPHY documentation for control sequence). In this case, the D-PHY cell can only transmit data in LPDT thus maximum bandwidth is 10 Mbits/s).
3. More drastic methods are to shut-down some parts of the design. The D-PHY and the DSI themselves can be shut down.

When D-PHY and DSI are both shut-down and the display is powered down, the restart is a normal start procedure as described in [Section 12.6.4.7.3, Start-up procedure](#).

When only the D-PHY is stopped, it is placed in either the stop or ULP state. Restarting the D-PHY is similar to the regular start-up procedure, however, after the lanes are enabled by the DSI Controller (clk_lane_en, dat1_en, dat2_en, dat3_en and dat4_en in register mctl_main_en are set), the D-PHY generates a rising edge on the stopstate signal to indicate to the DSI Controller that the enable request has been effective within the D-PHY. After that the start-up procedure may continue up to the point that the DSI link is ready to begin transmission.

Note that when setting the D-PHY into the ULP state, the application needs to wait enough time between the time it sets the ULP request in register and the time the D-PHY is disabled – this ensures that the ULP request is detected on the D-PHY interface.

12.6.4.7.7 Video Mode Settings

All values contained in the Control Block (CB) registers must be set with meaningful values and are expressed with a range of different units: clock cycles, bytes, number of lines.

12.6.4.7.7.1 Video Stream Presentation

In [Figure 12-442](#), it shows the list of packets that can be part of a video stream and the associated register fields. In the four following figures ([Figure 12-443](#), [Figure 12-444](#), [Figure 12-445](#), [Figure 12-446](#)), different video streams that can be generated are presented.

dsi-017

Figure 12-442. DSI Packet Terminology

Red text - behaviour not possible.

Blue text - register fields used to specify the packet size.

The BLLP (Blanking – Low Power) periods allow the DPHY link to perform the following sequences:

- Host Transmit blanking packets in HS.
- Host Transmit command packets in HS or LP (Escape mode).
- Host Transmit packets using interleaving to a different virtual Channel in HS or LP (Escape mode).
- Host performs BTA and waits for response packets from the panel using Escape Mode followed by a panel BTA.

dsi-018

Figure 12-443. Video Pulse Mode (Non-Burst) Timing Diagram

Note

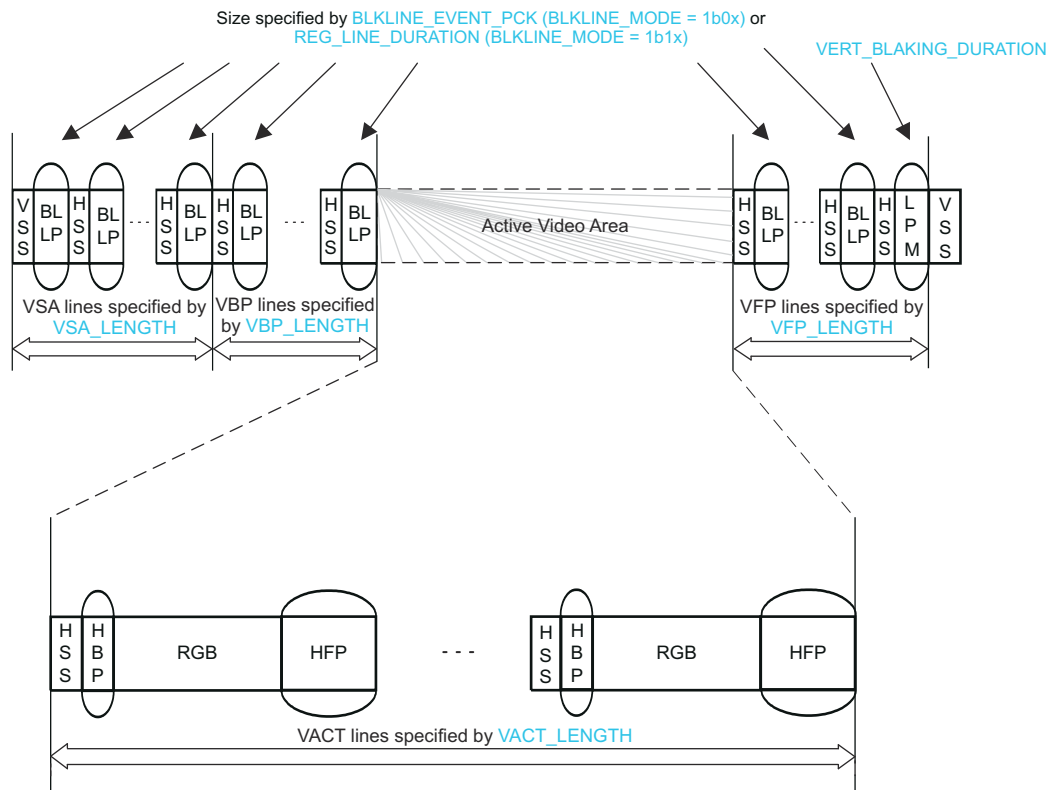

This sequence is no longer specified in the MIPI spec Version 1.02.00 28-Jun-2010 but supported by the DSI-controller.

dsi-019

Figure 12-444. Video Pulse Mode (Non-Burst)**Note**

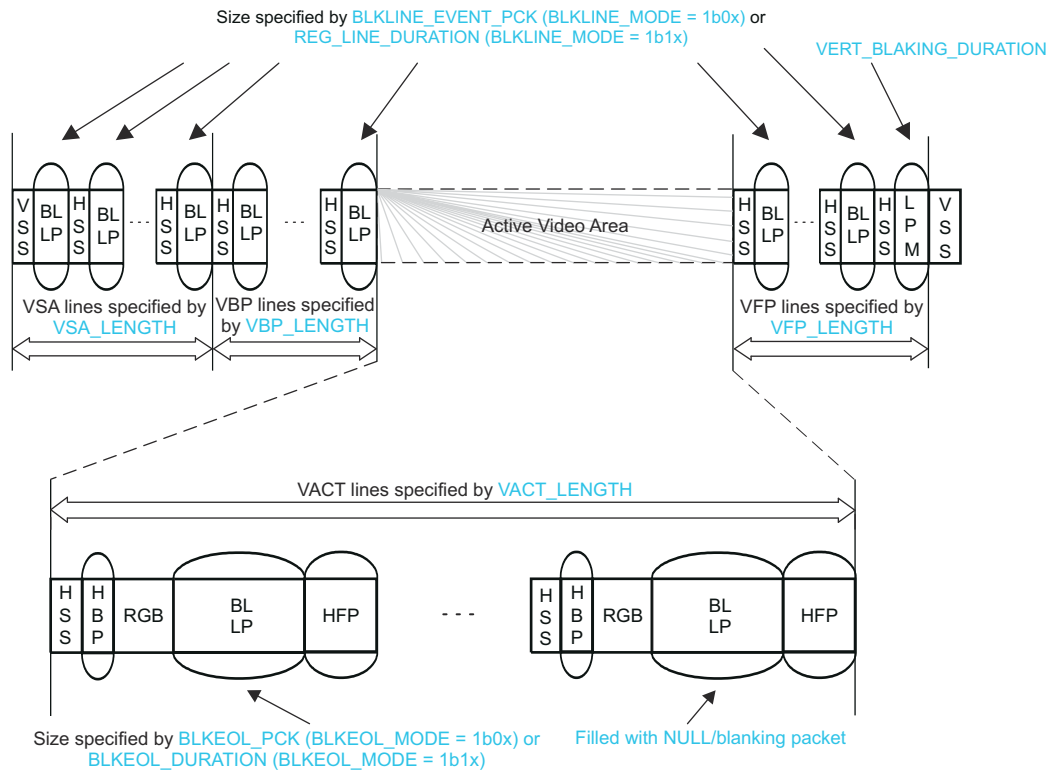

In the MIPI spec 1.02.00 June 2010, the line (VSE/HSA/HSE/BLLP) has been moved from VSA lines part to the VBP lines part. The sequence is the same but in the design the VSA lines has one more line and the VBP lines has one line less. This must be considered during the VSA and VBP register programming if the DSI MIPI spec 1.02.00 is used as reference.

dsi-020

Figure 12-445. Video Event Mode (Non-Burst)

burst_mode = sync_pulse_active = sync_pulse_horizontal = 0 - all spec versions.

dsi-021

Figure 12-446. Video Sync Event in Burst Mode

burst_mode = 1 and sync_pulse_active = sync_pulse_horizontal = 0 - all spec versions.

Burst Mode operation requires the tx_byte_clk to be set to double the bit rate compared to the non-burst case. The calculations for the video parameters must then be increased to match the higher rate. The DPI FIFO must also be large enough to store at least half of the active line bytes before the output transmission begins otherwise it will underrun.

12.6.4.7.7.2 Video Stream Settings (VSG)

The following is all the registers that need to be set before using the video in SDI or DPI interface operation.

- vid_vsize1, 2
- vid_hsize1, 2
- vid_blksize1, 2
- vid_pck_time
- vid_dphy_time

- vid_vca_setting1, 2
- vid_main_ctl – programmed last in sequence of vid registers to apply to DSI registers

This section addresses the dependencies between all video registers, and details how the TVG and VCA registers must be set per VSG registers.

vid_main_ctl

- header information must correspond with the vid_pixel_mode used to control the generation of the recovery streams. The header information is used to be enable management of future cases where the DSI link could be used to pass streams with formats that differ from those currently supported directly.
- sync_pulse_horizontal can only be asserted if sync_pulse_active = 1.

When sync_pulse_active is set to one, the HSYNC pulses are emulated only during the active part of the frame. When both sync_pulse_horizontal and sync_pulse_active are set, the HSYNC pulses are present on all lines of the frame.

vid_vsize - the variables are expressed in line numbers in this register.

- vsa_length should be at least one (in order VSG can insert at least the vertical synchronization start VSS line) and greater or equal to 2 when pulse mode (sync_pulse_active = 1).
- vbp_length 0 to 63.
- vfp_length must be greater than 0.
- vact_length must be greater than 0.
- vid_hsize1: - the numbers are expressed in number of bytes (the fields are specifying the payload).

vid_hsize1 - the numbers are expressed in number of bytes (the fields are specifying the payload of the corresponding packet).

- hsa_length need to be at least set to one if pulse mode is enabled. The expected normal operating range is 1 to 255, large values for the HAS length will impact on the size of the DPI FIFO required.
- hbp_length can have any value. However, when set to 0, a HBP packet is generated with 0 payload.

vid_hsize2 - again the fields are specifying the payload of the corresponding packet (in byte).

- hfp_length can have any value. However, when set to 0, no HFP blanking packet is generated.
- rgb_size must match the number of pixel per line of the display multiplied by the number of byte per pixel.

vid_blksize1 - still specifying size of the payload in byte.

- blkline_event_pck defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when reg_blkline_mode = 0b01 or 0b00 and when sync_pulse_active = 0. It is also needed by the VSG when reg_blkline_mode = 0b1x. Its value depends on the hbp, rgb, blkcol, and hfp packet length.
- blkline_event_pck defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when reg_blkline_mode = 0b01 or 0b00 and when sync_pulse_active = 0. It is also needed by the VSG when reg_blkline_mode = 0b1x. Its value depends on the hbp, rgb, blkcol, and hfp packet length.

-- 32767 = 0x7FFF = max value on 15 bits and -100 to take

margin blkeol_pck < 32767 - hfp_length - hbp_length - hsa_length - rgb_size - 100;

The blkeol_pck (and blkeol_duration) must be adapted to the reg_wakeup_time in case VCA is authorized to go back in LP.

vid_blksize2 - still specifying size of the payload in byte.

- blkline_pulse_pck has almost the same definition than blk_event_pck but it concerns blanking lines with sync pulse.

vid_pck_time - specifies duration in clock cycles.

- blkeol_duration: $\text{blkeol_duration} = \text{div_round_up}^{(1)}((\text{blkeol_pck} + 6), \text{lane_nb});$
- vert_blanking_duration is no longer used and can always be set to 0. It remains present in the design for legacy reason.

Note 1: The function div_round_up is a function that performs a division then round the result to the first entire number superior or equal to the division result.

vid_dphy_time: specifies duration in clock cycles. These are values that have external dependencies and thus need to be calculated first (and rest of VSG programming is calculated from these values).

reg_line_duration: depends on display type and size and of its programming (in some display, the blanking sizes can be adapted to provide a given number of frame per second with one of the D-PHY possible clock frequency (as PLL can only generate a given number of discrete frequencies)).

if (pulse mode) {

line_length = (blkline_pulse_pck + 6);

}

else (event mode) {

line_length = (blkline_event_pck + 6);

if (burst_mode and burst_lp and lane_nb == 2 and

hsa_length[0:0] == 1 and hfp_length[0:0] == 1)

line_length = line_length - 1;

}

result = div_round_up(line_length, lane_nb);

Note 1: The function div_round_up is a function that performs a division then round the result to the first entire number superior or equal to the division result.

Additional Notes about the line duration:

- If line length (in bytes) is a multiple of the number of lanes enabled, DSI will never face any timing jitter except due to the resynchronization in SP/DCB.
- If line length (in bytes) is NOT a multiple of the number of lanes enabled For Non LP operation, there should not have any problem since the line is once longer, once shorter than the "normal" value. For example: if line length is 491 bytes, it will be 245 then 246 in clock cycles with 2 lanes for an average value of 245.5.

For LP enabled operation, the controller cannot allow underflow of the line and frame timing. With the previous example, the LP line length in clock cycles will be 246 since we cannot start the HS transmission in the middle of a clock cycle. And there is no mechanism to have one line in 245 and the next one in 246 cycles. For LP see section 0.

reg_wakeup_time must be shorter than line duration and depends on the D-PHY cell plus some pipelines delays inserted by the DSI link. This value strongly depends on the DPHY PLL programming and configuration, and is a mix of both internal and external analog and digital timing factors, therefore it is very difficult to provide an exact formula. The recommended approach to selecting a suitable value for this parameter is to characterize

behaviour in at the system level environment using simulation, emulation (e.g. Palladium) or validation (e.g. FPGA).

The DPHY needs 100 ns + time for THXS-EXIT to go to Low Power mode.

The timing for the clock lane TXRequestHS going active to the TXReadyHS will be determined by the DPHY DDR bit rate clock frequency. The timing will be the total number of DDR bit clk cycles for the TXRequestHS to be detected and the clock lane to transition to High Speed, so TLPX + TCLK-PREPARE + TCLK_ZERO. Additional time is required between the clock lane driving HS clocks and the Data Lanes being activate, TCLK-PRE. All of these parameters can be calculated from the DPHY datasheet.

Figure 12-447 shows timing diagram for clock lane activation/deactivation.

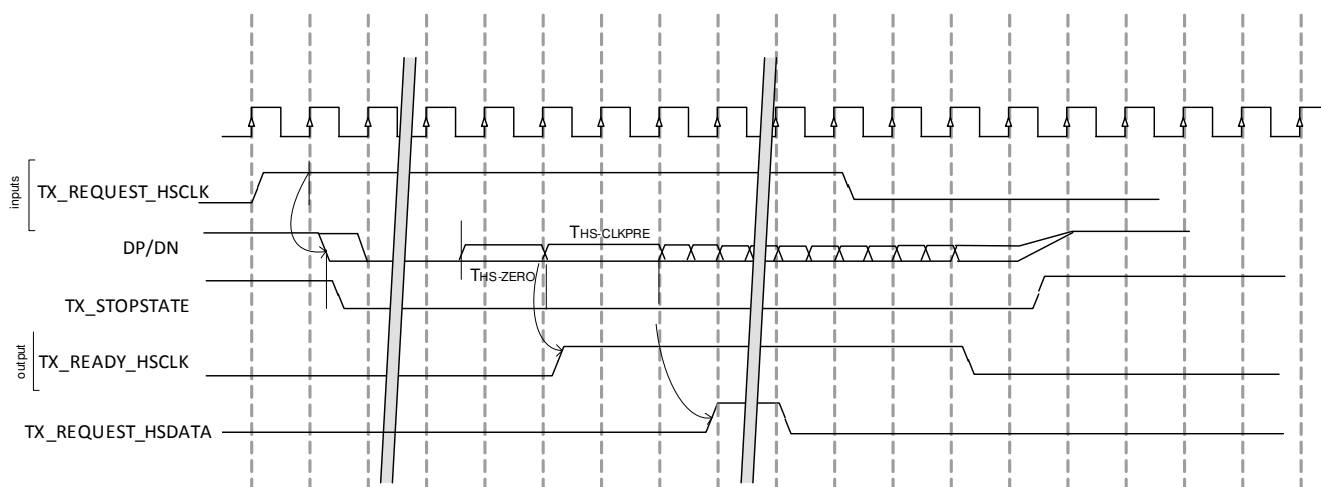

Figure 12-447. Timing Diagram for Clock Lane Activation/Deactivation

The data lane request follows a similar timing sequence from the TX_Request_HS to TX_Ready_HS, TLPX + THS-PREPARE + THS_ZERO. The data lane requests will be activated once the clock lane is ready, i.e TX_Ready_HSCLK is high.

Figure 12-448 shows timing diagram for data lane activation/deactivation.

Figure 12-448. Timing Diagram for Data Lane Activation/Deactivation

Table 12-438. Timing Parameters

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
TLPX	Transmitted length of any Low- Power state period.	50 ns		50 ns

Table 12-438. Timing Parameters (continued)

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
TCLK-PREPARE	Time that the transmitter drives the Clock Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	38 ns	95 ns	38-95 ns
TCLK-PREPARE + TCLK-ZERO	TCLK-PREPARE + time that the transmitter drives the HS-0 state prior to starting the Clock.	300 ns		300 ns
Wakeup Time CL				388-445 ns
TCLK-PRE	Time that the HS clock shall be driven by the transmitter prior to any associated Data Lane beginning the transition from LP to HS mode.	8 UI		12.3 ns
THS-PREPARE	Time that the transmitter drives the Data Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	40 ns + 4 × UI	85 ns + 6 × UI	~ 46-95 ns
THS-PREPARE + THS-ZERO	THS-PREPARE + time that the transmitter drives the HS-0 state prior to transmitting the Sync sequence.	145 ns + 10 × UI		160 ns
Wakeup Time DL				~ 270 ns

So the wakeup time values expressed as tx_byte_clk (12.3ns) cycles, CL = 36 and CLKPRE + DL = 22.

Figure 12-449 shows wakeup time timing diagram.

Figure 12-449. Wakeup Time Timing Diagram

Here is the example of the calculation done for the system running at **650 MHz**.

```
if (clk_continuous == TRUE) {
wakeup_time_cl = 0x1;
} else {
wakeup_time_cl = 0x24;
};
wakeup_time_dsi = 0xA; -- from request on VSG to request HS on DL1 (+ 1 for VSG internal cycle)
wakeup_time_dl = 0x14; -- from stop state falling edge to tx_ready rising edge
reg_wakeup_time = wakeup_time_dsi + wakeup_time_cl + wakeup_time_dl + (hs_host_eot × 4 / lane_nb)
```

Note: It is not necessary to program all the register values every time because some of them are used only in some modes. For instance, blkline_event_pck and blkline_pulse_pck are used depending on the way SYNC is generated, and then in pulse mode, there is no need to program blkline_event_pck and vice-versa.

12.6.4.7.7.3 VCA Configuration

The VCA setting done in two registers: vid_vca_setting_1 and vid_vca_setting_2. Their programming must respect the following rules:

- vid_vca_setting_1:
 - max_burst_limit specifies the size of the bigger packet that generates the following sequence RGB + packet + NULL packet + BLK packet; it must be linked with blkeol_pck (same size minus the smaller NULL packet). It is equal to blkeol_pck - 6.
 - burst_lp can be set to 1'b1 if blkeol_pck > 2 × reg_wakeup_time × lane_number (reg_wakeup_time is only specifying the time to go from LP to HS thus need to consider the time to go from HS to LP too).
- vid_vca_setting_2:
 - exact_burst_limit: as it specifies (in byte) the payload of the packet that generates a sequence RGB + packet + HFP, it must have the same value as of blkeol_pck when the DSI link is in burst mode.
 - max_line_limit specifies the maximum size of a packet that generates HSS + (HSA + HSE) + packet + NULL packet. It then depends on line_duration, hsa_length regardless if the system is using pulse or event synchronizing. Its size is linked to vert_blanking_duration.

```
if (sync_pulse_active == 0) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = (blkline_event_pck-6);
};
if (sync_pulse_active == 1) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = gen_blkline_pulse_pck-6;
```

Another constraint to respect when using VCA is to ensure that only supported operations are sent from command side when video is active. For instance, no TE should be attempted, because it could break the video stream (TE completion time can be long). Command messages can be inserted into the LP states provided there is sufficient space for the message bytes and any associate bytes for the header and CRC, if a long packet type.

12.6.4.7.7.4 TVG Configuration

The TVG has a single register: tvg_img_size that should complies with the following rules against VSG settings:

tvg_line_size: must be equal to rgb_size set for VSG

tvg_nblne: must be equal to vact_length set for VSG

The TVG generates a data stream in the same format than the one specified at the output of the VRS. The content of that flow is specified by the following registers:

- Image size - TVG_LINE_SIZE[14:0] and TVG_NBLINE[12:0] registers: Number of bytes per line and number of lines per frame.
- Image kind - TVG_MODE[1:0] register: Single color, vertical stripes or horizontal stripes.
- Stripe width - TVG_STRIPE_SIZE[2:0] register: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128.
- Pixel kind VID_PIXEL_MODE[3:0] register: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB.
- Color one - COL1_GREEN[11:0], COL1_RED[11:0], COL1_BLUE[11:0] registers: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered.
- Color two - COL2_GREEN[11:0], COL2_RED[11:0], COL2_BLUE[11:0] registers: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered.
- Start pulse and stop handshake (+ stop mode) (see TVG_CTL register).

The Test Video Generator can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

Figure 12-450 presents TVG MODE patterns.

Figure 12-450. TVG MODE Patterns

An example of the sequence is as follows:

- Select TVG for video stream generation instead of DPI/SDI 1 interface.
 - IF1_EN bit to 0 (SDI stall signal at 1) in MCTL_MAIN_EN.
- Select video mode for interface 1 in MCTL_MAIN_DATA_CTL.
 - TVG_SEL bit to 1 in MCTL_MAIN_DATA_CTL register to select stream from TVG.
- Select generated frame format in TVG_CTL register.
 - Image format (single color, H stripes, V stripes) in TVG_MODE field.
 - Image color selection in TVG_COLOR1, TVG_COLOR1_BIS, TVG_COLOR2, VG_COLOR2_BIS.
 - Stripes size in TVG_STRIPE_SIZE field.
 - Image size in TVG_IMG_SIZE register.

Note: The TVG settings on active area for the number of lines per frame and number of bytes per line must match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG_STOPMODE field of TVG_CTL.
 - TVG video stream generation start/stop controlled by the TVG_RUN bit in TVG_CTL register.
 - Polling TVG run status from the TVG_RUNNING bit in TVG_STS register is useful when setting TVG_RUN to 0. TVG video stream generation does not stop the instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

12.6.4.7.8 DPI To DSI Programming

The DPI interface will normally be driven from a graphics driver that will be configured to match a frame geometry and refresh rate for a panel display. The DPI driver will use the expected refresh rate and geometry for the active and blanking parts of a frame to determine the pixel rate clock. The DSITX controller will then translate this to match the incoming byte information to send across the DSI DPHY link.

A system will always expect the bandwidth of the incoming pixels × BPP to match the transmission of bytes from the DSI DPHY based on the number of active lanes. The relationship of DPI clock to TX byte clock must ideally hold with the following formula:

$$F_{\text{pixel_clk}} = F_{\text{tx_byte_clk}} \times \text{active_lanes} \times 8 \div \text{bits_per_pixel};$$

The DSI will supply packets to the DPHY interface using the internal sequencing and counters clocked from the tx_byte clock. The normal system operation will mean that the DSI must always have the correct number of tx_byte clock cycles to match the number of pixel clock cycles. This means that all the events used for the packet generation will be directly impacted by the delay that exists in the DPHY High Speed request to ready.

The DSITX controller relies upon the DPHY PLL being programmed and locked before starting the DPI video. The DSITX controller can then be configured and enabled (clock lane and data lanes) before starting the video transmission.

The DSITX controller will begin data transmission with a High Speed request after it receives the falling edge of the VSYNC on the DPI interface. The controller will then begin to build the bytes for the VSYNC packets (VSS, HSA, Blanking packets) during the delay period before the ready is returned from the DPHY. This delay will add an interval effect on all the packets that follow.

The DPI FIFO size must be sufficient to buffer all the incoming pixel data during the active line stage while the DSITX controller continues to send the previous lines packet information due to this interval effect.

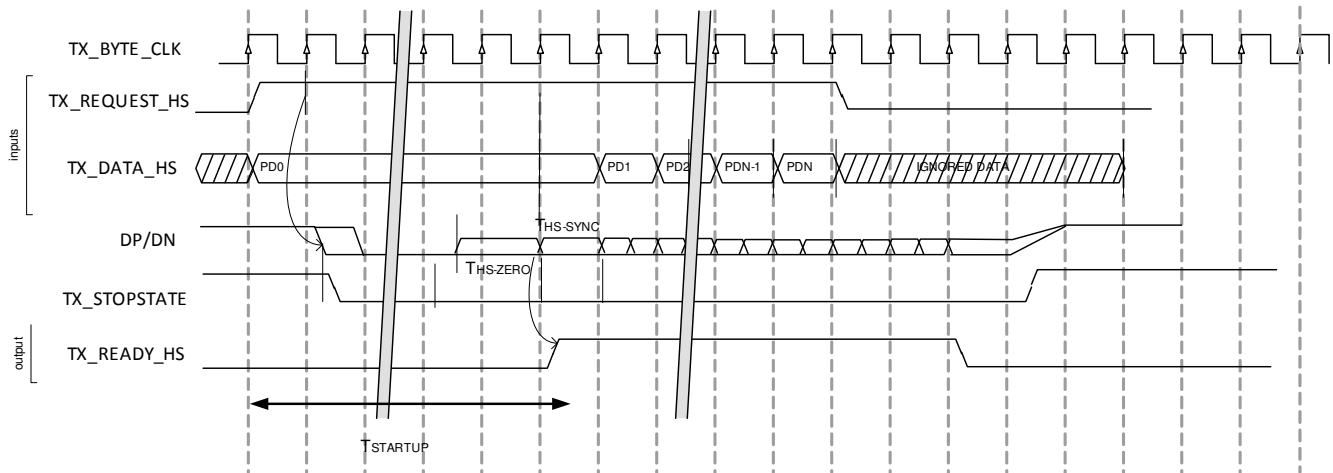

Figure 12-451. Timing Diagram

The DPI and DSI system may not be able to guarantee the exact frequency on the pixel clock input or tx_byte clock from the DPHY. The DSI configuration can be adjusted to support a small deviation in frequencies using the size of the HFP packet so that it changes the alignment of packets on the active lanes to absorb the different pixel clock cycles during the line. More details are given in section0.

12.6.4.7.8.1 DSI and DPHY Operation

The DPI FIFO is used to buffer all the active pixel data from the DPI interface during the active line. The depth of the FIFO must be selected to allow the pixel to be stored after the DPHY request to ready delay is introduced at the start of every frame. The FIFO will fill to a depth based on the tx_byte clock cycles used from the point where VSYNC is identified to the response from the DPHY link after it has exited Low Power and entered the zeroes state on the active data lanes.

Figure 12-452 presents DPI interface to DSI DPHY timing diagram.

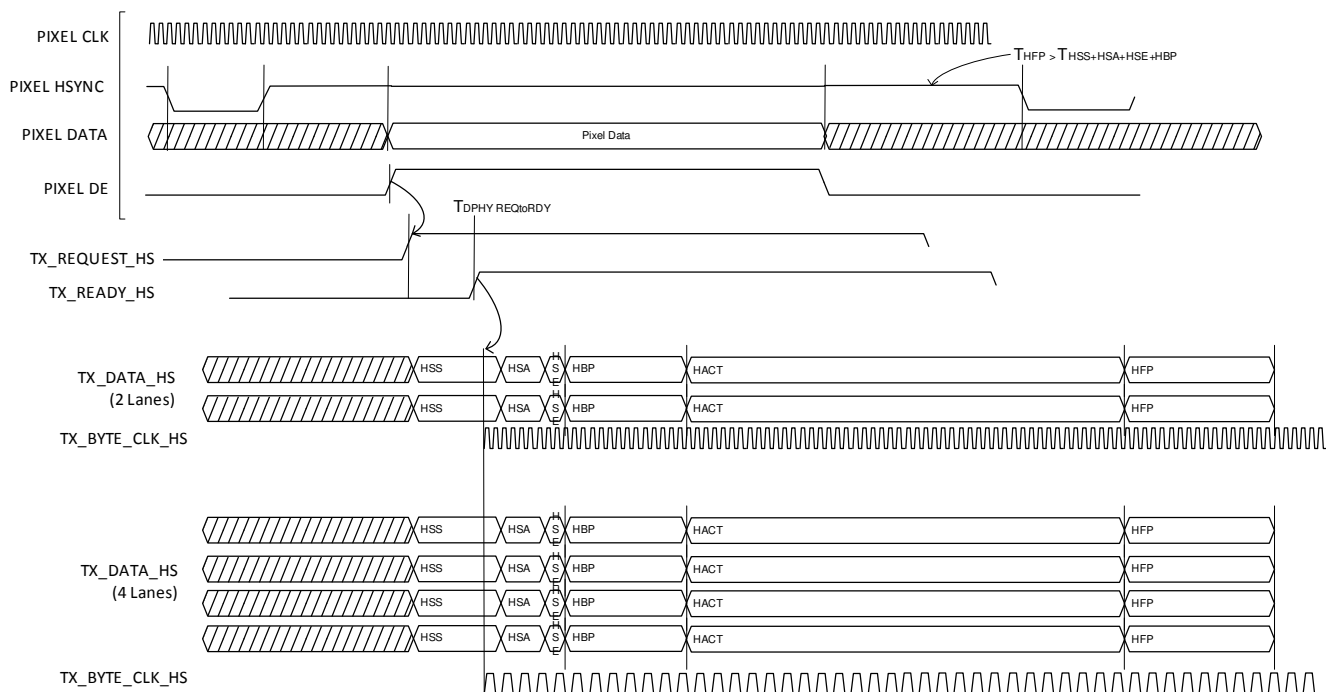

Figure 12-452. DPI Interface to DSI DPHY Timing Diagram

The timing diagram above illustrates how the packets are generated for a DPHY with two and with four lanes activated. The diagram shows that the tx_byte clock changes based on the number of lanes, and that the configuration register values for the number of bytes used for HSA, HBP and HFP will remain the same.

The register values calculated for each of the line synchronization stages needs to take the number of bytes used to form the packet into account so that the timing for each stage aligns to the timing of the DPI input and most importantly that the total number of bytes exactly matches the number of byte clock cycles. The values used for the Horizontal Front porch must be larger than the combined horizontal sync and back porch to allow the DPI FIFO to empty.

The basic rule is that the values used for the DSI will be based on the $\text{DPI} \times \text{BPP}/8$.

The DPI graphics driver must be configured with horizontal values that can be directly translated to DSI packet payloads.

- The minimum values for the DPI HSA must convert to be greater than:
 - Non-Burst Sync Pulses – 15 bytes
 - Non-Burst Sync Events – 11 bytes
- The minimum values for the DPI HBP must convert to be greater than:
 - Non-Burst Sync Pulses – 7 bytes
 - Non-Burst Sync Events – 7 bytes

These values will then form the number of tx_byte_clk cycles used to send the bytes over the number of active lanes. So, for an RGB888, DSI configuration the minimum values will be:

- $\text{HSA} = \text{roundup}(15/3) = 5$
- $\text{HBP} = \text{roundup}(11/3) = 4$

The diagram below, D-PHY Timings Control (see [Figure 12-453](#)), illustrates the byte mapping for a four lane DPHY link. In this example, the calculation for the horizontal sync stage aligns exactly across the four byte lanes.

- HSS – Four Bytes
- HSA – Blank Packet with Header (4) + HSA_Count + CRC(2)
- HSE – Four Bytes

The next stage is the horizontal back porch:

- HBP – Blank Packet with Header (4) + HBP_Count + CRC(2)

The value used in the HBP count can be used to account for the Header bytes used in the active data packet in next stage, although it is best to add this to the HFP stage calculation and allow time to empty the FIFO.

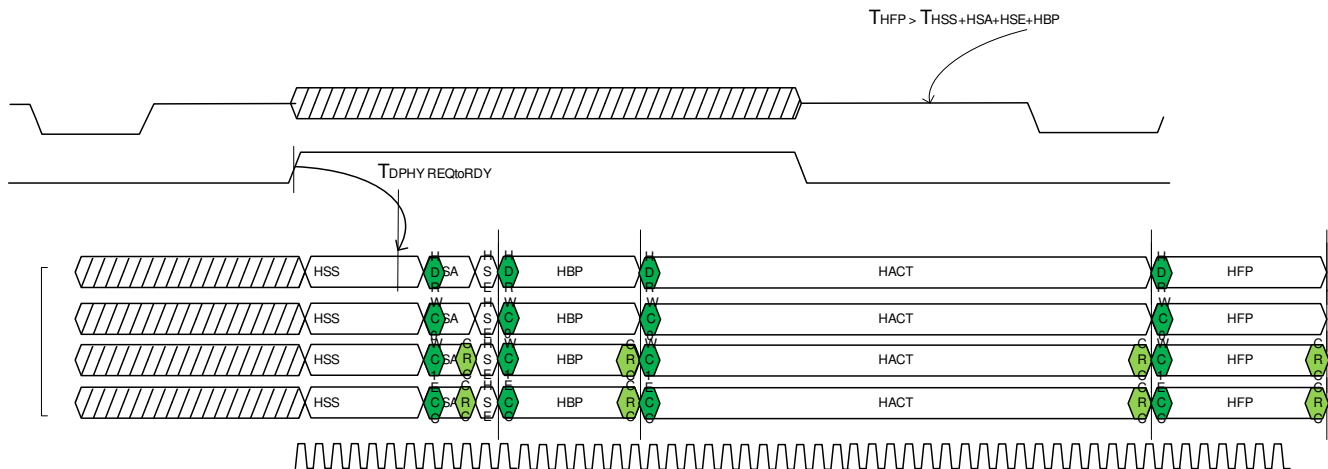

Figure 12-453. Horizontal Line Packet Timing Diagram

The Active part of the line will be a fixed size based on the line size and BPP, and include the six bytes for the packet header and CRC. The final stage is the horizontal front porch.

- HFP – Blank Packet with Header (4) + HFP_Count + CRC(2)

The HFP value should be adjusted to ensure that the number of tx_byte clock cycles for the horizontal line exactly matches the pixel clock cycles for the line times the BPP.

The timing diagram below, Control Block, illustrates the byte alignment changing when the HBP calculated is two bytes shorter than the previous case. This leads to the active and front porch packet headers beginning two bytes earlier, however the HFP count is adjusted to keep the end of the line on exactly the same tx_byte_clk cycle count.

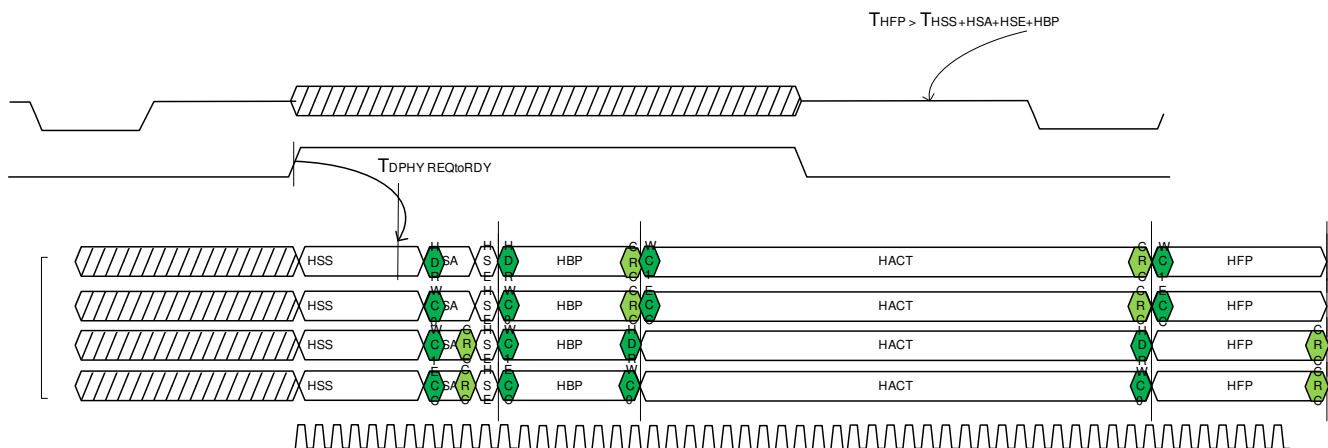

Figure 12-454. Horizontal Line Packet - Shorter HBP - Longer HFP Timing Diagram

The recommendation is to ensure that the total bytes for each horizontal line results in an exact integer tx_byte clock cycles (Total_bytes MOD num_of_lanes = zero), except for the case where the clocks are not exactly matched.

12.6.4.7.8.2 Pixel Clock to TX_BYTE_CLK Variation

The selection of the Pixel clock rate and DPHY Bit clock rate should ideally match based on the ratio of bpp on the pixel side compared to the tx_byte_clk. The timing for the horizontal sync, back and front porch will also be configured to allow the pixel data to be transferred without any over or underflow of the DPI FIFO.

The DPI FIFO fill level register (DPI_CFG) can be used to track that the parameters are sufficient and that any clock variation can still be handled by the FIFO depth. This register will show the pixel data held in the buffer, so during the HSA and HBP packet generation stages DPI pixel data will be stored and this value will increment. Once the data packet is being generated, the DPI_CFG level will remain constant, as the buffer is emptied at the same bandwidth as it is filled. Finally, the value will reduce to zero during the HFP stage.

The packet length of the HFP can be adjusted to help absorb small differences in the pixel_clk to tx_byte_clk relationship. The DSITX controller will concatenate all of the packets during High Speed transmission, so for example adding to the byte value of the HFP will make the bytes at the end of the packet move to align on another lane.

The packets that follow will then be concatenated and aligned to the next available lane, so if the tx_byte_clk is faster than the expected pixel clock times bpp the extra byte will delay the start of the new line tx_byte_clk × extra_byte/lanes.

Figure 12-455, Video coherency, illustrates the impact of increasing the HFP by one byte so that the next line begins ¼ tx_byte clock later. This allows averaging out across the line length of small differences in the pixel to tx_byte clocks when the tx_byte clock is not ideally matched to the expected pixel clock multiplied by bpp.

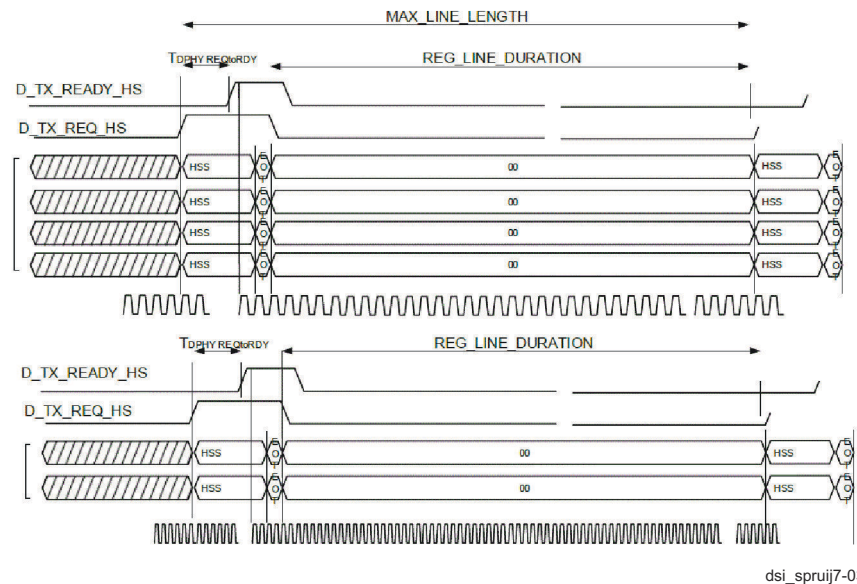

Figure 12-455. Packet Alignment Control Using HFP Byte Increase - tx_byte_clk Faster than Ideal Rate

The DPI_CFG register will show any clock misalignment as an increasing/decreasing value for the FIFO fill level on each line of pixels (must be read mid-line for an accurate reading of the level). When the byte count adjustment is made, the DPI_CFG register will return to the original fill level value every four lines.

12.6.4.7.8.3 LP Operation

The DSITX controller can be configured to perform a transition between LP state and HS state during the horizontal lines which have long periods of blanking. The registers controlling the timing for the DPHY wakeup time and the reg_line_duration must be programmed to exactly match the DPI cycles of the horizontal line to the tx_byte_clk cycles required for the number of active lanes selected.

dsi_spruij7-031

Figure 12-456. Low Power Operation with Four and Two Active Lanes

The LP operation for each vertical blanking line will require the reg_line_duration to be configured to match the following:

- Max_line_length (in tx_byte_clk cycles see 2.2.4) minus Eot (if enabled), also minus further 10 if CLOCK lane is non-continuous.

Note REG_WAKEUP_TIME is used internally to adjust the cycles for each vertical LP line.

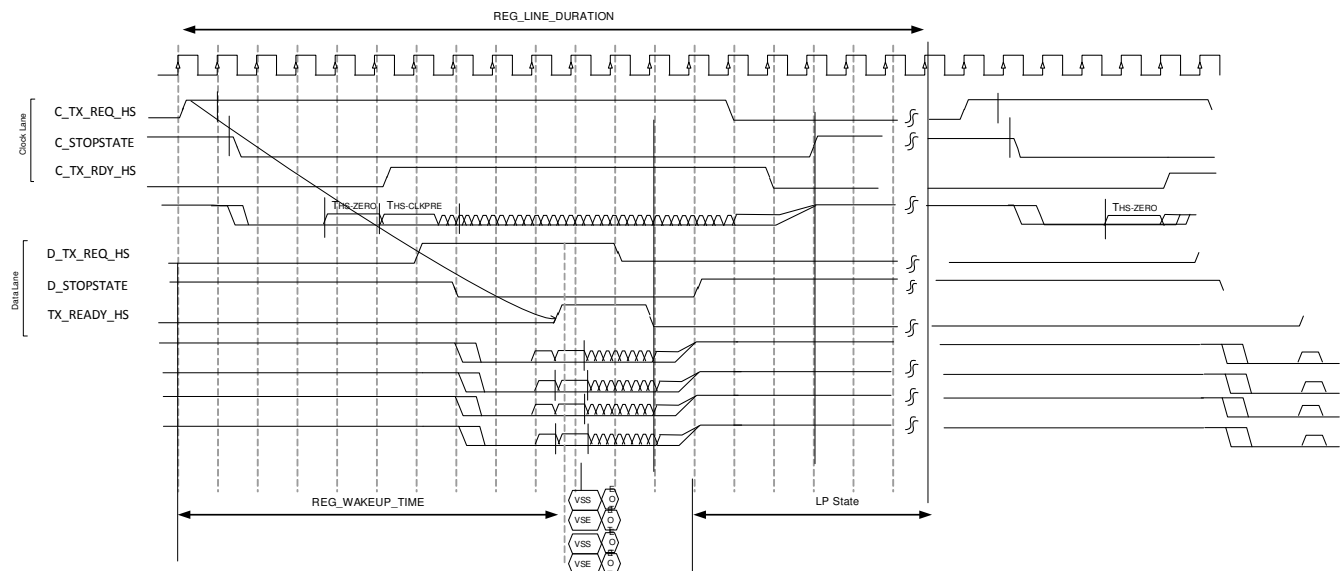

Figure 12-457. REG_LINE_DURATION Timing Example for LP Operation

12.6.4.7.8.4 DPI Interface Burst Operation

The DSITX controller can support burst operation on the DPI interface provided the DPI FIFO size is large enough to store the line pixel data with enough data to not underflow. The burst operation will use a tx_byte_clk that is faster than normal event based operation, so the DPI FIFO size will be impacted by the ratio of the pixel_clk and BPP input to the tx_byte_clk and number of lanes on the output.

The recommended operation is to set the DSI HSA and DSI HFP registers to zero, and adjust the DSI HBP size to control the number of bytes prefilled in the DPI FIFO before the burst is sent.

Figure 12-458 shows DPI operation with event burst mode.

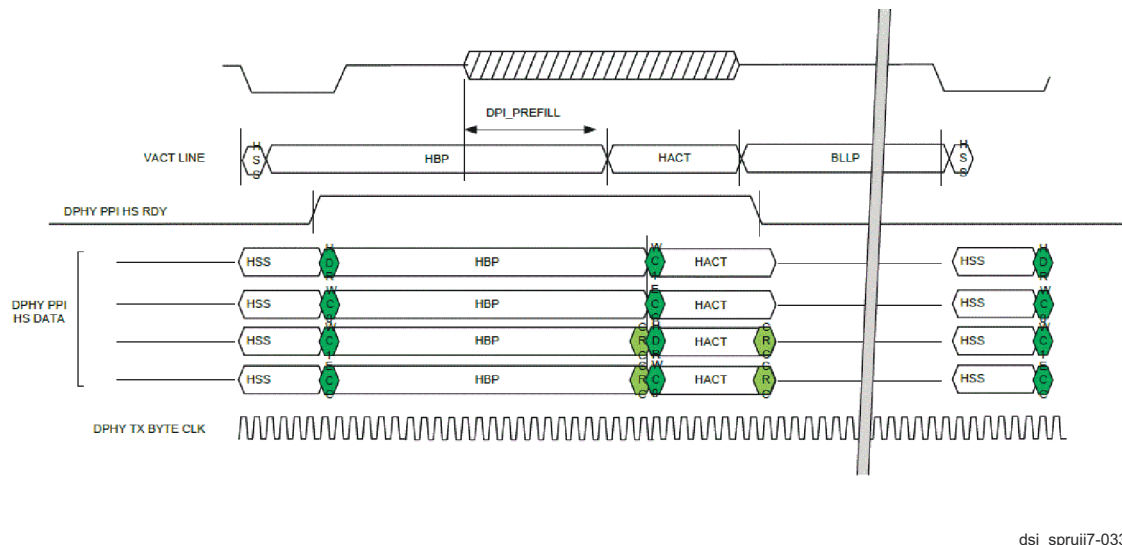

Figure 12-458. DPI Operation with Event Burst Mode

12.6.4.7.9 Programming the DSITX Controller to Match the Incoming DPI Stream

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. Assuming that is the case, then the blanking and active data periods must be matched up.

For each frame of video the time will be:

$$(V_{\text{total}} * H_{\text{total}})_{\text{@pixel_clk}} = (V_{\text{total}} * H_{\text{total}})_{\text{@tx_byte_clk}} \times \text{bits_per_pixel}/8;$$

So for example, the time for a full HD frame 1920x1080 with reduced blanking in RGB565 will be:

$$2200 \times 1200 \text{ pixels} = 2200 \times 1200 \text{ tx_bytes} \times 16/8;$$

The DSITX controller will slave its frame timing to the incoming DPI vsync, as long as it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered. The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

12.6.4.7.9.1 Vertical Timing

The DSITX controller will generate vertical packets for each part of the frame beginning with the VSS and VSE combined with blanking packets to fill the VSA. The blanking packets for the pulse mode program the DSI vertical size registers as follows:

- VSA = DPI_VSI (lines, minimum of 2 → VSS and VSE)
- VBP = DPI_VBP (lines, minimum of 0)
- VACT = DPI_VACT (lines)
- VFP < DPI_VFP (minimum of 1)

DPI horizontal timing is measured in pixel clocks, whereas the DSITX controller uses byte clocks. The horizontal timing should also be matched per line; therefore the blanking and active periods of each line should match. The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. The timing for a horizontal line for the DPI driver side will be the number of pixel cycles for the **HLINE** = (HSA + HBP + HACT + HFP) and this will form **HLINE** × bpp/8 bytes for the controller. These bytes will then be sent using 1, 2, 3 or 4 data lanes, so the DSITX controller will required 1, 1/2, 1/3, 1/4 this number of tx_byte_clk cycles respectively.

e.g a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line.

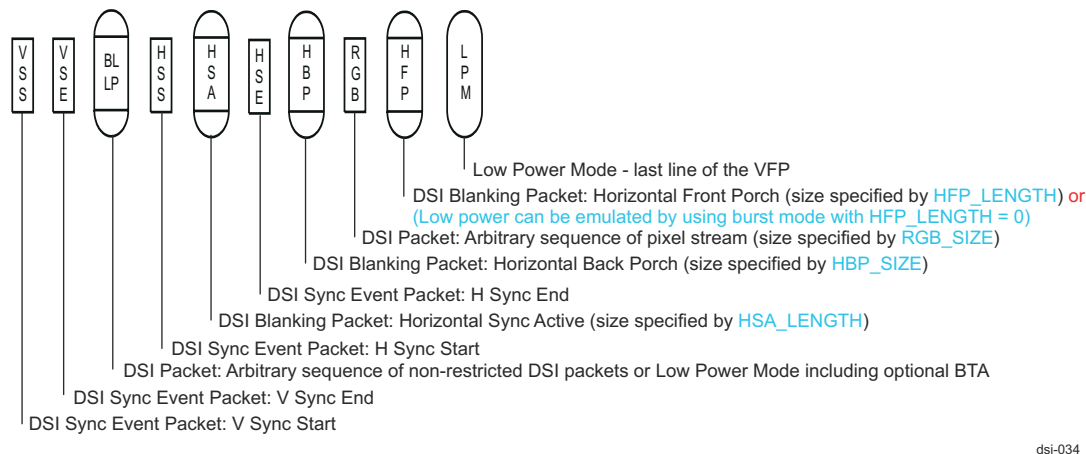

This gives the DSI horizontal lines 3936 bytes to transmit and would use 984 tx_byte_clks on a four lane system, or 1312 on a three lane system etc..

The horizontal configuration uses different registers depending on the Mode (Pulse or Event) and the control of the BLKLINE_MODE register bit.

- Non-Burst Mode with Sync Pulses – enables the peripheral to accurately reconstruct original video timing, including sync pulse widths.

Note that for accurate reconstruction of timing, packet overhead including Data ID, ECC, and Checksum bytes should be taken into consideration.

- Non-Burst Mode with Sync Events – similar to above, but accurate reconstruction of sync pulse widths is not required, so a single Sync Event is substituted.
- Burst mode – RGB pixel packets (active video) portion are time-compressed, leaving more time during a scan line for LP mode (saving power) or for multiplexing other transmissions onto the DSI link.

dsi-034

Figure 12-459. Vertical Timing

12.6.4.7.9.2 Horizontal Timing for Non-Burst Mode with Sync Pulses

Sync Pulse Mode uses the Short packet and Long packet structures to accurately track the DPI interface timing. Figure 12-460 illustrates the packet sequence for a single frame.

dsi-035

Figure 12-460. Vertical Timing

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal line based on the DPI line configuration and the BPP for the colour pixel data.

The packet structure for each type of line during the frame is shown below, Trigger Mapping Information. The calculation of the total number of bytes in any horizontal line must always be $HLINE \times bpp/8$ bytes.

Figure 12-461. Non-Burst Mode With Sync Pulse Line Structures

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and CRC footer (4 + 2 bytes) and the HSE short packet (4 bytes).
- HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes).
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.

Finally for lines with no active data, the controller will use either:

- BLKLINE_PULSE_PCK: Total line size ($HLINE \times bpp/8$) in bytes minus the HSA 20 bytes (14 for HSA header and CRC, 6 for the remaining blanking which is all combined into a single packet).
- REG_LINE_DURATION: Total line size ($HLINE \times bpp/8$) in tx_byte_clk cycles minus the calculated HSA in tx_byte_clk cycles ($HSA \times bpp/8$ minus 14 bytes (14 for HSA header and CRC) minus the EOT packet (4 bytes) if required, divided by number of lanes). This should be aligned to the number of active lane so rounding the value so that $REG_LINE_DURATION \text{ MOD } \text{Lanes}$ equals zero.
- VERT_BLANKING_DURATION: Total line size ($HLINE \times bpp/8$) in tx_byte_clk cycles minus the calculated HSA in tx_byte_clk cycles ($HSA \times bpp/8$ minus 14 bytes (14 for HSA header and CRC) divided by number of lanes).

Program the DSI horizontal size registers as follows:

burst_mode = 0 and sync_pulse_active = sync_pulse_horizontal = 1;

HSA = $(\text{DPI_HSA} \times \text{bpp}/8) - 14$ – DPI HSA min value 5 for RGB888

HBP = $(\text{DPI_HBP} \times \text{bpp}/8) - 12$ – DPI HBP min value 5 for RGB888

HACT = $(\text{DPI_HACT} \times \text{bpp}/8)$

HFP = $(\text{DPI_HFP} \times \text{bpp}/8) - 6$ – DPI HFP min value 10 for RGB888

Note: $(\text{DPI_HACT} \times \text{bpp}/32)$ must be an integer. Total Line Length = $\text{div_roundup}((HLINE \times \text{bpp}/8), \text{num of lanes})$;

$(\text{BLKLINE_PULSE_PCK} \text{ bytes}) = (HLINE \times \text{bpp}/8) - 20 - \text{HSA}$;

$(\text{REG_LINE_DURATION})_{\text{tx_byte_clks}} = \text{Total Line Length} - \text{div_roundup}((\text{HSA} \times \text{bpp}/8) - 14, \text{number of lanes});$

$(\text{VERT_BLANKING_DURATION})_{\text{tx_byte_clks}} = \text{Total Line Length} - \text{div_roundup}((\text{HSA} \times \text{bpp}/8) - 14, \text{number of lanes});$

For example; a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI HLINE of 3936 bytes. So for 4 lanes, 984 tx_byte_clk cycles;

$$\text{HSA} = (12 \times 16/8) - 14 = 10$$

$$\text{HBP} = (12 \times 16/8) - 12 = 12$$

$$\text{HACT} = (1920 \times 16/8) = 3840$$

$$\text{HFP} = (24 \times 16/8) - 6 = 42$$

$$\text{Total Line} = \text{div_roundup}((12 + 12 + 1920 + 24) \times 16/8, 4) = 984 \text{ tx_byte_clk cycles} = 3936 \text{ bytes};$$

$$\text{BLKLINE_PULSE_PCK} = (3936) - 20 - 10 = 3906$$

$$\text{REG_LINE_DURATION} = 984 - \text{div_roundup}(12 \times 2, 4) = 978$$

$$\text{VERT_BLANKING_DURATION} = 984 - \text{div_roundup}(12 \times 2, 4) = 978$$

Confirming the calculation for each line with BLKLINE_MODE = 0;

$$\text{VSS} = \text{VSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{BLK_LINE_PULSE_PCKPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$$

$$\text{VSALine} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{BLK_LINE_PULSE_PCKPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$$

$$\text{VSE} = \text{VSEPKT} + \text{HSAPkt} + \text{HSEPkt} + \text{BLK_LINE_PULSE_PCKPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$$

$$\text{VACT} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{HBPPkt} + \text{HACTPkt} + \text{HFPPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 12 + 2) + (4 + 3840 + 2) + (4 + 42 + 2) = 3936;$$

$$\text{VFP} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{BLK_LINE_PULSE_PCKPkt} = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$$

$$\text{VFPLast} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{VERT_BLANKING_DURATION} = 4 + (4 + 10 + 2) + 4 + (978 \times 4) = 3936;$$

Confirming the calculation for each line with BLKLINE_MODE = 1 matches the tx_byte cycles;

$$\text{VSS} = \text{VSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{REG_LINE_DURATION} = \text{div_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$$

$$\text{VSALine} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{REG_LINE_DURATION} = \text{div_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$$

$$\text{VSE} = \text{VSEPKT} + \text{HSAPkt} + \text{HSEPkt} + \text{REG_LINE_DURATION} = \text{div_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$$

$$\text{VACT} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{HBPPkt} + \text{HACTPkt} + \text{HFPPkt} = \text{div_roundup}((4 + (4 + 10 + 2) + 4 + (4 + 12 + 2) + (4 + 3840 + 2) + (4 + 42 + 2)), 4) = 984;$$

$$\text{VFP} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{REG_LINE_DURATION} = \text{div_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$$

$$\text{VFPLast} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPkt} + \text{VERT_BLANKING_DURATION} = \text{div_roundup}((4 + (4 + 10 + 2) + 4 + (3912)), 4) = 984;$$

12.6.4.7.9.3 Event Mode Horizontal Timing

Non Burst Event Mode uses the Short packet and Long packet structures to track the DPI interface timing without accurate reconstruction of sync pulse widths, so a single Sync Event is substituted. [Figure 12-462](#) illustrates the packet sequence for a single frame.

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal.

dsi-037

Figure 12-462. Horizontal Timing - 1

line based on the DPI line configuration and the BPP for the colour pixel data. The packet structure for each type of line during the frame is shown in Figure 12-463:

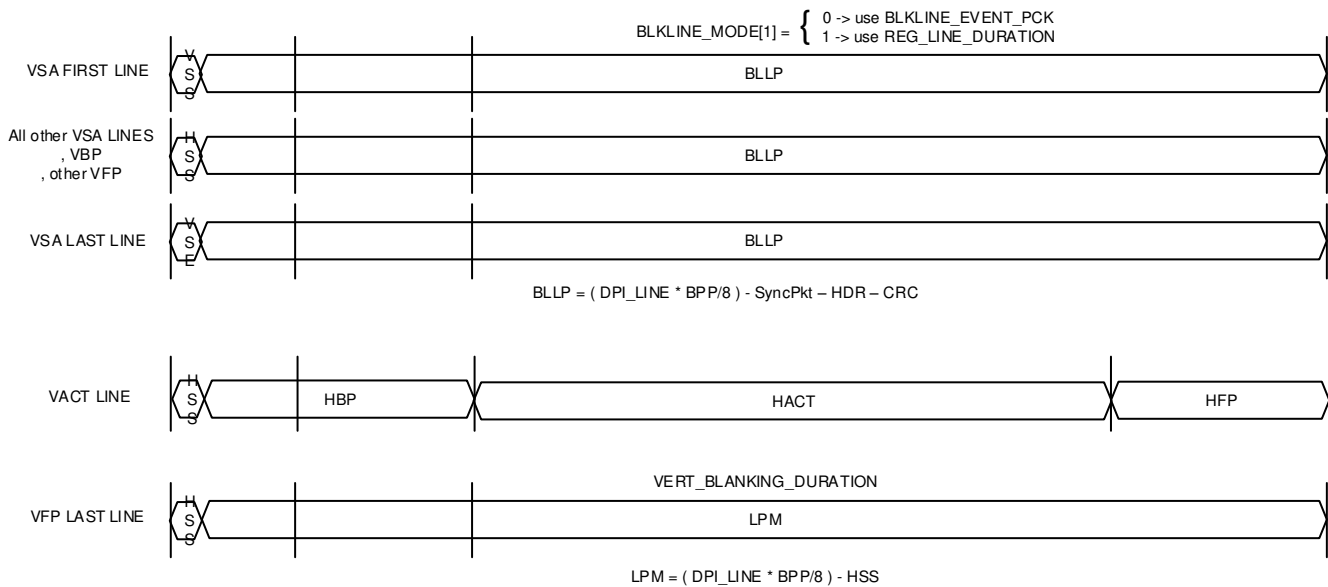

Figure 12-463. Horizontal Timing - 1

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).
- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (2 bytes). This will match the DPI_HSA + DPI_HBP minus the Sync Short packet.
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer and footer of the active data.

Finally, for lines with no active data, the controller will use either:

- **BLKLINE_EVENT_PCK**: Total line size (HLINE × bpp/8) in bytes minus 10 bytes (4 for VSS/VSE/HSS, 6 for the remaining blanking header/footer which is all combined into a single packet).
- **REG_LINE_DURATION**: Total line size div_roundup(HLINE × bpp/8, num_of_lanes) in tx_byte_clk cycles minus tx_byte cycles for the 8 bytes (4 for VSS/VSE/HSS, and 4 for EOT). This should be aligned to the number of active lane so round the value so that REG_LINE_DURATION MOD Lanes equals zero.
- **VERT_BLANKING_DURATION**: Total line size div_roundup(HLINE × bpp/8, num_of_lanes) in tx_byte_clk cycles minus tx_byte cycles for the 4 bytes (4 for HSS).

Program the DSI horizontal size registers as follows:

burst_mode = 0 and sync_pulse_active = sync_pulse_horizontal = 0;

- HSA = 0
- HBP = ((DPI_HSA + DPI_HBP) × bpp/8) - 12 – DPI HSA + HBP min value 5 for RGB888
- HACT = (DPI_HACT × bpp/8)
- HFP = (DPI_HFP × bpp/8) - 6 – DPI HFP min value 10 for RGB888

Note: (DPI_HACT × bpp/32) must be an integer. Total Line Length = div_roundup((HLINE × bpp/8), num of lanes).

(BLKLINE_EVENT_PCK) bytes} = (HLINE × bpp/8) - 10

(REG_LINE_DURATION) tx_byteclks} = Total Line Length - div_roundup(8, number of lanes)

(VERT_BLANKING_DURATION) tx_byteclks} = Total Line Length - div_roundup(4, number of lanes)

For example: a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI HLINE of 3936 bytes.

HSA = 0

HBP = ((12 + 12) × 16/8) - 12 = 24

HACT = (1920 × 16/8) = 3840

HFP = (24 × 16/8) - 6 = 42

Total Line = div_roundup((12 + 12 + 1920 + 24) × 16/8, 4) = 984

BLKLINE_EVENT_PCK = (HLINE × bpp/8) – 10 = 981

REG_LINE_DURATION = 984 – div_roundup(8, 4) = 982

VERT_BLANKING_DURATION = 984 – div_roundup(4, 4) = 983

Confirming the calculation for each line:

VSS = VSSPkt + BLK_LINE_EVENT_PCKPkt = 4 + (4 + 3926 + 2) = 3936

VSALine = HSSPkt + BLK_LINE_EVENT_PCKPkt = 4 + (4 + 3926 + 2) = 3936

VSE = VSEPKT + BLK_LINE_EVENT_PCKPkt = 4 + (4 + 3926 + 2) = 3936

VACT = HSSPkt + HBPPkt + HACTPkt + HFPPkt = 4 + (4 + 24 + 2) + (4 + 3840 + 2) + (4 + 42 + 2) = 3936

VFP = HSSPkt + BLK_LINE_EVENT_PCKPkt = 4 + (4 + 3926 + 2) = 3936

VFPLast = HSSPkt + VERT_BLANKING_DURATION = 4 + (983 × 4) = 3936

12.6.4.7.9.4 Burst Event Mode Horizontal Timing

Burst Event Mode uses the Short packet and Long packet structures to transmit the video information in short bursts and allow the system to use the Low Power states to save active power. This can only be supported with DSITX controllers able to store a horizontal line in the DPI FIFO. The burst mode will expect the tx_byte_clk to be twice the rate of the non burst event mode, and the register calculation will expect the total bytes for each line to double. [Figure 12-464](#) illustrates the packet sequence for a single frame.

Figure 12-464. Burst Event Mode Horizontal Timing - 1

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal line based on the DPI line configuration and the BPP for the colour pixel data.

The packet structure for each type of line during the frame is shown below, with the DSI HFP = 0 to select BLLP operation.

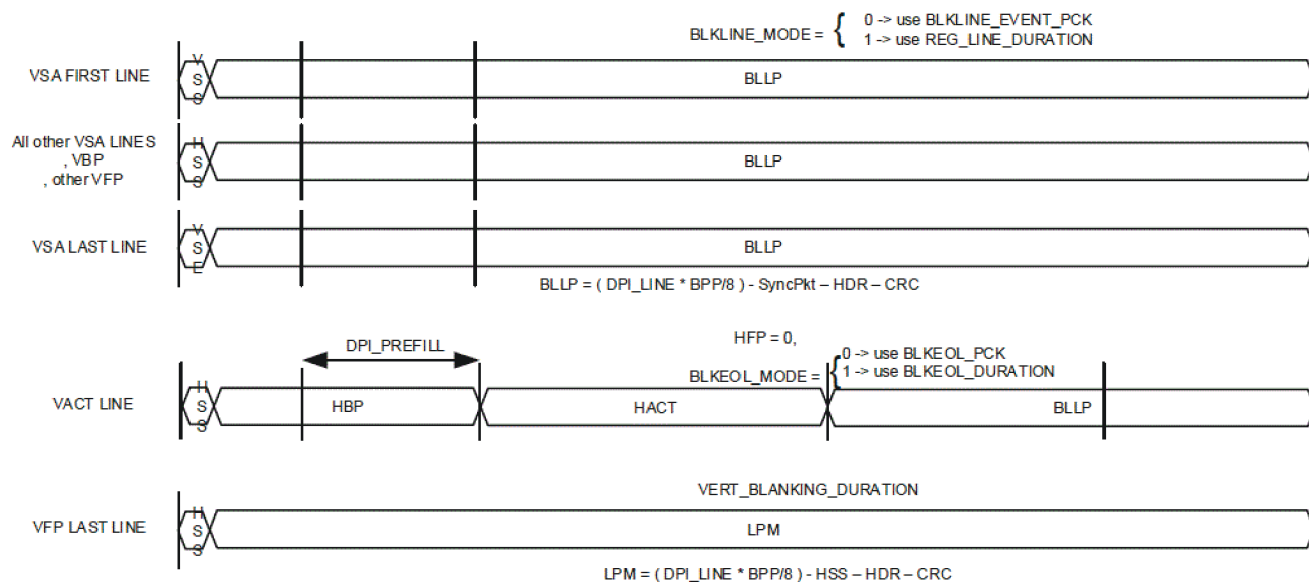

Figure 12-465. Burst Event Mode Horizontal Timing - 2

The DSI short packets and packet headers that are inserted by the controller for active lines must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).

- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes). This will match the DPI_HSA + DPI_HBP minus the Sync Short packet. In this case the DPI must also reduce the HSA and HFP timing.
- BLLP uses BLKEOL_PCK or BLKEOL_DURATION and will change depending on the HFP use case:
 - HFP can be zero to extend the BLKEOL_x values (recommended).
 - or a non-zero value to transmit a Blanking Packet instead of LP state. The Blanking Packet HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.
 - The host_eot state will cause the BLLP to either add an EOT cycle or not. The BLKEOL_PCK or BLKEOL_DURATION value will need to be adjusted to include this extra cycle if host_eot is disabled.

Finally for lines with no active data, the controller will use either:

- BLKLINE_EVENT_PCK in bytes, excluding the header and crc.
- REG_LINE_DURATION or VERT_BLANKING_DURATION.
- Both are the total expected tx_byte_clk cycle for the line minus the number of cycles required to send the header packet bytes (4 for VSS/VSE/HSS) over the active lanes.

Program the DSI horizontal size registers as follows:

burst_mode = 1 and sync_pulse_active = sync_pulse_horizontal = 0;

- HSA = 0
- HBP = $(2 \times (\text{DPI_HSA} + \text{DPI_HBP}) \times \text{bpp}/8) - 12 + \text{DPI FIFO Prefill}$
- HACT = $(\text{DPI_HACT} \times \text{bpp}/8)$ NOTE: $(\text{DPI_HACT} \times \text{bpp}/32)$ must be an integer.
- HFP = Zero

Total Line Length = $\text{div_roundup}((\text{HLINE} \times \text{bpp}/8), \text{num of lanes})$;

$(\text{BLKLINE_EVENT_PCK}) = (\text{HLINE} \times \text{bpp}/8) \times 2 - 4$

$(\text{REG_LINE_DURATION}) = \text{Total Line Length} \times 2 - \text{div_roundup}(4, \text{number of lanes})$

$(\text{VERT_BLANKING_DURATION}) = \text{Total Line Length} \times 2 - \text{div_roundup}(4, \text{number of lanes})$

$(\text{BLKEOL_DURATION}) = \text{Total Line Length} \times 2 - \text{TX_BYTE_CYCLES}$

$(\text{BLKEOL_PCK}) \text{ bytes} = \text{Total Line Length} \times 2 - (\text{HACT} + \text{HBP} + \text{HSS})$

Note: TX_BYTE_CYCLES = TX Byte clock cycles to send Active Line bytes on the number of active lanes = $\text{div_roundup}(\text{HBP} + \text{HACT}, \text{number of lanes})$.

Burst Operation Frame Configuration

Burst mode operation can be used to save power provided the system configuration can support the higher tx_byte clock rate. The user should consider if the power saving during LP states is more than reducing the number of active lanes and running in non-burst mode.

The burst mode can only be used if the controller configuration can support it; either using SDI video interface, or DPI interface with a buffer size large enough to prefill the data. The video driver timing from the DPI side will also need to be changed.

dsi_spruij7-041

Figure 12-466. DSITX Controller Video Frames for Burst Mode Compared with DPI Driver Side

For example:

The VESA configuration for a 1920x1200 frame at 60-frames per second with normal blanking would have a pixel clock at 193.25 MHz, HSA 200 pixels, HBP 336 pixels, HFP 136 pixels and total line 2592 pixels. This would need to be reconfigured to move the active area earlier in the horizontal line for the DSITX controller, so could be changed to; HSA 20 pixels, HBP 30 pixels, HFP 622 pixels. This would allow the HFP LP state to be almost $\frac{1}{4}$ of the line (622/2592).

12.6.4.7.9.5 Burst Mode Operation

The DSI IP offers different options for behavior in the BLLP areas:

- Insertion of blanking or null packets.
- Switch to LP (power saving).
- Insertion of commands (if any) + blanking or null packet.

Figure 12-467 shows burst mode operation.

Figure 12-467. Burst Mode Operation

The user should balance the increase in the clock frequencies for transmission of the active display, against the power saving by using BLLP(Null) or LP state.

For Burst with the LP state the register fields must be programmed for `burst_lp = 1` and `reg_blkeol_mode = 2'b2`.

Command Insertion Operation

The DSITX can use the burst operation to allow the blanking/LP stages to be used for DCS/GEN command insertion by programming the size of the space available after the sync of each line.

Only one command packet can be passed within each video line. The decision to insert a command in a video line is done at the beginning of the slot just after the previous video packet. If a command arrives in the middle of the slot, it is not processed in that line, the decision to accept the command will be taken in the next line.

If the packet does not fit in a short slot (size bigger than `reg_max_burst_limit` and not equal to `reg_exact_burst_limit`), it is delayed up to next long slot. The signal `reg_err_burstwrite` is flagged (it is only an information that can help application software control). If its length is longer than `reg_max_line_limit`, it is discarded and the error `reg_err_linewrite` is generated.

Read commands and BTA requests are only passed during long slots, as there is no way to calculate their duration exactly. In the case where their duration takes longer time than the vertical blanking period, the error `reg_err_longread` is flagged.

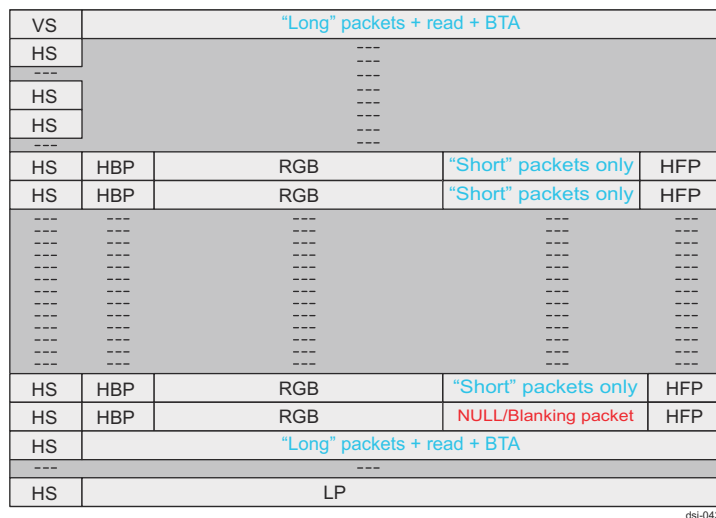

Figure 12-468. Burst Mode Command Locations During Video Frame

Command Insertion Registers in Burst Operation

The burst operation requires the configuraton of the registers to control the size of the packets that will fit in the space available on each type of horizontal line.

In VSA, VBP or VFP: Insertion of short and long command packets, read or BTA are allowed.

dsi-045

- In VACT: Only short packets can be inserted.
- Command, if inserted, is inserted right after the HSA or HSE or the video packet.
- Only one command can be inserted by line.
- When a command is inserted on a video line, no switch to LP but Null packet insertion.
- Trigger and TE insertion not supported.

VID_VCA_SETTING1 register:

[16] BURST_LP: After an active line, in burst mode, the system can switch in LP (1) or should complete the line with NULL packet (0).

VID_VCA_SETTING1 register:

[15:0] MAX_BURST_LIMIT: Maximum length of a packet (number of bytes) that can be passed during the blanking period at the end of an active line (in burst mode) followed by a NULL packet with no data (6 bytes).

VID_VCA_SETTING2 register:

[15:0] EXACT_BURST_LIMIT: Exact maximum size of the burst packet (packet that fits after pixel data in burst mode), that is with no Null packet insertion afterwards.

VID_VCA_SETTING2 register:

[31:16] MAX_LINE_LIMIT: The "maximum" packet (number of bytes) that can be passed during the vertical blanking period.

If the packet does not fit in a short slot (size bigger than MAX_BURST_LIMIT and not equal to EXACT_BURST_LIMIT), it is delayed up to next long slot.

- If the packet length is longer than MAX_LINE_LIMIT, it is thrown away (an error is asserted).

Table 12-439 outlines the expected behaviour of each packet type during the video frame.

Table 12-439. Behavior of the DSITX Transmission when Both Video and Command are Running

Packet type	Packet Size	Behavior	Error Flagged
VACT Active Line - Read and BTA do not pass			
No packet	-	LP mode null packet sent	
Short packet		Packet passed followed by a null packet	
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	
Long packet	size = reg_exact_burst_limit	Packet passed	
Long packet	reg_max_burst_limit < size < reg_exact_burst_limit	Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite

**Table 12-439. Behavior of the DSITX Transmission when Both Video and Command are Running
(continued)**

Packet type	Packet Size	Behavior	Error Flagged
Long packet	reg_exact_burst_limit < size <= reg_max_line_limit	packet is delayed to non-active part of frame: Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite
Packet type	Packet Size	Behavior	Error Flagged
Long packet	size > reg_max_line_limit	Packet thrown, LP mode packet thrown, null packet sent	Linewrite Linewrite
Read packet	-	Packet delayed, LP mode Packet delayed, null packet sent	-
BTA request	-	Packet delayed, LP mode Packet delayed, null packet sent	-
VSA, VBP, VFP - Long packet, read and BTA can be passed			
No packet	-	LP mode	-
Short packet	-	Packet passed followed by a null packet	-
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	
Long packet	size > reg_exact_burst_limit	packet thrown, LP mode	Linewrite
Read packet	read completed (direction) before end of slot	Packet passed	
Read packet	read not completed (direction) before end of slot	Packet passed	Longread If operation lasts too long
BTA request	-	Packet passed	Longread If operation lasts too long

Note that for burst operation with Low Power, the command will be sent as a high-speed packet even if the request is made to send as Low Power. Also, the next active line will return to using LP during the HFP phase if no other commands are requested.

12.6.4.7.9.6 Example Configurations

1. Here is an example for a VGA frame with 24bpp @60fps using non burst pulse sync mode: With blanking, total size 500 lines, each line is 800 pixels.

400000 DPI cycles/frame @ 24 MHz pixel clock <=> 300000 DSI cycles/frame @ 18 MHz byte clock;

800 DPI cycles/line @ 24 MHz <=> 600 DSI cycles/line @ 18 MHz;

Table 12-440. DPI and DSI Parameters - 1

Parameter	DPI	DSI
VSA	5	5
VBP	5	5
VACT	480	480
VFP	10	5
HSA	40	106 (120-14)
HBP	40	108 (120-12)
HACT	640	1920
HFP	80	234 (240-6)

Table 12-440. DPI and DSI Parameters - 1 (continued)

Parameter	DPI	DSI
HTOTAL	800 pixel cycles	2400 bytes

burst_mode = 0

sync_pulse_active = 1

sync_pulse_horizontal = 1

BLKLINE_PULSE_PCK = 2380 (2400-20)

REG_LINE_DURATION = 2380

VERT_BLANKING_DURATION = 2384

Note: The controller will send 4 VFP lines then transition to LP for the duration equivalent to 6 lines.

2. Here are some example values for a 24fps UHD frame size with 24bpp using non-burst event mode: With blanking, total size 2250 lines, each line is 4000 pixels.

9000000 DPI cycles/frame @ 216 MHz pixel clock <-> 6750000 DSI cycles/frame @ 162 MHz byte clock

4000 DPI cycles/line @ 216 MHz <-> 3000 DSI cycles/line @ 162 MHz

Table 12-441. DPI and DSI Parameters - 2

Parameter	DPI	DSI
VSA	2	2
VBP	0	0
VACT	2160	2160
VFP	40	1
HSA	40	0
HBP	40	228 (120 + 120 - 12)
HACT	3840	11520
HFP	80	234 (240 - 6)
HTOTAL	4000	12000

burst_mode = 0

sync_pulse_active = 0

sync_pulse_horizontal = 0

BLKLINE_EVENT_PCK = 11990 (12000-10)

REG_LINE_DURATION = 11990

VERT_BLANKING_DURATION = 11996

Note: After the active data the controller will transition immediately to LP for the duration equivalent to 88 lines, giving the maximum power saving between lines.

If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure.

12.6.4.7.9.7 Stereoscopic Video Support

The DSI controller can support stereoscopic display format (SDF) using both command and video modes.

- Command Mode
 - APB Direct Command 3D Commands – Use get_3D_control with Read
 - SDI Command Mode – DCS Writes

- Video Mode – Single Link Operation
 - VSYNC Parameter1 Definition (L/R, Mode, Format)
 - SDI Video Mode
 - DPI Video Mode – Video stream will expect to follow expected format; frame, line, pixel
 - 3DVSYNC = 0 not currently supported.

The DSI must be configured to enable the 3D operation and identify the format that is being used using the register control to enable the 3D features and the configuration that matches the video stream from the system.

The SDF format requires the system to provide frame and synchronisation information using the two parameter fields within the vertical sync short packet (VSS).

Configured the DSI mctl_3dvideo_ctl register to match format – L/R Pixel, L/R Line, L/R Frame Drive video stream based on orientation and format.

Note: DSI Controller will not perform any on-the-fly pixel manipulation for L-R ordering.

Example Video Operation

For a 3D video stream where the DSI video is given the combined images as one continuous large frame, the VSYNC packet would identify that the left image is sent first, it is a line based format and in landscape mode (see [Table 12-442](#)).

Table 12-442. Example Video Operation

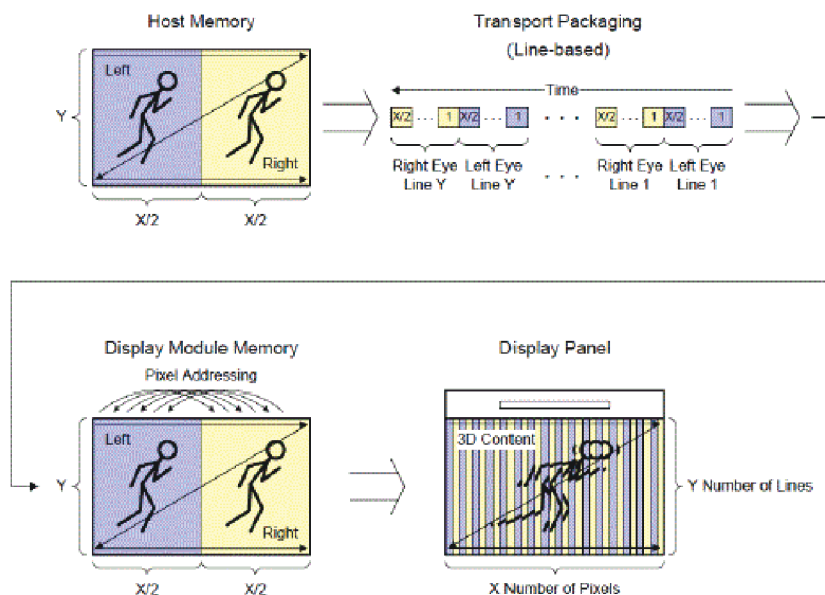

Position	D7	D6	D5	D4	D3	D2	D1	D0
Value	0	0	0	0	0	0	1	0
Description	Rsvd	Rsvd	Left First	No Sync	Line-based		Landscape	

mctl_3dvideo_ctl (0x20)

Table 12-443. VSYNC Parameter 1

[7]	vid_vsync_3d_en	1
[5]	vid_vsync_3d_lr	0
[4]	vid_vsync_3d_second_en	1
[3:2]	vid_vsync_3dformat	00
[1:0]	vid_vsync_3dmode	10

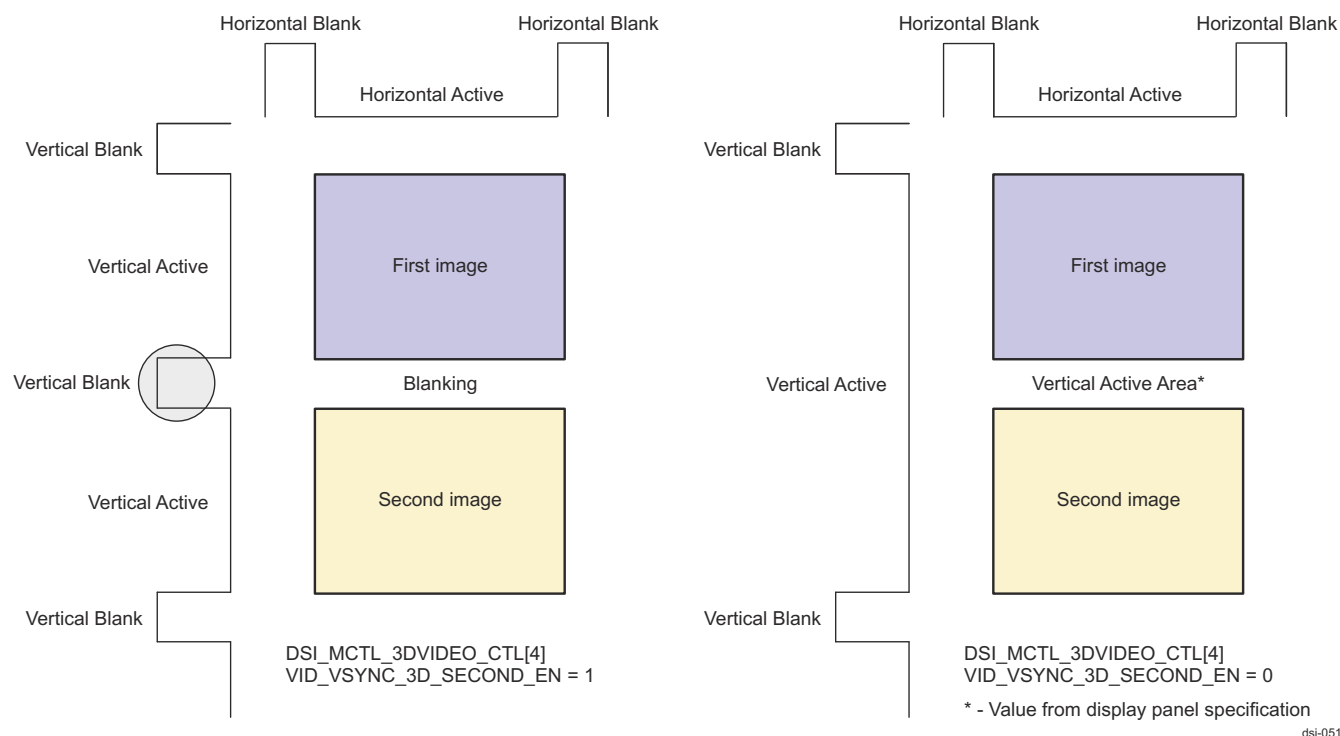

The video stream would then be configured in the DSI to be twice the line length of the normal image.

dsi_spruij7-050

Figure 12-469. Example DPI Image Format for SDF Combining Left And Right Pixels

Note: The vertical operation DSI controller will expect the system to provide the left and right as two individual frames with SYNC to allow the blanking to be generated. The DSI does not insert the vertical blanking area when VSYNC = 0.

dsi-051

Figure 12-470. 3D Image format for 3DVSYNC splitting first and second images

12.6.4.7.10 DSITX Video Stream Variable Refresh

The DSITX Controller can be programmed to allow the video stream sequence from a video source to halt between frames and enter Low Power state. The DPI video stream can halt before the new VSYNC is sent and remain in this state until the host video system wants to begin transmitting the new frame.

The DSITX will not perform the normal frame recovery mechanism when this is enabled, however it will continue to recover from line errors until the end of the frame.

Table 12-444. DSITX Video Stream Variable Refresh

Variable refresh rate operation enable control	Configures how the video generation timing is controlled. 0, 1 DPI mode operation supports = 1 (enabled). For SDI operation, this parameter can optionally be set to FALSE (= 0) when the system clock and tx_byte_clk are generated from the same reference clock source, or TRUE to allow variable refresh rate control.

12.6.5 Embedded DisplayPort (eDP) Transmitter

12.6.5.1 EDP Block Diagram

Figure 12-471 shows the high level architecture of EDP and system integration.

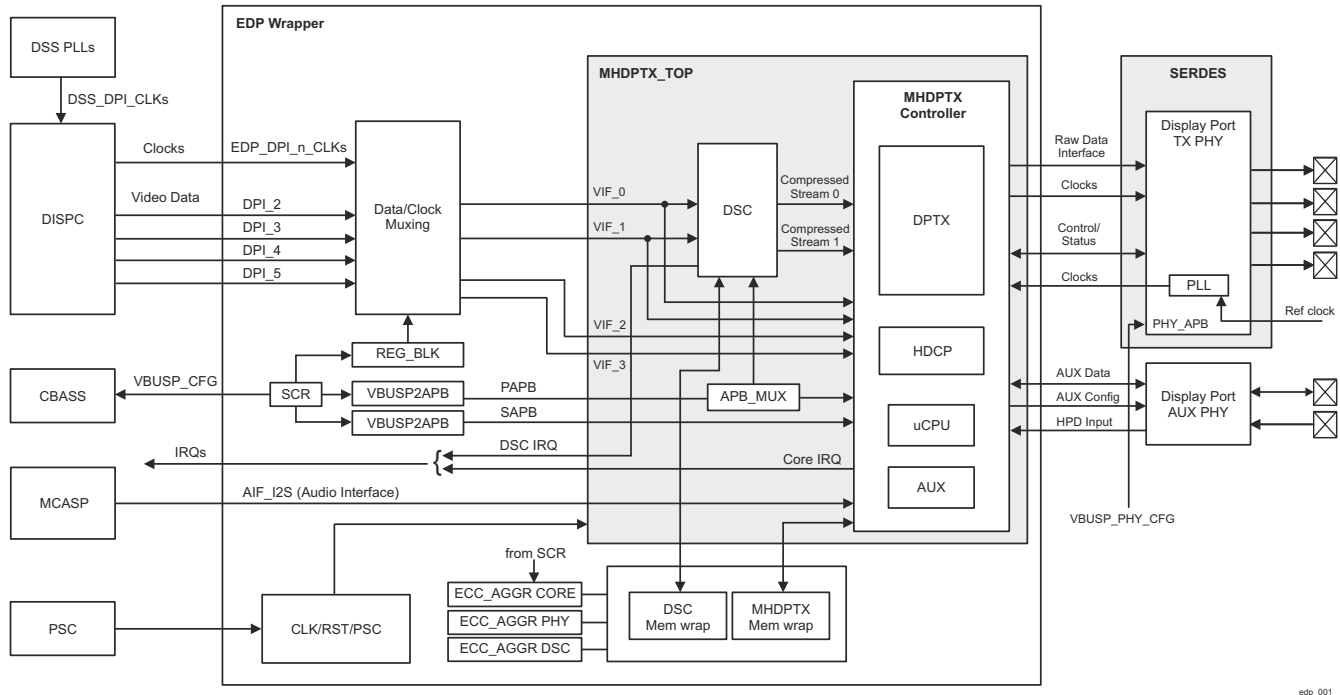

Figure 12-471. EDP System Integration Block Diagram

12.6.5.2 EDP Wrapper Functions

The EDP Wrapper provides logics for following interfaces:

- Interface Bridges - Map VBUS_CFG bus to APB interfaces via CBASS switch and VBUSP2APB bridges
- Video Stream Clock/Data Muxing - Muxes the DPI (from DSS) streams and maps the selected streams to MHDPTX_TOP video interface (VIF) inputs
- SERDES PHY Interface Mapping
- Clock/Reset/Power Management
- Configurations – Provides a register bank to configure/control the top level EDP wrapper functions

12.6.5.2.1 Video Stream Clock/Data Muxing

The EDP wrapper supports up to 6 DPI inputs and internally maps 4 of them to the MHDPTX module, which can support up to 4-stream transmission in Multiple Stream Transport (MST) mode.

Each DPI interface supports the following:

- CEA-861 signaling/timing compatible interface
- Pixel clock rate range from 25MHz to 600MHz
- Frame Resolution - 4K@60Hz equivalent frame size – supporting various frame resolutions and aspect ratios that are equivalent to 4Kx2K@60Hz UHD (Ultra High Definition – 4096x2160 pixels)
- Progressive video timing only
- Maximum Width - 8x1024 pixels wide
- RGB (or YUV444) format only

Table 12-445 describes the DPI interface signals at EDP Wrapper boundary.

Table 12-445. EDP Wrapper DPI Interface Signals

Signal Name ⁽¹⁾	Direction	Default Value	Description
dpi_n_data[47:0]	Input	48'd0	Pixel Data

Table 12-445. EDP Wrapper DPI Interface Signals (continued)

Signal Name ⁽¹⁾	Direction	Default Value	Description
dpi_n_m_mdata[47:0]	Input	48'd0	Master Meta Data Only bit [10] secure mode bit is used
dpi_n_de	Input	1'd0	Data Enable (active high)
dpi_n_vs	Input	1'd0	Start of frame or Vsync (active low)
dpi_n_hs	Input	1'd0	Start of line or Hsync (active low)

(1) n = 0 to 5

Figure 12-472 shows the DPI data mapping to VIF ports via muxing in the EDP wrapper.

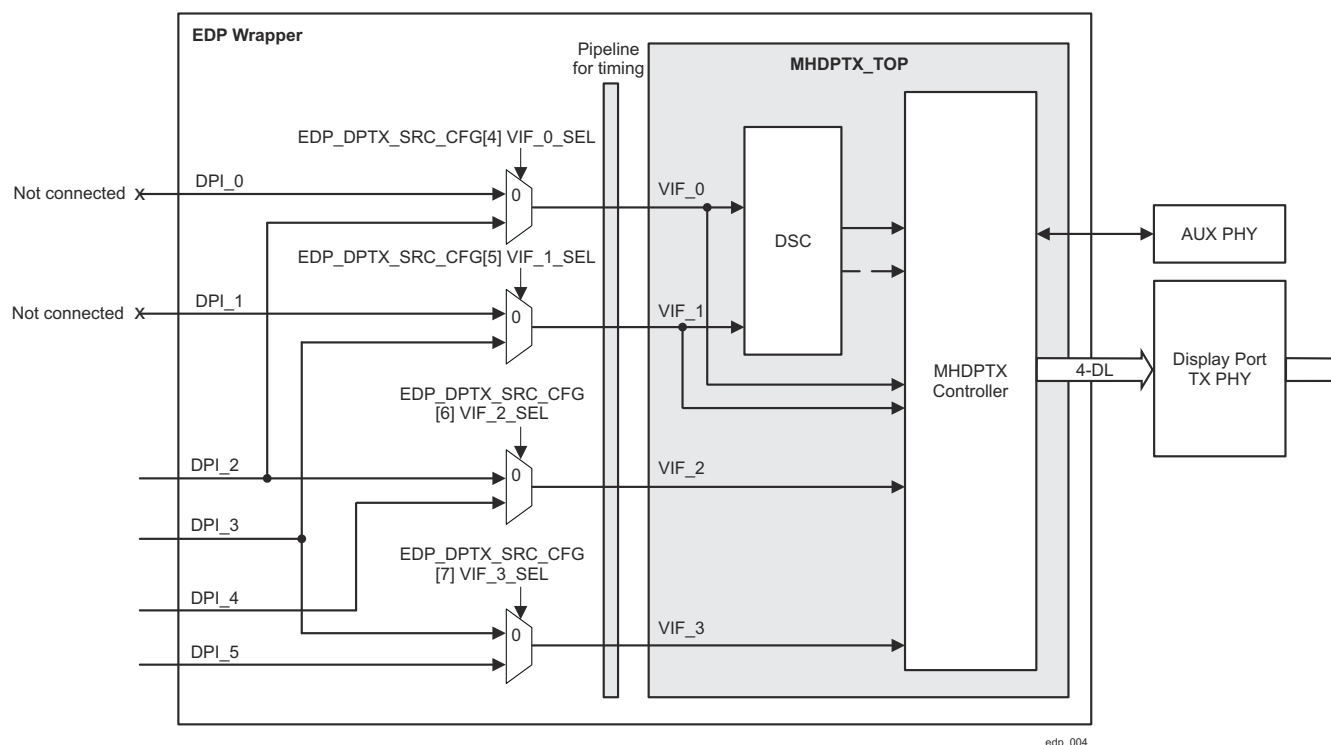

Figure 12-472. DP Wrapper DPI Data Muxing and VIF Mapping

The following data stream transport modes are supported by the DPI data mapping to VIF ports:

SST Mode (Single Stream Transport) – VIF0 used

- DPI_2 - Single Panel Input (optional DSC compression) mapped to VIF0
- DPI_2/DPI_3 - Split Panel Dual Inputs (for DSC compression only) mapped to VIF0 (via DSC) (see Note 1)

MST Mode (Multi-Stream Transport) – All VIFs used

- DPI_2 - Single Panel Input (optional DSC compression) mapped to VIF0
- DPI_3 - Single Panel Input (optional DSC compression in dual panel mode) mapped to VIF1 (see Note 2 and Note 3)
- DPI_2/DPI_3 - Split Panel Dual Inputs (for DSC compression only - two L/R streams compressed separately but outputs combined as one stream) with compressed output mapped to VIF0 (via DSC)
- DPI_2 or DPI_4 - Single Panel Input (no DSC compression) mapped to VIF2
- DPI_3 or DPI_5 - Single Panel Input (no DSC compression) mapped to VIF3

Notes:

1. DSC can be enabled to perform compression on a single input stream as Left and Right panel data for high resolution video (pixel clock > ~400 MHz) that cannot be compressed with a single DSC encoder. In this mode, two input streams share the same video timing (vs/hs/de) and identical input pixel clocks. This mode is referred to as **"split panel mode"**.

2. DSC can also be enabled to perform compression of two unrelated input streams of the same resolution. These streams must share the same pixel input clock since the DSC encoders require two encoder clocks to be synchronous. But, in this case, two streams can be asynchronous in terms of video timing (vs/hs/de). This mode is also referred to as **"dual panel mode"**.
3. When DSC is using only one encoder, then it is required to be on Enc0 input (meaning the stream to be compressed must be on DPI_2). In MST mode (where this constraint is applicable), the single stream that is to be compressed must be placed on DPI_2 and therefore the DP sink device (that receives the compressed stream) will be assigned to receive the STREAM_0.

When DSC is in split or dual panel mode, the DSS uses a common clock to send two streams. In the EDP, two DSC input clocks are sourced from the same DPI_2 source clock to keep these clocks to be the same (per DSC requirement) in order to minimize the skew between two DSC encoder clocks.

For detailed description of the clock diagrams, including the clock muxes per data selection, refer to [Section 12.6.5.5.1, Clock Diagram](#).

12.6.5.2.2 Secure Video Content Protection

Each DPI_n input port includes a 48-bit DPI_n_M_MDATA bus from DSS (DISPC) which carries attribute sideband signals associated with the DPI interface. The EDP sets the security status (DPISECURE) of the incoming DPI interface using the DPI_n_M_MDATA[10] bit as shown in [Table 12-446](#).

Table 12-446. EDP Secure Video Content Protection

Sideband bit(s)	Name	Description
DPI_n_M_MDATA[10]	DPISECURE	DPI-np secure bit 1: DPI-np is secure 0: DPI-np is not secure

The EDP performs a simple security check on the selected DPI connection by comparing the value of the selected DPISECURE bit (per EDP_DPTX_SRC_CFG[7-4] VIF_n_SEL bits (where n = 0 to 3)) to the EDP_DPTX_VIF_SECURE_MODE_CFG[3-0] VIF_n bits.

If the selected DPISECURE bit is set to 1, the video content is considered to be secure and the connection (transmission via DPTX) is only made if the EDP_DPTX_VIF_SECURE_MODE_CFG[3-0] VIF_n bits are also set to 1 (indicating the display is also secure). Otherwise, the EDP forces the DSS_DPI_DATA to be 0h while leaving the sync signals alone – in effect, causing the video to go black. If the DPISECURE bit is set to 0, then the connection is also enabled.

12.6.5.2.3 DPI_DATA Input Pixel Format Supported

[Figure 12-473](#) shows the supported by the EDP pixel packing formats in the DSS_DPI_DATA.

Default: **RGB121212** - 36-bit pixel data (12 bpc) LSB aligned in 48-bit data bus

Optional: **RGB101010** - 30-bit pixel data (10 bpc) LSB aligned in 48-bit data bus

EDP_005

Figure 12-473. EDP Wrapper Supported Input DSS_DPI_DATA Pixel Formats

The selection between these two formats is made per VIF_n source by configuration EDP_DPTX_SRC_CFG[11-8] VIF_n_IN30B parameters. The default is 36-bit format (RGB121212). Optionally, the 30-bit format (which is the pixel format when the DPI_data is generated from the DSS's merge/split module) can be selected to match the DSS configuration.

Internally, the EDP wrapper performs following pixel data/component realignments to match the input pixel data alignment required by the MHDPTX core (MSB alignment) and DSC (native LSB alignment).

Figure 12-474 shows the internal mapping from the LSB packed pixel bus to MSB-aligned container packed bus: the 30 or 36-bit pixel data remapped to 48-bit (16 bpc (bits per component) MSB aligned within color component). The MHDPTX core extracts MSB 8/10/12-bits from each 16-bit color component to include in the display port video transport packet (see Table 12-447, *EDP Video Interface Pixel Mapping (MSB Mapping)*).

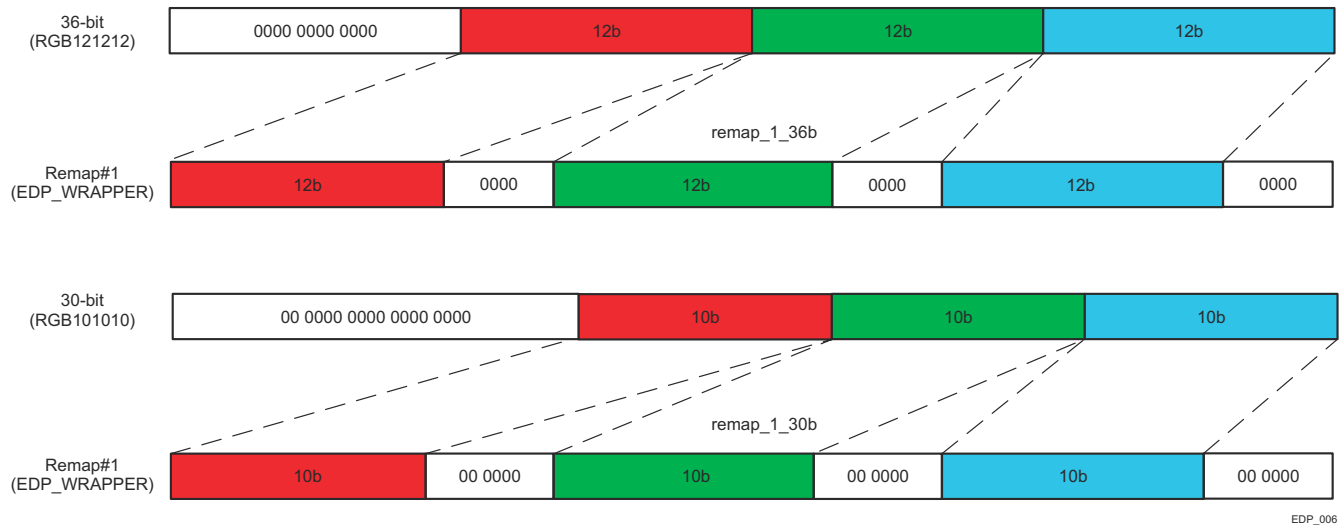

Figure 12-474. EDP Wrapper Internal Pixel Bus Remapping (First Stage)

DSC Input Data Re-alignment (Optional for DSC enabled VIF_0 and VIF_1) – From the 48-bit aligned data bus, the EDP wrapper performs additional re-alignment (LSB aligned component data per DSC requirement) and pixel data alignment per DSC input processing bit size configuration.

For this LSB alignment, EDP_DPTX_DSC_CFG[6-5] DSC_1/0_10BPC bits must be configured to extract significant 8 or 10-bit component data from the input pixel bus, as shown on Figure 12-475.

The parameters in these bits must match the parameters in the EDP_CORE_ENC0_MAIN_CONF_P/EDP_CORE_ENC1_MAIN_CONF_P[1-0] IPUT_BPC bitfields.

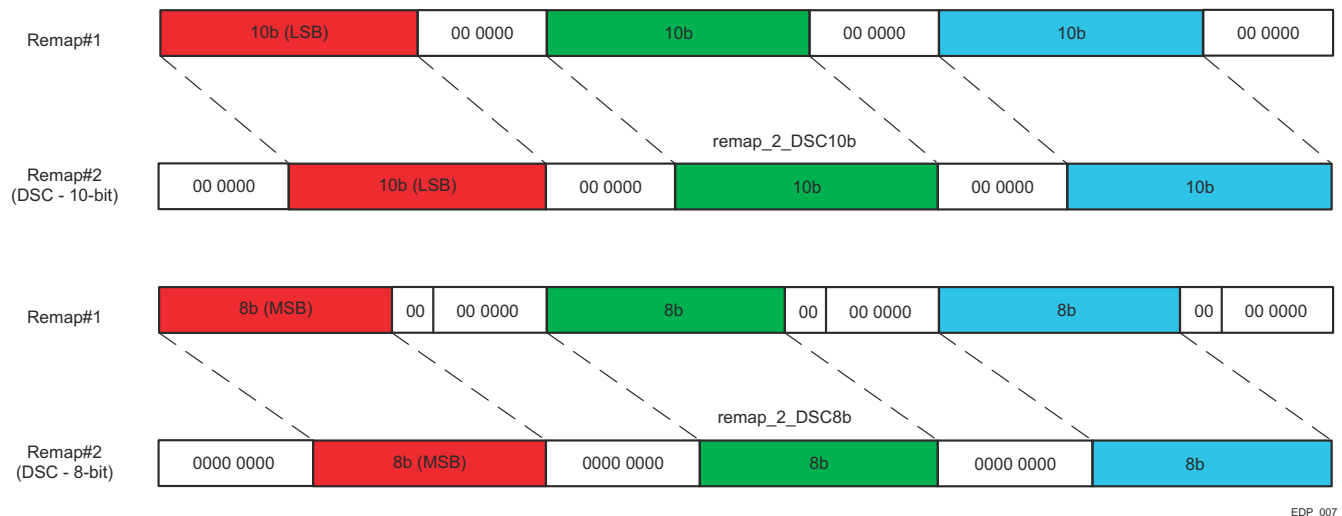

Figure 12-475. EDP Wrapper Internal Pixel Remapping (Additional for DSC Bound Pixel Data Bus)

Pixel data alignment within the MHDPTX_TOP should be set to be MSB always to enable the pixel mapping, as shown in Table 12-447. DSC bound pixel data bus is to be LSB aligned and requires no other MHDPTX_TOP configuration.

Table 12-447. EDP Wrapper Video Interface Pixel Mapping (MSB Mapping)

Video Bus	Source RGB/YCbCr444 (C of YCbCr422 ⁽²⁾)				
	Bit Width	8-bit	10-bit	12-bit	16-bit ⁽¹⁾
Channel 2	[47:40]	R/Cr[15:8] / C[15:8]	R/Cr[15:6] / C[15:6]	R/Cr[15:4] / C[15:4]	R/Cr[15:0] / C[15:0]
	[39:38]				
	[37:36]				
	[35:32]				
Channel 1	[31:24]	G/Y[15:8]	G/Y[15:6]	G/Y[15:4]	G/Y[15:0]
	[23:22]				
	[21:20]				
	[19:16]				
Channel 0	[15:8]	B/Cb[15:8]	B/Cb[15:6]	B/Cb[15:4]	B/Cb[15:0]
	[7:6]				
	[5:4]				
	[3:0]				

(1) 16-bit source format is not supported. When selected, lower 4 bits are set to 0x0.

(2) YCbCr422 format is locally generated from YCbCr444 input from DSS (by a simple chroma decimation).

12.6.5.2.4 Audio Input Interface

The audio input interface provides the following features:

- One I2S interface configured to support multiple physical audio channels (up to 8-channels)
- Frame Format – TDM mode
 - Multiple Physical Channels N = 1, 2, or 4
 - Variable TDM time slots M = 2 or 8
 - Time slot size: 32, 24, or 16
 - Variable word length (28, 24, 20, 16) configured as left or right justified
- I2S_DATA - 4-bits wide
- Supports data rate up to 8-channel L-PCM @192 kHz (Buffer dependent)
- SPDIF mode is not supported

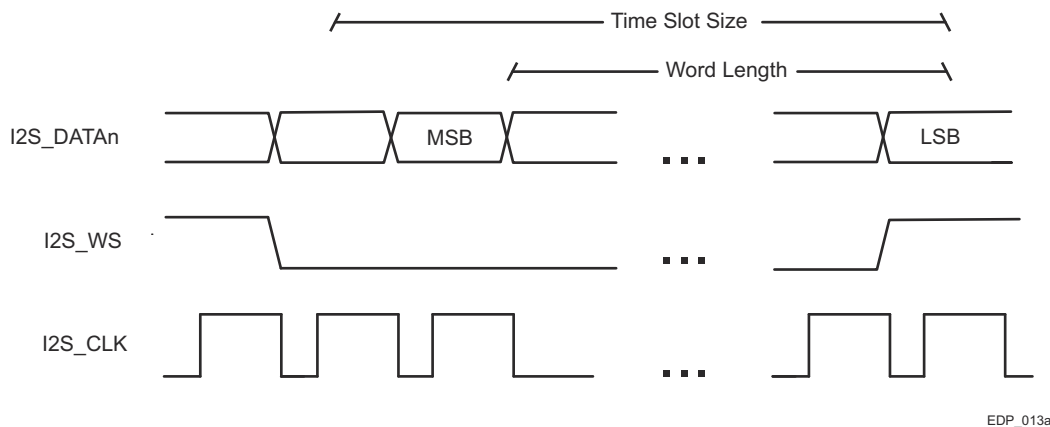

12.6.5.2.4.1 Audio I2S Signals/Timing

Table 12-448 shows the I2S signals and timing.

Table 12-448. EDP Audio I2S Signals/Timing

Signal Name	Direction	Default Value	Description
AIF_I2S_CLK	Input	1'd0	I2S clock
AIF_I2S_DATA[3:0]	Input	4'd0	I2S data for up to 4*M logical channels. Number of physical channels: 1, 2, or 4 M – number of time slots: 2 or 8
AIF_I2S_WS	Input	1'd0	I2S word-select indication. In TDM mode, WS = 0 indicates channel 0.

Figure 12-476 and Figure 12-477 show the I2S timing.

EDP_013a

Figure 12-476. EDP Audio I2S Timing - Bit Allocation (Right Justification)

EDP_013b

Figure 12-477. EDP Audio I2S Timing - TDM Time Slot Allocation (M = 8)

12.6.5.2.4.2 Audio I2S Clock Frequency

The bit clock frequency is defined as below:

- Bit clk freq = Sampling_rate * Number_of_bits_per_channel * Number_of_channels

For 16-bit/44.1 kHz stereo channels:

- I2S_CLK (freq) = 44.1 kHz x 16 x 2 = 1.4112 MHz

For 24-bit/192 kHz stereo channels:

- I2S_CLK (freq) = 192 kHz x 24 x 2 = 9.216 MHz

12.6.5.3 EDP Transmitter Controller Subsystem (MHDPTX_TOP)

The EDP Transmitter Controller Subsystem (MHDPTX_TOP) integrates the following major components:

- Display Stream Compression (DSC) v1.1 Encoder – VESA Compression Engine
- Display Port TX Controller (MHDPTX Controller) - EDP/DP Transmitter Controller

12.6.5.3.1 Display Stream Compression Encoder (DSC)

This module performs the VESA Digital Stream Compression encoding for the Display Port TX interface. The DSC contains two parallel Hard Slice Encoders, which support compression for VESA Display Port transmitter.

12.6.5.3.1.1 DSC Encoder Features

The DSC Encoder supports the following main features:

- Maximum image width and height per encoder slice can be configured with up to 8K
 - Programmable slice width and height
 - All slices must be the same height, including the final slice of the picture
- 8 bits/component (24 bits/pixel)
- 10 bits/component (30 bits/pixel)
 - An encoder built for 10 bits/component will be able to run in either 8 or 10 bits/component mode based on a register value

- RGB/YCbCr with 4:4:4 sampling support only on the input streams
- Single or Dual Pixel input(s)
 - Single pixel input (one encoder slice processing only)
 - Dual pixel inputs
 - Split Panel (Left/Right) streams – requires low skew between streams
- Support for all DSC 1.1 encoding mechanisms
 - MMAP, BP, MPP predictions and ICH
 - Flatness detection and signaling
- Supports CBR (Constant Bit Rate) mode only - Configurable target bpp (bits per pixel), non-integer values supported. The following modes are available:
 - 8 bpp and 12 bpp compressed bit rates for 8 bits/component - Corresponds to 3:1 and 2:1 compression
 - 10 bpp and 15 bpp compressed bit rates for 10 bits/component - Corresponds to 3:1 and 2:1 compression
 - 12 bpp and 18 bpp compressed bit rates for 12 bits/component
- Each Hard Slice encoder instance can be configured (with the parameter NB_SS_ENC) to support the following number of slices per line
 - Supports 1 or 2 slices (soft slices) per line
 - When configured with support for 2 slices per line, the encoder support dynamically the configuration of both 1 and 2 slices per line.
 - Thus a total of up to 4 slices per line can be supported with two Hard Slice Encoders
- Encoder data flow supported:
 - Synchronous Streaming mode – no back pressure support
- Implements the following active internal diagnostic mechanisms:
 - Self-Checking during VBLANK
 - Control output diagnostics
 - SRAM Protection
 - Configuration and Status Register (CSR) Protection
 - Fault avoidance mechanism

12.6.5.3.1.2 Usage Models for EDP

Table 12-449 summarizes the usage models supported by DSC instantiated in the MHDPTX_TOP subsystem.

Table 12-449. EDP DSC Usage Models

Usage Models			
	Single Panel Mode (SST/MST)	Split Panel Mode (SST/MST)	Dual Panel Mode (Only in MST)
ENC0	Stream 0 Full Frame	Stream 0 Left Frame	Stream 0
ENC1	Not Used	Stream 0 Right Frame	Stream 1

The shaded boxes in Table 12-449 indicate the encoder slice enabled for EDP usage. The active paths for these two modes are shown on Figure 12-478.

Figure 12-478. EDP DSC Single Input/1-Transport Link Mode and Split Panel/Dual Panel Mode

12.6.5.3.2 Display Port Transmitter Controller (MHDPTX Controller)

Figure 12-479 shows a simplified block diagram of the EDP Display Port Transmitter Controller (MHDPTX) that is included in the EDP subsystem.

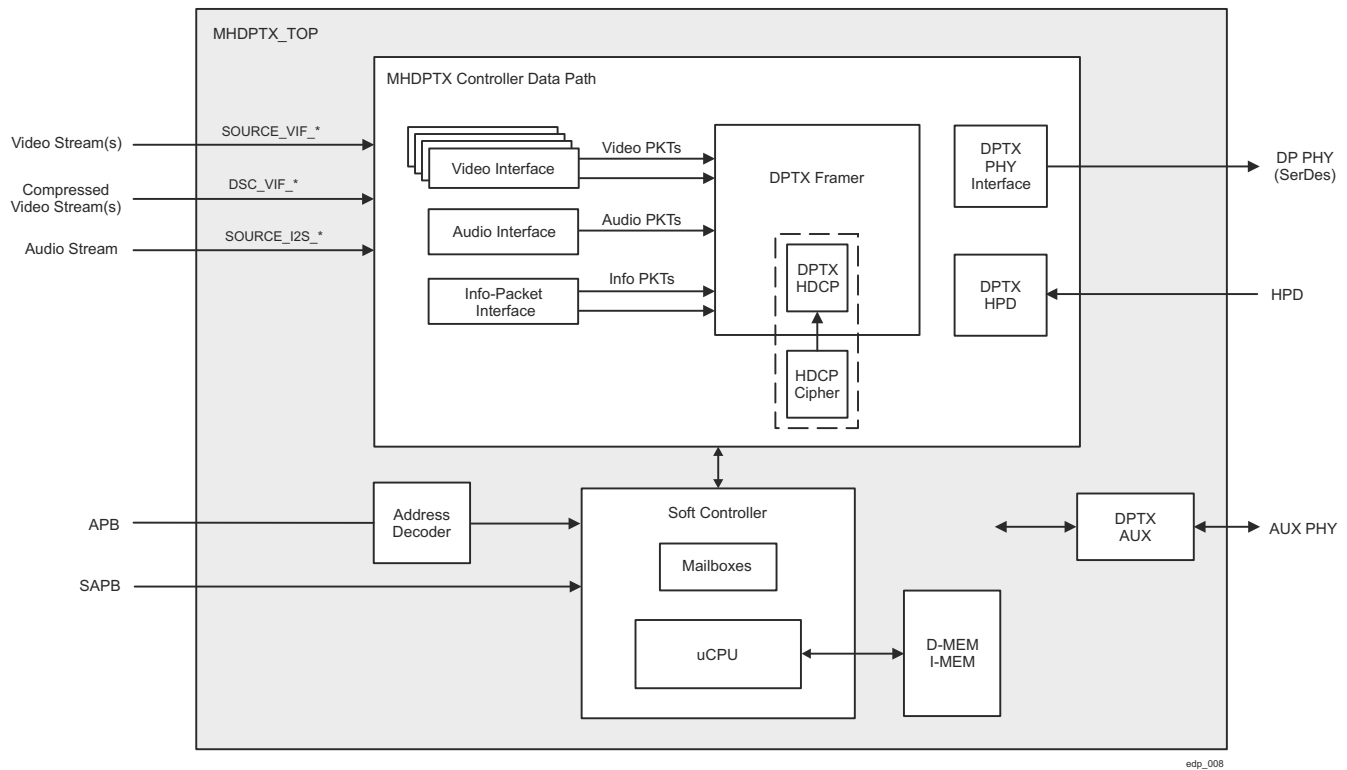

Figure 12-479. EDP Display Port Transmitter Controller Functional Block Diagram

n = 0 to 3

12.6.5.3.2.1 EDP Transmitter Controller Mode Configurations

This section describes the configuration mode input signals of the MHDPTX_TOP module.

SOURCE_SECURE_MODE

This mode configuration signal sets the "source_secure_mode" of the MHDPTX's APB interface to provide additional security control on the host interface. The main APB interface in "debug" mode can be used to access almost all internal registers as well as IIRAM/DRAM of the internal uCPU. This signal must be set to 0 to load FW during boot time. By setting SOURCE_SECURE_MODE to 1, this functionality can be disabled to only allow mailbox and basic control register accesses.

In EDP, this signal is mapped to a wrapper level configuration register within the EDP_CFG region: EDP_DPTX_IPCFG[0] APB_SECURE_REG_BLOCK_EN. If tempering of this register should be blocked, the EDP_CFG region should be firewalled to grant access only to a secure host only.

If the DP firmware regions are needed to be protected (to prevent either corruption or altering of the firmware), a secure host can change this setting to 1 after initializing the firmware memories. Then, a non-secure host can come and take the CPU out of reset and enable the DP function without an ability to alter the firmware.

SOURCE_CRYPTO_DIS

This mode configuration signal is used to completely disable HDCP functionality by disabling Crypto module (module responsible for keys encryption during authentication). Refer to *EDP eFuse Tie-Off*, for eFuse tie-off information.

12.6.5.4 EDP AUX_PHY Interface

The AUX PHY module is required for each Display Port interface. The AUX_PHY module is integrated with the EDP controller as shown on [Figure 12-480](#). The AUX PHY has no configuration interface. All configuration and control signals are supplied from EDP_CORE_APB memory-mapped registers.

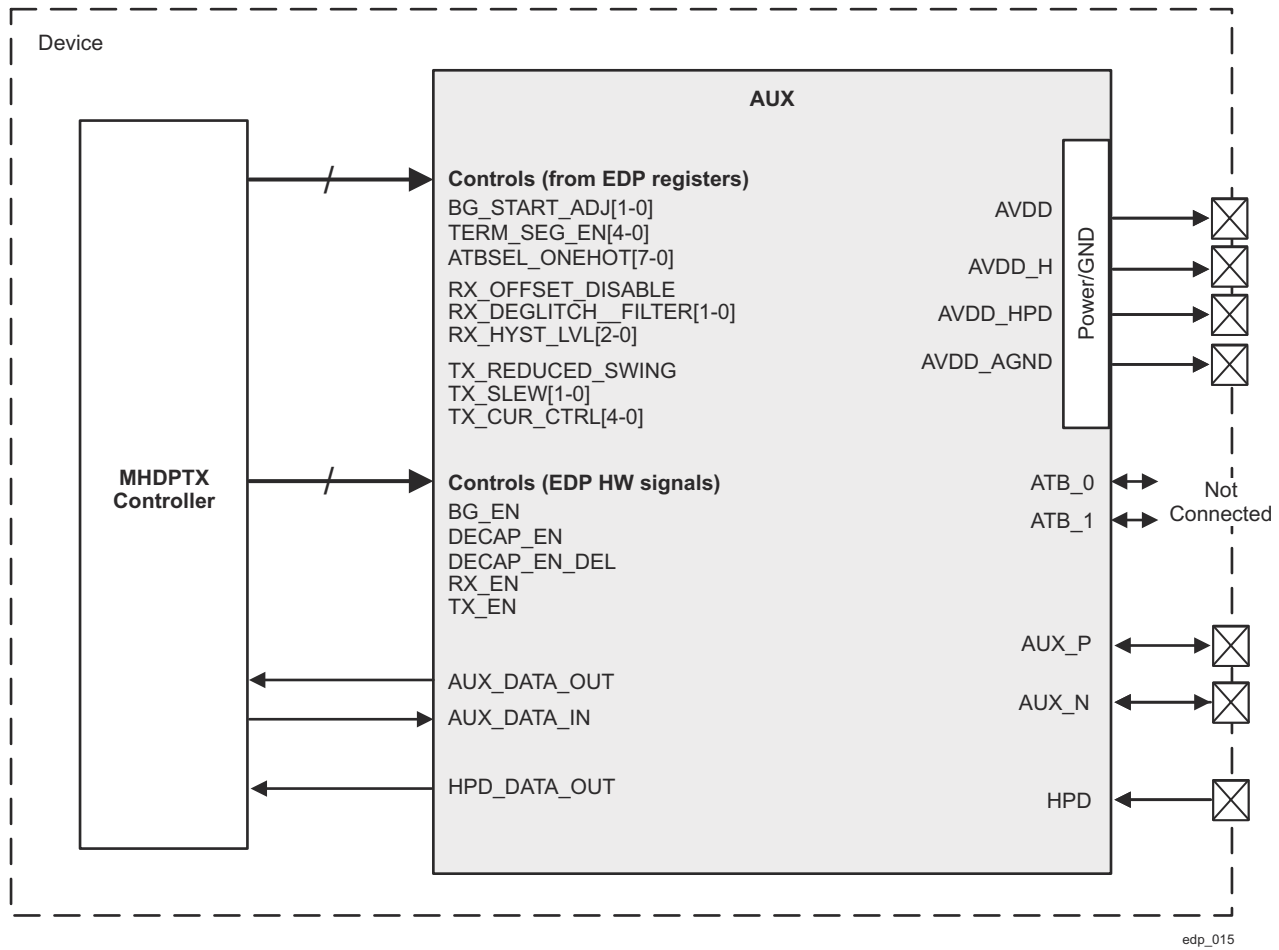

Figure 12-480. EDP Interface to AUX PHY

The configurations and controls in [Figure 12-480](#) are specified through EDP_CORE_AUX_CONFIG_P and EDP_CORE_AUX_CTRL_P registers.

12.6.5.5 EDP Clocks

12.6.5.5.1 Clock Diagram

[Figure 12-481](#) shows the input clocks of eDP and muxing on the DPI input clocks to match the pixel data selection.

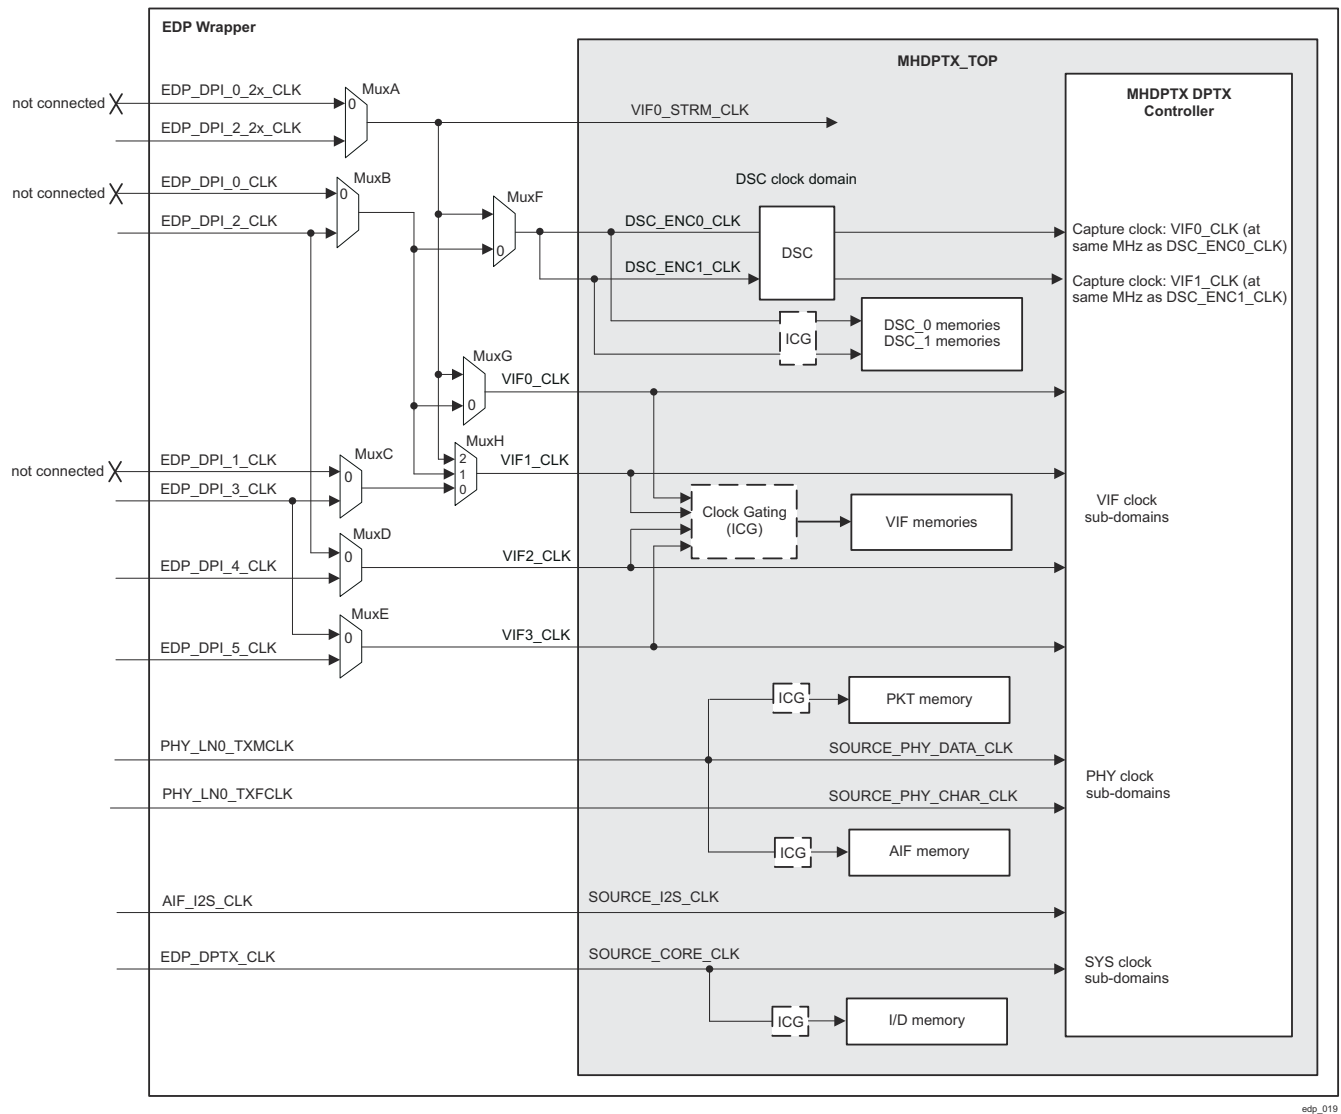

Figure 12-481. EDP Clock Diagram

12.6.5.5.1.1 DPI Interface Clock Sourcing

In default (non-DSC enabled) modes, the EDP performs the matching pixel data clock selection (MuxA - MuxE) based only on the VIF input source selection (EDP_DTPX_SRC_CFG[7-4] VIF_n_SEL register fields) settings.

For VIF0_CLK, the source selection in non-DSC enabled mode comes from the output of MuxA (EDP_DPI_0_2x_CLK or EDP_DPI_2_2x_CLK). These clocks are full pixel data frequency clocks.

When DSC is enabled, the DSC_ENC0_CLK and DSC_ENC1_CLK clocks are sourced (MuxF) from:

- Full pixel data frequency clock (MuxA selected clock) - when DSC is configured in a non-split panel mode (EDP_DPTX_DSC_CFG[1-0] MODE_SEL != 0h AND EDP_DPTX_DSC_CFG[2] SPLIT_PANEL_EN = 0h)
- Half pixel data frequency clock (MuxB selected clock) – when DSC is configured in the split panel mode (EDP_DPTX_DSC_CFG[1-0] MODE_SEL = 2h AND eDP_DPTX_DSC_CFG[2] SPLIT_PANEL_EN = 1h)

VIF0_CLK and VIF1_CLK selection goes through additional muxing (MuxG/MuxH) to match the DSC encoder clocks.

12.6.5.5.1.2 Memory Clock Gating

Memory clock gating is handled at the wrapper based on the scheme described below.

Functional mode clock enable (functional clock gating – for memory):

- DPTX firmware memory (I/D mem) clocks are enabled when EDP_DPTX_IPCFG[1] FW_MEM_CLK_EN = 1.
- Memory clocks for all DPTX data memories in the normal functional mode are only enabled when the corresponding source (video/audio/pif) is enabled per DPTX_SRC_CFG.
 - Clocks for the video stream memories (vif_mem) are enabled whenever the stream is enabled (EDP_DPTX_SRC_CFG[3-0] VIF_n_EN).
 - Clocks for the packet memories (pkt_mem) are enabled whenever the packet stream interface is enabled (EDP_DPTX_SRC_CFG[3-0] VIF_n_EN).
 - Similarly clock for the audio buffer (aif_mem) is enabled whenever the audio stream is enabled (EDP_DPTX_SRC_CFG[16] AIF_EN).
- Clocks for the DSC memories (DSC_ENC0 and DSC_ENC1 mem) are enabled based on the ENC0/ENC1 usage (EDP_DPTX_DSC_CFG[1-0] MODE_SEL). When EDP_DPTX_DSC_CFG[1-0] MODE_SEL is not 0 (that is, at least one DSC encoder is enabled), the wrapper enables VIF_n_MEM clock based on the DSC usage

Functional mode clock enable override:

- Clocks for all ECC memories can be forced to turn on (that is, functional clock gating bypassed) during ECC diagnostic access mode by setting EDP_ECC_MEM_CFG[0] CLK_EN = 1.

12.6.5.5.1.3 PHY Clock Connections

There are multiple clocks from/to the physical interface. Figure 12-482 shows clocks used for the PHY clock domain logic (TXMCLK/TXFCLK) and for the return data clock (TXCLK). Not shown in the diagram are RX mode input clocks unused by EDP (TX only mode) – PHY_INn_RXCLK/RXFCLK/REFCLK.

Figure 12-482. EDP PHY Clock Connections

12.6.5.5.2 Clock Groups

Following are the major groups of clocks in the EDP subsystem:

- System clock – This is the VBUSP configuration clock. It is used to source the clock for all internal configuration interfaces (VBUSP and PAB) and the core logic of the MHDPTX controller.
- DPI clocks - These are video stream source clocks. These can be sourced either directly from PLL or DSS (that is, DPI_CLK outputs, DSS sourced mode).

- PHY I/O clocks - These are clocks used to transmit display port raw data to the SERDES or the clock used to receive audio data from MCASP.

Table 12-450 describes clocks at the EDP boundary.

Table 12-450. EDP Clocks

Clock	Freq Min	Freq Max	Source	Description
EDP_DPTX_CLK	125 MHz	125 MHz	System PLL	Functional clock (all VBUSP/APB/DPTX_core logics are clocked by this clock) Valid Freq: 100 – 200 MHz (125 MHz chosen to be 1/4x of CBASS 500 MHz clock)
EDP_DPI_2_2x_CLK	25 MHz	600 MHz	Video PLL or DSS EDP_DPI_2x_CLK	DPI Streaming Clock – Typically 1x of the corresponding EDP_DPI_2_CLK. But, in DSC split-panel mode, 2x of the EDP_DPI_2_CLK
EDP_DPI_2/3/4/5_CLK	25 MHz	600 MHz	Video PLL or DSS EDP_DPI_CLK	DPI Clock – pixel clock of the EDP_DPI_DATA bus. In DSS-sourced mode, EDP_DPI_n_CLK is the pixel clock of the EDP_DPI_n_DATA bus. In PLL-sourced mode, the pixel clock needs to be internally muxed between EDP_DPI_2_2x_CLK and EDP_DPI_2_CLK depending on the EDP_DPI_DATA type (split panel data or not).
EDP_AIF_I2S_CLK	1 MHz	125 MHz	MCASP	Audio I2S Clock (192 kHz clock)
PHY_LN0_TXMCLK (SOURCE_PHY_DATA_CLK)	81 MHz	405 MHz	DP-SERDES (PHY) PLL	PHY Data clock (1/2 Char Clock)
PHY_LN0_TXFCLK (SOURCE_PHY_CHAR_CLK)	162 MHz	810 MHz	DP-SERDES (PHY) PLL	PHY Char Clock

12.6.5.6 EDP Resets

The EDP subsystem has one synchronous active low reset input. The entire subsystem is reset by this reset. All resets for different clock domains (both synchronous and asynchronous) are generated internally using this reset.

All resets within the MHDPTX_TOP are asynchronous. Each clock's sub-domain resets are synchronized with respective software reset.

12.6.5.7 EDP Interrupt Requests

The interrupt signals generated by the EDP subsystem and propagated to SoC level are shown in Table 12-451.

Table 12-451. EDP Subsystem Interrupts

Interrupt	Description
EDP_INTR[3:0]	EDP Controller Interrupt Event (Functional)
EDP_INTR_ASF[6:0]	EDP Controller ASF Error Interrupt

12.6.5.7.1 EDP_INTR Interrupt Description

Table 12-452 provides details on the EDP_INTR[3:0] interrupt lines. Each of the interrupts listed in Table 12-452 has a corresponding set of memory-mapped interrupt registers (status/mask/clear).

Table 12-452. EDP_INTR Interrupts

Interrupt Bit	Source	Description	Status Register	Mask Register	Clear Register
[3]	DSC	DSC Enc1 interrupt event detected	EDP_CORE_ENC1_IN T_STAT_P	EDP_CORE_ENC1_IN T_MASK_P	EDP_CORE_ENC1_IN T_CLR_P
[2]		DSC Enc0 interrupt event detected	EDP_CORE_ENC0_IN T_STAT_P	EDP_CORE_ENC0_IN T_MASK_P	EDP_CORE_ENC0_IN T_CLR_P

Table 12-452. EDP_INTR Interrupts (continued)

Interrupt Bit	Source	Description	Status Register	Mask Register	Clear Register
[1]	MHDPTX Controller	DPTX SIRQ - Secure APB domain interrupt event. Set when an interrupt in the status register is reported.	EDP_CORE_APB_STA_TUS_S	EDP_CORE_APB_INT_MASK_S	-
[0]		DPTX PIRQ - General DPTX interrupt event. Set when an interrupt in the status register is reported.	EDP_CORE_APB_INT_STATUS_P	EDP_CORE_APB_INT_MASK_P	-

12.6.5.7.2 EDP_INTR_ASF Interrupt Description

Table 12-453 provides details on the EDP_INTR_ASF[6:0] interrupts lines. Each of the interrupts listed in Table 12-453 has corresponding set of memory-mapped interrupt registers (status/mask/clear).

Table 12-453. EDP_INTR_ASF Interrupts

Interrupt Bit	Source	Description	Status Register	Mask Register	Clear Register
[6]	ECC_AGGR_DSC	ECC Aggregator Uncorrected Error Interrupt	EDP_ECC_DSC_DED_STATUS_REG0	EDP_ECC_DSC_DED_ENABLE_SET_REG0	EDP_ECC_DSC_DED_ENABLE_CLR_REG0
[5]	ECC_AGGR_PHY	ECC Aggregator Uncorrected Error Interrupt	EDP_ECC_PHY_DED_STATUS_REG0	EDP_ECC_PHY_DED_ENABLE_SET_REG0	EDP_ECC_PHY_DED_ENABLE_CLR_REG0
[4]	ECC_AGGR_CORE	ECC Aggregator Uncorrected Error Interrupt	EDP_ECC_CORE_DED_STATUS_REG0	EDP_ECC_CORE_DED_ENABLE_SET_REG0	EDP_ECC_CORE_DED_ENABLE_CLR_REG0
[3]	DSC	ASF Corrected interrupt detected in DSC	EDP_CORE_ENC_ASF_INT_STAT_P	EDP_CORE_ENC_ASF_INT_MASK_P	EDP_CORE_ENC_ASF_INT_CLR_P
[2]		ASF Un-Corrected interrupt detected in DSC			
[1]	MHDPTX Controller	ASF Corrected (NonFatal) event detected in MHDPTX Controller. Set if non-fatal error occurs.	EDP_CORE_ASF_INT_STATUS ⁽¹⁾	EDP_CORE_ASF_INT_MASK ⁽¹⁾	-
[0]		ASF Un-corrected (Fatal) event detected in MHDPTX Controller. Set when fatal error occurs.			

(1) Each interrupt can be individually defined as fatal or non-fatal in the EDP_CORE_ASF_FATAL_NONFATAL_SELECT register.

12.6.5.8 EDP Embedded Memories

12.6.5.8.1 MHDPTX Controller Memories

Table 12-454. EDP MHDPTX Controller Memories

Name	ECC	Description
IRAM	Yes	uCPU Instruction Memory. Contains uCPU FW, loaded by host during boot time.
DRAM	Yes	uCPU DATA Memory. Contains uCPU data-memory, mailbox for communication between uCPU and host processor and EDID segment. In DisplayPort mode, it contains DPCD registers and AUX mailbox. In HDMI mode, it contains SCDC standard registers. When HDCP is supported, it contains keys and protected information.
PKT_MEM_n (n = 0 to 3)	Yes	Source Packet Memory. Contains up to 16 info-frames. Accessed by host processor (over APB) for write and by HD Display TX Controller for read.

Table 12-454. EDP MHDPTX Controller Memories (continued)

Name	ECC	Description
VIF_MEM_n (n = 0 to 3)	No (No ECC for the video buffer)	Video Memory. Elastic buffer, compensating the difference between the pixel clock and the line clock.
AIF_MEM	Yes	Audio Memory. Buffer audio samples during H active period.

12.6.5.8.2 DSC Memories**Table 12-455. EDP DSC Memories**

Name	ECC	Description
ENC0/1_LB	Yes	Line Buffer RAM. Stores the reconstructed pixels that will be re-used for next line processing.
ENC0/1_OB0	Yes	Output Buffer RAM. Holds (as FIFO) results of encoder slices.
ENC0/1_SSM_S	Yes	Sub-stream Mux Size RAM. Holds context information required to generate the proper order of the mux words.
ENC0/1_SSM_D	Yes	Sub-stream mux balance FIFO RAM. Holds stream data for re-ordering.

12.6.5.8.3 ECC Aggregation

The tasks of ECC detection/correction of 'ECC enabled' memories are handled within the MHDPTX Controller. The EDP wrapper provides 'ECC error injection' using a combination of ECC_Wrapper (to access the memory) and ECC_Aggregator (to allow system to access the ECC injection logic). An ECC_Aggregator can access multiple ECC_Wrappers of the same clock group. [Table 12-456](#) shows how the ECC memories (and the EDC_CTRL for Parity Inv) in the EDP are grouped to three ECC aggregators.

Table 12-456. EDP ECC_Aggregator (Based on Clock Group)

Memory / Logic	ECC Vector_ID	ECC_Aggregator
IRAM	0	ECC_AGGR_CORE
DRAM	1	
EDC_CTRL (Parity)	2	
PKT_MEM_0	0	ECC_AGGR_PHY
PKT_MEM_1	1	
PKT_MEM_2	2	
PKT_MEM_3	3	
AIF_MEM	4	N/A (No ECC for the video buffer)
VIF_MEM_0	-	
VIF_MEM_1	-	
VIF_MEM_2	-	
VIF_MEM_3	-	ECC_AGGR_DSC
ENC0_LB	0	
ENC0_SSM_S	1	
ENC0_SSM_D	2	
ENC0_OB0	3	
ENC1_LB	4	
ENC1_SSM_S	5	
ENC1_SSM_D	6	
ENC1_OB0	7	

Furthermore, each ECC_Aggregator is connected to the VBUSP_CFG via the main CBASS SCR (with asynchronous bridge). All ECC aggregator bound VBUSP_CFG transactions are mapped to a separate RSEL (in EDP case, RSEL=3), see [Figure 12-483](#).

Each ECC_Aggregator and the asynchronous VBUSP interface of the aggregator are clocked using the read clocks used to read the memory, as follows:

- ECC_AGGR_CORE: EDP_DPTX_CLK
- ECC_AGGR_PHY: SOURCE_PHY_DATA_CLK (PHY_LN0_TXMCLK)
- ECC_AGGR_DSC: EDP_DPI_0_CLK or EDP_DPI_2_CLK (selected by mux)

The clocks to some ECC memories may be disabled when the associated video or audio channel is not enabled. If none of the memories for an ECC aggregator is enabled (for example, DSC memory clocks are disabled, if the DSC is not enabled), then the clock for the aggregator is also disabled and the aggregator is disconnected from the CBASS (resulting in null return for any VBUSP access to the aggregator)

But, if any of the ECC memories connected to an ECC aggregator is enabled, the clock for the ECC aggregator must also be enabled. Any access to the ECC_CTRL of the disabled memory will result in TIMEOUT error (interrupt generated) since the memory clock is not running.

If ECC diagnostics/access are needed for all ECC memories whether the memories are enabled or not, the ECC software can set the clock enable override configuration register - EDP_ECC_MEM_CFG[0] CLK_EN to bypass the clock gating.

Even with this bit set, the ECC_CTRL connected to the ECC_AGGR_PHY aggregator may not get any clock if the PHY is not enabled and properly configured. The EDP_PHY_CLK_STATUS[0] VALID status register tells whether the PHY data clock is running or not.

The DSC clock is sourced from the system video PLL and therefore it should be running. Therefore, the ECC software just need to ensure the clock gating is not active and/or set the ECC CLK_EN override bit to get the clock to the memory.

The ECC_CORE Aggregator clock should be running whenever the EDP is enabled. There is no clock gating to the IRAM/DRAM memories.

12.6.5.9 EDP Programmer's Guide

12.6.5.9.1 EDP Controller Programming

Table 12-457 provides a summary of the bus interfaces and the MMR regions mapped to each interface in this module.

Region Name	Firewall Secure Mode Settings ⁽¹⁾ (2)
INTG_CFG_VP	Should be Secure
V2A_CORE_VP_REGS_APB	Secure (for Secure display) / Non-secure
V2A_S_CORE_VP_REGS_SAPB	Must be Secure always (HDCP configuration)
MHDPTX_WRAPPER_ECC_AGGR_CORE_CFG	Secure (for Secure display) / Non-secure
MHDPTX_WRAPPER_ECC_AGGR_PHY_CFG	Secure (for Secure display) / Non-secure
MHDPTX_WRAPPER_ECC_AGGR_DSC_CFG	Secure (for Secure display) / Non-secure

2046 J784S4 AM69x TDA4VH TDA4AH TDA4VP TDA4AP
J742S2 AM69x-27 TDA4VPE TDA4APE Processors
Texas Instruments Families of Products

- The V2A_S_CORE_VP_REGS_SAPB (secure APB) region must be restricted to secure host access only (for HDCP key protection)
 - The INTG_CFG_VP region should be set to secure host access only since this region controls the security of the DPI ports and controls the clock enables.
 - Other regions should be set to secure, if the display connected is to be secure.
- (2) Word-access only for RSEL (1 and 2) – accessing APB and SAPB regions of MHDPTX core. Any non-word access request will result in either rstatus=1 or sstatus=1.

Table 12-458 shows the MHDPTX Controller register/memory regions that are accessible during various operational modes:

Table 12-458. EDP MHDPTX Controller APB/SAPB Memory Map and Access Modes

Description	Address Base [19:0]	Register Bank	Direct access (x= APB (x= APB /SAPB)	Mailbox access (x= APB (x= APB /SAPB)	FW (uCPU) access	APB debug (Bootmode) access
Main configuration and Mailbox control registers. Each APB interface has its own set of these registers.	0x00000	APB_CFG	x			x

Fault reporting module	0x30B00	ASF	APB			x

Table 12-458. EDP MHDPTX Controller APB/SAPB Memory Map and Access Modes (continued)

Description	Address Base [19:0]	Register Bank	Direct access (x= APB (x= APB /SAPB)	Mailbox access (x= APB (x= APB /SAPB)	FW (uCPU) access	APB debug (Bootmode) access
DSC encoder	0x30C00 - 0x30F00	DSC	APB			x

Access Modes:

- APB Debug (Boot Mode) Access - After a hardware reset, MHDPTX comes up in this mode – allowing APB access to all regions including IMEM/DMEM (for FW download)
- Direct Access - Once the boot mode initialization is complete, APB_CTRL register is cleared. This takes it out of the Boot mode and into the direct access mode in which only the mailbox control (APB_CFG space) and regions marked as APB in the direct access column.
- Mailbox Access - While in Direct Access mode, all configurations of the DPTX for DP operation are done through the APB mailbox accesses. Secure transactions (secure refers to transactions to protect "secure" content) are done through the secure mailbox access via SAPB interface. The SAPB access is made through the secure EDP vbusp region (must be configured as such in the cfg Firewall)
- FW (uCPU) Access – This column indicates register/memory bank accessible by FW access.

12.6.5.9.1.2 Boot Sequence

After reset, the uCPU is disabled. The full MHDPTX Controller address space is accessible for the host processor for debugging purposes, and the I-MEM and D-MEM.

The host processor must perform the following:

- Load the FW into the memories.
- Enable the uCPU.
- Verify that FW is running as expected.

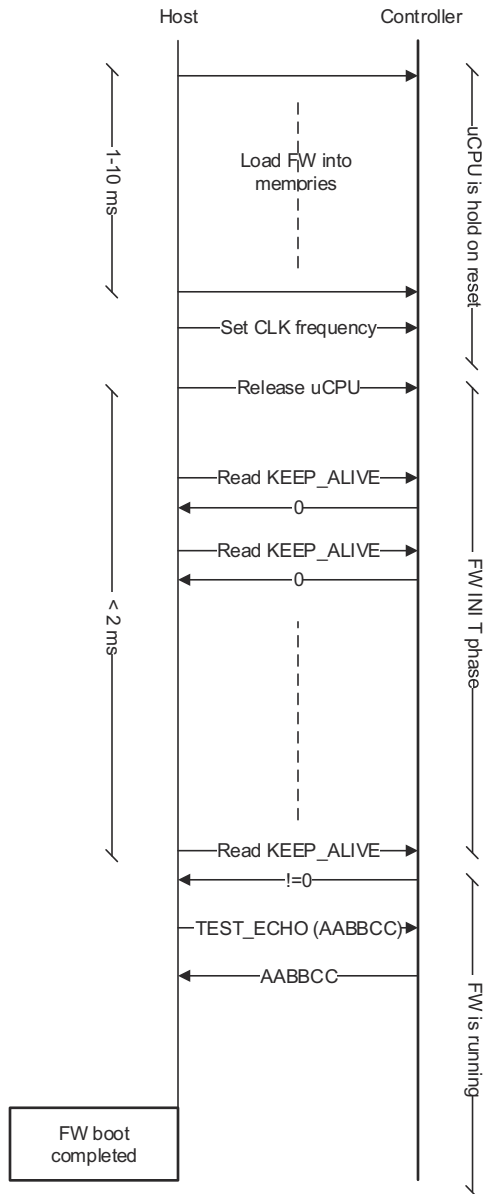

Figure 12-484. EDP MHDPTX Controller Boot Sequence

12.6.5.9.1.3 Setting Core Clock Frequency

The FW relies on a known core_clock frequency for configuring time HW dividers and timeout counters.

Therefore, core_clock frequency (SW_CLK_H, SW_CLK_I) must be configured by the host processor, prior to booting the FW.

12.6.5.9.1.4 Loading Firmware

The FW binaries are provided in the hexadecimal format that is composed from two files IRAM0.DATA and DRAM0.DATA.

The IRAM0.DATA contains the instruction memory and the DRAM0.DATA contains the variables initialization.

The external host processor should load the FW into the I-MEM and D-MEM, and enable the uCPU. Accessing the I-MEM, D-MEM is enabled only after reset (after reset, the system is going into debug mode, after loading FW and set EDP_CORE_APB_CTRL_P register to 0 system is going out from debug mode, and only reset can bring the system back to debug mode).

After loading the memories, the host processor should select the uCPU to be the master of the I-MEM and D-MEM memories, and enable the uCPU by writing 0x00 to the EDP_CORE_APB_CTRL_P register.

12.6.5.9.1.5 FW Running indication

After loading the FW, the embedded FW takes approximately 2ms to complete the INIT phase and start running. The EDP_CORE_KEEP_ALIVE_P register specifies whether the FW is running.

KEEP_ALIVE – The EDP_CORE_KEEP_ALIVE_P register is a counter initialized to 0 after reset and incremented by the FW on any scheduler loop.

When a valid FW is running, this register will be changed on every FW Scheduler loop (< 2ms). The host processor may use the mailbox channel immediately after reset, FW will response after the completion of INIT phase.

Operational mode

After completion of boot sequence, the FW set the MHDPTX Controller in a standby mode. In the standby mode, it is ensured that no transaction is executed over the external interfaces (that is, AUX, PHY, Video).

Switching into active mode is done by executing the GENERAL_MAIN_CONTROL command.

12.6.5.9.1.6 Software Events Handling

Software events are captured by the MHDPTX Controller FW, where the Event Value is stored in a designated area (in the D-MEM) and a bit is set by the FW in EDP_CORE_SW_EVENTS0_P register, see [Table 12-459](#).

The host processor should poll the EDP_CORE_SW_EVENTS0_P register (cleared after read) and following a detection of event(s) the host processor should call the relevant command which returns the Event Value.

The Event Value holds the latest value associated with the event.

The EDP_CORE_SW_EVENTS0_P register is not cleared by the FW. Therefore, it is recommended to read this register (dummy read) to initialize the events to zero.

While any bit in EDP_CORE_SW_EVENTS0_P register is set, the MHDPTX Controller raises a hardware interrupt.

Table 12-459. EDP MHDPTX Controller Software Events

Bit	Event	Description
31:8	RESERVED	-
7	HDCCP_TX_IS_RECEIVER_ID_VALID	IP has an ID to check if it is valid, HDCCP_TX_IS_RECEIVER_ID_VALID_REQ needs to be called.
6	HDCCP2_TX_STORE_KM	IP has Km to store, HDCCP2_TX_STORE_KM_REQ needs to be called.
5	HDCCP2_TX_IS_KM_STORED	IP need to check if Km is stored, HDCCP2_TX_IS_KM_STORED_REQ needs to be called.
4	HDCCP_TX_STATUS	HDCCP TX was changed, HDCCP_TX_STATUS_REQ needs to be called.
3:1	RESERVED	-
0	DPTX_HPDP	HPDP was changed, DPTX_READ_EVENT_REQUEST needs to be called.

12.6.5.9.1.7 DisplayPort Source (TX) Sequence

[Figure 12-485](#) shows the expected host processor and uCPU tasks executed to start a video/audio transmission.

Figure 12-485. EDP Operation Sequence – DisplayPort

Figure 12-486 shows the expected host processor and uCPU tasks executed for updating a video format and Figure 12-487 - the audio format.

Figure 12-486. EDP Operation Sequence – DisplayPort Video Format Change

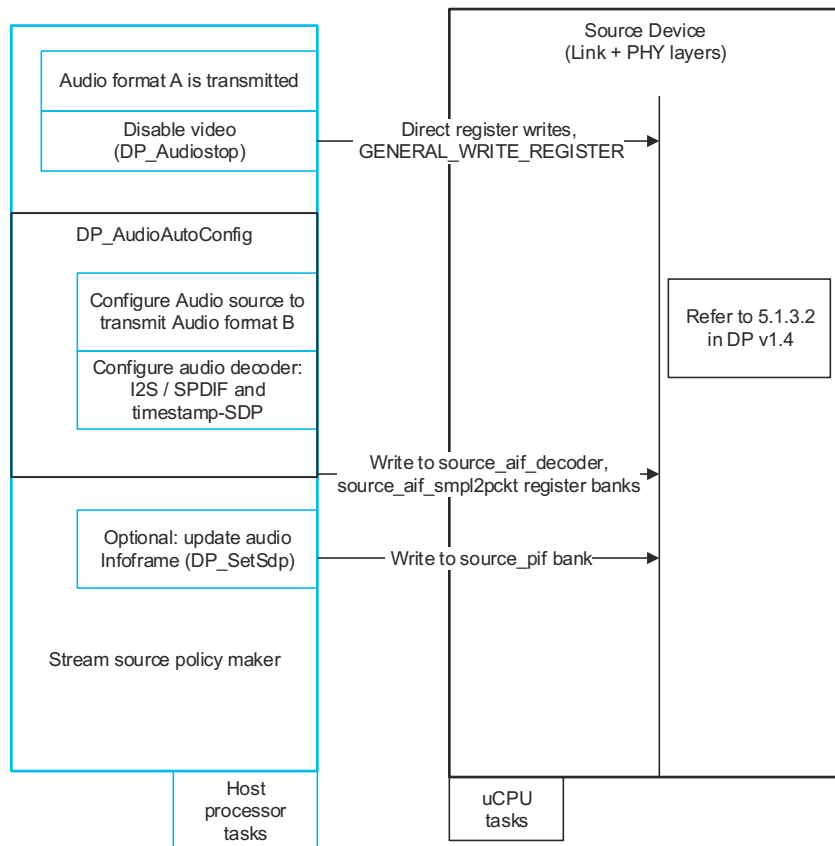

Figure 12-487. EDP Operation Sequence – DisplayPort Audio Format Change

12.6.5.9.1.8 HDCP

The FW supports embedded HDCP crypto, with optional Km-key encryption.

12.6.5.9.1.8.1 Embedded HDCP Crypto

In this mode, the HDCP functionality is fully supported by the MHDPTX Controller. The AKE phase and the corresponding cryptographic operations are handled by the FW.

Following the AKE phase, the FW initializes the stream cipher with the session key.

The host processor communicates with the MHDPTX Controller for:

- Configuring the capabilities
- Loading the HDCP keys (or certificate)
- Monitoring authentication status.

Note

Commands that carry secret information must be protected from tampering. Therefore, SAPB must be used to carry secured commands over mailbox.

Table 12-460. EDP HDCP Commands With Secret Information

HDCP command	Description
HDCP_GENERAL_2_SET_LC	Refer to HDCP 2.2 Appendix A
HDCP_GENERAL_SET_SEED	External TRNG must be used for generating a true random seed number. Therefore, it is expected that the seed number will meet the high entropy level.
HDCP2_TX_RESPOND_KM	Refer to HDCP 2.2 Appendix A
HDCP1_TX_SEND_KEYS	Refer to HDCP 1.4 Appendix B
HDCP2_TX_STORE_KM	Refer to HDCP 2.2 Appendix A

Figure 12-488 and Figure 12-489 show the operation sequences for an embedded HDCP 2.2 and HDCP 1.4

Figure 12-488. EDP Operation Sequence – Embedded HDCP 2.2

Figure 12-489. EDP Operation Sequence – Embedded HDCP 1.4

12.6.5.9.1.8.2 Additional Security Features

12.6.5.9.1.8.2.1 KM-Key Encryption

In order to provide higher security level an optional Km-key encryption is provided. If Km-key encryption is enabled while sending `HDCP1_TX_CONFIGURATION` command, then HDCP controller will expect Master Key, 1.4 Device Keys and Global Constant. These keys will be decrypted using Km-key (loaded using `HDCP2_TX_SET_KM_KEY_PARAMS` command) by the controller's internal Firmware and used during Authentication and Key Exchange procedure. The Km-key encryption will also assure that when host reads Master Key it will receive it in encrypted form.

Enabling Km-key encryption affects the following commands or their parameters:

- `HDCP2_TX_RESPOND_KM/Km`
- `HDCP1_TX_SEND_KEYS/Transmitter Device Key`
- `HDCP2_TX_STORE_KM_RESP/Km`
- `HDCP_GENERAL_2_SET_LC`

12.6.5.9.1.8.2.2 Cyphertext Stealing

In order to use Km-key encryption for the 1.4 Device Keys and avoid changes in the API a Cyphertext Stealing technique is used. This technique allows to apply AES-ECB in Km-key encryption while 1.4 Device Key does not have size equal to multiple of 16.

12.6.5.9.1.9 HD Display TX Controller

12.6.5.9.1.9.1 Info-Frame Handling

Info-frames, which include meta-data (that is, auto type or video format), are initialized by the host processor.

The host processor directly initializes the PKT-MEM (which stores the info-frames). Initialization includes loading info-frame into PKT-MEM and updating the PKT LUT. Refer to DP_SetSdp, DP_RemoveSdp.

12.6.5.9.1.9.1.1 EDID Handling

The MHDPTX Controller issues command for reading EDID data from the remote side (sink). The EDID is sent to the host processor in a single block, that is, each block in one message. The MHDPTX Controller does not parse the EDID blocks. Refer to DP_ReadEdid.

12.6.5.9.1.9.1.2 Audio Control

When changing an audio stream format, the host processor must follow a specific programming sequence by configuring the I2S decoder and audio info frame packet. Refer to DP_AudioAutoConfig.

12.6.5.9.1.9.1.3 Video Control

The host processor need to configure the video timing before enabling the video stream over the VIF interface.

12.6.5.9.1.10 DPTX TX Controller

12.6.5.9.1.10.1 Protocol over Auxiliary

The firmware provides an interface for the AUX and I2C-over-AUX data transactions. The host processor may use it for direct DPCD (including the HDCP address range) or EDID access.

12.6.5.9.1.10.2 PHY (Physical layer) Handling

Separate PHY driver is used to initialize PHY.

DPTX PHY is handled by Core Driver, during link training (that is, Lane count, Link Rate, Pre-emphasis and Voltage Swing control).

12.6.5.9.2 EDP PHY Wrapper Initialization

EDP connects to the SERDES PHY wrapper (WIZ) using the RAW data mode. To enable this connection, the WIZ configuration registers in the SERDES PHY must be configured. For details on the SERDES PHY wrapper configuration, see Section 10-G SerDes Programming Guide.

The following is an example configuration for enabling 4-data lane RAW data mode for Display Port connection.

// SERDES_TOP_CTRL register bit-field settings:

// PMA_CMN_REF_CLK_MODE = 2'b10, PMA_CMN_REF_CLK_INT_MODE = 2'b10,
PMA_CMN_REFCLK_DIG_DIV = 0, PMA_SUSPEND_OVERRIDE = 0

SERDES_TOP_CTRL register value = 32'h30000000

// SERDES_RST register bit-field settings:

// PHY_RESET_N = 0 (PHY in reset)

// PHY_EN_REFCLK = 0 (PHY reference clock output disabled)

// PLL1/0_REFCLK_SEL = 0 (for cmn_refclk_<p/m> select), 1 (for pma_cmn_refclk_int select)

// REFCLK_TERM_DIS = 1 (termination disabled)

// REFCLK_DIG_SEL = 1 (PMA common reference clock select: 0 for cmn_refclk_<p/m>, 1 – pma_cmn_refclk_int)

```
// If the reference clock is sourced from internal digital input:
// PLL1_REFCLK_SEL = 1, PLL0_REFCLK_SEL = 1, REFCLK_TERM_DIS = 1, REFCLK_DIG_SEL = 1
SERDES_RST register value = 32'h39000000

// Alternatively, if the reference clock is sourced from <p/m> inputs:
// PLL1_REFCLK_SEL = 0, PLL0_REFCLK_SEL = 0, REFCLK_TERM_DIS = 0, REFCLK_DIG_SEL = 0
SERDES_RST alternative register value = 32'h00000000

// LANECTLx register bit-field settings:
// P0_ENABLE = 0, P0_FORCE_ENABLE = 1, P0_ALIGN = 1, P0_RAW_AUTO_START = 1,
P0_STANDARD_MODE = 0, P0_FULLRT_DIV = 0
LANECTL0 register value = 32'h70000000 // for lane 0
// P0_ENABLE = 1, P0_FORCE_ENABLE = 0, P0_ALIGN = 0, P0_RAW_AUTO_START = 0,
P0_STANDARD_MODE = 0, P0_FULLRT_DIV = 0
LANECTL1 register value = 32'h80000000 // for lane 1
LANECTL2 register value = 32'h80000000 // for lane 2
LANECTL3 register value = 32'h80000000 // for lane 3

// LANEDIVx register bit-field settings:
// P0_MAC_DIV_SEL0 = 7'b1, P0_MAC_DIV_SEL1 = 9'b1
LANEDIV0 register value = 32'h00010001 // for lane 0
LANEDIV1 register value = 32'h00010001 // for lane 1
LANEDIV2 register value = 32'h00010001 // for lane 2
LANEDIV3 register value = 32'h00010001 // for lane 3

// Set DIAG_REG register to 0
DIAG_TEST register value = 32'h0
```

Note

The SERDES PHY reset is not driven by the EDP controller (that is, by writing to the EDP_CORE_PHY_RESET_P[8] PHY_RESET register bit. Instead, the SERDES PHY reset is mapped to the SERDES_RST[31] PHY_RESET_N register bit in the SERDES PHY wrapper. But, the EDP_CORE_PHY_RESET[8] PHY_RESET bit is still used in the EDP controller to disable the controller's output to the SERDES. Therefore, after reset, the EDP_CORE_PHY_RESET[8] PHY_RESET bit must be set to 1 (reset off). After this, the SERDES reset can be controlled strictly with the SERDES_RST[31] PHY_RESET_N bit.

12.6.5.9.3 EDP PHY Programming

Table 12-461 shows information on how to program the EDP PHY (SERDES).

Table 12-461. EDP PHY (SERDES) Programming Details

General Information	
Standards / links / lanes supported	Display port and embedded display port / 2 links / 1, 2, or 4 lanes per link
Reference clock information and setup	
External / internal reference clock selection	Set up external or internal reference clock.
Reference clock frequency selection	Set up the reference clock programming for the selected reference clock frequency
PLL and high speed clocking information and setup	

Table 12-461. EDP PHY (SERDES) Programming Details (continued)

General Information	
PLL 0, Mode 0	Display port link 0. Note, if only link 1 is used, PLL 0 must be programmed in the same was as PLL 1.
PLL 0, Mode 1	Unused
PLL 1, Mode 0	Display port link 1. Note, if only link 0 is used, PLL 1 must be programmed in the same was as PLL 0.
PMA common full rate and data rate clocks	Unused
PMA transceiver full rate and data rate clocks	Full rate and data rate clocks are used as specified in the PMA spec table Clock rates for supported standards.
Top level pins	
PMA: cmn_pll0_mode_sel (Driven by PHY internal logic)	1'b0
PMA: cmn_pll1_mode_sel (Driven by PHY internal logic)	1'b0
PHY: phy_{nn:00}_mode[1:0]	2'b11
PHY: phy_link_cfg_ln_{n:1}	1'b0 for slave lanes of each link 1'b1 for the master lane of each link
PHY configuration specific registers	
SERDES register PHY_AUTO_CFG_SPDUP, bit-fields [1] PHY_PLL_CFG_1 and [0] PHY_PLL_CFG_0	16'h0000 for single DP link configuration 16'h0002 for 2 DP link configuration
Set PLL analog clock divider values	
SERDES register CMN_PDIAG_PLL0_CLK_SEL_M0__CMN_PDIAG_PLL0_CTL_M0	Link 0: Program it as described
SERDES register CMN_PDIAG_PLL1_CLK_SEL_M0__CMN_PDIAG_PLL1_CTL_M0	Link 1: Program it as described
Select analog high speed clock, and transceiver clock divider values	
SERDES register XCVR_DIAG_HSCLK_DIV__XCVR_DIAG_HSCLK_SEL_j, bits [15:0] Link 0 Link 1	16'h0000 16'h0001
SERDES register XCVR_DIAG_HSCLK_DIV__XCVR_DIAG_HSCLK_SEL_j, bits [31:16]	Program it as described
Select digital PLL clock and data rate divider values	
SERDES register XCVR_DIAG_PLLDRC_CTRL__XCVR_DIAG_XDP_PWRI_S TAT_j Link 0 Link 1	16'h0001 16'h0009
Protocol specific setup	
Display port and embedded display	Program it as described

12.7 Camera Subsystem

This section describes the Camera Subsystem in the device.

12.7.1 Camera Streaming Interface Receiver (CSI_RX_IF)

The following sections describe the camera streaming receiver interface (CSI_RX_IF) modules in the device.

12.7.1.1 CSI_RX_IF Overview

The integration of the CSI_RX_IF module allows the device to stream video inputs from multiple cameras to the image processing accelerator (VPAC) or to internal memory. The video input may also be retransmitted via the transmitter CSI (CSI_TX_IF) for debug and test purposes.

12.7.1.1.1 CSI_RX_IF Features

The CSI_RX_IF module supports the following features:

- Compliant to MIPI CSI v1.3
- Supports up to 16 virtual channels per input (partial MIPI CSI v2.0 feature)
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to DPHY_RX
- Programmable formats including YUV420, YUV422, RGB, Raw, and User Defined (over 25 different formats supported)
- Four independent (simultaneous) output streams:
 - Two VP 32-bit streams to VISS inputs of VPAC image processing accelerator:
 - 2x 16-bit pixels per clock cycle
 - One virtual channel and data type per port
 - Raw format only (8-16 bits)
 - 32bit, 2 pixels wide, elastic buffer mode
 - Data[15:0]: Pixel n (MSB zero padding)
 - Data[31:0]: Pixel n+1 (MSB zero padding)
 - Internal full flag (FF) based FIFO (2048x32)
 - VP clock asynchronous to CSI_RX_IF main clock. Crossing done internally.
 - One (up to 4 channels) PPI 16-bit pixel retransmission interface to CSI_TX_IF:
 - 2x 16-bit pixels per clock cycle
 - 32bit retransmission width
 - No external buffer
 - Raw format only (8-20 bits, partial MIPI CSI v2.0 feature)
 - CSI_RX_IF and CSI_TX_IF main clocks must be running at the same frequency and synchronous.
 - One (up to 32 Channels) DMA interface through a 128-bit PSI_L connection to NAVSS for transfers to memory:
 - Byte packed (32x4) format, elastic buffer mode
 - Max rate 1 data cycle every 4 main clocks
 - ByteValid per byte in Last Data Phase (LDP)
 - 32 thread ID's supported (virtual channel & data type combinations); Flexible number of threads (32 Max)
 - Virtual channels and data types mapped via mmr to PSI_L thread ID's
 - Internal FF based FIFO; RAM based buffer (2kx128)
- Functional and data path error interrupts
- ECC support

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.7.1.1.2 CSI_RX_IF Ports

This section describes the CSI_RX_IF ports related to clocks, resets, and hardware requests.

Table 12-462. CSI_RX_IF Clocks and Resets

Clocks	
Module Clock Input	Description
CSI_RX_MAIN_CLK	Main functional clock.
CSI_RX_VBUS_CLK	The VBUS clock runs at always half the speed of the CSI_RX_MAIN_CLK.
CSI_RX_VP_CLK	Video port interface clock. It must run at the same speed or higher than the CSI_RX_MAIN_CLK. It can be async to the CSI_RX_MAIN_CLK clock. However, it must be sync to VPAC video clock.
CSI_RX_BYTE_CLK	The byte clock is the clock supplied by the DPHY_RX.
Resets	
Module Reset Input	Description
CSI_RX_RST	Asynchronous module global reset, driving all collater asynchronous resets of the 4 clock domains to the low state.

Table 12-463. CSI_RX_IF Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type
CSI_RX_IF_CSI_ERR_IRQ_0	Stream error detected. The CSI_RX_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI_RX_CSI_ERR_IRQ.	Level
CSI_RX_IF_CSI_IRQ_0	Global interrupt that various resynchronized sources converge into interrupt generation.	Level
CSI_RX_IF_CSI_LEVEL_0	PSI_L fifo overflow or VP0/VP1 frame/line mismatch	Level
CSI_RX_IF_CORR_LEVEL_0	This interrupt is for checking the interface signals of the CSI_RX_IF controller for parity.	Level

12.7.1.2 CSI_RX_IF Environment

The CSI_RX_IF has no dedicated pins. At the device level, video inputs come from the DPHY_RX; see [Section 12.8.2](#).

12.7.1.3 CSI_RX_IF Functional Description

12.7.1.3.1 CSI_RX_IF Block Diagram

Figure 12-490 depicts a simplified internal block diagram of the CSI_RX_IF and its surroundings.

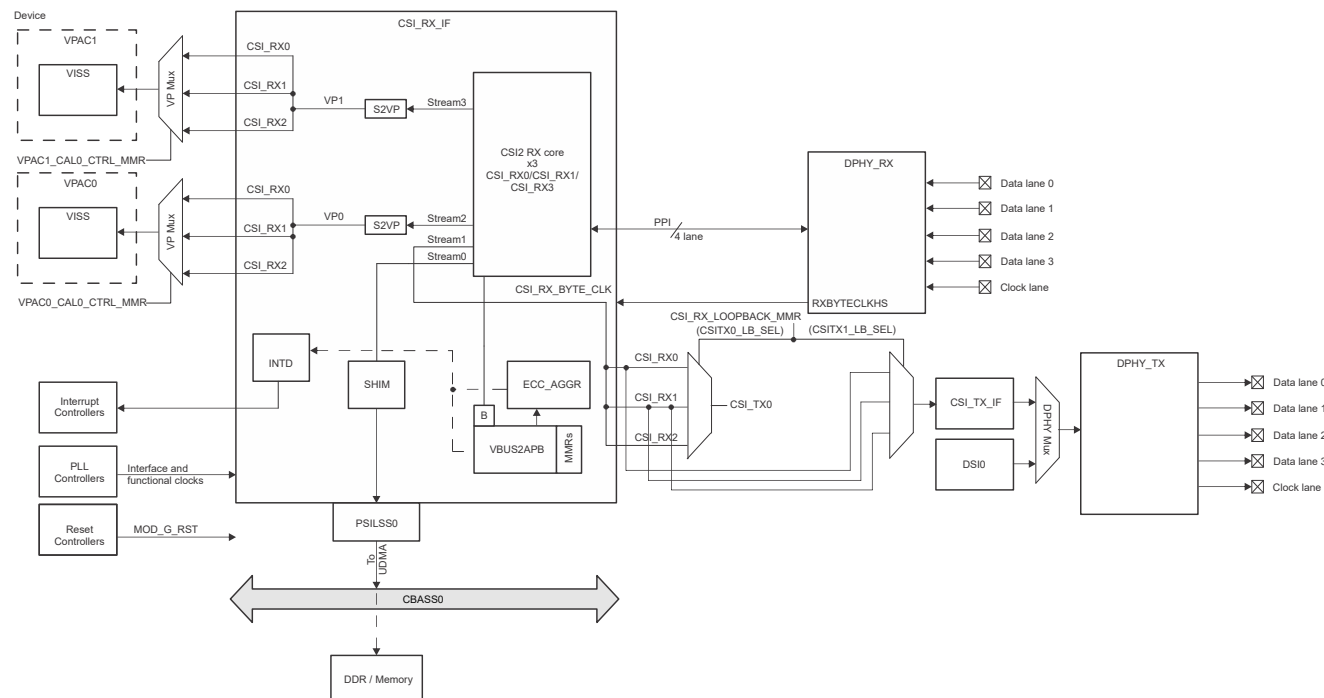

Figure 12-490. CSI_RX_IF Block Diagram

The CSI2 core streams 4 channels of data to the several export paths.

Stream0 (high BW DMA up to 32 channel contexts) streams 32-bits worth of data, that is re-formatted and sent as pixel format into 128 bits as PSIL data. There are 32 sets of MMRs/Registers that map virtual channels and data type to PSIL threads. Data is sent out PSIL in FIFO order as it is received. There is no priority. Data re-formatting is done to end up with correct data organization in memory so that other ip can use the data. The data type must be configured in MMRs to ensure proper reformatting. See [Section 12.7.1.3.5](#). The large buffer of PSIL data (2048x128) has ECC protection, see [Section 12.7.1.3.7](#)

Stream1 (unlimited channel contexts, minimal buffering) streams an optional loopback output to CSI_TX_IF controller for diagnostic check.

12.7.1.3.2 CSI_RX_IF Hardware and Software Reset

An active low asynchronous hardware reset is provided to CSI_RX_IF by device LPSC. It is internally resynchronized to the functional clock domain.

A software reset is triggered by configuring the CSI_RX_IF_VBUS2APB_SOFT_RESET bit-fields for protocol reset and/or module reset.

12.7.1.3.3 CSI_RX_IF Clock Configuration

There are four clock domain in the CSI_RX_IF.

1. The CSI_RX_MAIN_CLK clock runs the CSI2 core, PSIL DMA, and retransmits to CSI_TX_IF. The minimum clock rate for the CSI_RX_MAIN_CLK is 312.5MHz when DPHY is at max data rate (slower clock permissible when DPHY is at lower data rates). When CSI_RX_MAIN_CLK is operating lower than 312.5MHz, then the clock is essentially limiting the clock rate of the DPHY_RX. Said another way, CSI_RX_MAIN_CLK must be at least the CSI_RX_BYTE_CLK rate, else FIFOs will overflow. The maximum clock rate is 500MHz 16ffc, 650 Max

$$f(\text{CSI_RX_BYTE_CLK}) \times \text{nb_lanes} / 4$$
 where $f(\text{CSI_RX_BYTE_CLK})$ is the minimum frequency of CSI_RX_BYTE_CLK.

2. The CSI_RX_VBUS_CLK is the interface configuration clock that runs at half the speed of the CSI_RX_MAIN_CLK.
3. The CSI_RX_VP_CLK is the video port interface clock. It must run at the same speed or higher than CSI_RX_MAIN_CLK. It can be async to CSI_RX_MAIN_CLK clock. It also must be sync to VPAC video clock. Up to 720MHz max rate
4. The CSI_RX_BYTE_CLK is the clock supplied by the DPHY_RX PLL and is divided down to byte clock. The DPHY_RX is designed for max of 10gbps. This translates to a max byte clock of 312.5MHz. The clock is inactive when DPHY_RX is not in HS operation.

Table 12-464 shows the CSI_RX_IF and DPHY_RX inter-clock dependencies.

Table 12-464. CSI_RX_IF Inter-clock Dependencies

	CSI_RX_MAIN_CLK	CSI_RX_VBUS_CLK	CSI_RX_VP_CLK	CSI_RX_BYTE_CLK
Min freq	CSI_RX_BYTE_CLK freq	CSI_RX_MAIN_CLK / 2 freq	CSI_RX_BYTE_CLK freq	N/A
Max freq	500MHz	CSI_RX_MAIN_CLK / 2 freq	720MHz	312.5MHz

12.7.1.3.4 CSI_RX_IF Interrupt Events

This section describes the register configuration of the interrupt events that can trigger the several CSI_RX_IF interrupt signals. For detailed description and mapping of the interrupt of the device interrupt processors see *CSI_RX_IF Integration*.

The interrupts are generally handled within the INTD module of the CSI_RX_IF, although there are several interrupt registers in the ECC_AGGR for ECC errors and in the VBUS2APB for stream monitoring errors/flags.

Table 12-465 lists the event generation and corresponding registers of the CSI_RX_IF controller.

Table 12-465. CSI_RX_IF Interrupt Events Cross Table

Event	Mask Register	Status Register	Description
CSI_RX_CSI_ERR_IRQ	CSI_RX_IF_VBUS2APB_ERROR_IRQS_MASK_CFG	CSI_RX_IF_VBUS2APB_ERROR_IRQS	Stream error detected. The CSI_RX_IF0 will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI_RX_CSI_ERR_IRQ. Read the status register bitfields to trace the source of the event.
CSI_RX_CSI_IRQ	CSI_RX_IF_CP_INTD_ENABLE_REG_LEVEL_0 CSI_RX_IF_VBUS2APB_ERROR_IRQS_MASK_CFG	CSI_RX_IF_CP_INTD_STATUS_REG_LEVEL_0 CSI_RX_IF_VBUS2APB_ERROR_IRQS	Global functional interrupt that various resynchronized sources converge into interrupt generation.
CSI_RX_CSI_LEVEL	CSI_RX_IF_VBUS2APB_MONITOR_IRQS_MASK_CFG	CSI_RX_IF_VBUS2APB_STREAM0_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM1_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM2_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM3_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM0_FIFO_FILL_LVL	PSI_L fifo overflow or VP0/VP1 frame/line mismatch (at the minimum an error interrupt will occur at the end of frame but may be issued within the frame as well). Read the status register bitfields to trace the source of the event.
CSI_RX_CORR_LEVEL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	This interrupt is for checking the interface signals of the CSI_RX_IF0 controller for parity.
CSI_RX_UNCORR_LEVEL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	This interrupt is for checking the interface signals of the CSI_RX_IF0 controller for parity.

Table 12-465. CSI_RX_IF Interrupt Events Cross Table (continued)

Event	Mask Register	Status Register	Description
CSI_RX_CSI_FATAL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_RX_IF_VBUS2APB_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_RX_IF_VBUS2APB_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.
CSI_RX_CSI_NONFATAL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	ASF port non-fatal interrupt. Level sensitive. Set CSI_RX_IF_VBUS2APB_ASF_FATAL_NONFATAL_SELECT to whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_RX_IF_VBUS2APB_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.

12.7.1.3.5 CSI_RX_IF Data Memory Organization Details

12.7.1.3.6 CSI_RX_IF PSI_L (DMA) Interface

Note

This section describes CSI_RX_IF PSI_L specific functionality related to the camera interface. The general PSI_L functional description and registers are described in the PSI_L specific chapter (see *PSIL Subsystem (PSILSS)*).

12.7.1.3.6.1 PSI_L DMA framing

The CSI_RX_IF stream interface provides the usual VSYNC/HSYNC signals. The signals are per virtual channel where the transition from 1-to-0 or 0-to-1 represents SOF/EOF or SOL/EOL. VSYNC/HSYNC transition is usually not coincident with a valid data phase, though there are use cases where it can be. Because of the nature of CSI protocol, the VSYNC and HSYNC transactions require at least a single clock cycle and can only transition sequentially (important fact in handling of VSYNC events).

There is a rarely used mode of CSI where an entire frame is passed in a single packets without line breaks. In this mode, there are no HSYNC transitions at line starts/ends.

Lastly, there is redundant information provided with each CSI packet where the packet length is supplied in bytes.

To overcome these framing restrictions, the CSI_RX_IF PSILSS0 passes metadata through the DMA FIFO. Anytime metadata is inserted into the FIFO, the CSI_RX_IF stream is stalled for a clock cycle. The forms of supported meta tags are:

- SOF for a given virtChan
- EOF for a given virtChan
- Packet length in bytes for a given dmaCntx

The PSILSS0 will disregard the HSYNC signal entirely. The long packet beginning is used as SOL and the EOL will be "counted" using the packet length provided. In the special case where packets are of FRAME length, the SOL/EOL handling is identical.

The PSILSS0 solution for VSYNC handling is to create the concept of metadata FIFO entry which is indicated by a metadata bit. The SOF or EOF VSYNC information plus the virtualChan index is fed into the FIFO. On the output of the FIFO, the SOF is saved for each context of that virtualChan type. The very next data phase of that channel context will be marked as SOF. Additionally a state bit per context is maintained indicating the channel is MOP (middle of packet). Once the EOF arrives at the FIFO output, all contexts of that type virtual channel (and currently in MOP state) will receive a PSI_EOP with zero active bytes of data.

CAUTION

The line and frame size is not known outside the CSI core (i.e. not passed to the DMA interface). Therefore any mismatches at system level programming will be unknown. If the DMA line/frame size does not match the CSI_RX_IF line/frame size, it is assumed the DMA will not result in any adverse side effects as a result of not enough data or too much data.

12.7.1.3.6.2 PSI_L DMA error handling due to FIFO overflow

The DMA error handling is also called a PSI_L protocol enforcer. It is intended to prevent hang of the PSILSS0. Unnatural packet size should not cause hang so only SOP/SOL/EOL/EOP framing is enforced. The following list highlights the error handling mechanism:

- For context cleanup the protocol enforcer:
 - cycle through each context index checking if context is in MOL or MOP
 - close out MOP with EOP and MOL&MOP with EOL&EOP
- dropOnFloor SOP if currently in MOPstate
- dropOnFloor EOP if not currently in MOPstate
- dropOnFloor FIFO data
- EOL context if EOP and MOLstate
- After closing out all open contexts the PSILSS0 logic will then wait till end of frame per virtual channel. Once a new frame starts it will then start sending out data from that new frame

12.7.1.3.7 CSI_RX_IF ECC Protection Support

ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC protection on the CSI_RX_IF RAM provides Single Error Correction and Double Error Detection (SEC/DED). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC protection also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

The ECC aggregator in the CSI_RX_IF subsystem level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. It provides a single EOI-handshake based interrupt to the interrupt processors (for both single and double error detections) and a standard 32-bit VBUSP interface for configuring and querying the ECC register set, see *CSI_RX_IF ECC Registers*. For complete details on the features and functions of the ECC aggregator, see chapter *ECC Aggregator*.

12.7.1.3.8 CSI_RX_IF Programming Guide

12.7.1.3.8.1 Overview

This section details specific steps on how to program the CSI_RX_IF controller.

12.7.1.3.8.2 Controller Configuration

The CSI_RX_IF streams will default to accept all virtual channels and all data types after reset, so the user must program the stream configuration and pixel interface to match the system use case.

Note

The CSI_RX_IF controller can be configured so that the reset values can adopt the users Power_On state. This can reduce the programming steps required by the system.

The CSI_RX_IF controller is designed to operate all the defined streams with all virtual channels and all data types passed to the pixel interface. Also, the connection to the front interface adopts reset values that will allow the connection of the lanes to expect no remapping.

The basic system configuration steps are then programming the number of enabled data lanes and starting the streams.

The system can also decrease the virtual channel and data type processed by the stream by configuring the data config (CSI_RX_IF_VBUS2APB_STREAM0_DATA_CFG - CSI_RX_IF_VBUS2APB_STREAM3_DATA_CFG) registers.

The user must perform a read from the stream config register (CSI_RX_IF_VBUS2APB_STREAM0_CFG - CSI_RX_IF_VBUS2APB_STREAM3_CFG) at power up to identify the number of streams and pixel interface mode. The stream FIFO depth must be determined from the system configuration information defined at build time to ensure that any programmed [31-16] FIFO_FILL level is valid for the available FIFO depth.

12.7.1.3.8.3 Power on Configuration

The CSI_RX_IF requires the system to perform the configuration of the DPHY_RX interface before starting the streams of the controller. The default configuration of the controller and each stream can be identified by reading the device ID CSI_RX_IF_VBUS2APB_DEVICE_CONFIG register.

The FW must read the CSI_RX_IF_VBUS2APB_DEVICE_CONFIG register at power up. This will provide the FW the number of streams that will need to be configured, and all the default system information for the FIFO structures in the available streams.

Table 12-466. CSI_RX_IF_VBUS2APB_DEVICE_CONFIG bitfield details

STREAMx_NUM_PIXELS	The width of the pixel interface and the bits per pixel for the selected datatype will determine how many pixels can be output in a single cycle. Default will be 1 pixel per clock. 00 -> 1 pixel per clock 01 -> 2 pixels per clock 10 -> 4 pixels per clock
DATAPATH_SIZE	Internal Datapath width 00 - 32 bit, all other values are reserved.
NUM_STREAMS	Number of Stream interfaces (1-4) = (value+1)
MAX_LANE_NB	Max Number of Lanes (1-4) = (value+1)

Figure 12-498 shows the minimal sequence of registers that will configure the DPHY_RX and then start the stream; this will output all the pixel information for all virtual channels and all data types detected in the link data stream.

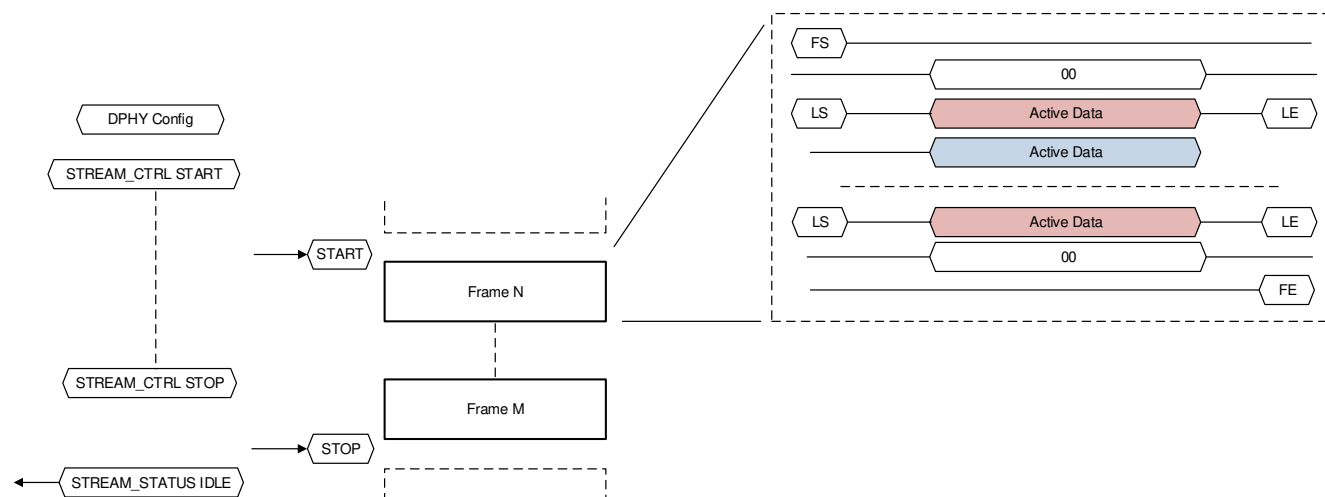

Figure 12-498. Minimal Stream Control - Start and Stop

12.7.1.3.8.4 Stream Start and Stop

The CSI_RX_IF will perform management of the stop and halt control to the pixel stream during functional operation to allow any stream to change the virtual channel or data type information that the stream will process.

- The FW will use the stream control register (CSI_RX_IF_VBUS2APB_STREAM0_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_CTRL) to perform a stop (set bit 1) and wait for the end of any current frame, and wait for the stream to return its state to IDLE, which can be read from stream status register (CSI_RX_IF_VBUS2APB_STREAM0_STATUS - CSI_RX_IF_VBUS2APB_STREAM3_STATUS)[31] RUNNING = 1.
- The FW will use the stream control register to perform an abort and wait for the end of any current line, and wait for the stream to return its state to IDLE, which can be read from register STREAM_STATUS[31] RUNNING = 1.

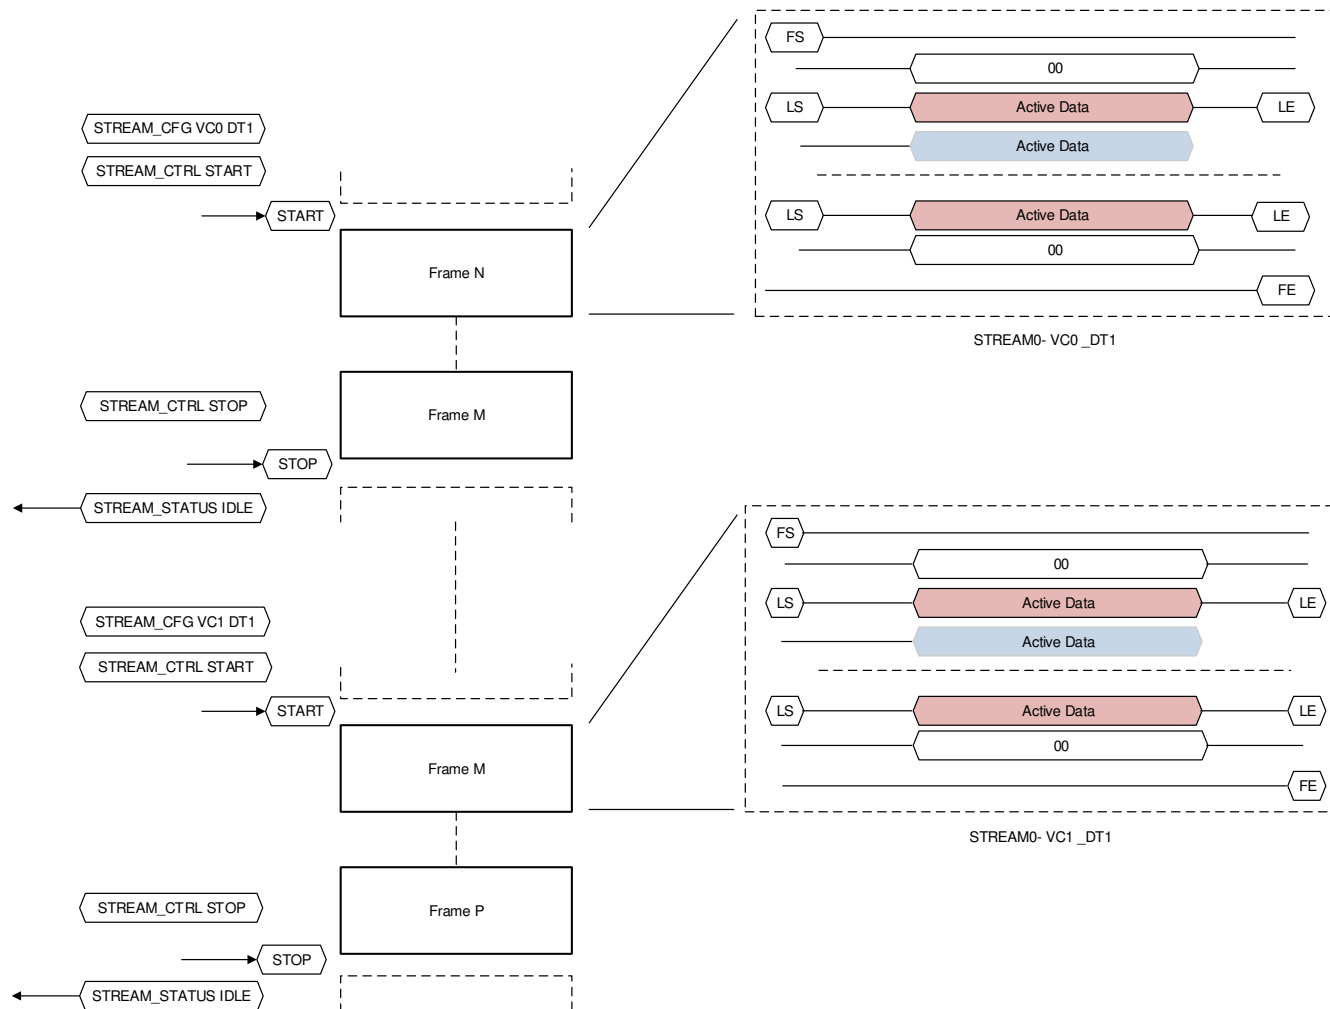

Figure 12-499. Stream Reconfiguration Using Start Stop Start Flow

The CSI_RX_IF will use the monitor control or STOP mechanism to stop the stream processing at the end of the active frame. The stream monitor, configuration and interrupt registers can be redefined and then the stream restarted. The pixel interface will begin processing at the next frame start.

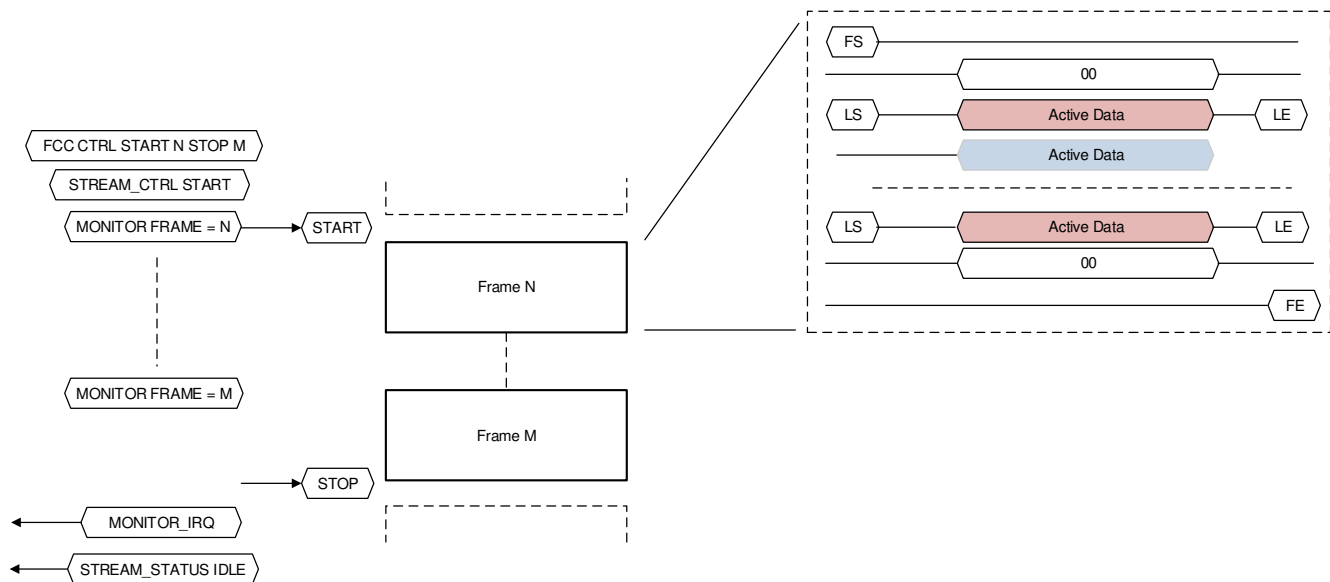

Figure 12-500. Stream Start and Stop Using Monitor Control

12.7.1.3.8.5 Error Control With Soft Resets

The CSI_RX_IF will perform control of the soft reset either for error event recovery or to clear a stream FIFO or internal state machine.

- The FRONT block can be soft reset if the DPHY_RX becomes unresponsive and the controller wishes to maintain its configuration. In this case the DPHY_RX resets can be applied and the DPHY_RX enabled to begin the transfer again.
- The Protocol block can be soft reset if the FRONT soft reset is required, and the protocol is not in the IDLE state.
- The stream soft resets (CSI_RX_IF_VBUS2APB_STREAM0_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_CTRL)[4] SOFT_RST can be used to clear the stream to the stop state and reset all the stream state machines and FIFO. If the system has a failure and wishes to clear the stream FIFO and return to a safe state on the pixel interface, the stream soft reset should be asserted.

12.7.1.3.8.6 Stream Error Detected – No Error Bypass Mode

The CSI_RX_IF will default to stop processing the frame whenever a header Reserved DT or ECC error is detected, or when a long packet payload CRC is identified.

The CSI_RX_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI_RX_IF_VBUS2APB_ERROR_IRQS.

The CSI_RX_IF will stop processing the current frame and stop the stream.

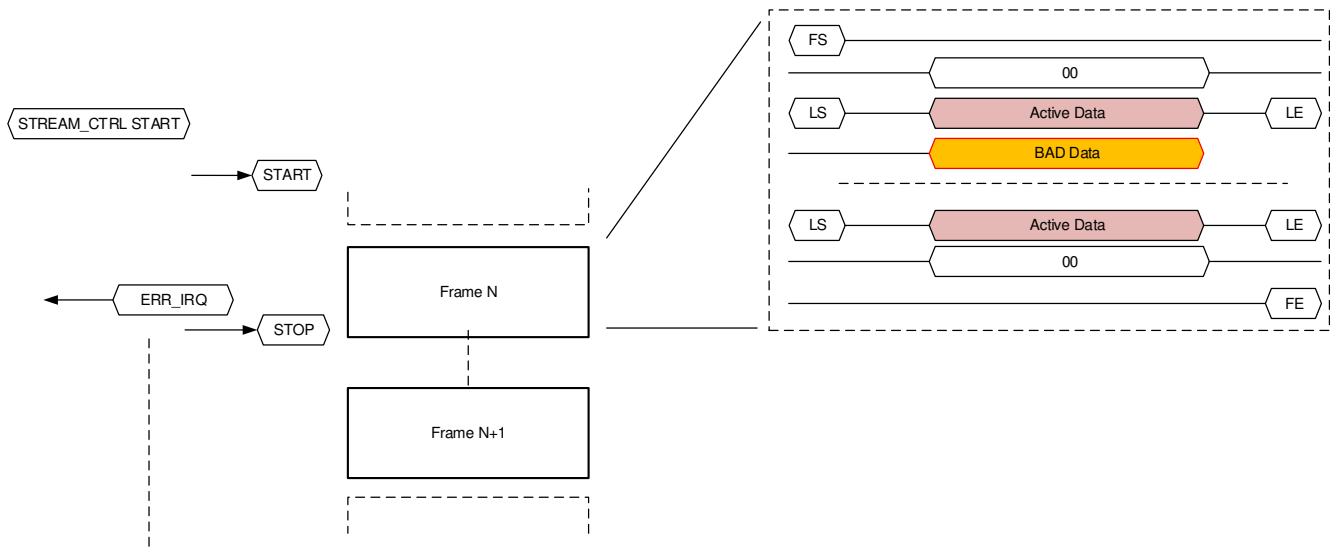

Figure 12-501. Stream Error Detection Causing Stop

12.7.1.3.8.7 Stream Error Detected – Error Bypass Mode

The CSI_RX_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI_RX_IF_VBUS2APB_ERROR_IRQS.

The CSI_RX_IF will continue processing the current frame and continue the stream when a header Reserved DT or a long packet payload CRC error is detected.

The CSI_RX_IF will stop processing the current frame and continue the stream when a packet header ECC error is detected, as the current frame synchronisation cannot be maintained.

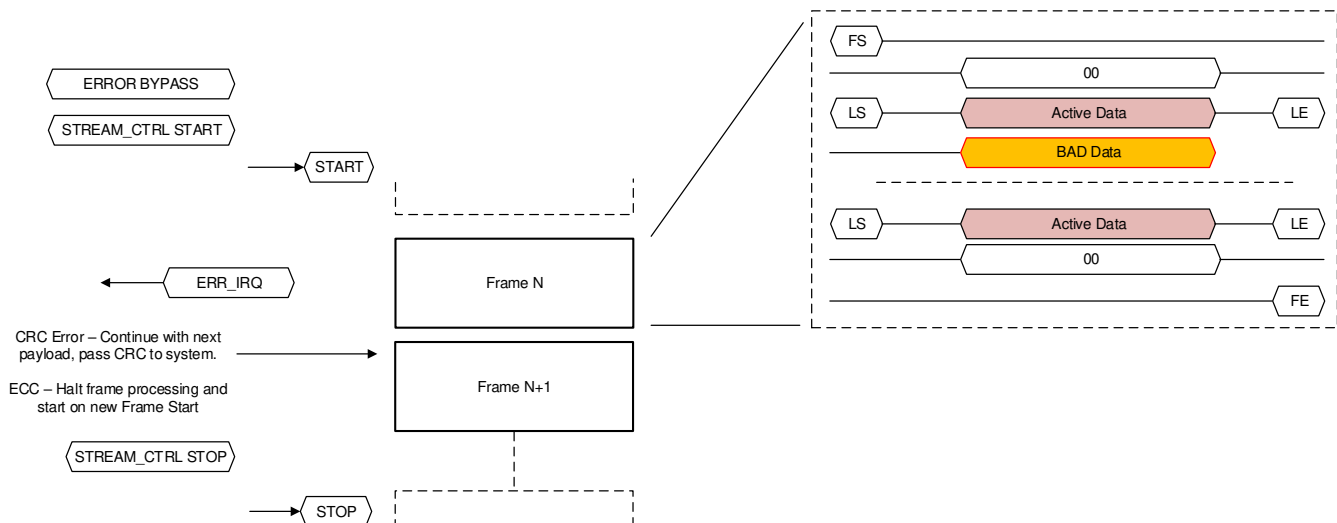

Figure 12-502. Stream Error Bypass - CRC Error During Payload

12.7.1.3.8.8 Stream Error Detected – Soft Reset Recovery

The CSI_RX_IF will stop processing the current frame and continue the stream when a packet header ECC error is detected, as the current frame synchronisation cannot be maintained.

The system can perform a soft reset on the individual stream to clear the pixel interface and payload FIFO and allow the system to restart the stream from the next frame start.

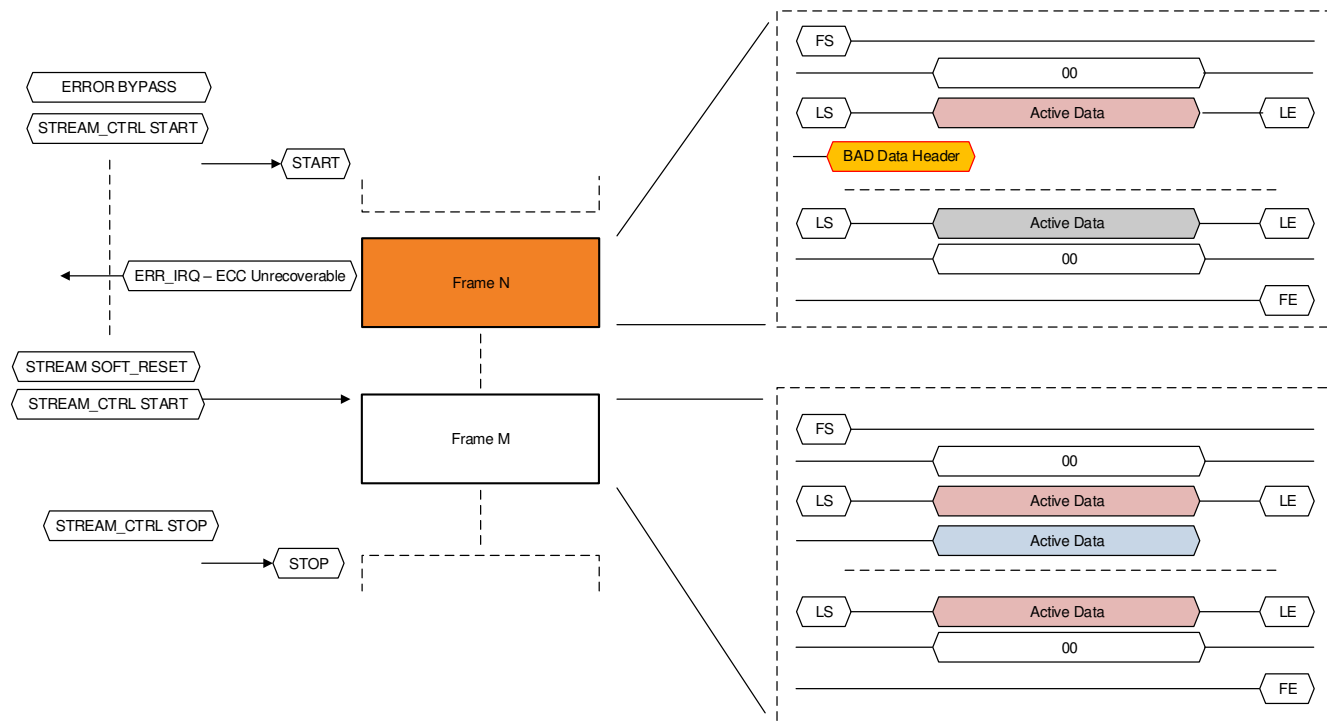

Figure 12-503. Stream Soft Reset After ECC Non-Recoverable Error

12.7.1.3.8.9 Stream Monitor Configuration

The CSI_RX_IF will use the monitor control (CSI_RX_IF_VBUS2APB_STREAM0_MONITOR_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_MONITOR_CTRL) or STOP mechanism to stop the stream processing at the end of the active frame. The stream monitor, configuration and interrupt registers can be redefined and then the stream restarted. The pixel interface will begin processing at the next frame start.

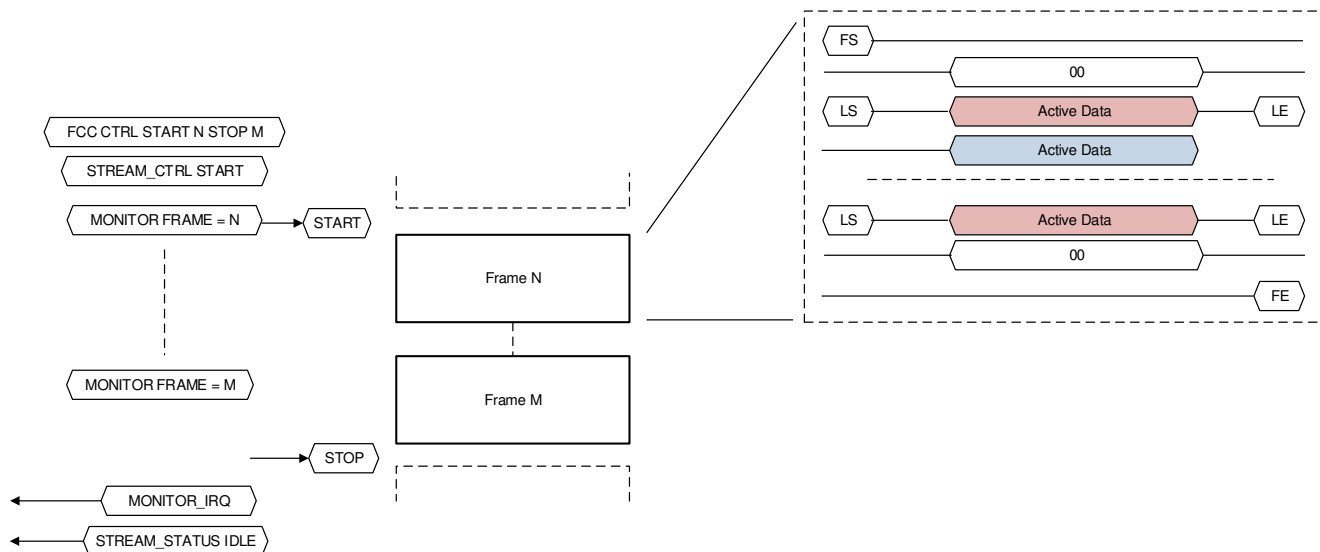

Figure 12-504. Stream Start and Stop Using Monitor Control

The FW will use the FCC config control register (CSI_RX_IF_VBUS2APB_STREAM0_FCC_CFG - CSI_RX_IF_VBUS2APB_STREAM3_FCC_CFG) to perform a start and stop as soon as a frame count is detected. The FCC config control register will define the start and stop frame count and the stream will identify when these values are matched. The stream output will begin when start frame is detected and then stop once the stop frame is reached. The virtual channel can be defined

in CSI_RX_IF_VBUS2APB_STREAM0_FCC_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_FCC_CTRL[4-1] FCC_VC, and must match the virtual channels that are available to the stream in the CSI_RX_IF_VBUS2APB_STREAM0_DATA_CFG - CSI_RX_IF_VBUS2APB_STREAM3_DATA_CFG register.

The frame capture is enabled when CSI_RX_IF_VBUS2APB_STREAM0_FCC_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_FCC_CTRL[0] FCC_EN is set '1'

The FW can check the current frame counter value from the CSI_RX_IF_VBUS2APB_STREAM0_FCC_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_FCC_CTRL[31:16] FRAME_COUNTER

12.7.1.3.8.10 Stream Monitor Frame Capture Control

To use Monitor Frame Capture Control Start and Stop operations:

1. Set Stop and Start values in config register (CSI_RX_IF_VBUS2APB_STREAM0_FCC_CFG - CSI_RX_IF_VBUS2APB_STREAM3_FCC_CFG). Set to '0' for free-running.
 - a. [31:16] FRAME_COUNT_STOP -> define desired value
 - b. [15:0] FRAME_COUNT_START -> define desired value
2. Set the Virtual Channel to the one that is enabled and the enable in register CSI_RX_IF_VBUS2APB_STREAM0_FCC_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_FCC_CTRL.
 - a. [4:1] FCC_VC -> define VC used
 - b. [0] FCC_EN -> set to '1'

This will allow visual checking, by setting the Start/Stop as the following examples, this is the behaviour to be observed:

- Stop = 1 / Start = 1: Output (i.e. display) will show a Frame of the Input (i.e. camera)
- Stop = F / Start = 1: Output will show live image from the input during 14 frames and then will freeze in the last one.

Optionally software can read back the frame count value from register (CSI_RX_IF_VBUS2APB_STREAM0_FCC_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_FCC_CTRL).

In order to do that, software will first need to enable the monitor control register.

1. Define the same Virtual Channel as above and enable the monitor control register (CSI_RX_IF_VBUS2APB_STREAM0_MONITOR_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_MONITOR_CTRL).
 - a. [15] FRAME_MON_EN -> set to '1'
 - b. [14:11] FRAME_MON_VC -> define VC used
2. Read frame_counter containing the current frame number being processed from CSI_RX_IF_VBUS2APB_STREAM0_FCC_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_FCC_CTRL (only when frame numbers are coming from the protocol, not when internal counter)
 - a. [31:16] FRAME_COUNTER -> read frame number value

The easiest way to check that the frame number matches the Start and/or Stop values defined, is to use the interrupts in CSI_RX_IF_VBUS2APB_MONITOR_IRQS register. To be able to do that you will need to allow those interrupts through the mask register CSI_RX_IF_VBUS2APB_MONITOR_IRQS_MASK_CFG.

1. By default, the CSI_RX_IF_VBUS2APB_MONITOR_IRQS_MASK_CFG register is set to all '0's, meaning all interrupts are disabled.
 - a. [4] STREAM0_FCC_STOP_IRQM -> set to '1'
 - b. [3] STREAM0_FCC_START_IRQM -> set to '1'
2. Create an interrupt handler to read from CSI_RX_IF_VBUS2APB_MONITOR_IRQS.
 - a. [4] STREAM0_FCC_STOP_IRQ -> read, if '1', Stop interrupt triggered
 - b. [3] STREAM0_FCC_START_IRQ -> read, if '1', Start interrupt triggered

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI_RX_IF has been configured and enabled if software is using Frame Counter Control features.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

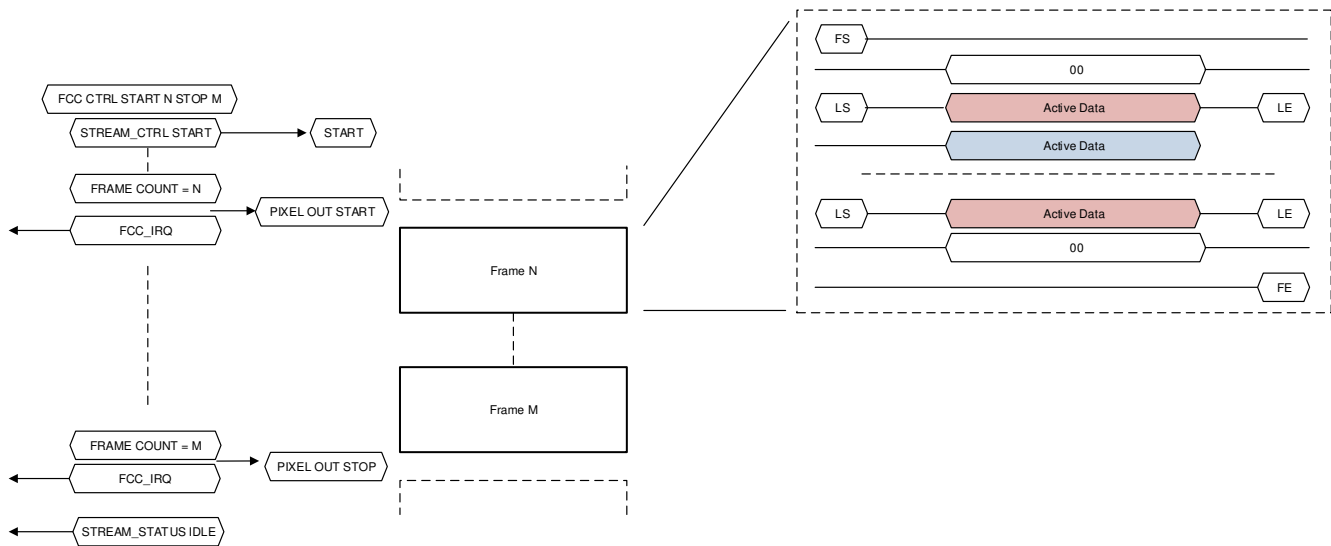

Figure 12-505. Stream Frame Capture Control Flow Diagram

12.7.1.3.8.11 Stream Monitor Timer interrupt

To use the Stream Monitor Timer operations:

1. Set Count value in timer register (CSI_RX_IF_VBUS2APB_STREAM0_TIMER - CSI_RX_IF_VBUS2APB_STREAM3_TIMER). If set to 0 won't count but interrupt will still trigger every EOF or SOF.
 - a. [24:0] COUNT -> define desired value
2. Set the Virtual Channel to the one that is enabled, define timer_eof and set enable in the monitor controll register (CSI_RX_IF_VBUS2APB_STREAM0_MONITOR_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_MONITOR_CTRL).
 - a. [15] FRAME_MON_EN -> set to '1'
 - b. [14:11] FRAME_MON_VC -> define VC used
 - c. [10] TIMER_EOF -> set to '1' to count from EOF, set to '0' to count from SOF
 - d. [9] TIMER_EN -> set to '1'
 - e. [8:5] TIMER_VC -> define VC used

Software should now use the interrupts in register CSI_RX_IF_VBUS2APB_MONITOR_IRQS. To be able to do that you will need to allow those interrupts through the mask register CSI_RX_IF_VBUS2APB_MONITOR_IRQS_MASK_CFG.

1. By default, the CSI_RX_IF_VBUS2APB_MONITOR_IRQS_MASK_CFG register is set to all '0', meaning all interrupts are disabled.
 - a. [0] STREAM0_TIMER_IRQM -> set to '1'
2. Create an interrupt handler to read from monitor_irqs.
 - a. [0] STREAM0_TIMER_IRQ -> read, if '1', timer interrupt is triggered

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI_RX_IF has been configured and enabled.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

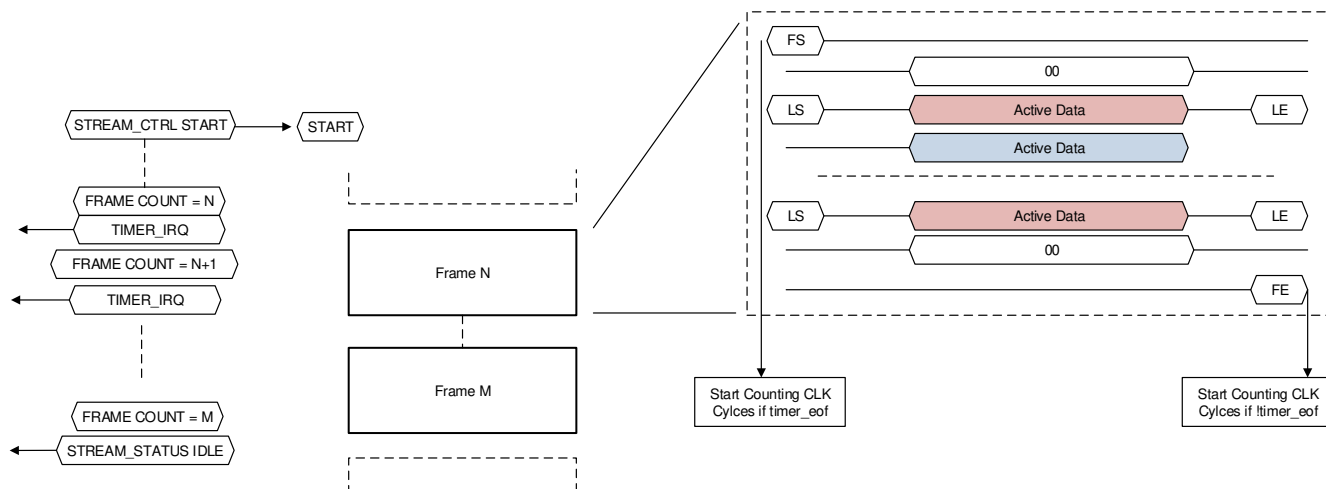

Figure 12-506. Timer Interrupt Flow Diagram

12.7.1.3.8.12 Stream Monitor Line/Byte Counters Interrupt

To use the stream Monitor Line and Byte counters operations:

1. Set LineCount and ByteCount values in register (CSI_RX_IF_VBUS2APB_STREAM0_MONITOR_LB - CSI_RX_IF_VBUS2APB_STREAM3_MONITOR_LB).
 - a. [31:16] LINE_COUNT -> define desired value
 - b. [15:0] BYTE_COUNT -> define desired value
2. Set the Virtual Channel to the one that is enabled, and set enable in register SI_RX_IF_VBUS2APB_STREAM0_MONITOR_CTRL.
 - a. [15] FRAME_MON_EN -> set to '1'
 - b. [14:11] FRAME_MON_VC -> define VC used
 - c. [4] LB_EN -> set to '1'
 - d. [3:0] LB_VC -> set to VC used

Software should now use the interrupts in register CSI_RX_IF_VBUS2APB_MONITOR_IRQS. To be able to do that you will need to allow those interrupts through the mask register CSI_RX_IF_VBUS2APB_MONITOR_IRQS_MASK_CFG.

1. By default, the CSI_RX_IF_VBUS2APB_MONITOR_IRQS_MASK_CFG register is set to all '0', meaning all interrupts are disabled.
 - a. [7] STREAM0_LINE_CNT_ERROR_IRQM -> set to '1'
 - b. STREAM0_LB_IRQM [1] -> set to '1'
2. Create an interrupt handler to read from CSI_RX_IF_VBUS2APB_MONITOR_IRQS.
 - a. [7] STREAM0_LINE_CNT_ERROR_IRQ -> read, if '1', line count error interrupt is triggered
 - b. [1] STREAM0_LB_IRQ -> read, if '1', line/byte counter interrupt is triggered

Note that the interrupt will trigger on each frame when it reaches byte number BYTE_COUNT in line number LINE_COUNT.

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI_RX_IF has been configured and enabled.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

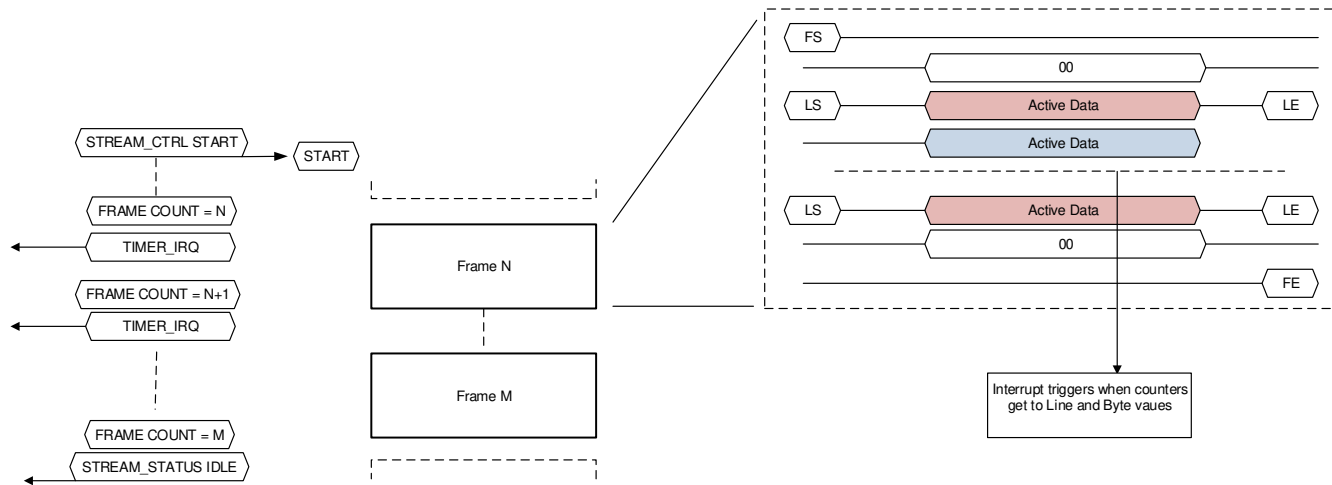

Figure 12-507. Line/Byte Counters Interrupt Flow Diagram

12.7.1.3.8.13 Example Controller Programming Sequence (Single Stream Operation)

The single stream operation will provide the smallest multi-lane IP configuration with the reduced registers configuration removing some control and status registers. The stream will not require a large FIFO configuration and the clock rates will be matched to simplify the implementation to single pixel transfers using all the available interface bits, (i.e. up to 32).

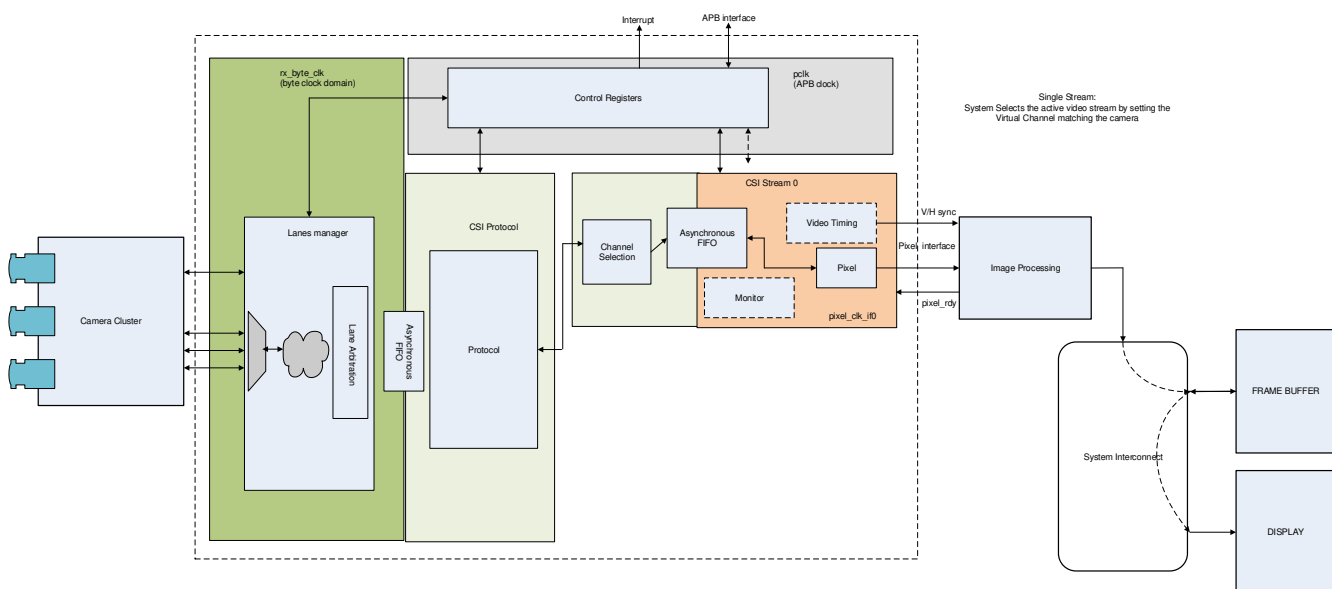

Figure 12-508. Basic Single Stream Use Case Illustration

For single pixel stream configuration, elastic buffer, RAW8 Data type on VC2, one pixel per cycle:

1. Configure the number of DPHY_RX lanes:
 - a. See CSI_RX_IF_VBUS2APB_STATIC_CFG register
2. Set Error Interrupt mask:
 - a. See CSI_RX_IF_VBUS2APB_ERROR_IRQS_MASK_CFG register
3. Set the Pixel Interface and FIFO configuration. See CSI_RX_IF_VBUS2APB_STREAM0_CFG - CSI_RX_IF_VBUS2APB_STREAM3_CFG.
 - a. Set [9-8] FIFO_MODE to select the elastic buffer configuration -> '1'
 - b. Set the FIFO fill level that will determines the FIFO depth that must be reached before data is output -> 0x0000

- c. Select the number of pixels to be output on each cycle -> '0'.
- d. Set the type of stream interface to "pixel" mode -> '0'
4. Select the virtual channel and data types to be processed. See CSI_RX_IF_VBUS2APB_STREAM0_DATA_CFG - CSI_RX_IF_VBUS2APB_STREAM3_DATA_CFG register.
 - a. Set [31-16] VC_SELECT and virtual channel bits if not supporting all virtual channels -> 1h, 2h
 - b. Set [7] ENABLE_DT0 and [5-0] DATATYPE_SELECT0 values for one or both data types (default all DT) -> 0h, 1h, 2Ah
5. Enable the stream to begin processing the incoming data from the DPHY_RX. See CSI_RX_IF_VBUS2APB_STREAM0_CTRL - CSI_RX_IF_VBUS2APB_STREAM3_CTRL.
 - a. Set [0] START bit -> '1'

The stream will begin to pass pixel data matching the configuration on the next frame start.

12.7.1.3.8.14 CSI_RX_IF Programming Restrictions

The following CSI_RX_IF programming restrictions apply:

- Full line buffer mode is not supported.
- LS/LE detection has a restriction to be disabled
- Only use Pixel transmit mode can be used, never packet mode
 - In pixel mode only single, dual, or quad mode can be used. It is not allowed to mix these based on data format or virtual channels.
- LSB alignment only
- In CSI_RX_IF to CSI_TX_IF loop back, the stream needs to have the same mode on both controllers(single, dual, quad). Can not mix dual on CSI_RX_IF and single on CSI_TX_IF.
- Video port(VP) stream interfaces must be programmed in the CSI_RX_IF to meet the following restrictions:
 - Raw 8-16 formats only
 - Dual pixel mode
 - Filtering for single virtual channel and single data type

Note

CSI_RX_IF has a limitation that any line must fully be exported on its stream interface before a new line or even end of frame is sent on the D-PHY interface. To meet this requirement, software will need to take into account export rates on stream interface(single, dual, quad modes) at 500MHz versus D-PHY 32-bits @ byte clock frequency to know when a new line or end of frame can be sent in after last line was sent over D-PHY interface.

Table 12-467 shows the CSI_RX_IF programming requirements for pixel modes and data sizes.

Table 12-467. CSI_RX_IF Programming requirements for pixel modes and data sizes

Format	Pixel transmit mode used	Size	Details
RAW(6-8), user defined 8-bit	Single	0	
RAW(6-8), user defined 8-bit	Dual	1	
RAW(6-8), user defined 8-bit	Quad	2	
RAW(10-16), user defined 16-bit	Single	1	
RAW(10-16), user defined 16-bit	Dual	2	
RAW20	Single	2	
YUV422-8	Single	0	must set dual mode=0
YUV422-8	Dual	0	must set dual mode=1
YUV422-10	Single	1	
YUV420-8	Single	0	must set dual mode=0
YUV420-8	Dual	0	must set dual mode=1
YUV420-10	Single	1	

12.7.1.3.8.15 CSI_RX_IF Real-time operating requirements

Care must be taken on blanking requirements for next line, end of frame, or start of frame. The previous packets(long or short) must be fully consumed before any new line, end of frame, or start frame can be sent over the CSI interface. Software will get various error conditions if these are not met. Below are some sample equations to determine this blanking time. Note that this is not blanking data. High level details are that the internal FIFO must be completely empty prior to sending any thing new into it. below are some sample equations to determine how much time is needed to empty the FIFO and blanking time needed. Byte clock rates, pixel data type, and export modes play into the calculation as well.

$$\text{Byte_clock_rate} \times 8 \times \#\text{lanes} \times \text{Tcsi} = \text{pixel_clock_rate} \times \text{BPP} \times \text{Tpix} = \text{total bits} \quad (27)$$

BPP = Bits Per Pixel. This number is how many bits are sent per pixel clock cycle is based on single, dual, quad modes and data type.

Tcsi = Time for csi interface to complete 1 line

Tpix = Time for pixel interface to complete 1 line

Tpix16 = Tpix+16/pixel_clock_rate

(Tpix16-Tcsi) = required blanking time on CSI interface

Tpix16-Tcsi <= 0 implies 0

12.7.2 MIPI D-PHY Receiver (DPHY_RX)

The following sections describe the MIPI D-PHY receiver (DPHY_RX) modules in the device.

12.7.2.1 DPHY_RX Overview

The integration of the DPHY_RX camera physical port module allows the device to grab video streams from external sensor cameras and other CSI2 compliant sources.

12.7.2.1.1 DPHY_RX Features

The DPHY_RX module supports the following features:

- Compliant to MIPI D-PHY standard v1.2
- Supports up to 4 data and 1 clock lanes
- Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
- Clock lane control / interface logic type is CIL-SCNN for HS and low power receiving:
 1. **Slave**
 2. **Clock**
 3. **N/A** forward, **N/A** reverse escape mode features
- Data lane control / interface logic type is CIL-SFAN for HS and low power receiving:
 1. **Slave**
 2. **Forward** direction only for high speed mode
 3. **All** forward direction escape mode features are supported
 4. **No** reverse direction escape mode features are supported
- Data lanes can be independently operated in HS or ULP mode
- Swapping of DP/DN signals within each clock/data pair (Facilitated by CSI_RX_IF controller)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.7.2.1.2 DPHY_RX Ports

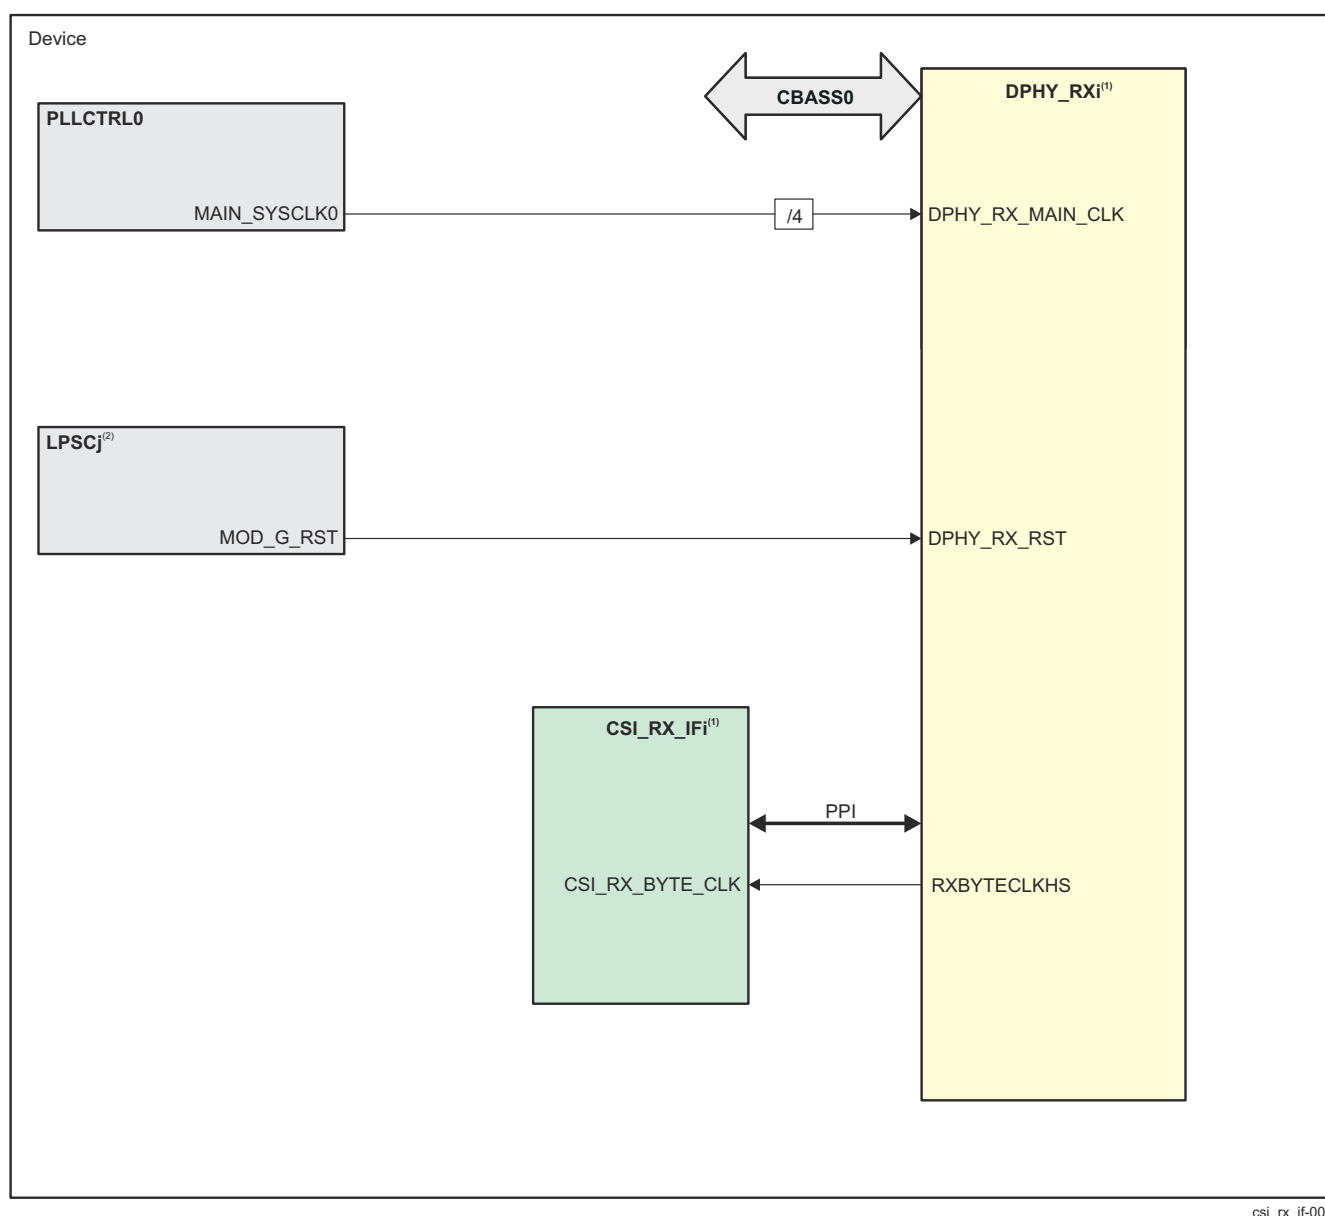

This section describes the DPHY_RX ports related to clocks, resets, and hardware requests.

Table 12-468. DPHY_RX Clocks and Resets

Clocks	
Module Clock Input	Description
DPHY_RX_MAIN_CLK	Main functional clock.
CSI_RX_BYTE_CLK	The byte clock is the clock supplied by the DPHY_RX.
Resets	
Module Reset Input	Description
DPHY_RX_RST	Asynchronous module global reset.

12.7.2.1.2.1 DPHY_RX Integration in MAIN Domain

There are several DPHY_RX modules integrated in the device MAIN domain. [Figure 12-509](#) shows the integration of DPHY_RX modules.

csi_rx_if-005

A. i = 0 to 1

B. j = LPSC index, see [Table 12-469](#)

Figure 12-509. DPHY_RX Integration

[Table 12-469](#) through [Table 12-470](#) summarize the integration of DPHY_RX in the device MAIN domain.

Table 12-469. DPHY_RX Integration Attributes

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
DPHY_RX0	PSC0	PD2	LPSC58	CBASS0
DPHY_RX1	PSC0	PD2	LPSC59	CBASS0

Table 12-470. DPHY_RX Clocks and Resets

Clocks		
Module Instance	Module Clock Input	Description
DPHY_RX0	DPHY_RX_MAIN_CLK	Main functional clock.
	CSI_RX_BYTE_CLK	The byte clock is the clock supplied by the DPHY_RX.
DPHY_RX1	DPHY_RX_MAIN_CLK	Main functional clock.
	CSI_RX_BYTE_CLK	The byte clock is the clock supplied by the DPHY_RX.
Resets		
Module Instance	Module Reset Input	Description
DPHY_RX0	DPHY_RX_RST	Asynchronous module global reset.
DPHY_RX1	DPHY_RX_RST	Asynchronous module global reset.

Note

For more information on the interconnects, see *System Interconnect*.

For more information on the power, reset and clock management, see the corresponding sections within *Device Configuration*.

12.7.2.2 DPHY_RX Environment

This section describes the DPHY_RX application fields from an environment point of view (external connections).

[Table 12-471](#) describes the external signals of the DPHY_RX.

Table 12-471. DPHY_RX I/O Signals

Device Level Signal	I/O	Description
CSI0_RXN0	I	Lane 0 Receive Differential Data (Negative)
CSI0_RXP0	I	Lane 0 Receive Differential Data (Positive)
CSI0_RXN1	I	Lane 1 Receive Differential Data (Negative)
CSI0_RXP1	I	Lane 1 Receive Differential Data (Positive)
CSI0_RXN2	I	Lane 2 Receive Differential Data (Negative)
CSI0_RXP2	I	Lane 2 Receive Differential Data (Positive)
CSI0_RXN3	I	Lane 3 Receive Differential Data (Negative)
CSI0_RXP3	I	Lane 3 Receive Differential Data (Positive)
CSI0_RXCLKN	I	Lane 3 Receive Differential Clock (Negative)
CSI0_RXCLKP	I	Lane 3 Receive Differential Clock (Positive)
CSI0_RXRCALIB	A	Pin for external calibration resistor. An external resistor must be connected between this pin and package ground. Refer to the device-specific Datasheet for a recommended resistor value.
CSI1_RXN0	I	Lane 0 Receive Differential Data (Negative)
CSI1_RXP0	I	Lane 0 Receive Differential Data (Positive)

Table 12-471. DPHY_RX I/O Signals (continued)

Device Level Signal	I/O	Description
CSI1_RXN1	I	Lane 1 Receive Differential Data (Negative)
CSI1_RXP1	I	Lane 1 Receive Differential Data (Positive)
CSI1_RXN2	I	Lane 2 Receive Differential Data (Negative)
CSI1_RXP2	I	Lane 2 Receive Differential Data (Positive)
CSI1_RXN3	I	Lane 3 Receive Differential Data (Negative)
CSI1_RXP3	I	Lane 3 Receive Differential Data (Positive)
CSI1_RXCLKN	I	Lane 3 Receive Differential Clock (Negative)
CSI1_RXCLKP	I	Lane 3 Receive Differential Clock (Positive)
CSI1_RXRCALIB	A	Pin for external calibration resistor. An external resistor must be connected between this pin and package ground. Refer to the device-specific Datasheet for a recommended resistor value.

12.7.2.3 DPHY_RX Functional Description

12.7.2.3.1 DPHY_RX Programming Guide

12.7.2.3.1.1 Overview

This section details specific steps on how to program the DPHY_RX

12.7.2.3.1.2 Initial Configuration Programming

The DPHY_RX operation shows the registers that are written during the startup sequence.

This section provides description and timing diagrams for DPHY_RX operation. Unless otherwise described in this subsection, the DPHY_RX PPI interface is compliant with the timing diagrams described in the MIPI D-PHY v1.2 specification.

12.7.2.3.1.2.1 Start-up Sequence Timing Diagram

The common configuration pins noted in [Figure 12-510](#) are ipconfig_cmnn, pll_ipdiv, pll_fbdiv, pll_opdiv, psm_clock_freq_cmnn. Drive these pins as per the pin description given in PHY pin list.

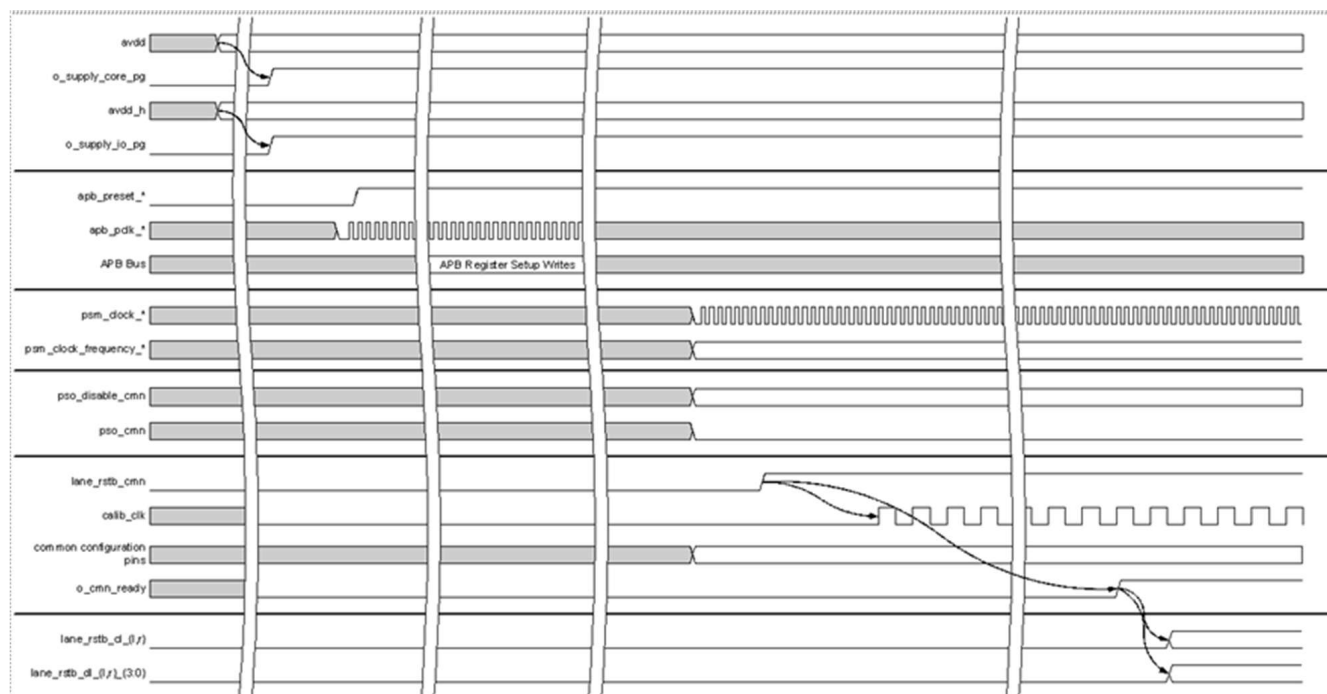

Figure 12-510. Common Power Up and Initialization Timing Diagram

Figure 12-511. Lane Power Up and Initialization Timing Diagram

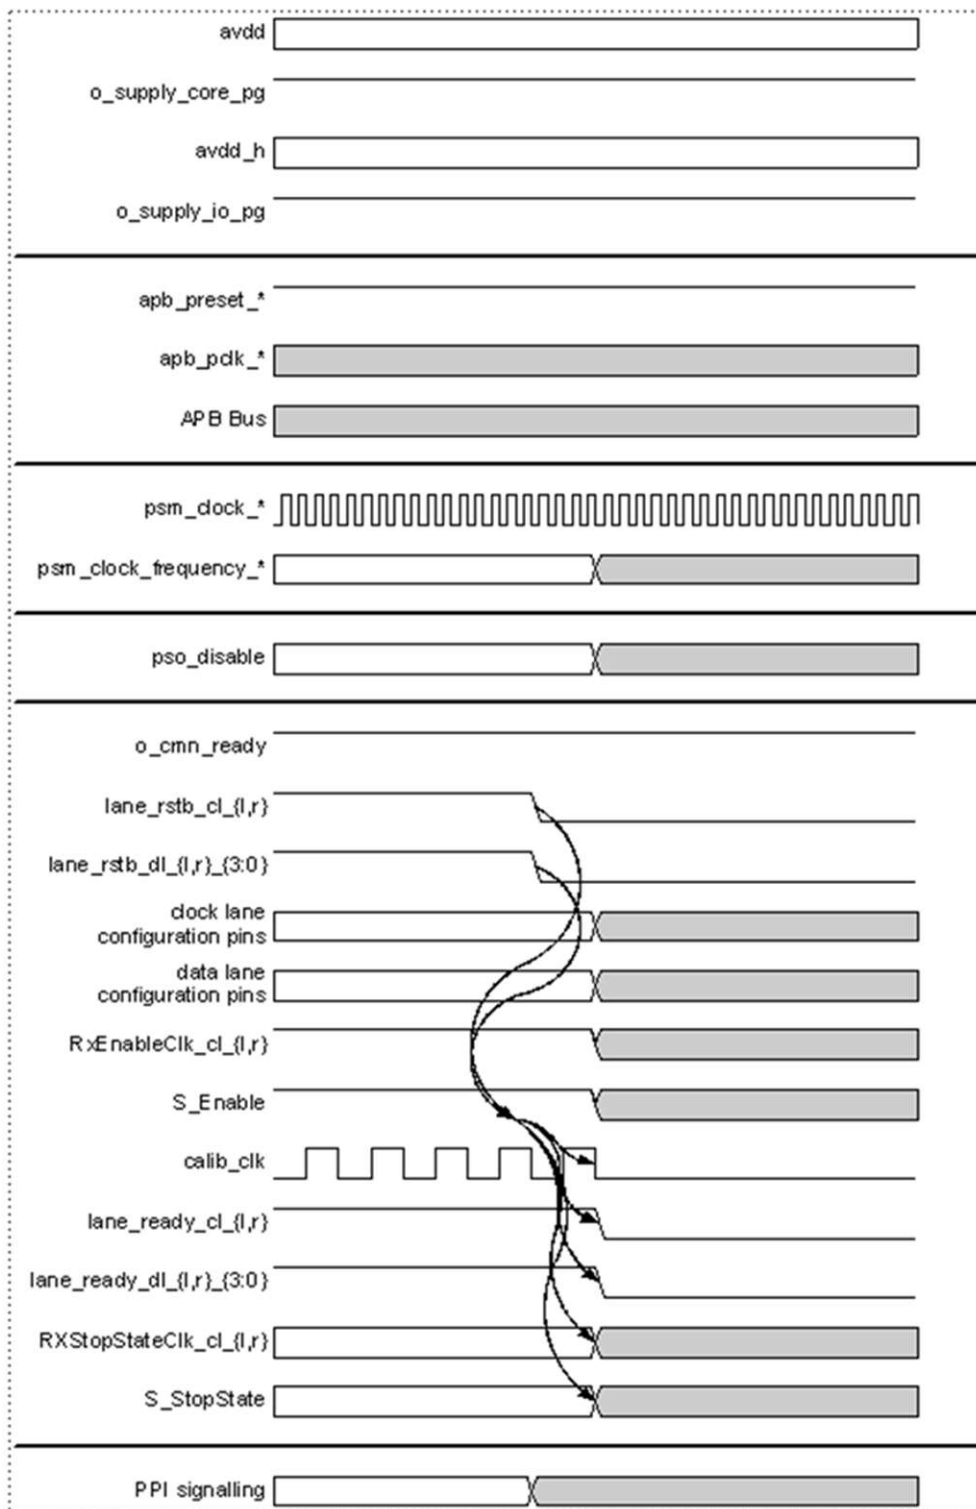

Figure 12-512. PHY Disable Timing Diagram

For initial set up, the DPHY_RX must be configured/set (registers and configuration input pins) for the common module prior to releasing it from reset, and the lane modules prior to releasing them from reset. Registers shall be configured (as required) between releasing the APB from reset and releasing the common / lanes from reset.

Note that in some cases, the option exists to configure a function using either a pin or a register. In such cases, both options will be specified and the you can select the preferred option.

12.7.2.3.1.3 Common Configuration

Table 12-472. Common Configuration-Related Setup

Configuration Register / Pin	Configuration Requirement
PHY Pin: psm_clock_freq PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 1	Set the PMA state machine clock frequency divider. Set either the pin or the register, as specified in the respective description, for the required PMA state machine clock.
PHY Pin: ipconfig_cmh PHY Register: DPHY_RX_MMR_SLV_LANE[11-9] IPCONFIG_CMN	Set the clock lane configuration. Set as specified in the description for the required clock lane configuration.
PMA Register: DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT2[0] O_CMN_SSM_EN, DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT2[10] O_CMN_RX_MODE_EN	Enable the startup state machines for TX mode of operation. Set both register bits to 1'b1.
PMA Register: DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT35	Set the RX oscillator calibration feedback clock counter start values. Set the register fields, as specified in the description for the required PMA state machine clock and oscillator clock.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 2	Set the required power island phase 2 time. Set the register to 32'hAAAAAAAA.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[7:4] POWER_SW_2_TIME_CL_R, DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[3:0] POWER_SW_2_TIME_CL_L	Set the required power island phase 2 time. Set the register to 8'hAA

12.7.2.3.1.4 Lane Configuration

Table 12-473. Lane Configuration-Related Setup

Configuration Register / Pin	Configuration Requirement
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 0	Set the lane band control value. Set the register fields, as specified in the register description for the required data rate.
PMA Register (clock lanes): DPHY_RX_VBUS2APB_CLK0_RX_DIG_TBIT2[18:15] RXDA_FREQ_BAND_SEL1 PMA Register (clock lanes): DPHY_RX_VBUS2APB_CLK0_RX_DIG_TBIT2[13:10] RXDA_FREQ_BAND_SEL2	Set the analog frequency band selects, as specified in the register description for the required data rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 0 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 0[21] TM_1P5TO2P5G_MODE_EN	Set the analog data rate select, as specified in the register description for the required data rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 0 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 0[16] TM_SETTLE_COUNT_SEL and [15-9] TM_SETTLE_COUNT	Set the HS-settle counter, as specified in the register description for the required data rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 3 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 3	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 5 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 5	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.

Table 12-473. Lane Configuration-Related Setup (continued)

Configuration Register / Pin	Configuration Requirement
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 7 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 7	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 9 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 9	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 12 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 12	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.

12.7.2.3.1.5 Procedure: Clock Lane Low Power Analog Receiver Functions Test

12.7.2.3.1.5.1 Description of Procedure

This procedure describes how the low power analog receiver functions (LPRX, and ULPRX) can be tested. The process used in this test is to enable test MUXes for the low power receiver functions, then write registers in common to drive LP signaling states to the lanes, and read registers in the lanes to detect the current state of the analog functions in the lane.

12.7.2.3.1.5.2 Details of the Procedure

- Follow the procedure described in section [Section 12.7.2.3.1.2](#), but do not release the common or lanes from reset.
- Write the following registers.
 - PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT21[0] O_RX_DIG_BIST_EN = 1'b1, to enable the analog BIST power island in common.
 - PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT28[23:20] = 4'b1111, to enable the clock lane diagnostic low power override functions, and drive LP11 from common to the clock lanes.
 - PMA Register (clock lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT2[24] = 1'b1, to enable the diagnostic low power override MUXes in the analog.
 - PMA Register (clock lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT2[1:0] = 2'b11, to force the analog ULPS receiver to be enabled.
- Release the common from reset, and wait for DPHY_RX_VBUS2APB_ISO_PHY_ISO_CMN_CTRL[5] O_CMN_READY to be driven to 1'b1.
- Release the clock and data lanes from reset, and wait for DPHY_RX_VBUS2APB_ISO_PHY_ISO_CMN_CTRL[8] LANE_READY_CMN to be driven to 1'b1.
- Poll PMA Register (CMN): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT56[20-11] I_CMN_RX_SSM_STATE until it is set to 9'b100000000.
- Repeat the following for each of the following values, to drive LP values from common and test the analog functions in the clock lanes: 2'b01, 2'b00, 2'b10, 2'b11.
 - Write the PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT28[22,20] = value.
 - Read and confirm the PMA Register (clock lanes): DPHY_RX_VBUS2APB_CLK0_RX_DIG_TBIT4[13:12] = value.
 - Read and confirm the PMA Register (clock lanes): DPHY_RX_VBUS2APB_CLK0_RX_DIG_TBIT4[9:8] = value.

12.7.2.3.1.6 Procedure: Data Lane Low Power Analog Receiver Functions Test

12.7.2.3.1.6.1 Description of Procedure

This procedure describes how the low power analog receiver functions (LPRX, and ULPRX) can be tested. The process used in this test is to enable test MUXes for the low power receiver functions, then write registers in common to drive LP signaling states to the lanes, and read registers in the lanes to detect the current state of the analog functions in the lane.

12.7.2.3.1.6.2 Details of the Procedure

1. Follow the procedure described in section [Section 12.7.2.3.1.2](#), but do not release the common or lanes from reset.
2. Write the following registers.
 - PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT21[0] O_RX_DIG_BIST_EN = 1'b1, to enable the analog BIST power island in common.
 - PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT28[19:16] = 4'b1111, to enable the data lane diagnostic low power override functions, and drive LP11 from common to the data lanes.
 - PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT30[1] TM_LPRX_BIST_EN = 1'b1, to enable the diagnostic low power override MUXes in the analog.
 - PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT1[9:8] = 2'b11, to force the analog ULPS receiver to be enabled.
3. Release the common from reset, and wait for DPHY_RX_VBUS2APB_ISO_PHY_ISO_CMN_CTRL[5] O_CMN_READY to be driven to 1'b1.
4. Release the clock and data lanes from reset, and wait for DPHY_RX_VBUS2APB_ISO_PHY_ISO_CMN_CTRL[8] LANE_READY_CMN to be driven to 1'b1.
5. Poll PMA Register (CMN): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT56[20-11] I_CMN_RX_SSM_STATE until it is set to 9'b100000000.
6. Repeat the following for each of the following values, to drive LP values from common and test the analog functions in the data lanes: 2'b01, 2'b00, 2'b10, 2'b11.
 - a. Write the PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT28[18,16] = value.
 - b. Read and confirm the PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT34[13:12] = value.
 - c. Read and confirm the PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT34[9:8] = value.

12.7.2.3.1.7 Procedure: Clock and Data Lane High Speed Receiver BIST Functions Test

12.7.2.3.1.7.1 Description of Procedure

This procedure describes how to use the high speed data BIST generation and checking functions to test the high speed data receiver functions. The process used in this test is to enable test MUXes for the low power and high speed data receiver functions, then write registers to setup, run and check the results of the BIST functions.

12.7.2.3.1.7.2 Details of the Procedure

1. Set up IP for BIST operations.
 - a. Follow the procedure described in section [Section 12.7.2.3.1.2](#), but do not release the common or lanes from reset.
 - b. Write the following registers.
 - PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT21[0] O_RX_DIG_BIST_EN = 1'b1, to enable the analog BIST power island in common.
 - PMA Register (clock lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT2 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT2 [24] = 1'b1, to enable the diagnostic low power override MUXes in the analog.
 - PMA Register (clock lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT2 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT2 [21:20] = 2'b11, to enable the diagnostic high speed override MUXes in the analog.
 - PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT30 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT30[1:0] = 2'b11, to enable the diagnostic low power and high speed override MUXes in the analog.
 - c. Release the common from reset, and wait for DPHY_RX_VBUS2APB_ISO_PHY_ISO_CMN_CTRL[5] O_CMN_READY to be driven to 1'b1.
 - d. Release the clock and data lanes from reset, and wait for DPHY_RX_VBUS2APB_ISO_PHY_ISO_CMN_CTRL[8] LANE_READY_CMN to be driven to 1'b1.
 - e. Poll PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT56[20-11] I_CMN_RX_SSM_STATE until it is set to 9'b100000000.
 - f. When running BIST at 1.5 Gbps, do the following, otherwise skip this if running BIST at 2.5 Gbps.

- i. Write PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT36[1] O_RX_TM_SEL_1P5G_M ODE= 1'b1.
 - ii. Wait 5 uSec.
2. Run BIST operations.
 - a. At this point, the BIST generator and checker registers can be written to the values required to generate the desired data patterns. One should see the BIST register descriptions for information about programming the various fields for creating different data patterns. If no registers are written, the BIST default pattern will be generated and checked.
 - b. If running infinite BIST mode is desired, write the PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT24[15] BIST_INF_MODE = 1'b1, to enable infinite BIST mode.
3. Write PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT27[0] = 1'b1, to enable the pattern checkers in the data lanes.
4. Write PMA Register (cmn): CMN_DIG_TBIT22[0] TM_BIST_EN = 1'b1, to enable the pattern generator in the common.
5. If infinite BIST mode was enabled, do the following.
 - a. Allow the BIST to run as long as required.
 - b. Write the PMA Register (cmn lanes): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT24[15] BIST_INF_MODE = 1'b0, to disable infinite BIST mode.
6. Wait for a minimum of 100 nSec.
7. Poll PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT50[1] BIST_COMPLETE until it is set to 1'b1, indicating that the BIST pattern generation process is complete.
8. Wait 1 uSec.
9. Read and confirm the PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT48 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT48[0] W_DRX_BIST_PASS = 1'b1, indicating the BIST checker has indicated a pass condition.
10. Read and confirm the PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT48 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT48[1] R_PAT_CHE_SYNC = 1'b1, indicating the BIST checker has observed a marker symbol.
11. Read and confirm the PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT48 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT48[2] W_BIST_ERROR = 1'b0, indicating the BIST checker has not detected any errors.
12. Read and confirm the PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT47 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT47[15:0] W_PAT_CHE_PKT_COUNT = the generated number of packets (15 by default).
13. Read and confirm the PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT47 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT47[31:16] W_PAT_CHE_ERROR_COUNT = 16'h0000, indicating the BIST checker error count is 0.
14. Clear the internal state of the BIST pattern checkers by doing the following:
 - a. Read PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT29 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT29[28] TM_CLEAR_BIST.
 - b. Write PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT29 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT29[28] TM_CLEAR_BIST = inverted value of what was read from this bit in the previous step.
15. Write PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT27 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT27[0] TM_BIST_EN = 1'b0, to disable the pattern checkers in the data lanes.
16. Clear the internal state of the BIST pattern generator by doing the following:
 - a. Write the PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT24[6] = 1'b1,
 - b. Write the PMA Register (cmn): CMN_DIG_TBIT24[6] BIST_CLEAR = 1'b0.
17. Write the PMA Register (cmn): DPHY_RX_VBUS2APB_CMN0_CMN_DIG_TBIT22[0] BIST_CONTROLLER_EN = 1'b0, to disable the BIST pattern generator.
18. If desired, the run BIST operations can be repeated without needing to run set up the IP for BIST operations again.

12.7.3 Camera Streaming Interface Transmitter (CSI_TX_IF)

The following sections describe the camera streaming transmitter interface (CSI_TX_IF) module in the device.

12.7.3.1 CSI_TX_IF Overview

The integration of the CSI_TX_IF module allows the device to stream out video data from memory, or retransmit from the CSI receivers as an optional loopback output for diagnostics, debug, and test purposes.

Figure 12-513 shows the CSI_TX_IF module overview.

A. $i = 0$ to 1

Figure 12-513. CSI_TX_IF Module Overview

12.7.3.1.1 CSI_TX_IF Ports

This section describes the CSI_TX_IF ports related to clocks, resets, and hardware requests.

Table 12-474. CSI_TX_IF Clocks and Resets

Clocks	
Module Clock Input	Description
CSI_TX_MAIN_CLK	Main functional(sometimes referred to as pixel clock) clock.
CSI_TX_VBUS_CLK	The VBUS clock runs at always half the speed of the CSI_TX_MAIN_CLK.
CSI_TX_ESC_CLK	20 MHz max clock input for low speed data transmission and some control signals.
DPHY_TXBYTECLKHS	The byte clock is the clock supplied by the DPHY_TX.
Resets	
Module Reset Input	Description
CSI_TX_RST	Asynchronous module global reset, driving all collateral asynchronous resets of the 4 clock domains to the low state.

Table 12-475. CSI_TX_IF Hardware Requests

Interrupt Requests		
Module Interrupt Signal	Description	Type

Table 12-475. CSI_TX_IF Hardware Requests (continued)

CSI_TX_IF_CSI_INTERRUPT_0	Global interrupt that various re-synchronized sources converge into interrupt generation.	Level
CSI_TX_IF_CSI_LEVEL_0	Error interrupt that is generated under the following conditions: <ul style="list-style-type: none"> Retransmit error on Stream2 (packet error on the stream interface) Retransmit error on Stream3 (packet error on the stream interface) 	Level
CSI_TX_IF_CSI_FATAL_0	ASF port fatal interrupt. Level sensitive.	Level
CSI_TX_IF_CSI_NONFATAL_0	ASF port non-fatal interrupt. Level sensitive.	Level
CSI_TX_IF_CDNS_RAM_CORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_CDNS_RAM_UNCORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_CORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_UNCORR_LEVEL_0	Interrupt on internal FIFO RAM	Level

12.7.3.2 CSI_TX_IF Features

The CSI_TX_IF module supports the following features:

- Compliant to MIPI CSI v1.3, MIPI CSI v2.1, and MIPI D-PHY v2.1
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to DPHY_TX
- Programmable formats including YUV422, RGB, Raw, and User Defined (over 25 different formats supported); Limitations apply depending on the stream used
- 16 virtual channel support
- Configurable input streams supported:
 - Stream0:** DMA interface through a 128-bit PSI_L connection for transfers from memory **OR** CSI_RX retransmit:
 - 128bit wide pixel data with bursting
 - ByteValid per byte in Last Data Phase (LDP)
 - 32 thread IDs supported (virtual channel & data type combinations); Flexible number of threads (32 Max).
 - Unpacking PSI_L data and converting to CSI video format
 - Internal FF based FIFO and external RAM based buffer
 - Stream1:** Color bar video data generator
 - 2 pixel wide
 - YUV422 8-bit format support only
 - Configurable frame/line size via registers
 - 1 programmable virtual channel
 - Internal FF based FIFO; No external buffer.
- Functional and data path error interrupts
- ECC support on external RAMs

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.7.3.2.1 CSI_TX_IF Legacy Compatibility

The following lists changes that must be considered compared to previous generation CSI_TX_IF:

- YUV420 is not supported, YUV420 configuration registers/bitfields are not used
- Word count must be programmed in the CSI_TX_IF, not in the TX Core.
- CSI_TX_IF compatibility mode must be used in Stream0 when retransmitting from CSI_RX_IF

12.7.3.3 CSI_TX_IF Environment

The CSI_TX_IF has no dedicated pins. At the device level, the CSI_TX_IF video output goes through the shared(with DSS_DSI) DPHY_TX. See chapter *Shared MIPI D-PHY Transmitter (DPHY_TX)*.

12.7.3.4 CSI_TX_IF Functional Description

12.7.3.4.1 CSI_TX_IF Block Diagram

Figure 12-514 depicts a simplified internal block diagram of the CSI_TX_IF and its surroundings.

Figure 12-514. CSI_TX_IF Block Diagram

The CSI2 core streams 4 channels of data to the several export paths.

Stream0 (from PSI_L) goes through the PSI_L that converts 128(4x32) bits pixel data and converts it to single 32-bit CSI streaming protocol of pixel data. Each 128 bit set of PSI_L data is split into N M-bit data transfers based on the SIZE_CFG bitfield setting in the CSI_TX_IF_DMACNTX_j register for a given thread. See memory organization details in *CSI_TX_IF Data Memory Organization Details*. Via register mapping in the CSI_TX_IF_DMACNTX_j register the PSI_L thread ID is mapped to a virtual channel and a data type. The CSI_TX_IF_DMACNTX_j register is the thread filter. There are 32 dma context registers. Figure 12-515 shows the stream to PSI_L thread mapping.

Figure 12-515. CSI_TX_IF PSI_L thread mapping

Software must take the following notes in consideration

- Interleaved data formats on single virtual channel and frame are supported.
- All PSI_L threads that open a frame must be closed before a new PSI_L thread can start a new frame. Until all channels close the frame other threads will be stalled.
- DATA is assumed in a specific organization for CSI_TX_IF to export data correctly. See memory organization details in *CSI_TX_IF Data Memory Organization Details*.
- Threads can only switch after full lines are received. PSI_L pushback will occur on all other threads.
- Thread priority is 0 - 31 and after a line is received will be re-arbitrated in that order for the next thread to send.

Registers CSI_TX_IF_L2L_DELAY_j control the line start to next line start. Also register CSI_TX_IF_L2L_DELAY_j control the last line of frame to next start of frame first line start of next frame. Buffering of PSI_L data is 2k×128 RAM.

Stream0 (from CSI_RX_IF) is a loopback stream from the CSI receiver muxed with PSI_L data stream.

Stream1 streams data from the Color Bar generator. It supports YUV422 8bit format only.

CSI_TX_IF_COLOR_PARAM register is used to control height and width information. Width is divided by 8 for each color section. Colors are defined below. Transfers are done on the Stream1 interface in 32-bit packed 8-bit pixel format(required programming in CSI_TX_IF core). Virtual channel and data type is configurable in CSI_TX_IF_COLOR_CNTL register. Data selection inside CSI_TX_IF controller maps data type information. CSI_TX_IF_COLOR_START_DELAY register can configure delays from enabled to start. CSI_TX_IF_COLOR_LINE_DELAY, and CSI_TX_IF_COLOR_FRAME_DELAY register can delay last line to first line of new frame. Once enabled, it will continuously send out frames until disabled. Once disabled, it will stop at end of current frame. [Table 12-476](#) shows the Color Bar format.

Table 12-476. CSI_TX_IF Color Bar format details

Color	Y	CB	CR
White	235	128	128
Yellow	162	44	142
Cyan	131	156	44
Green	112	72	58
Magenta	84	184	198
Red	65	100	212
Blue	35	212	114
Black	16	128	128

Figure 12-516. CSI_TX_IF PSI_L Color Bar sample output

Note

It is a requirement that only PSI_L/DMA, color bar, or CSI_RX_IF loopback streams are not active at the same point in time. The intended use model is not to have multiple combinations active at any given time. The main issue with this is that RAMs are not sized for concurrent operation and will likely overflow resulting in data loss.

12.7.3.4.2 CSI_TX_IF Hardware and Software Reset

An active low asynchronous hardware reset is provided to CSI_TX_IF by device LPSC. It is internally re-synchronized to the functional clock domain.

A software reset is triggered by configuring the CSI_TX_IF_TX_CONF[1] SOFT_RESET_REQUEST bit-field for protocol reset and/or module reset.

12.7.3.4.3 CSI_TX_IF Clock Configuration

There are four clock domain in the CSI_TX_IF.

1. The CSI_TX_MAIN_CLK (or also referred to as pixel clock) runs most of the logic. It needs to be same frequency as CSI_RX_MAIN_CLK main clock (500MHz). When CSI_TX_MAIN_CLK is operating lower than 312.5MHz, then the clock is essentially limiting the clock rate of the DPHY_TX. Said another way, CSI_TX_MAIN_CLK must be at least the DPHY_TXBYTECLKHS rate else FIFOs will overflow, crashing the module.
2. The CSI_TX_VBUS_CLK is the interface configuration clock that runs at half the speed of the CSI_TX_MAIN_CLK (250MHz).
3. The DPHY_TXBYTECLKHS is the clock supplied by the DPHY_TX PLL and is divided down to byte clock. The DPHY_TX is designed for max of 10gbps. This translates to a max byte clock of 312.5MHz. The clock is inactive when DPHY_TX is not in HS operation.
4. The CSI_TX_ESC_CLK escape clock runs at 20MHz. CSI_TX_ESC_CLK is rarely used by the CSI_TX_IF, usually is only to clock in some low speed control signals from DPHY_TX. The ESC interface is a low speed DPHY common link to the camera/sensor.

Table 12-477 shows the CSI_TX_IF and DPHY_TX inter-clock dependencies.

Table 12-477. CSI_TX_IF Inter-clock Dependencies

	CSI_TX_MAIN_CLK	CSI_TX_VBUS_CLK	DPHY_TXBYTECLKHS	CSI_TX_ESC_CLK
Min freq	DPHY_TXBYTECLKHS freq	CSI_TX_MAIN_CLK / 2 freq	N/A	N/A
Max freq	500MHz	CSI_TX_MAIN_CLK / 2 freq	312.5MHz	20MHz

12.7.3.4.4 CSI_TX_IF Interrupt Events

12.7.3.4.4.1 CSI_TX_IF Interrupt Events

This section describes the register configuration of the interrupt events that can trigger the several CSI_TX_IF interrupt signals. For detailed description and mapping of the interrupt to the device interrupt processors see *CSI_TX_IF Integration*.

The interrupts are generally handled within the INTD module of the CSI_TX_IF, although there are several interrupt registers in the ECC_AGGR for ECC errors and in the VBUS2APB for stream monitoring errors/flags.

Table 12-478 lists the event generation and corresponding registers of the CSI_TX_IF controller.

Table 12-478. CSI_TX_IF Interrupt Events Cross Table

Event	Mask Register	Status Register	Description
CSI_TX_IF_MAIN_0_CSI_INTERRUPT	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Global interrupt that various re-synchronized sources converge into interrupt generation. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_LEVEL	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Error interrupt that is generated under the following conditions: <ul style="list-style-type: none"> Retransmit error Unselected stream error. An unselected DMA path or CSI_RX_IF loopback path is sending data when not selected Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_CORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_UNCORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_UNCORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_FATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.
CSI_RX_CSI_NONFATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.

12.7.3.4.5 CSI_TX_IF Data Memory Organization Details

Figure 12-521. CSI_TX_IF RAW12 (PACKED) memory data organization

12.7.3.4.6 CSI_TX_IF PSI_L (DMA) Interface

The PSI_L (DMA) interfaces is common for both CSI_RX_IF and CSI_TX_IF, see chapter *Camera Streaming Interface Receiver (CSI_RX_IF) and MIPI DPHY Receiver (DPHY_RX)*, subsection *CSI_RX_IF PSI_L (DMA) Interface*.

12.7.3.4.7 CSI_TX_IF ECC Protection Support

The CSI_TX_IF has two ECC aggregators, one for byte clock (DPHY_TXBYTECLKHS) and the other one for all other clocks. The ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC protection on the CSI_TX_IF RAM provides Single Error Correction and Double Error Detection (SEC/DED). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC protection also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

The ECC aggregators on the CSI_TX_IF subsystem level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. They provide a single EOI-handshake based interrupt to the interrupt processors (for both single and double error detections) and a standard 32-bit VBUS interface for configuring and querying the ECC register set, see *CSI_RX_IF ECC Registers*. For complete details on the features and functions of the ECC aggregator, see *ECC Aggregator*.

12.7.3.5 CSI_TX_IF Programming Guide

Note

Software must keep the CSI_TX_IF_CONTROL1[0] PIXEL_RESET register in the asserted state in the control register until all CSI_TX_IF controller registers are programmed. Only after all CSI_TX_IF controller programming can software de-assert CSI_TX_IF_CONTROL1 register. If software has to reprogram any CSI_TX_IF controller registers it MUST have the control CSI_TX_IF_CONTROL1 register reset asserted.

It is a restriction that LS/LE detection is disabled.

12.7.3.5.1 CSI_TX_IF Programming (Configuration Mode)

Although it is always possible to read/write all control registers, it strongly recommended writing to the control registers only while configuration mode is active. To enter configuration mode, the CSI_TX_IF_TX_CONF[2]

CONFIGURATION_REQUEST bit must be set. CSI_TX_IF enters configuration mode when transmission of any ongoing frame has ended and the configuration request bit is set. Configuration mode is the default state after reset. While configuration mode is active, the CSI_TX_IF_STATUS[2] CONFIGURATION_ACTIVE bit is set. Traffic at the pixel interface is ignored during configuration mode, and it is safe to write to control registers and change configuration.

To exit configuration mode, the CONFIGURATION_REQUEST bit in the CSI_TX_IF_TX_CONF register must be cleared. The CSI_TX_IF then starts normal operation, with first new frame incoming after configuration mode exit.

During configuration mode, all interrupts are disabled.

Note

A mandatory assertion of soft reset occurs following the de-assertion of CONFIGURATION_REQUEST. This ensures the controller is in a known state and all the parameters set in the configuration registers have been loaded correctly into the internal state. The DPHY_TXBYTECLKHS must be active before the configuration request is completed.

12.7.3.5.2 CSI_TX_IF System Initialization Programming

The power up/reset release of the system will clear all the register values to their reset conditions. Software must perform programming of the virtual channel and data type registers to match the system operation if the reset conditions do not match the required values. Software must ensure that all the data type select registers are programmed with valid values for the pixel_dt_sel_if parameter used.

The CSI_TX_IF registers for all the DPHY_TX related control and delays must be set before starting the system. The DPHY_TX delays must be calculated using the system clock periods associated with CSI_TX_ESC_CLK and DPHY_TXBYTECLKHS. The wait burst time must be calculated using the relevant DPHY_TX data sheet to ensure that all the lanes begin new requests at the same point.

Software must configure the FIFO fill level control registers, if required to suit clock ratios used and the desired payload control configurations. When all registers are programmed the configuration can be made active. The pixel streams can then start requests.

Note

The CSI_TX_IF is configured at design time, such that the reset values adopt a generic preferred Power_On state. This reduces the programming steps required by the system for the general use case scenario.

12.7.3.5.3 CSI_TX_IF Lane Control Programming

The CSI_TX_IF links to the DPHY_TX clock and data lanes. After power up, software must identify that the DPHY_TX is powered on and the DPHY_TX PLL has locked. The DPHY_TX controls for swapping the DP/DN control can be modified using the CSI_TX_IF_DPHY_CFG1 register if required.

Software must then program the enable for the clock lane and each data lane that is required. The DPHY_TX lane signals can be checked using the CSI_TX_IF_DPHY_STATUS register to identify that the lane is in STOPSTATE and is ready for High Speed transmission. This register can also be used to identify when ULPS is active.

12.7.3.5.4 CSI_TX_IF Virtual Channel and Data Type Management

The following section provides information on how the configuration of virtual channels and data types may be used in conjunction with one or more stream inputs to meet the system requirements.

12.7.3.5.4.1 CSI_TX_IF Data Type Interleaving

The CSI_TX_IF can support interleaving of data types by configuring the pixel_dt_sel_if inputs at the pixel interface to select the required data type and pixel count values.

12.7.3.5.4.2 CSI_TX_IF Data Type Interleaving with Multiple Interfaces

The CSI_TX_IF will perform data type interleaving with one, two, or more pixel interfaces. In this scenario, Stream0 will be the master and one or more streams may be ganged together as slaves to the master stream. Therefore, for all the ganged streams, the virtual channel signals must be configured to the same value and the pixel streams must have the same active frame valid cycle (that is the virtual_channel_if* and frame_valid_if* must be wired in parallel). The STREAM_IF_*_SLAVE_MODE bit in the STREAM_IF_*_CFG registers must also be set for all slaved streams. This ensures that only one frame start and frame end are generated for all the ganged streams. Note that the pixel 0 interface is always the master and slave bits exist for the other streams, in the control registers, to determine if they are to operate in master or slave mode.

In the case where streams are ganged together as master and slave(s), all ganged interfaces must have the same virtual channel value, but the pixel_dt_sel_if inputs must be set to different values. Again, each of the interfaces can have the pixel_dt_sel_if input change on a line by line basis, so that interleaving is done with all the ganged streams.

Note

Each stream must have exclusive use of the data types allocated to it.

Data type interleaving is only done when the frame is valid (CSI_TX_IF_DEBUG_PROT*_FSM[11] FRAME_VALID_IF* bitfield input is asserted). The virtual channel will be sampled on the first cycle after the rising edge of the FRAME_VALID_IF input and this virtual channel will be used for all the packets originating from that stream during that frame. The FRAME_VALID_IF input must be the same on all ganged stream interfaces.

12.7.3.5.4.3 CSI_TX_IF Virtual Channel Interleaving

The CSI_TX_IF can support interleaving of virtual channels by using two or more pixel interfaces and configuring the value of the virtual channels signal differently on each interface. The data streams can then be controlled using the pixel_dt_sel_if inputs to select the data type for the lines. In this scenario, each pixel interface must have exclusive use of the virtual channel. Each stream will generate its own frame start and frame end synchronisation packets. In this case, all the stream protocol modules employing virtual channel interleaving must be configured as masters by clearing the STREAM_IF_*_SLAVE_MODE bit in the STREAM_IF_*_CFG registers.

Note that the virtual channel control input is sampled at the rising edge of the frame_valid_if input, and thereafter remains fixed for that frame, therefore the virtual channel cannot be switched on a line-by-line basis for any single pixel interface. While it is possible to switch the Virtual Channel control input from frame to frame, the timing-critical switching required here would indicate a requirement for hardware rather than software control.

12.7.3.5.4.4 CSI_TX_IF Virtual Channel and Data Type Interleaving

The CSI_TX_IF may be configured to perform a combination of the scenarios outlined in the previous sections if sufficient streams are available. One or more streams may be ganged with Stream0 to perform data type interleaving on the same virtual channel, whilst the remaining streams may be left autonomous to perform virtual channel interleaving.

In this case, the same rules governing the use of the virtual channels and data types must be observed. In this scenario, the virtual channel signals will be configured to the single value required for the ganged group (as they need to be controlled within the same frame valid active signal) and different values for those left to be autonomous (as they may generate their own frame start and frame end events). The slave stream for each virtual channel can have a different data type selected, and this may change on a line-by-line (or packet-by-packet) basis.

12.7.3.5.5 CSI_TX_IF Line Control

The line control block uses the DPHY_TXBYTECLKHS from the DPHY_TX PPI interface to take the line data from the packet interface FIFO and transfer the bytes to the active lanes of the DPHY_TX. The block detects when the DPHY_TX is ready to transmit high speed data and the pixel stream has packets available.

The line control block performs pixel stream arbitration using the line control arbitration block when more than one pixel stream is generated in the configuration. The block performs all the clock and data lane control required to activate the high-speed transmission and return the lane to ULPS state as required.

12.7.3.5.5.1 CSI_TX_IF Line Control Arbitration

The CSI_TX_IF controller uses a simple arbitration scheme for configurations with more than one pixel interface.

The arbitration has 2 levels; the first is a round-robin scheme and if no streams are granted by this a priority based scheme is used. The arbitration will select the first stream making a request if there is only one stream waiting or the first in the round robin after a stream has completed transmission. This means that there may be one cycle where the round-robin selector moves across a stream position that is not requesting to transmit.

The re-arbitration boundary is between packets except where line sync is used. In this case the line start packet, long packet and line end are grouped together.

The selected stream will pass the line data from the stream FIFO to the line control block for distribution to the active PPI lanes of the DPHY_TX.

12.7.3.5.6 CSI_TX_IF Lane Manager FSM

Data distribution to the available lanes is controlled via the lane manager FSM.

The state descriptions can be found in [Table 12-479](#).

Table 12-479. CSI_TX_IF Lane Manager FSM State Description

State (line_fsm_st_r)	Description
LINE_FSM_IDLE	Wait for new transmission to be ready. When start_hs_transmission_c is asserted then go to the transmission state per enabled lanes (lanes_enable_r)
LINE_FSM_BURST_1L	Transmit burst data over lane 0 until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_BURST_2L	Transmit burst data over lanes 0 and 1 until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_BURST_4L	Transmit burst data over all lanes until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_LRTE_EPD_SPACER	Insert spacer packets across each active lane. When finished, if EPD Option 1 then go to the LINE_FSM_LRTE_EPD_PDQ state, otherwise go to the LINE_FSM_IDLE state.
LINE_FSM_LRTE_EPD_PDQ	Tell D-PHY to initiate HS-IDLE state and insert PDQ.
LINE_FSM_BURST_END	Wait for being ready for new burst transmission. In this state counter counts until WAIT_BURST_TIME value in the register is reached.

12.7.3.5.7 CSI_TX_IF Data Lane Control FSM

Data lanes control uses a simple FSM to sequence entry and exit of Ultra Low Power mode. This FSM observes inputs from the control registers and based on these inputs it generates PPI outputs for ULP mode.

[Table 12-480](#) shows the state descriptions.

Table 12-480. CSI_TX_IF Data Lanes Control FSM State Description

State (ulps_data_fsm_st_r)	Description
DATA_LN_IDLE	Idle state. In this state HS transmission can be issued if the Clock Lane is in HS mode.
DATA_LN_ULPS_REQ	Request to enter ULP state. Waiting for activation ULP confirmed by the ppi_ulps_active_not_dl input.
DATA_LN_ULPS_ACTIVE	ULPS for Data Lanes is active. Waiting for the ulps_req_sync signal being low to exit ULPS.
DATA_LN_ULPS_EXIT	ULPS exiting, waiting for the time defined in the CSI_TX_IF_DPHY_ULPS_WAKEUP register.

12.7.3.5.8 CSI_TX_IF Application Examples

This section details specific steps on how to program the CSI_TX_IF.

12.7.3.5.8.1 CSI_TX_IF D-PHY Control and Configuration

The DPHY_TX will use a PLL to provide the bit clock for transmission. The CSI_TX_IF controller uses the associated byte clock as a primary clock source and this must be active and stable before the CSI_TX_IF is ready to transmit high speed data.

Software must perform the programming of the PLL dividers and monitor the lock status. Software must also ensure the correct sequence of programming the PLL, DPHY_TX and CSI_TX_IF to guarantee the clocks are active and resets are released, following the start-up sequence described in DPHY_TX chapter (See chapter *Shared MIPI D-PHY Transmitter (DPHY_TX)*).

12.7.3.5.8.2 CSI_TX_IF Clock and Data Lane Enable

The DPHY_TX lanes are controlled using the CSI_TX_IF_DPHY_CFG register. The clock enable will be asserted once the DPHY_TX is configured, PLL is programmed and locked and the lanes are enabled. Enabling the clock lane will then make the TX clock module stay in stop state with the DP/DN pads in LP11. The TX clock high speed ready state will be detected once the TX clock lane has completed the preamble and begun to drive the high speed clock.

The configured number of data lanes will be enabled at the same time as enabling the TX clock. The data lane will remain in LP until the high-speed clock is stable and the CSI_TX_IF makes the request for the data lane transitions from stop state to active (LP11-LP01-LP00).

12.7.3.5.8.3 CSI_TX_IF DP/DN Signal Swap

The DPHY_TX may have the capability to swap the data pin polarity or invert the clock lane polarity - the CSI_TX_IF_DPHY_CFG1 register is available within the controller for driving these pad level controls (using the DPHY_DIFF_INVERT_* fields). The DPHY_TX will identify any contention issues with the transmitter and flag this using the contention signals and error interrupt - this may be used by software to determine if the data pin or clock lane polarity switching is required or not (by optimizing to the minimum, preferably zero, rate of occurrence of contention issues).

In the DPHY_TX, the IO pads for the clock and data lanes support swapping of the polarity of the signals DP-DN. All dphy_differential_invert_* outputs should be treated as asynchronous. Note that, if these signals need to be asserted, they should be asserted before releasing the DPHY_TX reset.

Each lane can be controlled independently with the CSI_TX_IF_DPHY_CFG and CSI_TX_IF_DPHY_CFG1 registers.

12.7.3.5.9 CSI_TX_IF DPHY_TX Status

The status of clock and data lanes is available in the read only CSI_TX_IF_DPHY_STATUS register. The clock lane fields show the condition of the ppi_tx_ulps_active_not_cl and ppi_stopstate_cl PPI inputs. The data lane fields show the ppi_ulps_active_not_dl* and ppi_stopstate_dl* PPI inputs.

All the status signals are based on the active enabled lane configuration.

The DPHY_TX can signal error conditions for each lane for contention in low power transitions and signal errors at the start of high speed transitions, using the CSI_TX_IF_DPHY_IRQ register. The signals can be used to generate an error interrupt event if the relevant bits are set in the CSI_TX_IF_DPHY_IRQ_MASK register. The flag can be cleared by writing to the CSI_TX_IF_DPHY_IRQ register.

12.7.3.5.10 CSI_TX_IF ULPS Operation

Each lane can be put in ultra-low power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane must be in stop state.
- For data lanes, no data must be pending in the CSI_TX_IF module.

12.7.3.5.11 CSI_TX_IF System Frame Rate Measurement

The CSI_TX_IF provides an interrupt event to signal when the frame start (FS) and frame end (FE) packets are sent to the DPHY_TX. These events are generated on a stream basis for each virtual channel and allow a system configured to perform virtual channel interleaving to capture the events, and to derive the frame rate achieved based on the flow control and clock configuration.

The system performance will be impacted by the FIFO sizing and any flow control mechanism used by the pixel streams, so this provides a mechanism for checking that the system is scaled correctly.

12.7.3.5.12 CSI_TX_IF Configuration for PSI_L

Table 12-481 lists the settings that must be programmed before enabling CSI_TX_IF controller and sending PSI_L data.

Table 12-481. CSI_TX_IF Configuration table for PSI_L

Format	Pixel transmit mode used	Size	Details
YUV420-8	single	0	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV420-10	single	1	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	single	0	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-10	single	1	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	packed	2	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
RGB888, RGB666	single	2	
RGB565, RGB555, RGB444	single	1	
RAW6-7 ⁽¹⁾	single	0	
RAW8 ⁽¹⁾	dual	1	
RAW8 ⁽¹⁾	quad	2	
RAW10 ⁽¹⁾	single	1

RAW14 ⁽¹⁾	dual	2	
RAW16 ⁽¹⁾	single	1	
RAW20 ⁽¹⁾	single	2	

(1) User defined/blanking/generic data types are programmed the same way as RAW data types.

12.7.3.5.13 CSI_TX_IF Configuration for Color Bar

The following lists the Color Bar configuration requirements:

- Color bar must be set to packed YUV422-8 format, this is an extended datatype in CSI_TX_IF controller.
- Software must program CSI_TX_IF controller before enabling the color bar from the CSI_TX_IF_COLOR_CNTL[0] EN bit-field.
- Program CSI_TX_IF_COLOR_LINE_DELAY, CSI_TX_IF_COLOR_FRAME_DELAY, CSI_TX_IF_COLOR_START_DELAY, and CSI_TX_IF_COLOR_PARAM registers with appropriate configurations. Update CSI_TX_IF_COLOR_CNTL with virtual channel and data type desired and enable it.

12.7.3.5.14 CSI_TX_IF Error Recovery

When an underflow error occurs, software must reset the entire CSI_TX_IF by SoC PSC reset and restart over.

12.7.3.5.15 CSI_TX_IF Power up/down Sequence

The following lists the power up/down sequence requirements:

1. Software must ensure no more PSI_L traffic is directed toward the CSI_TX_IF module.
2. Software must then go through a tear down process on PSI_L gasket inside CSI_TX_IF wrapper. Refer to chapter *PSI_L* for tear down process.
3. Software must then check the stream idle values so that they are idle in the CSI_TX_IF_CONTROL1 register.
4. Software must then stop all traffic inside the CSI_TX_IF controller and wait till it is idle.
5. After that software can then proceed to do PSC power down routine.

12.8 Shared MIPI D-PHY Transmitter (DPHY_TX)

This section describes the features and functions of the shared MIPI D-PHY Transmitter (DPHY_TX).

12.8.1 DPHY_TX Subsystem Overview

The DPHY_TX module provides one option for video output interfacing by implementing a four-lane MIPI D-PHY Transmitter.

The device includes of DPHY_TX module.

12.8.1.1 DPHY_TX Features

The DPHY_TX module supports the following main features:

- Compliance with MIPI D-PHY 1.2 physical layer interface specification and features
- 1, 2 or 4 data lanes, in addition to clock signaling
- Maximum data rate up to 2.5 Gbps per data lane (with deskew) and 1.5 Gbps (without deskew)
- Protocol Peripheral Interface (PPI)
- HS (High-Speed) continuous and burst modes
- LP (Low-Power), ULPM (Ultra-Lower Power), and Shutdown modes
- Data lanes can be independently operated in HS or ULP mode.
- Forward direction and reverse direction escape modes (only on Lane-0)
- Automatic termination control in both high-speed and low-power modes
- Fault detection:
 - Contention detection
 - Sequence error detection (corruption on lanes)

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.8.1.2 DPHY_TX Ports

This section describes the DPHY_TX ports related to clocks and resets.

Table 12-482. DPHY_TX Clocks and Resets

Clocks	
Module Clock Input	Description
DPHY_TX_CLK	DPHY_TX interface clock
PSM_CLK	DPHY_TX reference clock
IP1_PPI_K_M_TXCLKESC	DPHY_TX escape mode clock
IP1_PPI_K_LN0_M_TXCLKESC	DPHY_TX escape mode clock for lane 0 for IP1_PPI
IP1_PPI_K_LN1_M_TXCLKESC	DPHY_TX escape mode clock for lane 1 for IP1_PPI
IP1_PPI_K_LN2_M_TXCLKESC	DPHY_TX escape mode clock for lane 2 for IP1_PPI
IP1_PPI_K_LN3_M_TXCLKESC	DPHY_TX escape mode clock for lane 3 for IP1_PPI
DPHY_REF_CLK	DPHY_TX reference clock.
PPI_0_TXBYTECLKHS	DPHY_TX byte clock for IP1_PPI
DPHY_0_RXCLKESC	DPHY_TX reverse escape mode recovered clock from lane 0
DPHY_TXBYTECLKHS	DPHY_TX byte clock for IP2_PPI
Resets	
Module Reset Input	Description
DPHY_TX_RST	DPHY_TX reset

12.8.2 DPHY_TX Environment

This section describes the DPHY_TX application fields from an environment point of view (external connections).

[Table 12-483](#) describes the DPHY_TX signals when transmitting data from a DSI module, and [Table 12-484](#) describes the DPHY_TX signals when transmitting data from a CSI_TX_IF module.

Table 12-483. DPHY_TX I/O Signals in DSI Mode

Device Level Signal	I/O ⁽¹⁾	Description
DSI_TXN0	I/O	DPHY_TX0 Lane 0 Transmit Differential Data (Negative)
DSI_TXP0	I/O	DPHY_TX0 Lane 0 Transmit Differential Data (Positive)
DSI_TXN1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Negative)
DSI_TXP1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Positive)
DSI_TXN2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Negative)
DSI_TXP2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Positive)
DSI_TXN3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Negative)
DSI_TXP3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Positive)
DSI_TXCLKN	O	DPHY_TX0 Transmit Differential Clock Lane (Negative)
DSI_TXCLKP	O	DPHY_TX0 Transmit Differential Clock Lane (Positive)
DSI_TXRCALIB	A	DPHY_TX0 pin for external calibration resistor. Refer to the device-specific Datasheet for a recommended resistor value.
DSI_ATB_0_H	I/O	DPHY_TX0 Analog Test Bus 0
DSI_ATB_1_H	I/O	DPHY_TX0 Analog Test Bus 1

(1) I = Input; O = Output.

CSI0_TXCLKP	O	DPHY_TX0 Transmit Differential Clock Lane (Positive)

12.9 Timer Modules

This section describes the timer modules in the device.

12.9.1 Global Timebase Counter (GTC)

This section describes the global timebase counter (GTC) in the device.

12.9.1.1 GTC Overview

The GTC module provides a continuous running counter that can be used for time synchronization and debug trace time stamping.

The device includes one GTC instance.

12.9.1.1.1 GTC Features

The GTC supports the following features:

- 64-bit up counter
- No rollover during the lifetime of the device
- Compatible with ARMv8 system counter requirements:
 - Disabled at power-up
 - Register definition and memory map aligned to ARMv8 definition
 - Implements memory-mapped counter control and status frames
- Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
- Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols

12.9.1.1.2 GTC Ports

Table 12-485. GTC Clocks and Resets

Clocks	
Module Clock Input	Description
GTC_CLK	Module functional (counter) clock.
GTC_VBUSP_CLK	Module interface clock.
Resets	
Module Reset Input	Description
GTC_POR_RST	Module reset. Affects counter and MMR logic.
GTC_SYS_RST	POR that is unstretched and not delayed by any sequential logic. Used for boot config to sample device pins.

Table 12-486. GTC Hardware Requests

Time Sync Events		
Module Sync Output	Description	Type
GTC_GTC_PUSH_EVENT_0	GTC hardware push event	Pulse

12.9.1.2 GTC Functional Description

12.9.1.2.1 GTC Block Diagram

The GTC is essentially comprised of a 64-bit up counter, a Gray encoder, a 64-bit multiplexer, and memory-mapped control registers. [Figure 12-522](#) shows a high-level block diagram of the GTC.

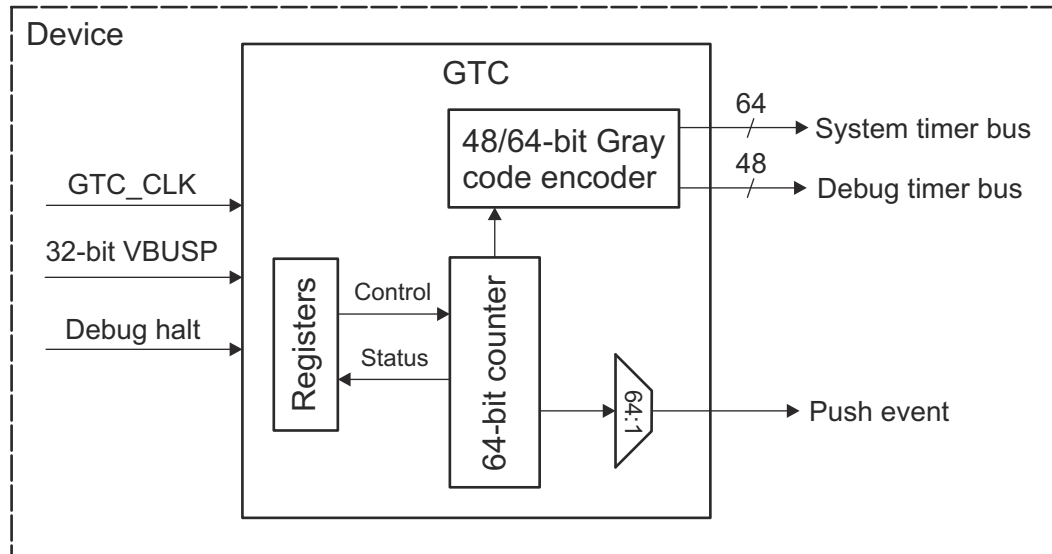

Figure 12-522. GTC Block Diagram

12.9.1.2.2 GTC Counter

The counter is a 64-bit binary up counter that increments on every GTC_CLK rising edge. The source for GTC_CLK is selected through a mux which is controlled via the CTRLMMR_GTC_CLKSEL[2-0] CLK_SEL register bit field.

The counter is disabled by default (at power-on-reset) and increments only when enabled by setting the GTC_CNTCR[0] EN bit to '1'. The current counter value is readable via the combined COUNTVALUE bit field of both GTC_CNTCV_HI (upper 32 bits) and GTC_CNTCV_LO (lower 32 bits) registers.

When counting is disabled, a new counter value can be loaded via a software write to the combined COUNTVALUE bit field. In this case, when the counter gets re-enabled, it will start counting from the last value written to this field.

The counter can be optionally configured to stop incrementing when a debug halt signal is issued, by writing a '1' to the GTC_CNTCR[1] HDBG bit. This condition is indicated through the GTC_CNTCR[1] DBGH status bit.

12.9.1.2.3 GTC Gray Encoder

The Gray encoder performs a realtime conversion of the binary counter value into a 64-bit Gray code. This value is exported as the system timer bus for distributing the counter value to:

- (2x) A72SS global timestamp input bus
- (1x) GPU timestamp input bus

A second realtime conversion of the 48 LSBs of the binary counter value into a 48-bit Gray code value is also performed and exported to:

- (2x) A72SS debug timestamp input bus
- (1x) DMPAC timestamp input bus
- (2x) VPAC timestamp input bus
- (1x) DMSC timestamp input bus

12.9.1.2.4 GTC Push Event Generation

The GTC can generate periodic push events for global time synchronization at up to half the GTC_CLK frequency. The frequency of the events is determined by selecting one of the counter bits through the internal [64:1] mux, which is controlled through the GTC_PUSHEVT[5-0] EXPBIT_SEL bit field.

12.9.1.2.5 GTC Register Partitioning

The ARMv8 architecture spec requires specific system-level components, each with one or two register frames. To accommodate this, the GTC memory-mapped registers (MMRs) are divided into four separate regions (4KB each):

- Peripheral MMRs (GTC0_GTC_CFG0): This region includes standard peripheral identification registers and any other control registers not associated with the ARMv8 system timer functions.
- Counter control MMRs (GTC0_GTC_CFG1): This region includes registers that provide control over the operation of the system timer.
- Counter status MMRs (GTC0_GTC_CFG2): This region includes registers that provide a mechanism for reading the status of the system timer.
- Timer control MMRs (GTC0_GTC_CFG3): This region includes registers that identify and provide a control mechanism for memory-mapped timer implementations. For this device, no memory-mapped timers are implemented and only the minimum registers required to indicate the presence of no timers are necessary.

12.9.2 Windowed Watchdog Timer (WWDT)

This section describes the Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module in the device.

CAUTION

The RTI module shall be used to serve only as a Digital Windowed Watchdog (DWWD).

The Real Time Interrupt module provides timer functionality for operating systems and for benchmarking code. The module incorporates several counters, which define the timebases needed for scheduling in the operating system.

This module is specifically designed to fulfill the requirements for OSEK (“Offene Systeme und deren Schnittstellen für die Elektronik im Kraftfahrzeug”; “Open Systems and the Corresponding Interfaces for Automotive Electronics”) as well as OSEK/Time compliant operating systems.

The timers also provide the ability to benchmark certain areas of code by reading the counter contents at the beginning and the end of the desired code range and calculating the difference between the values.

12.9.2.1 RTI Overview

12.9.2.1.1 RTI Features

The RTI modules include the following main features:

- Windowed Watchdog Timer (WWDT) feature.
- Two independent 64 bit counter blocks (counter block0 or counter block1). Each block consists of
 - One 32 bit up counter
 - One 32 bit free running counter
 - Two capture registers for capturing the prescale and free running counter on a special event.
- Free running counter 0 can be incremented by either the internal prescale counter or by an external event.
- Four configurable compare registers for generating operating system ticks . Each event can be driven by either counter block0 or counter block1.
- Fast enabling/disabling of events.
- RTI clock input derived from any of the available clock sources, selectable in the System Module
- Optional capability to drive a pulse-width modulated signal out on an interrupt line.

12.9.2.1.2 RTI Ports

12.9.2.2 RTI Functional Description

The MCU_RTII[1-0] and RTII (where i =) modules are hereinafter referred to as RTI module.

12.9.2.2.1 RTI Counter Operation

Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Figure 12-523 shows the RTI module counter blocks. The RTI module supports two counter blocks.

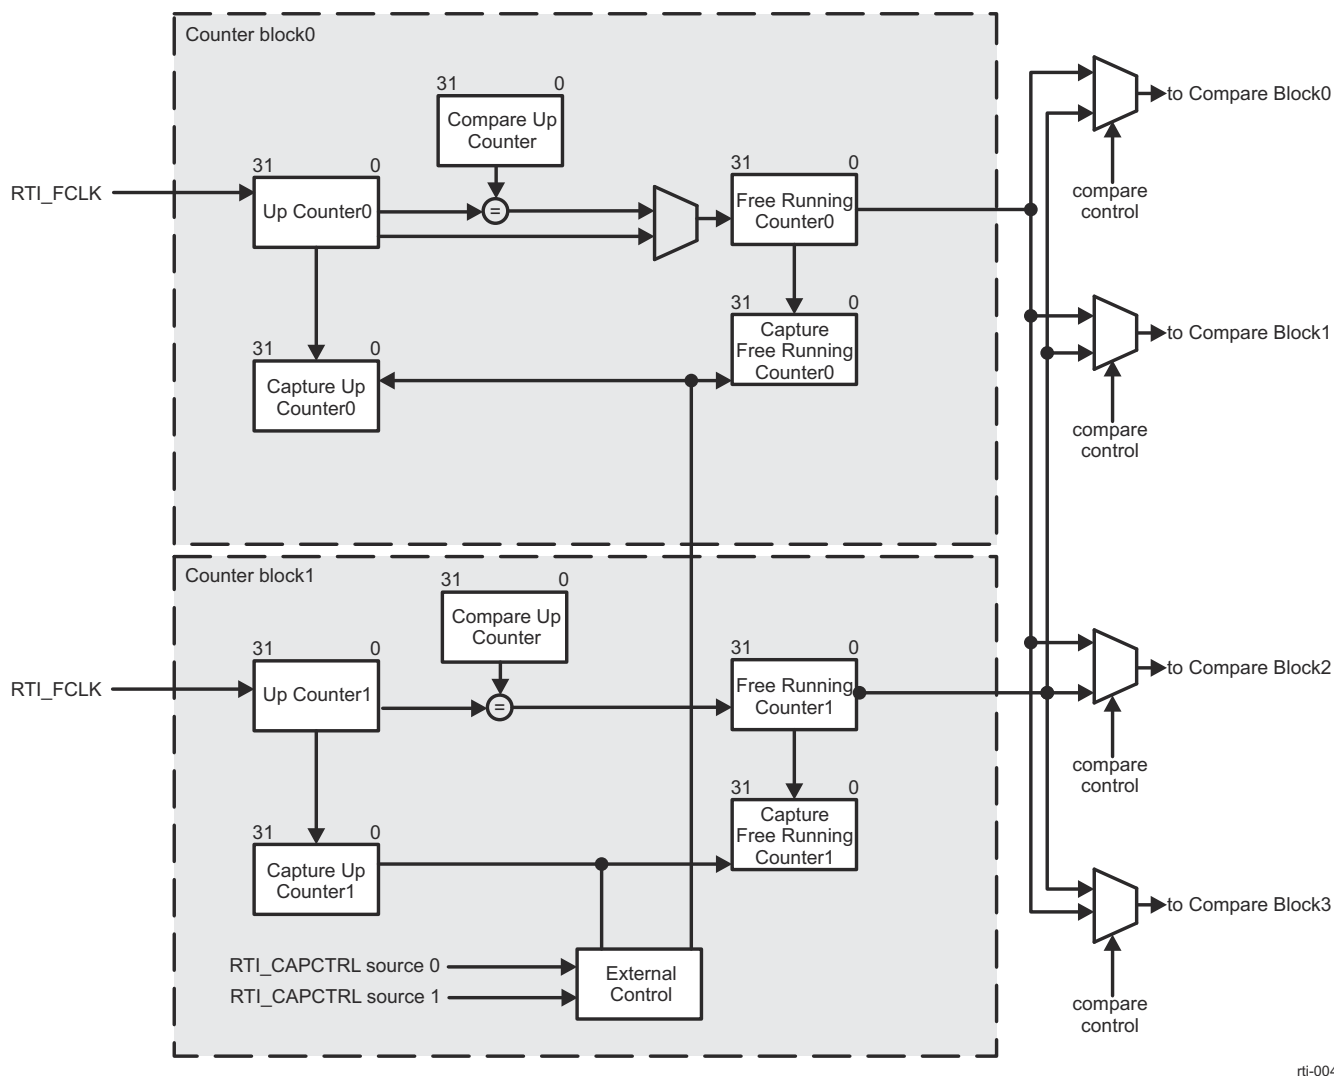

Figure 12-523. RTI Counters Block Diagram

Each block consists of two 32 bit up counters - Up Counter (UC) and Free Running Counter (FRC). The Up Counter (RTI_UC0 or RTI_UC1 register) is driven by the RTI_FCLK and counts up until the compare value in the Compare Up Counter register (RTI_CPUC0 or RTI_CPUC1) is reached. When the compare matches, the second counter (RTI_FRC0 or RTI_FRC1 register), which is a free running counter, is incremented. At the same time UCx is reset to zero.

To ensure the consistency of the counters, when both counter value have to be determined, the Free Running Counter has to be read first. This will ensure that at the CPU read cycle, the Up Counter value is stored in the

counter register. The second read is done on the Up Counter register, which holds then the value of the counter cycle of the previous read on the Free Running Counter register.

Both blocks provide also a capture feature on external events. Two capture sources can trigger the capture event. Which event triggers block 0 or block 1 is configurable from the RTI_CAPCTRL register. The sources are coming from the interrupt manager, in order to be able to generate a capture event when one of the peripheral modules has generated an interrupt. The peripheral, which can generate an event is configured in the interrupt manager. When the event is detected, UCx and FRCx are stored in Capture Up Counter (RTI_CAUC0 or RTI_CAUC1) and Capture Free Running Counter (RTI_CAFRC0 or RTI_CAFRC1) registers. The read order of the captured values has to be like the order of the actual counters. So the CAFRCx has to be read first and the CAUCx registers has to be read after the CAFRCx value was determined. While the CAFRCx is read the CAUCx value is loaded into a shadow register to ensure data consistency, if during the two reads of the captured data another capture event happens. If the application fails to read the two registers before a second capture event happens, the previous data will be overwritten.

Figure 12-524 shows the block diagram for one compare block. The RTI module supports four compare blocks.

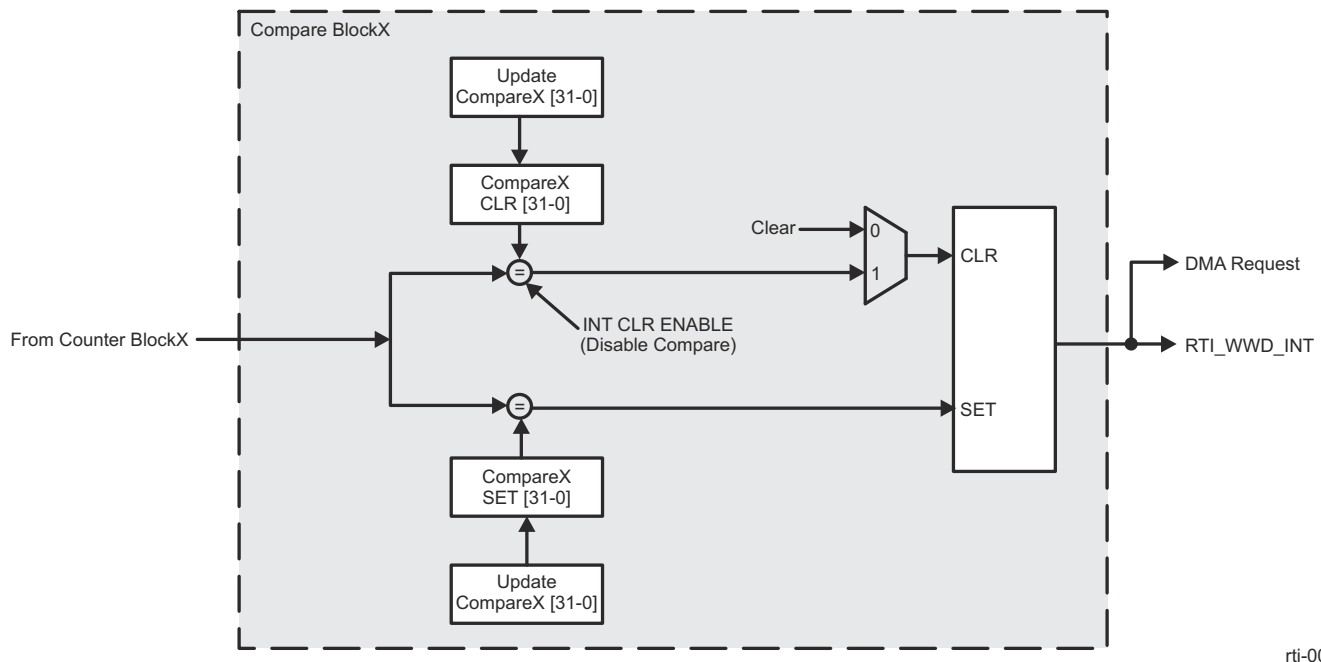

Figure 12-524. RTI Compare Block Diagram

In order to generate interrupt requests to the interrupt manager, there are four compare registers (RTI_COMP0, RTI_COMP1, RTI_COMP2, and RTI_COMP3). Each of the compare registers can be configured to work either on FRC0 (Counter block0) or FRC1 (Counter block1). When the counter value matches the compare value, an interrupt is generated. This sets an interrupt request line to the interrupt manager. The compare value gets updated automatically with the value stored in Update Compare (RTI_UDCP0, RTI_UDCP1, RTI_UDCP2, and RTI_UDCP3) registers when the compare matches. This gives the ability to generate periodic interrupts/DMA requests without having to update the compare value by software.

An optional feature allows an application to program another compare value which is then used to clear the interrupt request line. This feature is supported by four compare clear registers (RTI_COMP0CLR, RTI_COMP1CLR, RTI_COMP2CLR, and RTI_COMP3CLR). When the counter value matches the compare clear value, the interrupt line is cleared. This clears the interrupt request line to the interrupt manager. The compare clear value gets updated automatically with the value stored in Update Compare (RTI_UDCPx) registers when the compare matches.

12.9.2.2.2 RTI Digital Watchdog

Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Some applications might use a digital watchdog (DWD) integrated in the RTI module. The digital watchdog generates resets after a programmable period, if no correct key sequence is written to the RTI_WDKEY register. Figure 12-525 shows the digital watchdog functional block.

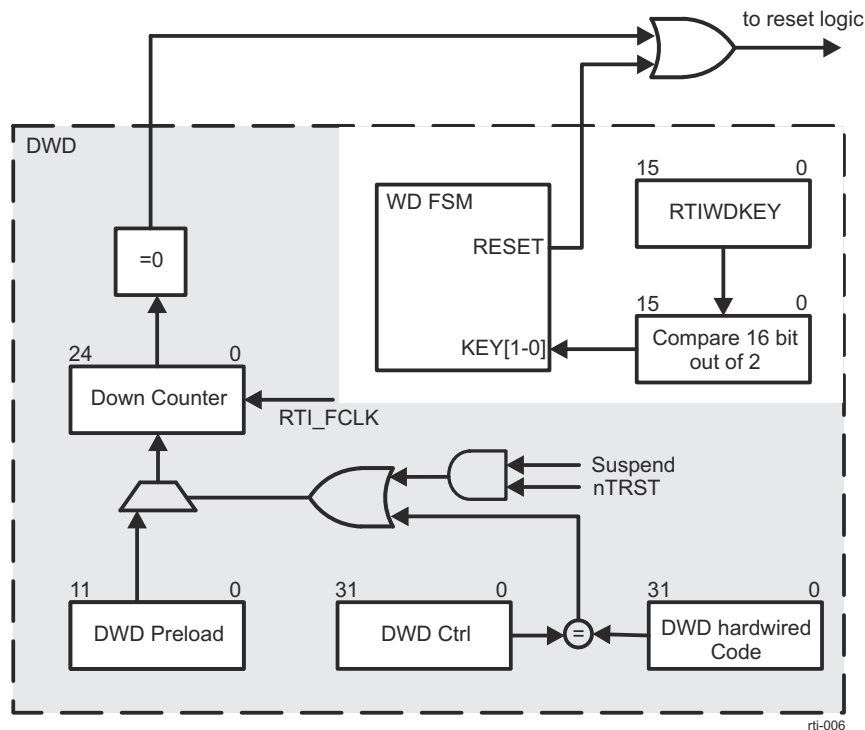

Figure 12-525. RTI Digital Watchdog Functional Block Diagram

The digital watchdog functionality is implemented such that it can be enabled by software.

The DWD starts counting down from the reset value of the RTI_WDWCNTR (DWD Counter Register). The DWD preload register can be configured at any time by the application according to the desired time-out period.

When enabled by software, the digital watchdog is disabled after system reset. If it should be used, it has to be enabled by writing A98559DAh to the RTI_WDCTRL register. The DWD timeout period must be configured using the DWD preload register before the DWD is enabled. The DWD cannot be disabled by the application once it is enabled.

Note

When the DWD is enabled by software, any system reset will disable the DWD. This reset could have been generated by the watchdog itself.

If the correct key sequence is written to the RTI_WDKEY register (E51Ah followed by A35Ch), the 25-bit DWD Down Counter is reloaded with the 12-bit preload value stored in RTI_WDPRLD register. If any incorrect value is written to the RTI_WDKEY register, a watchdog reset will occur immediately. A reset will also be generated, when the DWD Down Counter is decremented to 0.

The user has to take into account that the write to the RTI_WDKEY register takes 3 RTI_ICLK cycles. This needs to be considered for the DWD expiration calculation.

The DWD Down Counter will be decremented with RTI_FCLK frequency. If the RTI_FCLK is switched off via the disable registers of the Clock management, the DWD counter stops decrementing. The DWD module cannot generate a reset under this condition.

Figure 12-526. RTI Digital Watchdog Operation

The expiration time of the DWD Down Counter can be determined with following equation:

$$t_{exp} = (RTI_DWDPRLD + 1) \times 2^{13} / RTI_FCLK \quad (28)$$

where RTI_DWDPRLD = 0...4095

12.9.2.2.3 RTI Digital Windowed Watchdog

Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Note

Digital windowed watchdog (DWWD) timer is implemented using the digital windowed watchdog function of the RTI modules. Real time interrupt functionality is not supported. In this mode, the timer should default to disabled and user can adjust the period as desired before enabling the watchdog.

In addition to the time-out boundary configurable via the digital watchdog (DWD), some applications may also want to configure the start-time boundary of the watchdog. This is enabled by the digital windowed watchdog (DWWD) feature.

Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a non-maskable interrupt to the CPU. This is controlled by configuring the RTI_WWDRXNCTRL register. As stated earlier, when the watchdog needs to be enabled by software, the watchdog counter is disabled on a system reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The RTI_INTR_WWD interrupt handler needs to clear the watchdog violation status flag(s) and then service the watchdog by writing the correct sequence in the watchdog key RTI_WDKEY register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the RTI_INTR_WWD handler does not service the watchdog in time, it could count down all the way to zero and wrap around. No second exception for a time out is generated in this case.

Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD.

Figure 12-527. RTI Digital Windowed Watchdog Timing Example

Figure 12-528. RTI Digital Windowed Watchdog Operation Block Diagram

12.9.2.2.4 RTI Low Power Mode Operation

The operation of the RTI module is guaranteed in run, doze and snooze mode. In sleep or hibernate mode all clocks will be switched off and the RTI module will not work.

In doze and snooze modes all parts of the RTI are active, since it has to be able to wake up the device with compare and timebases interrupts. Capturing events generated by the interrupt module is also possible since in

both modes the peripheral modules are able to generate interrupts, which can trigger capture events. The RTI module will generate compare and timebases interrupts. The compare interrupts will periodically wake up the device.

Note

In the special case of doze mode with DPLL off, RTI_FCLK might have a different period than with DPLL enabled, since RTI_FCLK will be derived from the oscillator output. It has to be ensured that the RTI_ICLK to RTI_FCLK ratio is at least 3:1.

The DWD/DWWD remains active when the device enters low power mode as long as the RTI_FCLK is kept active.

Whenever the LPSC that controls an RTI is in any state other than Enable (see *Module States*), the RTI cannot count or generate interrupts. For more information, see *Power Control Modules*.

During standard SoC warm reset the RTI and the rest of the SoC are reset. In this case, the RTI counters are stopped and interrupts are not issued. During reset-isolated warm reset, if an R5FSS is put in reset-isolation, then the associated RTI also becomes reset isolated. As such, the R5FSS and the RTI are not reset, but RTI stops counting and cannot generate interrupts until R5FSS is taken out of CLKSTOP (brought to Enable state).

12.9.2.2.5 RTI Debug Mode Behavior

Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Once the system enters debug mode, the behavior of the RTI depends on the RTI_GCTRL[15] COS bit. If the bit is cleared and debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode.

The DWD counter will not decrement in debug mode and will hold its current value, regardless of the RTI_GCTRL[15] COS bit.

Note

The user must not service the watchdog while in debug mode.

12.9.3 Timers

This section describes the Timer modules for the device.

12.9.3.1 Timers Overview

There are thirty timer modules in the device.

All timers include specific functions to generate accurate tick interrupts to the operating system.

Each timer can be clocked from several different independent clocks. The selection of clock source is made from registers in the MCU_CTRL_MMR0/CTRL_MMR0.

In the MCU domain the device provides 10 timer pins to be used as MCU Timer Capture inputs or as MCU Timer PWM outputs. In order to provide maximum flexibility, these 10 pins may be used with any of MCU_TIMER0 through MCU_TIMER9 instances. System level muxes are used to control the capture source pin for each MCU_TIMER[9-0] and the MCU_TIMER[9-0] source for each MCU_TIMER_IO[9-0] PWM output.

In the MAIN domain the device provides 8 timer pins to be used as Timer Capture inputs or as Timer PWM outputs. For maximum flexibility, these 8 pins may be used with any of TIMER0 through TIMER19 instances. System level muxes are used to control the capture source pin for each TIMER[19-0] and the TIMER[19-0] source for each TIMER_IO[7-0] PWM output.

Each odd numbered timer instance from each of the domains may be optionally cascaded with the previous even numbered timer instance from the same domain to form up to a 64-bit timer. For example, TIMER1 may be cascaded to TIMER0, MCU_TIMER1 may be cascaded to MCU_TIMER0, etc.

When cascaded, TIMER_i acts as a 32-bit prescaler to TIMER_{i+1}, as well as MCU_TIMER_n acts as a 32-bit prescaler to MCU_TIMER_{n+1}. TIMER_i / MCU_TIMER_n must be configured to generate a PWM output edge at the desired rate to increment the TIMER_{i+1} / MCU_TIMER_{n+1} counter.

12.9.3.1.1 Timers Features

The following are the main features of the timer controllers:

- Slave interface supports:
 - 32-bit data bus width
 - 32-bit access supported
 - 10-bit address bus width
 - Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n , where $n = [0-8]$)
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- On-the-fly read/write register (while counting)
- Generates a 1-ms tick clock when functional clock is 32.768 kHz

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

(1) When configured for that function; I = Input, O = Output

12.9.3.3 Timers Functional Description

Each timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the `TIMER_IRQSTATUS_SET` and `TIMER_IRQSTATUS_CLR` register for the interrupt features, and a dedicated bit of the `TIMER_IRQWAKEEN` register for a wake-up. In addition, timers have a mechanism implemented to generate an accurate tick interrupt.

For each timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

For more information of the selection of the input clock source, see *Clocking*.

Each timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

12.9.3.3.1 Timer Block Diagram

[Figure 12-529](#) is a block diagram of the timers.

12.9.3.3.2 Timer Power Management

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Timers Not Supported Features*.

Table 12-492 lists the IDLEMODE settings and the related acknowledgment modes.

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The clock stop request is unconditionally acknowledged from the timer, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The clock stop request is never acknowledged from the timer. This mode is safe from a module point of view but is not efficient from a power-saving perspective because the clocks remain active.

Table 12-492. IDLEMODE Settings (continued)

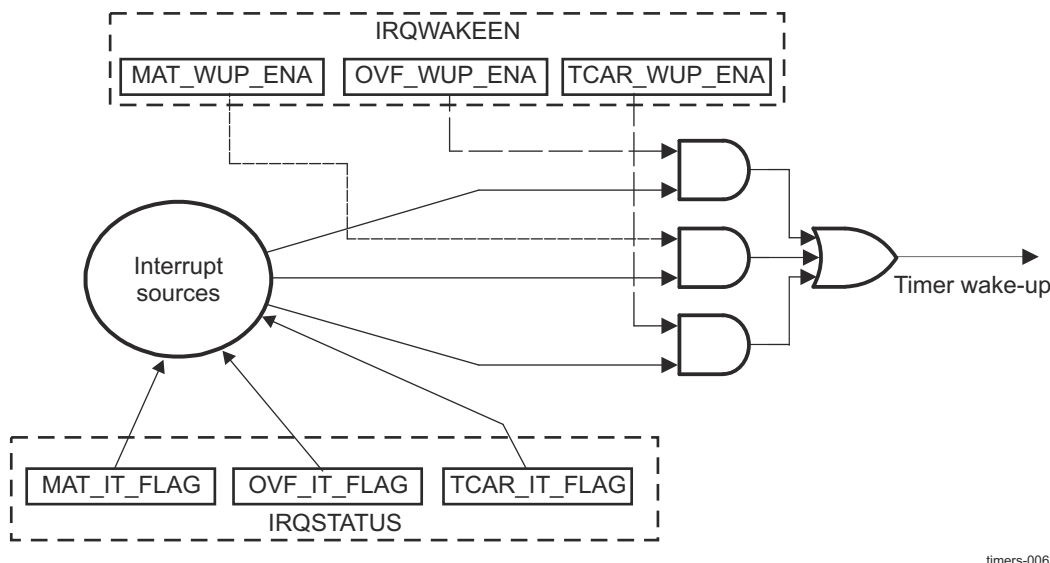

IDLEMODE Value	Selected Mode	Description
10	Smart-idle	The timer acknowledges the clock stop request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and interrupt requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

12.9.3.3.2.1 Wake-Up Capability**Note**

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Timers Not Supported Features*.

If the TIMER_TIOCP_CFG[3-2] IDLEMODE bit field sets the smart-idle mode or smart-idle with wake-up mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the clock stop acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if configured in smart-idle with wake-up mode.

Figure 12-530 shows the wake-up request generation.

**Figure 12-530. Wake-Up Request Generation**

The timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the Clock management sends a clock stop request. The expected source of the wake-up event is an overflow (TIMER_TCR), a timer match (the compare result of TIMER_TCR and TIMER_TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER_PIEVENTCAPT).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (TIMER_IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

Note

The status bit must be reset to re-enter idle mode.

12.9.3.3.3 Timer Software Reset

TIMER_TIOCP_CFG[0] SOFTRESET bit can initiate a software reset of the timer. This bit is autocleared to 0 when the reset is complete.

Before accessing or using the timer, the local host must ensure that internal reset is released by reading the TIMER_TIOCP_CFG[0] SOFTRESET bit. This bit monitors the internal reset status.

12.9.3.3.4 Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (TIMER_IRQSTATUS_SET) and disabled in the interrupt-disable register (TIMER_IRQSTATUS_CLR). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (TIMER_IRQSTATUS).

12.9.3.3.5 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the TIMER_TCLR[0] ST bit). The timer counter register (TIMER_TCRR) can be loaded when stopped or on-the-fly (while counting). TIMER_TCRR can be loaded directly by a TIMER_TCRR write access with a new timer value. TIMER_TCRR can also be loaded with the value held in the timer load register (TIMER_TLDR) by a trigger register (TIMER_TTGR) write access. The loading of TIMER_TCRR is done regardless of the written value of TIMER_TTGR. The value of TIMER_TCRR can be read when stopped or captured on-the-fly by a TIMER_TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the TIMER_TCLR[1] AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the TIMER_TCLR[1] AR bit is set to 1), TIMER_TCRR is reloaded with the value of TIMER_TLDR after a counting overflow occurs.

CAUTION

Do not put the overflow value (0xFFFF FFFF) in the TIMER_TLDR register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the TIMER_IRQSTATUS_SET[1] OVF_EN_FLAG bit is set to 1). A dedicated output pin (POTIMERPWM) can be programmed in the TIMER_TCLR[12] PT bit through the TIMER_TCLR[11-10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The TIMER_TCLR[12] PT bit selects pulse/toggle modulation (the TIMER_TCLR[11-10] TRG bit field selects trigger mode).

Figure 12-531 shows the TIMER_TCRR timing value.

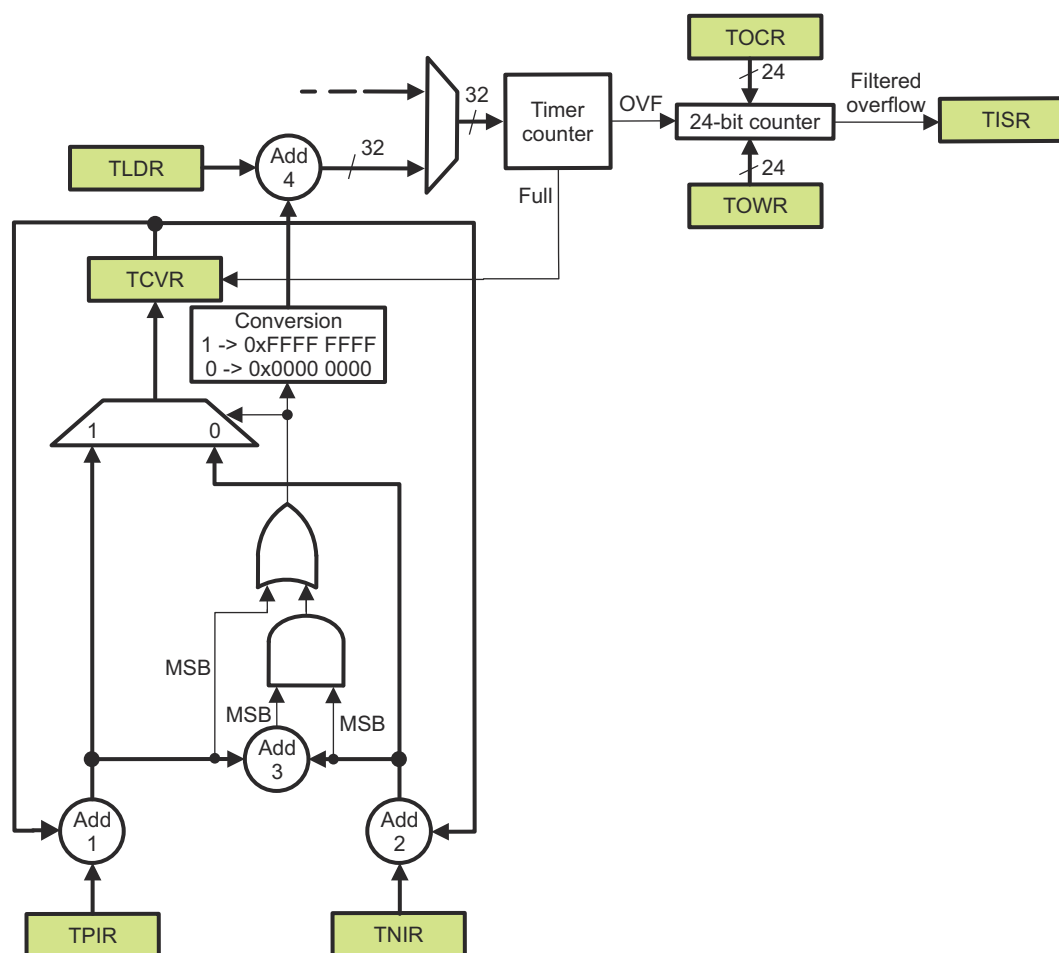

Figure 12-531. TIMER_TCRR Timing Value

12.9.3.3.5.1 1-ms Tick Generation

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 kHz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-kHz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See [Figure 12-532](#).

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the `TIMER_TPIR[31-0]` `POSITIVE_INC_VALUE` bit field) and the timer negative increment register (the `TIMER_TNIR[31-0]` `NEGATIVE_INC_VALUE` bit field). An automatic adaptation mechanism is used to simplify the programming model.

timers-009

Figure 12-532. Block Diagram of the 1-ms Tick Module

The `TIMER_TPIR`, `TIMER_TNIR`, and `TIMER_TCVR` registers and adders `Add1`, `Add2`, and `Add3` are used to define whether the next value loaded in the timer counter register (the `TIMER_TCRR[31-0]` `TIMER_COUNTER` bit field) is the value of the `TIMER_TLDR[31-0]` `LOAD_VALUE` bit field (period less than 1 ms) or the value of `TIMER_TLDR[31-0]` `LOAD_VALUE` - 1 (period greater than 1 ms).

[Table 12-493](#) lists the value loaded in the `TIMER_TCRR` according to the sign of the result of `Add1`, `Add2`, and `Add3`.

MSB = 0: Positive value; MSB = 1: Negative value

Table 12-493. Value Loaded in TIMER_TCCR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of TIMER_TCCR Register
0	0	0	TIMER_TLDR[31-0] LOAD_VALUE bit field
0	0	1	TIMER_TLDR[31-0] LOAD_VALUE bit field
0	1	0	TIMER_TLDR[31-0] LOAD_VALUE bit field
0	1	1	TIMER_TLDR[31-0] LOAD_VALUE –1
1	0	0	N/A
1	0	1	N/A
1	1	0	TIMER_TLDR[31-0] LOAD_VALUE –1
1	1	1	TIMER_TLDR[31-0] LOAD_VALUE –1

The values of the TIMER_TPIR and TIMER_TNIR registers are calculated using the following formulas:

- Positive increment value = $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] + 1) \times 1\text{e}6 - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$
- Negative increment value = $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$

Note

F_{clk} clock frequency (kHz)

T_{tick} tick period (ms)

The timer overflow counter register (TIMER_TOCR) and the timer overflow wrapping register (TIMER_TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TIMER_TOCR. When the values in the 24-bit TIMER_TOCR match the values in the 24-bit TIMER_TOWR and the timer overflow is asserted, the TIMER_TOCR is reset and an interrupt is generated to the TIMER_IRQSTATUS register.

Note

TIMER_TOWR has to be set to requested value. For example, if no interrupt needs to be masked TIMER_TOWR must be set to 0, if one interrupt needs to be masked TIMER_TOWR must be set to 1, if two interrupts need to be masked TIMER_TOWR must be set to 2 and so on.

It is important to have in mind that the case when FFFFFFF interrupts need to be masked is not possible.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of timers remain unchanged.

For 1-ms tick with a 32.768-kHz clock:

- TIMER_TPIR[31-0] POSITIVE_INC_VALUE = 232,000
- TIMER_TNIR[31-0] NEGATIVE_INC_VALUE = –768,000
- TIMER_TLDR[31-0] LOAD_VALUE = 0xFFFF FFE0

Note

Any value of the tick period can be generated with the appropriate value of the TIMER_TPIR, TIMER_TNIR, and TIMER_TLDR.

By default, the TIMER_TPIR, TIMER_TNIR, TIMER_TCVR, TIMER_TOCR, and TIMER_TOWR and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

12.9.3.3.6 Timer Capture Mode Functionality

When a transition is detected on the module input pin (PIEVENTCAPT), the timer value in the TIMER_TCCR can be captured and saved in the TIMER_TCAR1 or TIMER_TCAR2 register function of the mode selected in the TIMER_TCLR[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

The rising edge, falling edge, or both, can be selected in the `TIMER_TCLR[9-8]` TCM bit field to trigger the timer counter capture. The module sets the `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` bit when an active edge is detected, and at the same time, the counter value `TIMER_TCR` is stored in timer capture register `TIMER_TCAR1` or `TIMER_TCAR2`, as follows:

- If the `TIMER_TCLR[13] CAPT_MODE` bit is 0, on the first enabled capture event, the value of the counter register is saved in the `TIMER_TCAR1` register, and the next events are ignored (no update on the `TIMER_TCAR1` register and no interrupt triggering) until the detection logic is reset or the `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` is cleared by writing 1 to it.
- If the `TIMER_TCLR[13] CAPT_MODE` bit is 1, on the first enabled capture event, the value of the counter register is saved in the `TIMER_TCAR1` register, and on the second enabled capture event, the value of the counter register is saved in the `TIMER_TCAR2` register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on `TIMER_TCAR1/TIMER_TCAR2` and no interrupt triggering) until the detection logic is reset or the `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the `PIEVENTCAPT` input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` bit is cleared by writing 1 to it or when the edge detection mode bits (the `TIMER_TCLR[9-8]` TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (`PIEVENTCAPT`). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the `TIMER_IRQSTATUS_SET[2] TCAR_EN_FLAG` bit. See the examples in [Figure 12-533](#) and [Figure 12-534](#).

In [Figure 12-533](#), the value of the `TIMER_TCLR[9-8]` TCM bit field is 1h, and the `TIMER_TCLR[13] CAPT_MODE` bit is 0. Only the rising edge of `PIEVENTCAPT` triggers a capture in the `TIMER_TCAR1` and `TIMER_TCAR2` registers, and only the `TIMER_TCAR1` register updates.

Figure 12-533. Capture Wave Example for `TIMER_TCLR[13] CAPT_MODE = 0`

In [Figure 12-534](#), the value of the `TIMER_TCLR[9-8]` TCM bit field is 1h, and the `TIMER_TCLR[13] CAPT_MODE` bit is 1. Only the rising edge of `PIEVENTCAPT` triggers a capture in the `TIMER_TCAR1` register on the first enabled event, and the `TIMER_TCAR2` register updates on the second enabled event.

Figure 12-534. Capture Wave Example for TIMER_TCLR[13] CAPT_MODE = 1

12.9.3.3.7 Timer Compare Mode Functionality

When the compare-enable register `TIMER_TCLR[6]` CE bit is set to 1, the timer value (the `TIMER_TCRR[31-0]` `TIMER_COUNTER` bit field) is continuously compared to the value held in the timer match register (`TIMER_TMAR`). The value of the `TIMER_TMAR[31-0]` `COMPARE_VALUE` bit field can be loaded at any time (timer counting or stopped). When the `TIMER_TCRR` and the `TIMER_TMAR` values match, an interrupt is issued, if the `TIMER_IRQSTATUS_SET[0]` `MAT_EN_FLAG` bit is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the `TIMER_TMAR` before setting the `TIMER_TCLR[6]` CE bit.

The dedicated output pin (`POTIMERPWM`) can be programmed in the `TIMER_TCLR[12]` PT bit through the `TIMER_TCLR[11-10]` TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

12.9.3.3.8 Timer Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the `TIMER_TCLR[5]` PRE bit is set. The `TIMER_TCLR[4-2]` PTV bit field sets the 2^n division ratio (prescaler value is $2^{(PTV + 1)}$). The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 12-494 lists the prescaler/timer reload values versus contexts.

Table 12-494. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	<code>TIMER_TLDR[31-0]</code>
<code>TIMER_TCRR</code> write	Reset	<code>TIMER_TCRR[31-0]</code>
<code>TIMER_TTGR</code> write	Reset	<code>TIMER_TLDR[31-0]</code>
Stop	Reset	Frozen

12.9.3.3.9 Timer Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM (`POTIMERPWM`) output pin can be configured to toggle on an event. The `TIMER_TCLR[11-10]` TRG bit field determines on which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

Note

In toggle mode, when `TIMER_TCLR[11-10] TRG = 0x2` (overflow and match), the first event that toggles the PWM line is an overflow event.

The `TIMER_TCLR[7] SCPWM` bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the `TIMER_TCLR[11-10] TRG` bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In [Figure 12-535](#), the internal overflow pulse is set each time the $(0xFFFF\ FFFF - \text{TIMER_TLDR}[31-0] \text{ LOAD_VALUE} + 1)$ value is reached, and the internal match pulse is set when the counter reaches the value of `TIMER_TMAR`. Depending on the value of the `TIMER_TCLR[12] PT` bit and `TIMER_TCLR[11-10] TRG` bit field, the timer provides pulse or PWM event on the output pin (`POTIMERPWM`).

The `TIMER_TLDR` and `TIMER_TMAR` must keep values below the overflow value (`0xFFFF FFFF`) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the `TIMER_TMAR` and the value in the `TIMER_TLDR` must be at least two units. When match event is used, the compare mode `TIMER_TCLR[6] CE` bit must be set.

In [Figure 12-535](#), the `TIMER_TCLR[7] SCPWM` bit is set to 0. In [Figure 12-536](#), the `TIMER_TCLR[7] SCPWM` bit is set to 1. To obtain the desired wave form, start the counter at `0xFFFF FFFE` value (to ensure an overflow first) or adjust the line polarity (`TIMER_TCLR[7] SCPWM` bit).

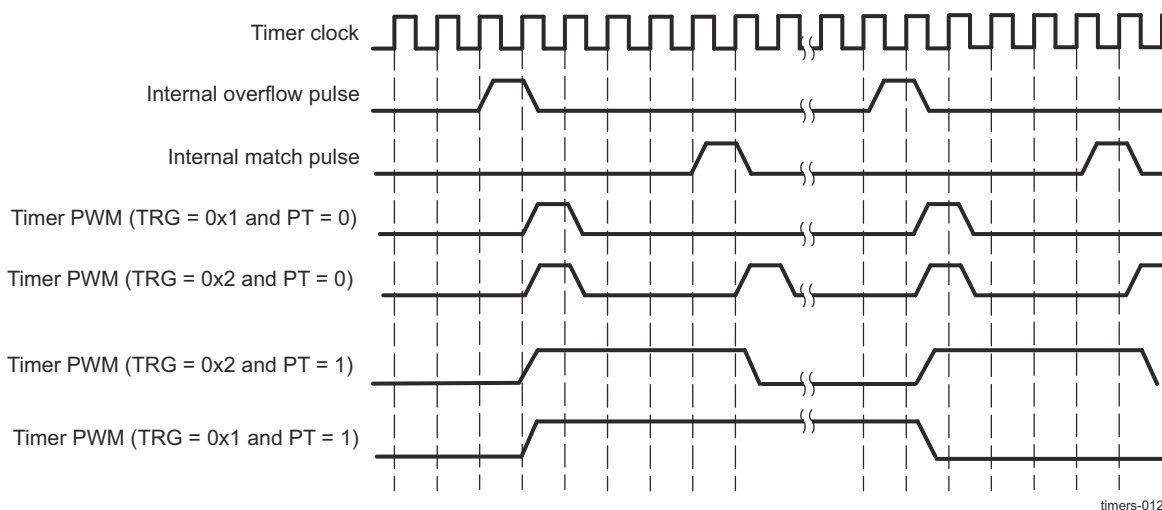

Figure 12-535. Timing Diagram of PWM With `TIMER_TCLR[7] SCPWM` Bit = 0

Figure 12-536. Timing Diagram of PWM With TIMER_TCLR[7] SCPWM Bit = 1

12.9.3.3.10 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the TIMER_TCLR[5] PRE bit and TIMER_TCLR[4-2] PTV bit field)
- Value loaded into the TIMER_TLDR

Table 12-495 lists the prescaler clock ratio values.

Table 12-495. Prescaler Clock Ratio Values

TIMER_TCLR[5] PRE	TIMER_TCLR[4-2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

$$\text{OVF_Rate} = (\text{0xFFFF FFFF} - \text{TIMER_TLDR} + 1) \times (\text{timer-functional clock period}) \times \text{PS}$$

With (timer-functional clock period) = $1/(\text{timer-functional clock frequency})$ and $\text{PS} = 2^{(\text{PTV} + 1)}$ if prescaler is enabled, or $\text{PS} = 1$ if prescaler is disabled.

CAUTION

Internal resynchronization causes any write to the TIMER_TCLR[1] ST bit to have some latency before the register is updated:

$2.5 \times$ functional clock cycles write_TIMER_TCLR_latency $3.5 \times$ functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the TIMER_TCLR[1] ST bit.

CAUTION

- In non-PWM mode, TIMER_TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, TIMER_TLDR must be maintained at less than or equal to 0xFFFF FFDD.

For example, with a timer clock input of 32 kHz and the TIMER_TCLR[5] PRE bit set to 0, the timer output period is as listed in [Table 12-496](#).

Table 12-496. Value and Corresponding Interrupt Period

TIMER_TLDR[31-0] LOAD_VALUE	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 μ s
0xFFFF FFFE	62.5 μ s

12.9.3.3.11 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the TIMER_TIOCP_CFG[1] EMUFREE bit.

If the TIMER_TIOCP_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the TIMER_TIOCP_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (MCU_TIMER_IO[9-0] or TIMER_IO[7-0]) is internally synchronized on two timer-clock rising edges.

12.9.3.3.12 Accessing Timer Registers

All accesses are posted mode, under the assumption that $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$, until software reconfiguration. In addition, it is not recommended to access the timer registers prior to the PLLs generating the timer and interface clocks have been configured and the clocks have stabilized. All registers are 32 bits wide, accessible through the configuration interface with 32-bit access (read/write).

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- TIMER_TCLR
- TIMER_TCRR
- TIMER_TLDR
- TIMER_TTGR
- TIMER_TMAR
- TIMER_TPIR
- TIMER_TNIR
- TIMER_TCVR
- TIMER_TOCR
- TIMER_TOWR

The following registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one interface clock cycle from command assertion:

- TIMER_TIDR
- TIMER_TIOCP_CFG
- TIMER_IRQSTATUS
- TIMER_IRQSTATUS_RAW
- TIMER_IRQSTATUS_SET
- TIMER_IRQSTATUS_CLR
- TIMER_IRQWAKEEN
- TIMER_TWPS
- TIMER_TSICR

12.9.3.3.12.1 Writing to Timer Registers

The host uses the configuration interface to write to the following registers synchronously with the timer interface clock:

- TIMER_TLDR
- TIMER_TCRR
- TIMER_TCLR
- TIMER_TIOCP_CFG
- TIMER_IRQSTATUS
- TIMER_IRQSTATUS_SET
- TIMER_IRQSTATUS_CLR
- TIMER_IRQWAKEEN
- TIMER_TTGR
- TIMER_TSICR
- TIMER_TMAR
- TIMER_TPIR
- TIMER_TNIR
- TIMER_TCVR
- TIMER_TOCR
- TIMER_TOWR

12.9.3.3.12.1.1 Write Posting Synchronization Mode

This mode is used if the TIMER_TSICR[2] POSTED bit is set to 1 (default value).

This mode uses a posted write scheme to update any internal register (TIMER_TCLR, TIMER_TCRR, TIMER_TLDR, TIMER_TTGR, TIMER_TMAR, TIMER_TPIR, TIMER_TNIR, TIMER_TCVR, TIMER_TOCR, and TIMER_TOWR). Therefore, the write transaction is immediately acknowledged on the configuration interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect, nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status (TIMER_TWPS) register. In this mode, it is mandatory that software check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the interface clock. Consequently, any read access to TIMER_TCRR does not add any resynchronization latency; the current value is always available.

Note

Because the overflow IRQ is generated when the value of TIMER_TCRR reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of ($1 \times PS \times$ timer functional clock period) before any read access to TIMER_TCRR to ensure a correct reading of its content.

Note

If TIMER_TTGR register is written during a posted write to TIMER_TCRR, the value to be written to TIMER_TCRR will be discarded.

If a posted write to TIMER_TCVR is started, the user must not write to TIMER_TPIR or TIMER_TNIR before the TIMER_TCVR write is finished, because the value of TIMER_TCVR is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range: $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$.

12.9.3.3.12.1.2 Write Nonposting Synchronization Mode

This mode is used if the `TIMER_TSICR[2] POSTED` bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the configuration interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the configuration interface frequency and the timer clock frequency.

12.9.3.3.12.2 Reading From Timer Counter Registers

Note

LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

The `TIMER_TCRR` is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. This capture scheme is also performed for the `TIMER_TCAR1` and `TIMER_TCAR2` registers as they can be changed due to internal processes too.

12.9.3.3.12.2.1 Read Posted

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. The recommended functional frequency range is $\text{freq}(\text{timer}) < \text{freq}(\text{interface clock})/4$.

Read posted mode is used if `TIMER_TSICR[2] POSTED = 0x1` or `TIMER_TSICR[3] READ_MODE` is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the configuration interface, prior to the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to `TIMER_TCRR`, `TIMER_TCAR1`, `TIMER_TCAR2`, `TIMER_TCVR`, and `TIMER_TOWR`, which needs resynchronization from functional to interface clock domains.

Note that in Posted mode, if the `TIMER_TCRR` is read immediately after wake-up and the interface clock is off during idle state, then it is possible to get an old value from just before going to idle state due to the fact the interface clock is needed for synchronization.

In order to avoid this situation, another synchronization mechanism is used for the first read operation after idle state. The `TIMER_TSICR[4] READ_AFTER_IDLE` bit is used to enable/disable the mechanism.

When the synchronization mechanism is disabled (`READ_AFTER_IDLE` bit is set to 1), first read transaction takes only 2 interface clock cycles, but the read value of `TIMER_TCRR` could be wrong.

When the synchronization mechanism is enabled (`READ_AFTER_IDLE` bit is set to 0), first read value of `TIMER_TCRR` is correct, but the read transaction takes more than 2 interface clock cycles.

12.9.3.3.12.2.2 Read Non-Posted

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. Recommended functional frequency range is $\text{freq}(\text{timer}) \geq \text{freq}(\text{interface clock})/4$.

Read non-posted mode is used if `TIMER_TSICR[2] POSTED = 0x0` and `TIMER_TSICR[3] READ_MODE = 0x1`. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the configuration interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to `TIMER_TCRR`, `TIMER_TCAR1`, `TIMER_TCAR2`, `TIMER_TCVR`, and `TIMER_TOWR`, which need resynchronization from functional to interface clock domains.

12.9.3.3.13 Timer Posted Mode Selection

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are `TIMER_TCLR`, `TIMER_TLDR`, `TIMER_TCRR`, `TIMER_TTGR`, `TIMER_TMAR`, `TIMER_TPIR`, `TIMER_TNIR`, `TIMER_TCVR`, `TIMER_TOCR`, and `TIMER_TOWR`. For read operation, the registers affected by this selection are: `TIMER_TCRR`, `TIMER_TCAR1`, `TIMER_TCAR2`, `TIMER_TCVR`, and `TIMER_TOWR`.

The interface clock domain synchronous registers `TIMER_TIDR`, `TIMER_TIOCP_CFG`, `TIMER_IRQSTATUS`, `TIMER_IRQSTATUS_SET`, `TIMER_IRQWAKEEN`, `TIMER_TWPS`, and `TIMER_TSICR` are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one interface clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in `TIMER_TSICR[2]` `POSTED` bit. The `TIMER_TSICR[3]` `READ_MODE` defines how the read operation is performed when the module is configured in non-posted mode (see `TIMER_TSICR`). The following cases are possible:

- `TIMER_TSICR[2]` `POSTED` = 0x1 and `TIMER_TSICR[3]` `READ_MODE` = x (don't care): read and write operations are expected in posted mode.
- `TIMER_TSICR[2]` `POSTED` = 0x0 and `TIMER_TSICR[3]` `READ_MODE` = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.
- `TIMER_TSICR[2]` `POSTED` = 0x0 and `TIMER_TSICR[3]` `READ_MODE` = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

12.9.3.4 Timers Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

12.9.3.4.1 Timer Operational Mode Configuration

12.9.3.4.1.1 Timer Mode

12.9.3.4.1.1.1 Main Sequence – Timer Mode Configuration

[Table 12-497](#) lists the steps in the timer mode configuration.

Table 12-497. Timer Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Enable overflow interrupt.	TIMER_IRQSTATUS_SET[1] OVF_EN_FLAG	0x1
Load timer counter value.	TIMER_TCRR	0x-
Load timer load value.	TIMER_TLDR	0x-
Start the timer.	TIMER_TCLR[0] ST	0x1

12.9.3.4.1.2 Timer Compare Mode

12.9.3.4.1.2.1 Main Sequence – Timer Compare Mode Configuration

[Table 12-498](#) lists the steps in the timer compare mode configuration.

Table 12-498. Timer Compare Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Enable match interrupt.	TIMER_IRQSTATUS_SET[0] MAT_EN_FLAG	0x1
Load timer counter value.	TIMER_TCRR	0x-
Load timer compare value.	TIMER_TMAR	0x-
Enable compare mode.	TIMER_TCLR[6] CE	0x1
Start the timer.	TIMER_TCLR[0] ST	0x1

12.9.3.4.1.3 Timer Capture Mode

12.9.3.4.1.3.1 Main Sequence – Timer Capture Mode Configuration

[Table 12-499](#) lists the steps in the timer capture mode configuration.

Table 12-499. Timer Capture Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See Section 12.9.3.4.1.3.2 .	
Enable capture interrupt.	TIMER_IRQSTATUS_SET[2] TCAR_EN_FLAG	0x1
Start the timer.	TIMER_TCLR[0] ST	0x1
Detect event.	See Section 12.9.3.4.1.3.3 .	

12.9.3.4.1.3.2 Subsequence – Initialize Capture Mode

[Table 12-500](#) lists the steps to initialize capture mode.

Table 12-500. Initialize Capture Mode

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-

Table 12-500. Initialize Capture Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Select TIMER[19-0] or MCU_TIMER[9-0] Capture input at device pins TIMER_IO[7-0] for TIMER[19-0] or at pins MCU_TIMER_IO[9-0] for MCU_TIMER[9-0].	TIMER_TCLR[14] GPO_CFG	0x1
Select single or second event capture.	TIMER_TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	TIMER_TCLR[9-8] TCM	0x-

12.9.3.4.1.3.3 Subsequence – Detect Event

Table 12-501 lists the steps in detecting an event.

Table 12-501. Detect Event

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	TIMER_IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	TIMER_TCAR1 and/or TIMER_TCAR2	
Clear capture interrupt request.	TIMER_IRQSTATUS[2] TCAR_IT_FLAG	0x1

12.9.3.4.1.4 Timer PWM Mode

12.9.3.4.1.4.1 Main Sequence – Timer PWM Mode Configuration

Table 12-502 lists the steps in the timer PWM mode configuration.

Table 12-502. Timer PWM Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Select trigger output mode.	TIMER_TCLR[11-10] TRG	0x-
Select pulse or toggle modulation PWM mode.	TIMER_TCLR[12] PT	0x-
Select TIMER[19-0] or MCU_TIMER[9-0] PWM output at device pins TIMER_IO[7-0] for TIMER[19-0] or at pins MCU_TIMER_IO[9-0] for MCU_TIMER[9-0].	TIMER_TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	TIMER_TCLR[7] SCPWM	0x-
Load timer load value.	TIMER_TLDR	0x-
Load timer compare value.	TIMER_TMAR	0x-
Enable compare.	TIMER_TCLR[6] CE	0x1
Start the timer.	TIMER_TCLR[0] ST	0x1

12.10 Internal Diagnostics Modules

This section describes the internal diagnostics modules in the device.

12.10.1 Dual Clock Comparator (DCC)

This section describes the Dual Clock Comparator (DCC) modules in the device.

12.10.1.1 DCC Overview

The Dual Clock Comparator (DCC) is used to determine the accuracy of a clock signal during the time execution of an application. Specifically, the DCC is designed to detect drifts from the expected clock frequency. The desired accuracy can be programmed based on calculation for each application. The DCC measures the frequency of a selectable clock source using another input clock as a reference.

12.10.1.1.1 DCC Features

The DCC uses two independent clock sources to detect when one is out of specification. Each DCC module implements the following features:

- Two independent counter blocks count clock pulses from each clock source
- Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
- Configurable timebase for error signal
- Error signal generation when one of the clocks is out of specification
- Clock frequency measurement

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.10.1.1.2 DCC Ports

Table 12-503. DCC Clocks and Resets

Interrupt Requests		
Module Interrupt Signal	Description	Type
DCC_INTR_DONE_LEVEL_0	DCC one-shot mode complete interrupt	Level
DCC_INTR_ERR_LEVEL_0	DCC error interrupt	Level

12.10.1.2 DCC Functional Description

The DCC module supports two selectable clock sources for Counter0 and Counter1. Figure 12-537 shows the DCC functional block diagram.

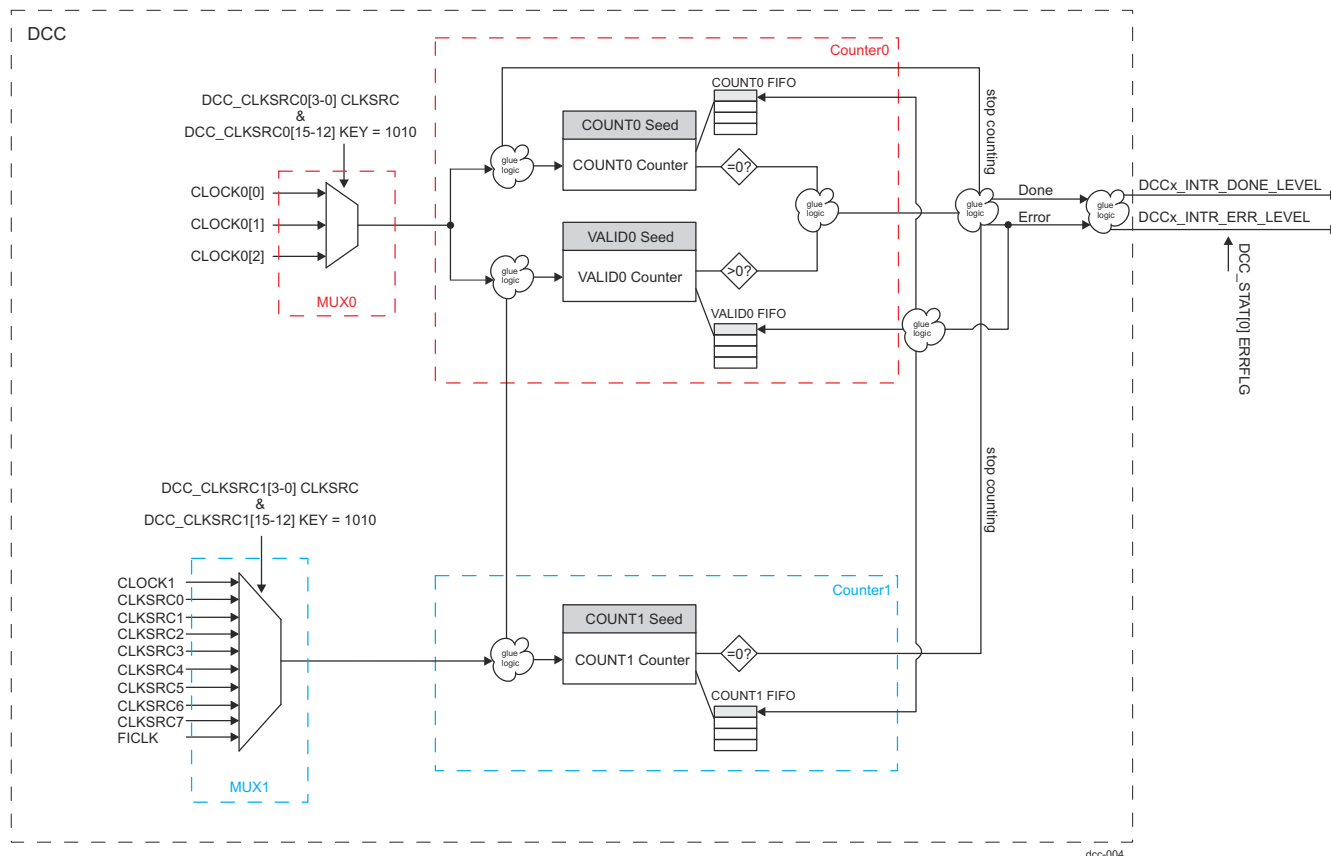

Figure 12-537. DCC Functional Block Diagram

12.10.1.2.1 DCC Counter Operation

Note

For detailed DCC compute calculations, refer to [Continuous Monitor of the PLL Frequency With the DCC App Note](#).

The DCC has two parallel counters that count clock pulses for two independent clock sources:

- Counter0 generates a fixed-width counting window (VALID0) after a pre-programmed number of pulses (COUNT0). The values for VALID0 and COUNT0 can be programmed in DCC_VALIDSEED0 and DCC_CNTSEED0 registers respectively.
- Counter1 generates a fixed-width pulse (1 cycle) after a pre-programmed number of pulses (COUNT1). This pulse sets an error signal if Counter1 does not reach 0 during the time when VALID0 is running. The seed value for COUNT1 can be programmed in DCC_CNTSEED1 register.

The error signal is generated by any one of the following conditions:

- Clock1 expires before the COUNT0 reaches 0.
- Clock1 expires after both COUNT0 and VALID0 reach 0.
- Clock1 not present.
- Clock0 not present.

Any of these errors causes the counters to stop counting. An application must then read out the counter values to determine what caused the error. Once the error is detected, the counters are stopped after 3 FICLK and 2 source clock cycles due to the cross clock domain synchronisation.

Reloads or restarts occur under two conditions:

- The module is reset or restarted through software (that is, software starts the module after reset, or software checks an error condition and decides to restart the module).
- COUNT0, COUNT1, and VALID0 all reach 0 without error.

CAUTION

The DCC module does not check jitter for Clock0 or Clock1.

As the counter preset signal is synchronized to either of the source clock domains, the counters begin downcounting after two corresponding source clock cycles.

The error signal is captured to the FICLK domain. There is 1 FICLK period uncertainty on either side of the fixed width counting window (VALID0) in generating the error signal since the counters work in different clock domains. This should be accounted for when setting the count value for VALID0.

Figure 12-538 through Figure 12-542 shows examples of counters relationship and error generation.

Figure 12-538. DCC Clock0 and Clock1 With no Error

Figure 12-539. DCC Clock1 slower than Clock0 results in an error and stops counting

Figure 12-540. DCC Clock1 faster than Clock0 results in an error and stops counting

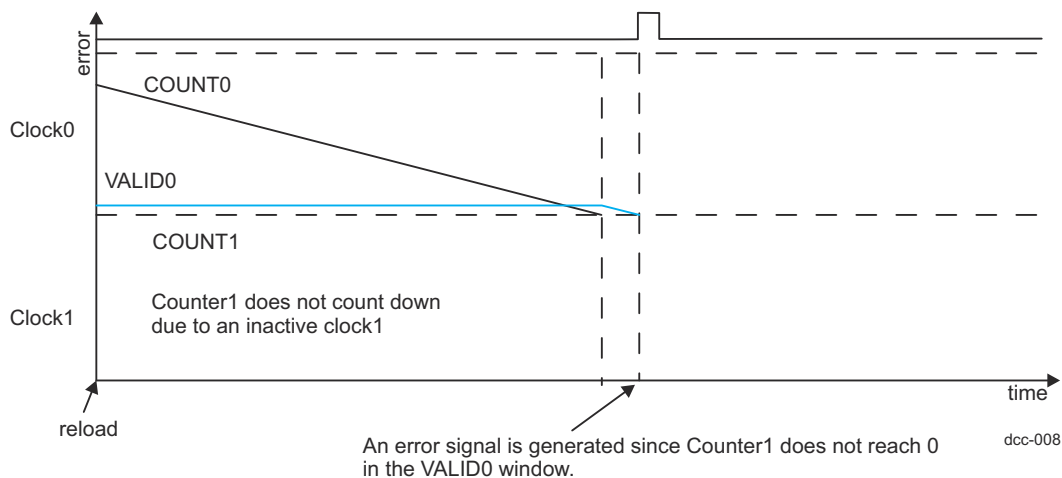

Figure 12-541. DCC Clock1 not present results in an error and stops counting

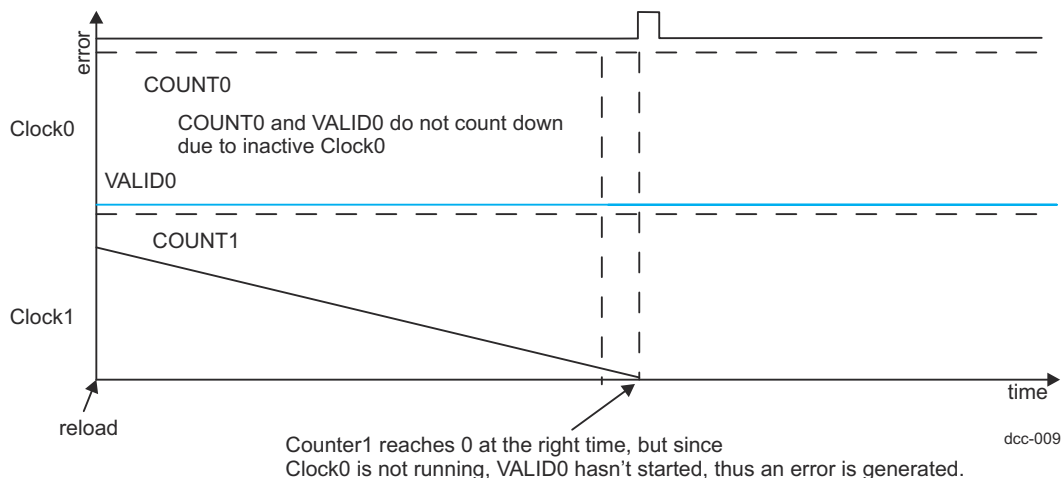

Figure 12-542. DCC Clock0 not present results in an error and stops counting

12.10.1.2.2 DCC Low Power Mode Operation

The DCC module does not function in Low Power Mode. It is the responsibility of software to stop the module before entering low power mode and to restart the module after exiting low power mode.

12.10.1.2.3 DCC Suspend Mode Behavior

The DCC module will continue running regardless of the state of emulation. All registers are readable via emulation reads.

12.10.1.2.4 DCC Single-Shot Mode

The DCC can be programmed to count down one time using single-shot mode. In this mode, the DCC stops operation when both COUNT0 and VALID0 reach 0.

At the end of one sequence in single-shot mode the DCC_GCTRL[3-0] DCCENA bitfield is set to disabled, which stops further counting. Single-shot mode is enabled from the DCC_GCTRL[11-8] SINGLESOT bitfield.

At the end of one sequence in single-shot mode, if there is no error which stops counting, then the done status bit is set in the DCC_STAT[1] DONEFLG bitfield and a done interrupt DCCx_INTR_DONE_LEVEL is generated. Software must clear the done bit before restarting the counting.

12.10.1.2.5 DCC Continuous mode

When DCC runs in continuous mode both the counts shall get reloaded with seed value upon completion of counts without error. If the counts end in error DCC stops the operation and counts are not reloaded.

12.10.1.2.5.1 DCC Continue on Error

During debug, if there are events which are causing clocks to be anomalous over short period covering more than one evaluation window then it would be important to capture trajectory of error event and period around such event. To allow capturing the successive error events DCC can be programmed to continue after error. DCC_GCTRL2 [3-0] CONT_ON_ERR shall be set to value other than "0101" to enable this mode. It is recommended to write "1010" to avoid single soft errors.

12.10.1.2.5.2 DCC Error Count

DCC also counts the number of error pulses generated since reset or since last time the error count is cleared. This is read/write register for CPU to clear when new trace of number of errors is required to be maintained.

12.10.1.2.6 DCC Control and count hand-off across clock domains

As the counters run in two different selectable clock domains and the register interface runs on the fixed bus clock domain, control signals and counter value hand-off have synchronizers implemented. These add to the margins of error while comparing the counts.

1. With all three counts synchronized to FICLK domain for comparison error detection there is delay in terms of FICLK domain.
2. Based on the error signal, the enable for the counters is synchronized back to the respective clock domains of the counters, which adds latency in terms of clock periods which are different, this would create a skew between start of count. Depending upon frequency ratios of the clocks used, the difference between two could vary.

Application needs to consider the worst case delay differences while measuring the clocks.

12.10.1.2.7 DCC Error Trajectory record

Once the clock errors out, the host can read the counter values to determine the extent of error to analyze type of failure. For short window comparisons this would become difficult, specially if there are back to back errors due to some transient event. Secondly, for random events which can cause an interrupt during the critical phase of application running, then event if not recorded may get overwritten and also not provide meaningful trace of error.

12.10.1.2.7.1 DCC FIFO capturing for Errors

DCC provides the FIFO for capturing COUNT0, VALID0, and COUNT1 information which captures all three counts upon "Error" event. For "Done" event no results are captured by default.

12.10.1.2.7.2 DCC FIFO in continuous capture mode

To track the VALID0 counter values regardless of "Error" or not, FIFOs can be configured to capture the count for each compare window. This is useful in validation and characterization exercise. DCC_GCTRL2[11-7]

FIFO_NONERR control when set to value other than "0101" this mode is set; it is recommended to write "1010" to avoid single soft errors. Note, this capture is applicable only in continuous mode and not in single shot mode.

12.10.1.2.7.3 DCC FIFO Details

The FIFO is 4 deep for each count and updates new count information for all the non-full FIFOs. Information is updated on every configured trigger of error or cycle completion. If full, the next values are not written till at-least one entry is read. Application owns responsibility to read the FIFOs uniformly to keep synchronisation between three entries of the FIFO. Both empty and full indications for individual FIFOs is provided through the DCC_STATUS2.

12.10.1.2.7.4 DCC FIFO Debug mode behavior

Upon debug access, the FIFO pointers should not advance hence not impacting the functional behavior. This requirement is same as other functional blocks in the device.

12.10.1.2.8 DCC Count read registers

DCC has provision to read the counts during operation. This is performed using DCC_CNT0, DCC_VALID0, and DCC_CNT1 registers. Read from these registers in default mode allows reading the present value of count. This is useful when in single shot mode or mode where DCC stops upon error.

These registers can be used to read the FIFO through the DCC_GCTRL2[7-4] FIFO_READ configuration. Reads on the empty FIFO shall provide the contents of last pointed location. Application shall track the empty/full conditions of the FIFOs to track the count records consistently.

Regardless of FIFO_READ configuration, the FIFO internally keeps updating records based on configured triggers till full.

12.10.2 Error Signaling Module (ESM)

This section describes the Error Signaling Module (ESM) in the device.

12.10.2.1 ESM Overview

The Error Signaling Module (ESM) aggregates events and/or errors from throughout the device into one location. It can signal both low and high priority interrupts to a processor to deal with an event and/or manipulate an I/O error pin to signal an external hardware that an error has occurred. Therefore an external controller is able to reset the device or keep the system in a safe, known state.

12.10.2.1.1 ESM Features

Each ESM module implements the following features:

- Up to 1024 error event inputs
 - Implemented in groups of 32 events
 - Level or Pulse inputs (Pulse inputs are triple redundant)
- Selectable low and high priority interrupt error pin prioritization of each error event
- Error pin to signal severe device failure
 - Support of level or PWM modes
- Configurable timebase for error signal
- Error forcing capability
- Internal redundant flops on critical fields

Unsupported Features:

- See the Module Integration section of this document for a list of module features not supported by the integration on this Device.

12.10.2.1.2 ESM Ports

12.10.2.2 ESM Environment

This section describes the ESM external connections (environment).

[Table 12-507](#) describes the ESM I/O signals.

Table 12-507. ESM I/O Signals

Module Pin	I/O ⁽¹⁾	Description
ERR_O	O	Active low error output signal.

(1) O = Output;

12.10.2.3 ESM Functional Description

The Error Signaling Module (ESM) centralizes fault reports. It provides mechanisms to classify errors by severity and to provide programmable error response. The error classification in the ESM is determined by programmed configuration for each individual error input. For each individual error input the configuration can be set to assert an output error pin, or generate an interrupt to a CPU, or both. When an individual error input is configured to generate an interrupt, the configuration will also select whether the interrupt that is generated will be one of high priority or low priority.

By reporting the faults in a central location, the system may determine what caused the fault and what action can be taken. In general, the faults can be split into two categories:

- Corrected faults
- Non-corrected faults

The ESM reports errors in two ways:

- An interrupt to a processor in the device. This allows the device to analyze and try to recover from an error.
- An external ERROR pin. This allows the system outside of the SoC to monitor for potentially fatal errors(errors that the device cannot self-recover from). Moreover, the external I/O (ERROR pin) can operate in level or PWM modes. In level mode, the output will remain asserted (active low) for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin will go inactive (high). If it does not go inactive in that time, then an external agent should intervene, as there may be an unrecoverable error. In PWM mode, the error will cause the output pin to maintain its value for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin will continue the PWM pattern. If it does not go inactive in that time, then an external agent should intervene, as there may be an unrecoverable error.

Both mechanisms can be used at the same time for the same fault, signaling both an interrupt and the external ERROR pin. This allows the device to attempt to recover, but if it fails, then the external system is still alerted. If it succeeds, then it can remove the ERROR pin assertion so that the external system knows that a potentially unsafe condition was avoided.

Lastly, the ESM does not specify any methods of intervention, only the process of alerting internal CPUs and external monitor(s) of an existing error event.

[Figure 12-543](#) shows the ESM module block diagram. Note that not all instances may be pinned out in the device. For more information, see *ESM Environment*.

esm-006

Figure 12-543. ESM Block Diagram**12.10.2.3.1 ESM Interrupt Requests**

The ESM module generates three output interrupts to the device interrupt controllers:

- Configuration error interrupt (see [Section 12.10.2.3.1.1](#))
- High priority error interrupt (see [Section 12.10.2.3.1.2](#))
- Low priority error interrupt (see [Section 12.10.2.3.1.3](#))

The error interrupt outputs are provided so that a processor in the device can be signaled to intervene when an error event occurs. Each error event input can be enabled, via software, to cause an error interrupt to occur (via the ESM_INTR_EN_SET_j register). Additionally, each error event input can be programmed to influence either the low priority (default) interrupt or the high priority interrupt (via the ESM_INT_PRIO_j). The low priority interrupt is intended for events that are of interest, but do not require immediate intervention. For example, an indication that there was a single bit error that was corrected may signal a low priority interrupt, so that information can be collected for statistical purposes. A high priority interrupt is intended for events that need immediate attention. For example, an indication that there was an uncorrected two-bit error may be signaled as a high priority interrupt.

12.10.2.3.1.1 ESM Configuration Error Interrupt

The configuration error interrupt (ESM_INT_CFG_LVL_0) indicates that there is an inconsistency in the configuration of one (or more) error group *j* registers (MMRs).

In such inconsistency in the internal copies of any of the MMRs caused by fault associated with error group *j*, the corresponding raw status will be set in the ESM_ERR_RAW register. If the corresponding bit is enabled in the ESM_ERR_EN_SET register, a configuration error interrupt will be triggered.

When a configuration error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM_ERR_STS register to determine which group has a configuration error
2. Write the correct values to the following group registers:

Note

If there has been a configuration error, the values in the below registers cannot be guaranteed to be correct anymore. Therefore, software should maintain a copy of the correct values prior to an error to ensure that they can be re-programmed with the correct configuration.

- a. ESM_INTR_EN_SET_j
- b. ESM_INTR_EN_CLR_j
- c. ESM_INT_PRIO_j
- d. ESM_PIN_EN_SET_j
- e. ESM_PIN_EN_CLR_j
3. Service any pending interrupts in steps 4, 5, and 6 below

Note

The raw status of any pending interrupts may be inconsistent. Servicing the interrupt will return it to consistency via the error group ESM_RAW_j register.

4. Write 0x1 to the appropriate bits in the ESM_ERR_STS register. This step will clear the raw status
 - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
 - b. If there are no additional errors, the level interrupt will go low
5. Write the end of interrupt vector to the ESM_EOI register
 - a. If there are additional configuration error interrupts pending, then a new pulse will be generated. The level interrupt will remain asserted and is unaffected by EOI.
 - b. If there are no additional low priority error interrupts pending, there will be no new pulse.

12.10.2.3.1.2 ESM Low Priority Error Interrupt

Events mapped to the low priority error interrupt (ESM_INT_LOW_LVL_0) are intended to be events of interest that should be addressed eventually, not events that require immediate attention. An example would be an event indicating a corrected error. The system may want to track this for statistical purposes, but it does not require immediate attention.

Any error event can be mapped to the low priority error interrupt. A low priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM_INTR_EN_SET_j register) and mapped to the low priority error interrupt (via ESM_INT_PRIO_j register) and the raw status is set (via the ESM_RAW_j register).

When a low priority error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM_LOW_PRI register
 - a. If both [31-16]PLS and [15-0]LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
 - b. If either [31-16]PLS or [15-0]LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
 - i. First option: Record the value in [31-16]PLS and [15-0]LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority low priority error event

Note

The global event map is neither defined by nor maintain in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

- ii. Second option:
 1. Read the ESM_LOW register to determine which event group(s) have pending low priority error interrupts
 2. Read the desired error group j ESM_STS_j register
 3. Identify which low priority interrupt to service
2. Determine, based on the global event map for the device, where the error event came from

3. Service the error event based on the IP's specification:
 - a. The system may take several actions including (but not limited to):
 - i. Fixing the error
 - ii. Resetting the errored IP peripheral
 - iii. Resetting the device
 - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.10.2.3.1.2.1](#)) or pulse (see [Section 12.10.2.3.1.2.2](#)) event.

12.10.2.3.1.2.1 ESM Low Priority Error Level Event

When a low priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the low priority error level event at the source
2. Write 0x1 to the appropriate bit in the error group *j* of the ESM_STS_j register. This step will clear the raw status
 - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
 - b. If there are no error events, the level will de-assert

Note

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

3. Write the end of interrupt vector to the ESM_EOI interrupt register
 - a. If there are low priority error level events enabled and pending, then a new pulse will be generated
 - b. If there are no additional low priority error level events enabled and pending, there will be no new pulse
 - c. The level interrupt output is unaffected by EOI
4. Write a CLEAR (0x5) to the ESM_PIN_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group *j* ESM_PIN_EN_SET_j register), but may be done regardless as an extra CLEAR is not harmful.

12.10.2.3.1.2.2 ESM Low Priority Error Pulse Event

When a low priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group *j* of the ESM_STS_j register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM_EOI interrupt register
 - a. If there are additional low priority error pulse events enabled and pending, then a new pulse will be generated. The level interrupt will remain asserted and is unaffected by EOI.
 - b. If there are no additional low priority error pulse events enabled and pending, there will be no new pulse
 - c. Note – a pulse error event input that stays asserted will be treated as a “new” pulse event when it is cleared in the ESM.
 - d. The level interrupt will remain asserted and is unaffected by EOI.
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM
4. Write a CLEAR (0x5) to the ESM_PIN_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group *j* ESM_PIN_EN_SET_j register), but may be done regardless as an extra CLEAR is not harmful.

12.10.2.3.1.3 ESM High Priority Error Interrupt

Events mapped to the high priority error interrupt are intended to be events that require immediate intervention from the system because a potentially dangerous error has occurred. An example would be an event indicating an uncorrected error. The system will want to diagnose the issue and intervene to ensure there are no violations.

Any error event can be mapped to the high priority error interrupt. A high priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM_INTR_EN_SET_j) register and mapped to the high priority interrupt (via the ESM_INT_PRIO_j) register and the raw status is set (via the ESM_RAW_j).

When a high priority error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM_HI_PRI register
 - a. If both [31-16] PLS and [15-0] LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
 - b. If either [31-16] PLS or [15-0] LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
 - i. First option: Record the value in [31-16] PLS and [15-0] LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority high priority error event.

Note

The global event map is neither defined by nor maintain in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

- ii. Second option:
 1. Read the ESM_HI register to determine which event group(s) have pending high priority error interrupts
 2. Read the desired error group *j* ESM_STS_j register
 3. Identify which high priority error interrupt to service
2. Determine, based on the global event map for the device, where the error event came from
3. Service the error event based on the IP's specification:
 - a. The system may take several actions including (but not limited to):
 - i. Fixing the error
 - ii. Resetting the errored IP peripheral
 - iii. Resetting the device
 - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.10.2.3.1.3.1](#)) or pulse (see [Section 12.10.2.3.1.3.2](#)) event.

12.10.2.3.1.3.1 ESM High Priority Error Level Event

When a high priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the error event at the source
2. Write 0x1 to the appropriate bit in the error group *j* of the ESM_STS_j register. This step will clear the raw status
 - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
 - b. If there are no error events, the level will de-assert

Note

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

3. Write the end of interrupt vector to the ESM_EOI interrupt register
 - a. If there are high priority error level events enabled and pending, then a new pulse will be generated
 - b. If there are no additional high priority error level events enabled and pending, there will be no new pulse
 - c. The level interrupt output is unaffected by EOI.

4. Write a CLEAR (0x5) to the ESM_PIN_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group *j* ESM_PIN_EN_SET_*j* register, but may be done regardless as an extra CLEAR is not harmful.

12.10.2.3.1.3.2 ESM High Priority Error Pulse Event

When a high priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group *j* of the ESM_STS_*j* register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM_EOI interrupt register
 - a. If there are high priority error pulse events enabled and pending, then a new pulse will be generated and the level interrupt will remain asserted
 - b. If there are no additional high priority error pulse events enabled and pending, there will be no new pulse
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM
4. Write a CLEAR (0x5) to the ESM_PIN_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group *j* ESM_PIN_EN_SET_*j* register), but may be done regardless as an extra CLEAR is not harmful.

12.10.2.3.2 ESM Error Event Inputs

The ESM can have up to 1024 error event inputs, configurable by groups of 32. For the mapping of system interrupt error events to ESM interrupt inputs, see *Interrupt Sources*.

Level error events (active high) are synchronized to the ESM clock. This synchronized value is captured in to a flop.

Pulse error events use rising edge detection. Each pulse error event has 3 redundant inputs. Each input has its own edge detection logic. Multiple transmission protects against Single Event Upsets (SEUs, transient errors) causing a pulse to be lost during transmission and against failure of the edge detection logic. Once an edge has been detected on any of the three inputs, the ESM_RAW_*j* status is set. Subsequent pulses are likely to come concurrently or quickly enough that software will not have reacted yet. This logic is intentionally biased against false negatives and towards false positives. An SEU that causes an event where none actually occurred will cause software to be called in to action. Software must observe that there is no real error and clear the false status.

12.10.2.3.3 ESM Error Pin Output

The error pin output (ERR_O) is used to signal an external agent that it needs to (or may need to) intervene because of an error. Each error event input can be programmed, via software, to influence the error pin output (via the ESM_PIN_EN_SET_*j* register). The error pin output is active low or PWM based on the ESM_EN[7-4] PWM_EN field. This bit field should only be modified when the ESM is disabled, based on the ESM_EN register.

During Power-On Reset (POR), the error pin is active (asserted low) and the device drives this via a weak internal pull-down. The I/O is under the control of the device. When POR is removed from the ESM, it will be driving the error pin so the device can hand over control to the ESM. The user may also add an external pull-down that is only active when the device is in reset.

During a warm reset the state of the error pin is unchanged, that is the error pin logic is only reset by a POR. The device leaves the I/O active during a warm reset.

The ESM has also a software error forcing capability on the error pin. That is, a force error can be set via the ESM_EN[3-0] KEY bit field.

CAUTION

The isolation value for the ERR_O output of ESM is active (0). This is intended and supposed to protect against an accidental transition to a low power state. If the actual low power mode transition is intended, the PMIC should be made aware by software to ignore the ESM error signal. Otherwise device resets will be asserted from companion chip.

Figure 12-544 describes the behavior of the error pin. Not shown is that a reset (Power-On-Reset only) will immediately transition the error pin to the ESM_RESET state and a Global Soft Reset will immediately transition the error pin to the ESM_IDLE state. A pending error interrupt event is any error event with the raw state set and the error pin Influence enabled. There are two types of "clear" events associated with servicing the error pin. The first is to clear the status of the pending event (see Section 12.10.2.3.1 for how to clear level and pulse pending events). The second is the CLEAR event meant to de-assert the error pin.

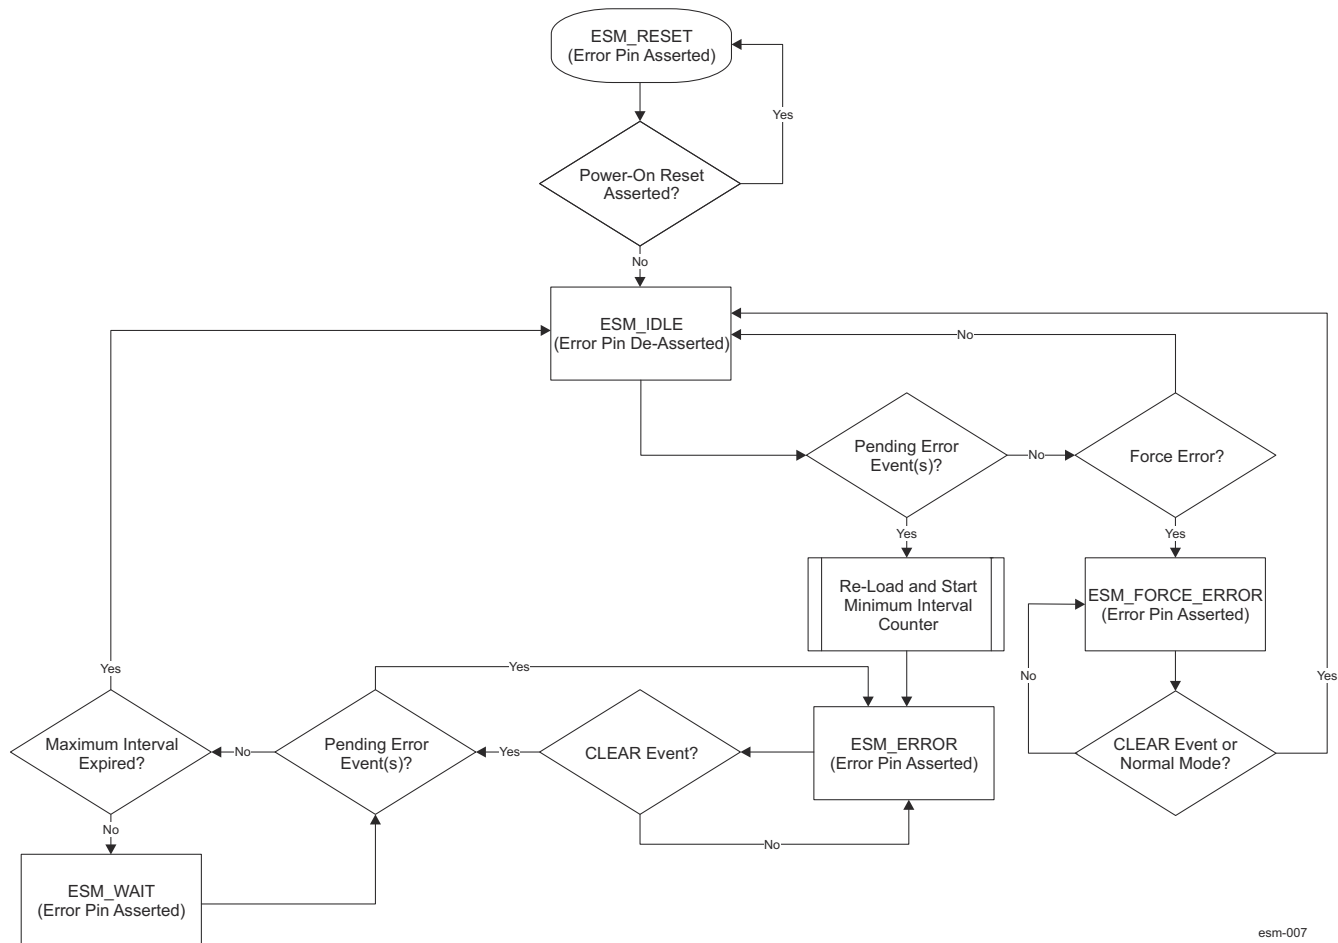

Figure 12-544. ESM Error Pin State Flowchart

If an error event happens that has been programmed to influence the error pin, the error pin will assert (active low) for a minimum time (as programmed by the ESM_PIN_CNTR_PRE register). In order for the error pin to de-assert, the following 3 things must happen:

1. The minimum time interval must expire
2. The event that caused the error pin to assert must be cleared (see Section 12.10.2.3.1)
3. A CLEAR (0x5) must be written to the ESM_PIN_CTRL register.

Note

Step 3 should happen after step 2, but either (or both) of these steps may happen before or after step 1.

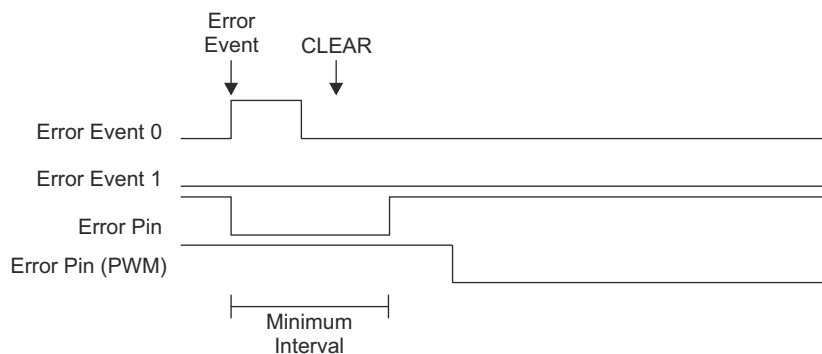

Figure 12-545 shows a typical error pin assertion.

esm-008

Figure 12-545. ESM Error Pin Assertion

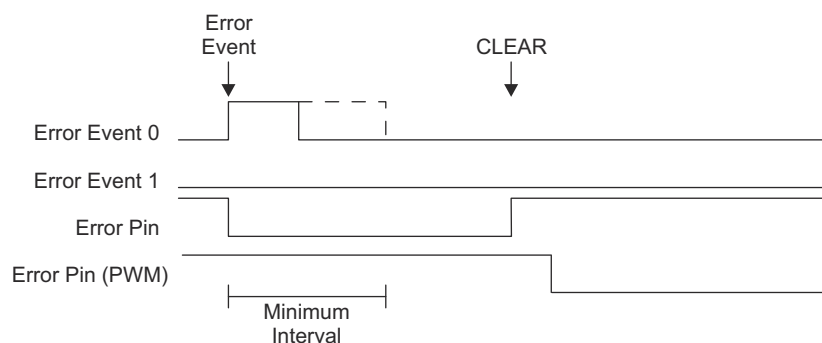

If, during the minimum time, CLEAR is written to the error key, then the error pin will de-assert after the minimum time interval, as shown in [Figure 12-546](#).

esm-009

Figure 12-546. ESM Error Pin Assertion with CLEAR during Minimum Interval

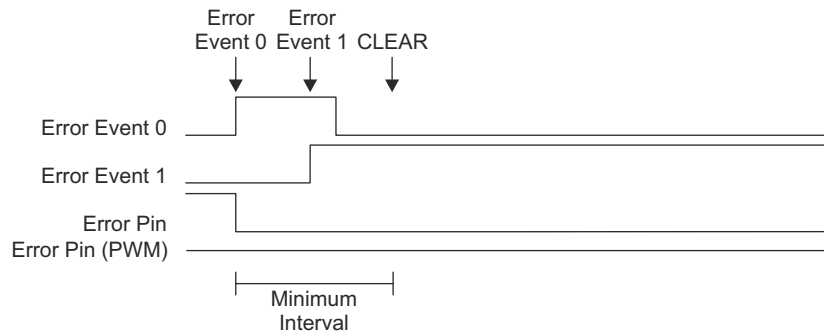

If CLEAR is not written till after the minimum time interval, the error pin will de-assert when CLEAR is written. This is regardless of whether the error interrupt event itself is removed before or after the minimum time interval, as shown by the dotted line in [Figure 12-547](#).

esm-010

Figure 12-547. ESM Error Pin Asserting with CLEAR after Minimum Interval

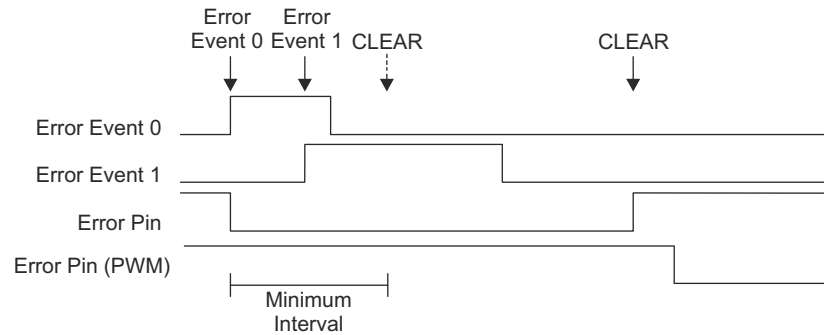

When in the ESM_ERROR state and a CLEAR event happen, if there are still pending error events, the ESM stays in the ESM_ERROR state with the error pin asserted. Multiple error events when in the ESM_ERROR state do not reset the minimum time interval counter as shown in [Figure 12-548](#).

esm-011

Figure 12-548. ESM Error Pin Asserting with Interval Reset by Additional Error Event(s)

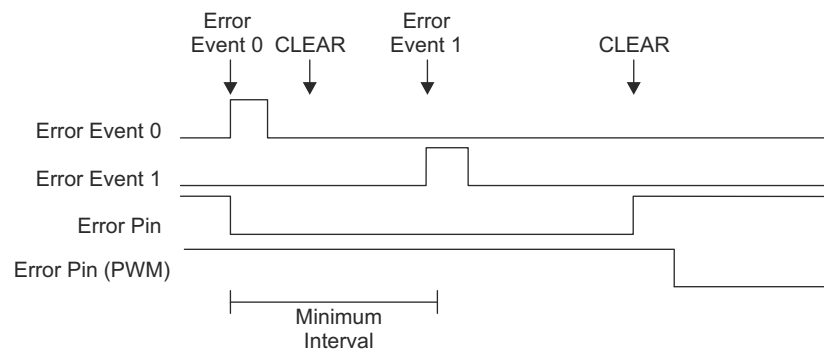

A CLEAR event causes a re-evaluation of whether there are any pending error events. As such, a single CLEAR can be used to clear the error pin after multiple error events. Multiple CLEAR events can occur (such as the one with the dotted arrow shown in Figure 12-549), but are not necessary. No matter how many error events occur nor when (or how many) CLEAR events occur, the error pin will always be asserted for at least the minimum time interval

esm-012

Figure 12-549. ESM Error Pin Asserting with Single CLEAR for Multiple Events

If all error events are cleared and the ESM is in the ESM_WAIT state, waiting for the minimum time interval to expire, and a new error interrupt event occurs, the ESM will go back to the ESM_ERROR state. The minimum time interval will not reset, but a new CLEAR event will be required as shown in Figure 12-550.

esm-013

Figure 12-550. ESM Error Pin Asserting with New Error During Minimum Time Interval

Table 12-508 shows some common scenarios of how the error pin as well as the two associated registers (ESM_PIN_CTRL and ESM_PIN_STS) will be set.

Table 12-508. ESM Error Pin Scenarios

Scenario	Error Pin State Value	ESM_PIN_CTRL[3-0] KEY	ESM_PIN_STS[0] VAL status value	Additional Notes
POR Asserted	0	N/A	N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
After de-assertion of POR	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was not asserted when reset asserted)	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was asserted when reset asserted)	0	0x0 (Normal Mode)	0x1	-
Force error pin	0	0xA (Force Error Mode)	0x0	Forcing error on the pin via software.

12.10.2.3.4 PWM Mode

If the error output pin is in PWM mode then when no error is detected it will toggle according to programmable MMR widths for high and low periods. When an error occurs, the error pin stops toggling and remains constant until the error is cleared. An external PMIC that is detecting the PWM toggles can identify the error if the pin stops toggling. The periods should be programmed such that they fit within the expectation of the external PMIC.

12.10.2.3.5 ESM Minimum Time Interval

The minimum time interval is the minimum amount of time that the error pin will be asserted (active low) when an enabled error interrupt event happens. This value is system dependent, but should be enough time so that the external monitoring agent can always see the error pin asserted, but short enough so that if all of the error events are cleared, then the error pin can be de-asserted before the external agent decides to intervene. This is highly dependent on the application and the Fault Tolerant Time Interval.

The Minimum Time Interval counter is clock cycle based, therefore the time of the interval is a combination of the value in the ESM_PIN_CNTR_PRE register and the clock frequency of the ESM. Software must calculate the value accordingly. The Minimum Time Interval should be set according to the needs of the application.

12.10.2.3.6 ESM Protection for Registers

The configuration for each error group j of registers are backed up by 3 flops in order to protect against single or double-bit errors. When written, all 3 bits are set to the same value. When read (and for functioning of the internal state machines) the value is the OR of all 3 bits. Whenever any of the bits disagree, the Configuration Error interrupt is asserted (if enabled). The registers covered by this mechanism are:

- ESM_ERR_RAW
- ESM_ERR_STS
- ESM_ERR_EN_SET
- ESM_ERR_EN_CLR
- ESM_RAW_j
- ESM_STS_j
- ESM_INTR_EN_SET_j
- ESM_INTR_EN_CLR_j
- ESM_INT_PRIO_j
- ESM_PIN_EN_SET_j
- ESM_PIN_EN_CLR_j

The error pin control register ESM_PIN_CTRL contains a multi-bit field KEY. The key value ensures normal operation on the error pin and that an error even will be generated if one occurs. Software should periodically read check the KEY bit field value and make sure it is 0x0. If the value is not 0x0, software must re-write it to this key value (unless in test mode forcing an error on the pin) to ensure the normal operation. [Table 12-509](#) lists the KEY values and their respective meaning.

Table 12-509. ESM Error Pin Control Values

ESM_PIN_CTRL[3-0] KEY	Description
N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
0x0 (Normal)	Normal operation mode - Error pin will activate when an enabled error event occurs.
0xA (Force Error)	Force error mode - Forces the error pin active. To clear the error pin (return to the ESM_IDLE state) write this field back to normal mode (writing a CLEAR event will also work). Force error mode must be set only while in IDLE. Attempting force error while in another state will have no effect.
0x5 (CLEAR)	CLEAR Event - generates a CLEAR event to the ESM state machine. KEY will return to normal mode (0x0) on the next cycle.
Other Values	All other values - Normal mode. Writing any of these values will have no effect. When reading any of these values indicates that one or more bits have experienced a single event upset, software should write the field back to 0x0. The ESM will continue to operate in normal mode.

The error pin counter pre-load register ESM_PIN_CNTR_PRE should also be read and checked periodically by software.

12.10.2.3.7 ESM Clock Stop

The ESM can only be put in to clock stop if all of the internal state machines are idle and the [3-0] KEY bit field for the global enable command is cleared in the ESM_EN register.

12.10.3 Memory Cyclic Redundancy Check (MCRC) Controller

This chapter describes the Memory Cyclic Redundancy Check (MCRC) controller in the device.

12.10.3.1 MCRC Overview

VBUSM CRC controller is a module which is used to perform CRC (Cyclic Redundancy Check) to verify the integrity of a memory system. A signature representing the contents of the memory is obtained when the contents of the memory are read into MCRC Controller. The responsibility of MCRC controller is to calculate the signature for a set of data and then compare the calculated signature value against a pre-determined good signature value. MCRC controller provides four channels to perform CRC calculation on multiple memories in parallel and can be used on any memory system.

12.10.3.1.1 MCRC Features

MCRC has the following features:

- Four channels to perform background signature verification on any memory subsystem
- Data compression on 8-, 16-, 32-, and 64-bit data size
- Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64-bit primitive polynomial
- Each channel has a CRC Value Register which contains the pre-determined CRC value
- Use timed base event trigger from timer to initiate DMA data transfer
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression
- Three modes of operation:
 - Auto
 - Semi-CPU
 - Full-CPU
- For each channel, CRC can be performed either by MCRC Controller or by CPU
- Automatically performs signature verification without CPU intervention in AUTO mode
- Generates interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification itself
- Generates CRC fail interrupt in AUTO mode if signature verification fails
- Generates Timeout interrupt if CRC is not performed within the time limit
- Generates DMA request per channel to initiate CRC value transfer
- An 128-byte block burst address for the PSA register to DMA without constant mode bus attribute

12.10.3.1.2 MCRC Ports

Table 12-510. MCRC Clocks and Resets

Clocks	
Module Clock Input	Description
MCRC_FICLK	MCRC clock. This clock is used for all interface and functional operations.
Resets	
Module Reset Input	Description
MCRC_RST	MCRC hardware reset

Interrupt Requests		
Module Interrupt Signal	Description	Type
INT_MCRC_INTR	MCRC Interrupt signal	Level
DMA Events		
Module DMA Event	Description	Type
DMA_EVENT_INTR0	MCRC DMA event for channel 1	Pulse
DMA_EVENT_INTR1	MCRC DMA event for channel 2	Pulse
DMA_EVENT_INTR2	MCRC DMA event for channel 3	Pulse
DMA_EVENT_INTR3	MCRC DMA event for channel 4	Pulse

12.10.3.2 MCRC Functional Description

12.10.3.2.1 MCRC Block Diagram

Figure 12-551 shows the MCRC internal blocks.

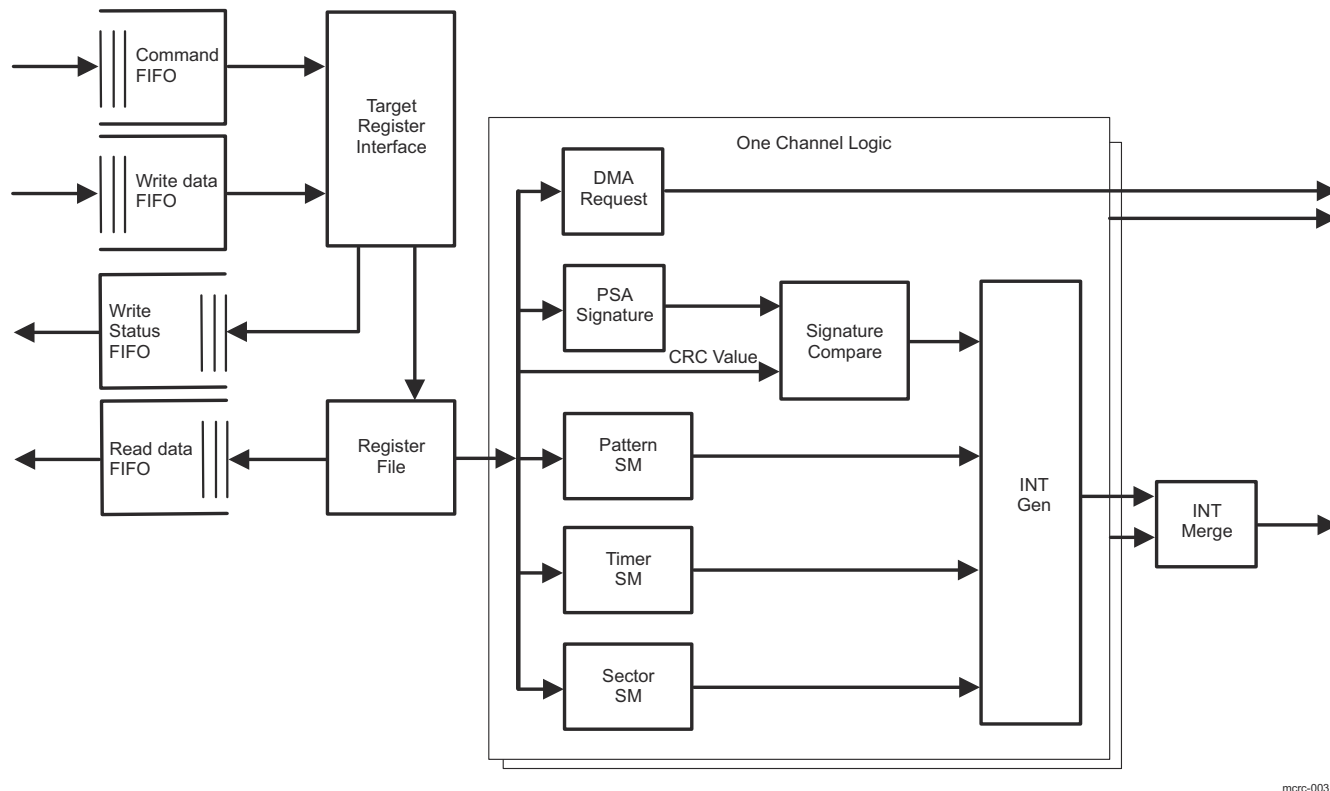

Figure 12-551. MCRC Block Diagram

- **Command FIFO:** The Command FIFO pipelines the commands to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 4 elements deep.
- **Write FIFO:** The Write FIFO pipelines the write data to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 2 elements deep.
- **Write Status FIFO:** The Write Status FIFO pipelines the write status back to the VBUSM. A write status will be issued on the final data phase of a write command. This FIFO is 2 elements deep.
- **Read Data FIFO:** The Read Data FIFO pipelines the read data back to the VBUSM. This FIFO is 3 elements deep.
- **Target Register Interface:** The Target Register Interface directs the written data to the register file.
- **PSA Signature:** The PSA Signature creates the signature of the data written. This data will then be compared to the CRC Value or read by software to determine goodness.
- **Pattern State Machine:** The Pattern State Machine determines when a block of data has been serviced.
- **Timer State Machine:** The Timer State Machine determines when overrun and under-run events are detected.
- **Sector State Machine:** The Sector State Machine determines when a sector error should be captured so the software can determine the errant block of data.
- **Signature Compare:** The Signature Compare block compares the current signature to the CRC Value register and sends the result to the Interrupt Generation block.

12.10.3.2.2 MCRC General Operation

There are four channels in MCRC controller and for each channel there is a PSA (Parallel Signature Analysis) Signature Register (MCRC_PSA_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC_CRC_REGL1-4).

A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be a 8-, 16-, 32-, or 64-bit data. MCRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory of which the contents to be verified to the memory mapped PSA Signature Register. When DMA transfers data to the memory mapped PSA Signature Register, a signature is generated.

A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed automatically by MCRC controller in AUTO mode or by CPU itself in Semi-CPU or Full-CPU mode. In AUTO mode, a self-sustained CRC signature calculation can be achieved without any CPU intervention.

12.10.3.2.3 MCRC Modes of Operation

MCRC Controller can operate in AUTO, Semi-CPU, and Full-CPU modes.

12.10.3.2.3.1 AUTO Mode

In AUTO mode, MCRC Controller in conjunction with DMA controller can perform CRC without CPU intervention. A sustained transfer of data to both the PSA Signature Register (MCRC_PSA_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC_CRC_REGL1-4) are performed in the background of CPU. When a mismatch is detected, an interrupt is generated to the CPU. A 16-bit, current sector ID register (MCRC_CRC_CURSEC_REG1-4) is provided to identify which sector causes a CRC failure.

12.10.3.2.3.2 Semi-CPU Mode

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register (MCRC_PSA_SIGREGL1-4). Instead of performing signature verification automatically, the CRC controller generates an compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register (MCRC_PSA_SECSIGREGL1-4) and compare it to a pre-determined CRC value.

12.10.3.2.3.3 Full-CPU Mode

In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register (MCRC_PSA_SIGREGL1). After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

12.10.3.2.4 PSA Signature Register

The 64-bit PSA Signature Register (MCRC_PSA_SIGREGL1-4 and MCRC_PSA_SIGREGLH1-4) is based on one of the selected CRC polynomials to produce the maximum length LFSR (Linear Feedback Shift Register).

$$\text{CRC16: } f(x) = x^{16} + x^{12} + x^5 + 1 \quad (29)$$

$$\text{CRC32: } f(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 \quad (30)$$

$$\text{CRC64: } f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (31)$$

$$\text{SAE J1850 CRC8: } f(x) = x^8 + x^4 + x^3 + x^2 + 1 \quad (32)$$

$$\text{H2F Autosar 4.0: } f(x) = x^5 + x^3 + x^2 + x + 1 \quad (33)$$

$$\text{CASTAGNOLI, iSCSI: } f(x) = x^{28} + x^{27} + x^{26} + x^{25} + x^{23} + x^{22} + x^{20} + x^{19} + x^{18} + x^{14} + x^{13} + x^{11} + x^{10} + x^9 + x^8 + x^6 + 1 \quad (34)$$

$$\text{E2E Profile 4: } f(x) = x^{31} + x^{30} + x^{29} + x^{28} + x^{26} + x^{23} + x^{21} + x^{19} + x^{18} + x^{15} + x^{14} + x^{13} + x^{12} + x^{11} + x^9 + x^8 + x^4 + x + 1 \quad (35)$$

- A. More details of the 64-bit primitive polynomial can be found at W. Stahnke, Primitive binary polynomials, Math. Comp. 27 (1973), 977–980.

There is one PSA Signature Register per CRC channel. PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHI_MODE bits (where i = 1 to 4). If CHI_MODE=0x0 (Data Capture), a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature.

MCRC Controller should be used in conjunction with the on-chip DMA controller to produce optimal system performance. The incoming data pattern to PSA Signature Register is typically initiated by the DMA controller. When DMA is properly setup, it would read data from the pre-determined memory system and write them to the memory mapped PSA Signature Register. Each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

After a system reset and when AUTO mode is enabled, MCRC Controller automatically generates a DMA request to request the pre-determined CRC value corresponding to the first sector of memory to be checked.

In AUTO mode, when one sector of data patterns is compressed, the signature stored at the PSA Signature Register is first copied to the PSA Sector Signature Register (MCRC_PSA_SECSIGREGL1-4) and PSA Signature Register is then cleared out to all zeros. An automatic signature verification is then performed by comparing the signature stored at the PSA Sector Signature Register to the CRC Value Register (MCRC_CRC_REGL1-4). After the comparison the MCRC Controller can generate a DMA request. Upon receiving the DMA request the DMA controller will update the CRC Value Register by transferring the next pre-determined signature value associated with the next sector of memory system. If the signature verification fails then MCRC Controller can generate a CRC fail interrupt.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. Software can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

MCRC Controller supports double word, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zeros before compression. Note that comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bits because a compressed value is always expressed in 64 bits.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros.

PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns is compressed

12.10.3.2.5 PSA Sector Signature Register

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the 64-bit PSA Sector Signature Register (MCRC_PSA_SECSIGREGL1-4 and MCRC_PSA_SECSIGREGH1-4). PSA Signature Register is a read-only register. During Semi-CPU mode, the host CPU must read from the PSA Sector Signature Register instead of reading from PSA Signature Register

for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the compression complete interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enabled to generate when overrun condition occurs.

12.10.3.2.6 CRC Value Register

Associated with each channel there is a 64-bit CRC Value Register (MCRC_CRC_REGL1-4 and MCRC_CRC_REGH1-4).

The CRC Value Register stores the pre-determined CRC value. After one sector of data patterns is compressed by PSA Signature Register, MCRC Controller can automatically compare the resulting signature stored at the PSA Sector Signature Register with the pre-determined value stored at the CRC Value Register if AUTO mode is enabled. If the signature verification fails, MCRC Controller can be enabled to generate an CRC fail interrupt. When the channel is set up for Semi-CPU mode, CRC controller first generates a compression complete interrupt to CPU. Upon servicing the interrupt, CPU will then read the PSA Sector Signature Register and then read the corresponding CRC value stored at another location and compare them. CPU must not read from the CRC Value Register during Semi-CPU or Full-CPU mode because the CRC Value Register is not updated during these two modes.

In AUTO mode, for first sector's signature, DMA request is generated when mode is programmed to AUTO. For subsequent sectors, DMA request is generated after each sector is compressed. Responding to the DMA request, DMA controller reloads the CRC Value Register for the next sector of memory system to be checked. The user software needs to configure the DMA to ensure that the DMA first writes to the MCRC_CRC_REGL1 followed by the MCRC_CRC_REGH1 register in during the AUTO Mode.

When CRC Value Register is updated with a new CRC value, an internal flag is set to indicate that CRC Value Register contains the most current value. This flag is cleared when CRC comparison is performed. Each time at the end of the final data pattern compression of a sector, MCRC Controller first checks to see if the corresponding CRC Value Register has the most current CRC value stored in it by polling the flag. If the flag is set then the CRC comparison can be performed. If the flag is not set then it means the CRC Value Register contains stale information. A CRC underrun interrupt is generated. When an underrun condition is detected, signature verification is not performed.

MCRC Controller supports double word, word, half word and byte access to the CRC Value Register. As noted before comparison between PSA Sector Signature Register and CRC Value Register during AUTO mode is carried out in 64 bits.

12.10.3.2.7 Raw Data Register

The raw or un-compressed data written to the PSA Signature Register is also saved in the 64-bit Raw Data Register (MCRC_RAW_DATAAREGL1-4 and MCRC_RAW_DATAAREGH1-4). This register is read only.

12.10.3.2.8 Example DMA Controller Setup

DMA controller needs to be setup properly in either AUTO or Semi-CPU mode as DMA controller is used to transfer data patterns. Hardware or a combination of hardware and software DMA triggering are supported.

12.10.3.2.8.1 AUTO Mode Using Hardware Timer Trigger

There are two DMA channels associated with each CRC channel when in AUTO mode. One DMA channel is setup to transfer data patterns from the source memory to the PSA Signature Register (MCRC_PSA_SIGREGL1-4). The second DMA channel is setup to transfer the pre-determined signature to the CRC Value Register (MCRC_CRC_REGL1-4). The trigger source for the first DMA channel can be either by hardware or by software. As illustrated in [Figure 12-552](#), a timer can be used to trigger a DMA request to

initiate transfer from the source memory system to PSA Signature Register. In AUTO mode, MCRC Controller also generates DMA request after one sector of data patterns is compressed to initiate transfer of the next CRC value corresponding to the next sector of memory. Thus a new CRC value is always updated in the CRC Value Register (MCRC_CRC_REGL1-4) by DMA synchronized to each sector of memory.

A block of memory system is usually divided into many sectors. All sectors are the same size. The sector size is programmed in the MCRC_CRC_PCOUNT_REG1-4 and the number of sectors in one block is programmed in the MCRC_CRC_SCOUNT_REG1-4 of the respective channel. MCRC_CRC_PCOUNT_REG1-4 multiplies MCRC_CRC_SCOUNT_REG1-4 and multiplies transfer size of each data pattern should give the total block size in number of bytes.

The total size of the memory system to be examined is also programmed in the respective transfer count register inside DMA module. The DMA transfer count register is divided into two parts. They are element count and frame count. Note that a hardware DMA request can be programmed to trigger either one frame or one entire block transfer. In [Figure 12-552](#), a hardware DMA request from a timer is used as a trigger source to initiate DMA transfer. If all four CRC channels are active in AUTO mode then a total of four DMA requests would be generated by MCRC Controller.

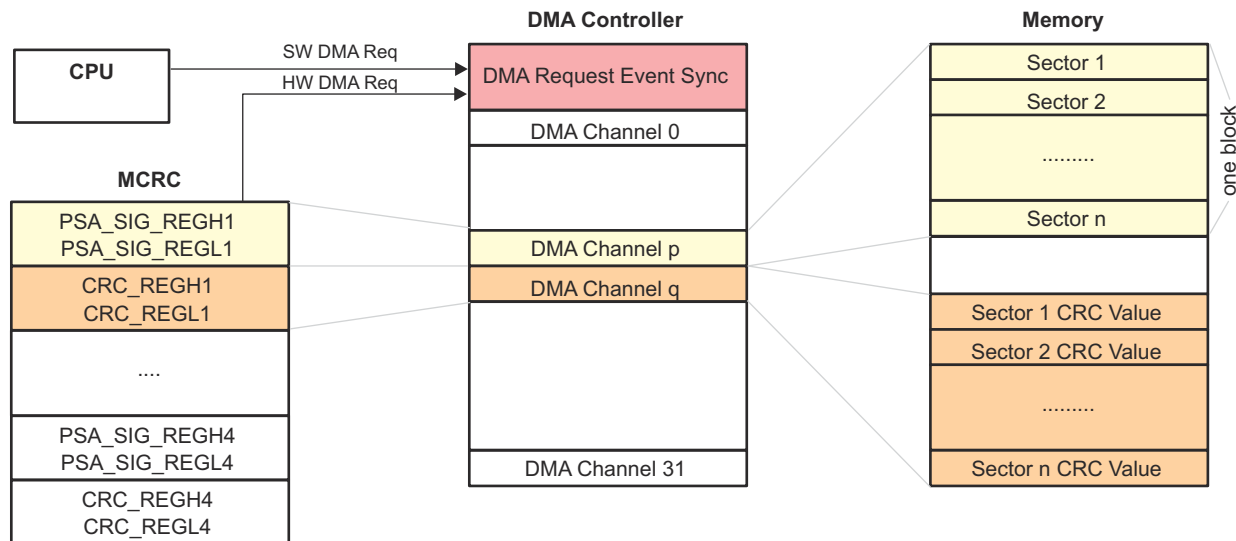

mrcr-004

Figure 12-552. AUTO Mode Using Hardware Timer Trigger

12.10.3.2.8.2 AUTO Mode Using Software Trigger

The data patterns transfer can also be initiated by software. CPU can generate a software DMA request to activate the DMA channel to transfer data patterns from source memory system to the PSA Signature Register. To generate a software DMA request CPU needs to set the corresponding DMA channel in the DMA software trigger register. Note that just one software DMA request from CPU is enough to complete the entire data patterns transfer for all sectors. Please see [AUTO Mode With Software CPU Trigger](#) for illustration.

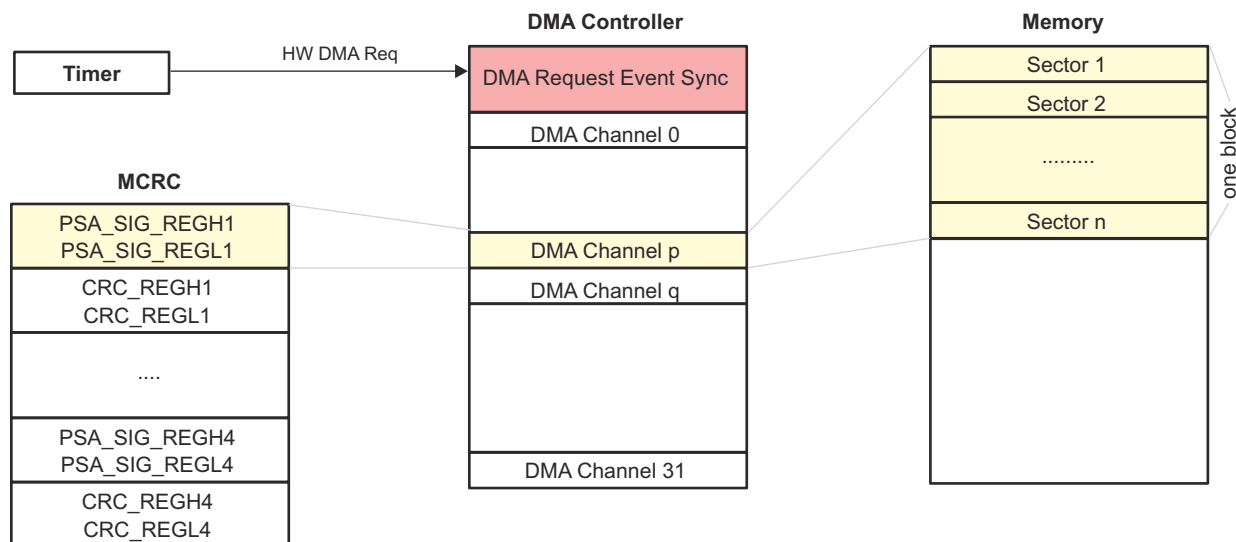

mrcr-005

Figure 12-553. AUTO Mode With Software CPU Trigger

12.10.3.2.8.3 Semi-CPU Mode Using Hardware Timer Trigger

During Semi-CPU mode, no DMA request is generated by CRC controller. Therefore, no DMA channel is allocated to update CRC Value Register. CPU should not read from CRC Value Register in semi-CPU mode as it contains stale value. Note that no signature verification is performed at all during this mode. Similar to AUTO mode, either by hardware or by software DMA request can be used as a trigger for data patterns transfer. [Figure 12-554](#) illustrates the DMA setup using semi-CPU mode with hardware timer trigger.

mrcr-006

Figure 12-554. Semi-CPU Mode With Hardware Timer Trigger

Table 12-512. DMA Request and Counter Logic Operation According to CRC Mode

CRC Mode	DMA Request	Pattern Counter	Sector Counter	Timeout Counter
AUTO	Active	Active	Active	Active
Semi-CPU	Inactive	Active	Active	Active
Full CPU	Inactive	Inactive	Inactive	Inactive

12.10.3.2.9 Pattern Count Register

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register (MCRC_CRC_PCOUNT_REG1-4). When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode and an automatic signature verification is performed in AUTO mode. In AUTO only, DMA request is generated to trigger the DMA controller to update the CRC Value Register.

Note

The data pattern count must be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

12.10.3.2.10 Sector Count Register/Current Sector Register

Each channel contains a 16-bit sector counter. The sector count register stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register (MCRC_CRC_CURSEC_REG1-4). If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure it is advisable to use the following equation during CRC and DMA setup.

$$\text{CRC Pattern Count} \times \text{CRC Sector Count} = \text{DMA Element Count} \times \text{DMA Frame Count} \quad (36)$$

The current sector register is frozen from being updated until both the current sector register is read and CRC fail (CHi_CRC_FAIL) status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

Current sector register is reset when the PSA software reset is enabled.

Note

Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

12.10.3.2.11 Interrupts

CRC generate several types of interrupts per channel. Associated with each interrupt there is a interrupt enable bit (see MCRC_CRC_INTS). No interrupt is generated in Full-CPU mode.

- Compression complete interrupt
- CRC fail interrupt
- Overrun interrupt
- Underrun interrupt
- Timeout interrupt

Table 12-513. Interrupt Conditions Per CRC Mode

CRC Mode	Compression Complete	CRC Fail	Overrun	Underrun	Timeout
AUTO	No	Yes	Yes	Yes	Yes
Semi-CPU	Yes	No	Yes	No	Yes
Full-CPU	No	No	No	No	No

12.10.3.2.11.1 Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated

12.10.3.2.11.2 CRC Fail Interrupt

CRC fail interrupt is generated in AUTO mode only. When the signature verification fails, the CRC fail flag is set, and CPU must take action to address the fail condition and clear the CRC fail flag after it resolves the CRC mismatch.

12.10.3.2.11.3 Overrun Interrupt

Overrun Interrupt is generated in either AUTO or Semi-CPU mode. During AUTO mode, if a CRC fail is detected then the current sector number is recorded in the current sector register (MCRC_CRC_CURSEC_REG1-4). If CRC fail status bit is not cleared and current sector register is not read by the host CPU before another CRC fail is detected for another sector then an overrun interrupt is generated. During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt. At the same time the signature is copied into the PSA Sector Signature Register (MCRC_PSA_SECSIGREGL1-4). If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value then an overrun interrupt is generated.

12.10.3.2.11.4 Underrun Interrupt

Underrun interrupt only occurs in AUTO mode. The interrupt is generated when the CRC Value Register is not updated with the corresponding signature when the data pattern counter finishes counting. During AUTO mode, MCRC Controller generates DMA request to update CRC Value Register in synchronization to the corresponding sector of the memory. Signature verification is also performed if underrun condition is detected. And CRC fail interrupt is generated at the same time as the underrun interrupt.

12.10.3.2.11.5 Timeout Interrupt

To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24-bit timeout counter per CRC channel. The timeout counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (MCRC_CRC_WDTPOLD1-4) and block complete timeout pre-load value (MCRC_CRC_BCTOPLD1-4). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of FICLK clock.

Watchdog timeout pre-load register (MCRC_CRC_WDTPOLD1-4) is used to check if DMA does supply a block of data responding to a request in a given time frame. Block complete timeout pre-load register (MCRC_CRC_BCTOPLD1-4) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with MCRC_CRC_WDTPOLD1-4 after either AUTO or Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with MCRC_CRC_BCTOPLD1-4 the block complete timeout pre-load value.

Block complete timeout pre-load value is used to check if one block of data patterns are compressed within a given time limit. If the timeout counter pre-loaded with MCRC_CRC_BCTOPLD1-4 value expires before one block of data patterns are compressed a timeout interrupt is generated. When one block (pattern count × sector count) of data patterns are compressed before the counter has expired, the counter is pre-loaded with MCRC_CRC_WDTPOLD1-4 value again. If the timeout counter is pre-loaded with zero then the counter is disabled and no timeout interrupt is generated.

12.10.3.2.11.6 Interrupt Offset Register

MCRC Controller only generates one interrupt request to interrupt manager. An interrupt offset register (MCRC_CRC_INT_OFFSET_REG) is provided to indicate the source of the pending interrupt with highest priority. [Table 12-514](#) shows the offset interrupt vector address of each interrupt in an ascending order of priority.

Table 12-514. Interrupt Offset Mapping

Interrupt Condition	Offset Value
Phantom	0x0

Table 12-514. Interrupt Offset Mapping (continued)

Ch3 Timeout	0x23
Ch4 Timeout	0x24

12.10.3.2.11.7 Error Handling

When an interrupt is generated, host CPU must take appropriate actions to identify the source of error and restart the respective channel in DMA and MCRC module. To restart a CRC channel user must perform the following steps in the ISR:

1. Write to software reset bit in MCRC_CRC_CTRL0 register to reset the respective PSA Signature Register
2. Reset the CHi_MODE bits to 0 in MCRC_CRC_CTRL2 register as Data capture mode
3. Set the CHi_MODE bits in MCRC_CRC_CTRL2 register to desired new mode again
4. Release software reset

The host CPU must use byte write to restart each individual channel.

12.10.3.2.12 Power Down Mode

MCRC module can be put into power down mode when the power down control bit MCRC_CRC_CTRL1[0] PWDN is set. The module wakes up when the PWDN bit is cleared. When MCRC controller is in power down mode, no data tracing alone will happen.

12.10.3.2.13 Emulation

A read access from a register in functional mode can sometimes trigger a certain internal event to follow. For example, reading interrupt offset register triggers an event to clear the corresponding interrupt status flag. During emulation when SUSPEND signal is high, a read access from any register should only return the register contents to the bus and should not trigger or mask any event as it would have in functional mode. This is to prevent debugger from reading the interrupt offset register, that is, during refreshing screen and cause the corresponding interrupt status flag to get cleared. Timeout counters are stopped to generate timeout interrupts in emulation mode. No VBUSM bus error will be generated if reading from the unimplemented locations. .

CEMUDBG is the VBUSM suspend signal which need not explicitly indicate that whether CPU is in suspend mode or not. In data trace mode, a separate suspend signal CPU_EMUSP, is used to indicate MCRC controller that the CPU is in suspend mode or not.

12.10.3.3 MCRC Programming Examples

12.10.3.3.1 Example: Auto Mode Using Time Based Event Triggering

A large memory area with 2 Mbyte (256 k × 32-bit [doubleword]) is to be checked in the background of CPU. CRC is to be performed every 1 Kbyte (128 doubleword). Therefore there will be 2048 pre-recorded CRC values. For illustration purpose, we map MCRC_CRC_REGL1 register to DMA channel 1 and MCRC_PSA_SIGREGL1 register to DMA channel 2. Let's assume all DMA transfers are carried out in 64-bit transfer size.

12.10.3.3.1.1 DMA Setup

- Setup DMA channel 1 with the starting address from which the pre-determined CRC values are stored. Setup the destination address to the MCRC_CRC_REGL1. Put the source address at post increment addressing mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1 to trigger a frame transfer.
- Setup DMA channel 2 with the source address from which the contents of memory to be verified. Setup the destination address to the MCRC_PSA_SIGREGL1. Program the element transfer count to 128 and the frame transfer count to 2048. Program the read and write element size to 64 bits. Put the source address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request for channel 2 to trigger an entire block transfer.

12.10.3.3.1.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 2. For example, software can setup the timer to generate a DMA request every 10 ms.

12.10.3.3.1.3 CRC Setup

- Program the pattern count MCRC_CRC_PCOUNT_REG1 to 128
- Program the sector count MCRC_CRC_SCOUNT_REG1 to 2048
- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load (MCRC_CRC_BCTOPLD1-4) value to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected MCRC Controller automatically generates a DMA request on channel 1. Around the same time the timer module also generates a DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC_PSA_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the MCRC_CRC_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC_PSA_SECSIGREGL1/H1 does not match the MCRC_CRC_REGL1/H1 Register. MCRC Controller generates a DMA request on DMA channel 1 when one sector of data patterns are compressed. This routine will continue until the entire 2 Mbytes are consumed. If the timeout counter reached zero before the entire 2 Mbytes are compressed, a timeout interrupt is generated. After 2Mbytes are transferred, the DMA can generate an interrupt to CPU. The entire operation will continue again when DMA responds to the DMA request from both the timer and MCRC Controller. The CRC is performed totally without any CPU intervention.

12.10.3.3.2 Example: Auto Mode Without Using Time Based Triggering

A small but highly secured memory area with 1 Kbytes is to be checked in the background of CPU. CRC is to be performed every 1 Kbytes. Therefore, there is only one pre-recorded CRC value. For illustration purpose, we map channel 1 MCRC_CRC_REGL1/H1 to DMA channel 1 and channel 1 MCRC_PSA_SIGREGL1/H1 to DMA channel 2. Assume all transfers carried out by DMA are in 64-bit transfer size.

12.10.3.3.2.1 DMA Setup

- Setup DMA channel 1 with the source address from which the pre-determined CRC value is stored. Setup the destination address to the MCRC_CRC_REGL1 Register. Put the source address at constant addressing mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1.

- Setup DMA channel 2 with the source address from which the memory area to be verified. Setup the destination address to the MCRC_PSA_SIGREGL1/H1. Program the element transfer count to 128 and the frame transfer count to 1. Put the source address at post increment addressing mode and put the destination address at constant address mode. Generate a software DMA request on channel 2 after CRC has completed its setup. Enable autoinitiation for DMA channel 2.

12.10.3.3.2.2 CRC Setup

- Program the MCRC_CRC_PCOUNT_REG1 to 128
- Program the MCRC_CRC_SCOUNT_REG1 to 1
- Leaving the timeout count MCRC_CRC_BCTOPLD1 register with the reset value of zero means no timeout interrupt is generated
- Enable AUTO mode and all interrupts

After AUTO mode is selected the MCRC Controller automatically generates a DMA request on channel 1. At the same time the CPU generates a software DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC_PSA_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the MCRC_CRC_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC_PSA_SECSIGREGL1/H1 does not match the MCRC_CRC_REGL1/H1. MCRC Controller generate a DMA request on DMA channel 1 again after one sector is compressed. After 1 Kbytes are transferred, the DMA can generate an interrupt to CPU. Responding to the DMA interrupt CPU can restart the CRC routine by generating a software DMA request onto channel 2 again.

12.10.3.3.3 Example: Semi-CPU Mode

If DMA controller is available in a system the CRC module can also operate in semi-CPU mode. This means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. The difference between semi-CPU mode and AUTO mode is that CRC controller does not automatically perform the signature verification. CRC controllers generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

A memory area with 2 Mbytes is to be verified with the help of the CPU. CRC operation is to be performed every 1 Kbyte. Since there are 2 Mbytes (256 K doublewords) of memory to be check and we want to perform a CRC every 1 Kbytes (128 doublewords) and therefore there must be 2048 pre-recorded CRC values. In Semi-CPU mode, the MCRC_CRC_REGL1/H1 is not updated and contains indeterminate data.

12.10.3.3.3.1 DMA Setup

- Setup DMA channel 1 with the source address from which the memory area to be verified are mapped. Setup the destination address to the MCRC_PSA_SIGREGL1/H1. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

12.10.3.3.3.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time-based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 1. For example, software can setup the timer to generate a DMA request every 10 ms.

12.10.3.3.3.3 CRC Setup

- Program the MCRC_CRC_PCOUNT_REG1 to 128
- Program the MCRC_CRC_SCOUNT_REG1 to 2048
- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load value MCRC_CRC_BCTOPLD1 to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz
- Enable AUTO mode and all interrupts.

The timer module first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the MCRC_PSA_SIGREGL1/H1, the CRC controller will compress it. After one sector of

data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the MCRC_PSA_SECSIGREGL1/H1. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2 Mbytes are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from MCRC_PSA_SECSIGREGL1 before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller.

12.10.3.3.4 Example: Full-CPU Mode

In a system without the availability of DMA controller, the CRC routine can be operated by CPU provided the CPU has enough throughput. CPU needs to read from the memory area from which CRC is to be performed.

A memory area with 2 Mbytes is to be checked with the help of the CPU. CRC operation is to be performed every 1 Kbyte. In CPU mode, the MCRC_CRC_REGL1/H1 is not updated and contains indeterminate data.

12.10.3.3.4.1 CRC Setup

- All control registers can be left in their reset state. Only enable Full-CPU mode.

CPU itself reads from the memory and write the data to the MCRC_PSA_SIGREGL1/MCRC_PSA_SIGREGH1 inside MCRC Controller. When the first incoming data pattern arrives at the MCRC_PSA_SIGREGL1/MCRC_PSA_SIGREGH1, the MCRC Controller will compress it. After n data patterns are compressed, CPU can read from the MCRC_PSA_SIGREGL1/MCRC_PSA_SIGREGH1. It is up to the CPU on how to deal with the PSA signature value just read. It can compare it to a known signature value stored at another memory location.

12.10.4 Logical Built-In Self-Test (LBIST)

12.10.4.1 LBIST Overview

Built-in Self-test (BIST) is a feature that allows self-testing of the memory areas and logic circuitry in an Integrated Circuit (IC) without any external test equipment. In an embedded system, these tests are typically used during boot time or shutdown of the system to check the health of an SoC.

LBIST is used to test the logic circuitry in an SoC associated with the CPU cores. There are multiple LBIST instances in the SoC, and each has a different processor core associated with it. There are LBIST tests that can be software-initiated, as well as LBIST status of HW Power on self-tests (POST).

- LBIST is expected to be run at startup
- LBIST must be initiated from a different core than is being tested. The reason for this is that the LBIST test will impact the S/W running on the core, upon which the LBIST test is being run.
- BIST is executed by hardware for MCU and SMS automatically at boot up as part of HW POST

For a list of LBIST modules, see *Device Configuration -> Module Integration -> LBIST*.

12.10.4.2 LBIST Functional Description

The Logic BIST Controller contains a Pseudo Random Pattern Generator (PRPG) and a Multiple Input Signature Register (MISR). The PRPG creates pseudo-random scan in data to drive the block's scan chains, and the MISR captures the scan out data and creates a signature based on this data. At the end of the test, the signature is compared with the expected signature value to determine if the test has passed or failed.

Each H/W module with Logic BIST has a standard Logic BIST Interface that is connected to the central Logic BIST MMR block. Control signals from the central MMR block fan out to all of the sub-chips, and status signals from the sub-chips back to the central MMR block connect to dedicated ports on the MMR block.

Logic BIST execution can be controlled by writing and reading registers in the MMR block. In a secure device, this MMR access will be limited by the SMS. An interrupt (generated by the MMR block) is sent back to the system when the LBIST execution is complete. The system processor can then use the MMRs to read the LBIST MISR signature and verify that the LBIST execution passed

Figure 12-555 shows the details of submodules with LBIST.

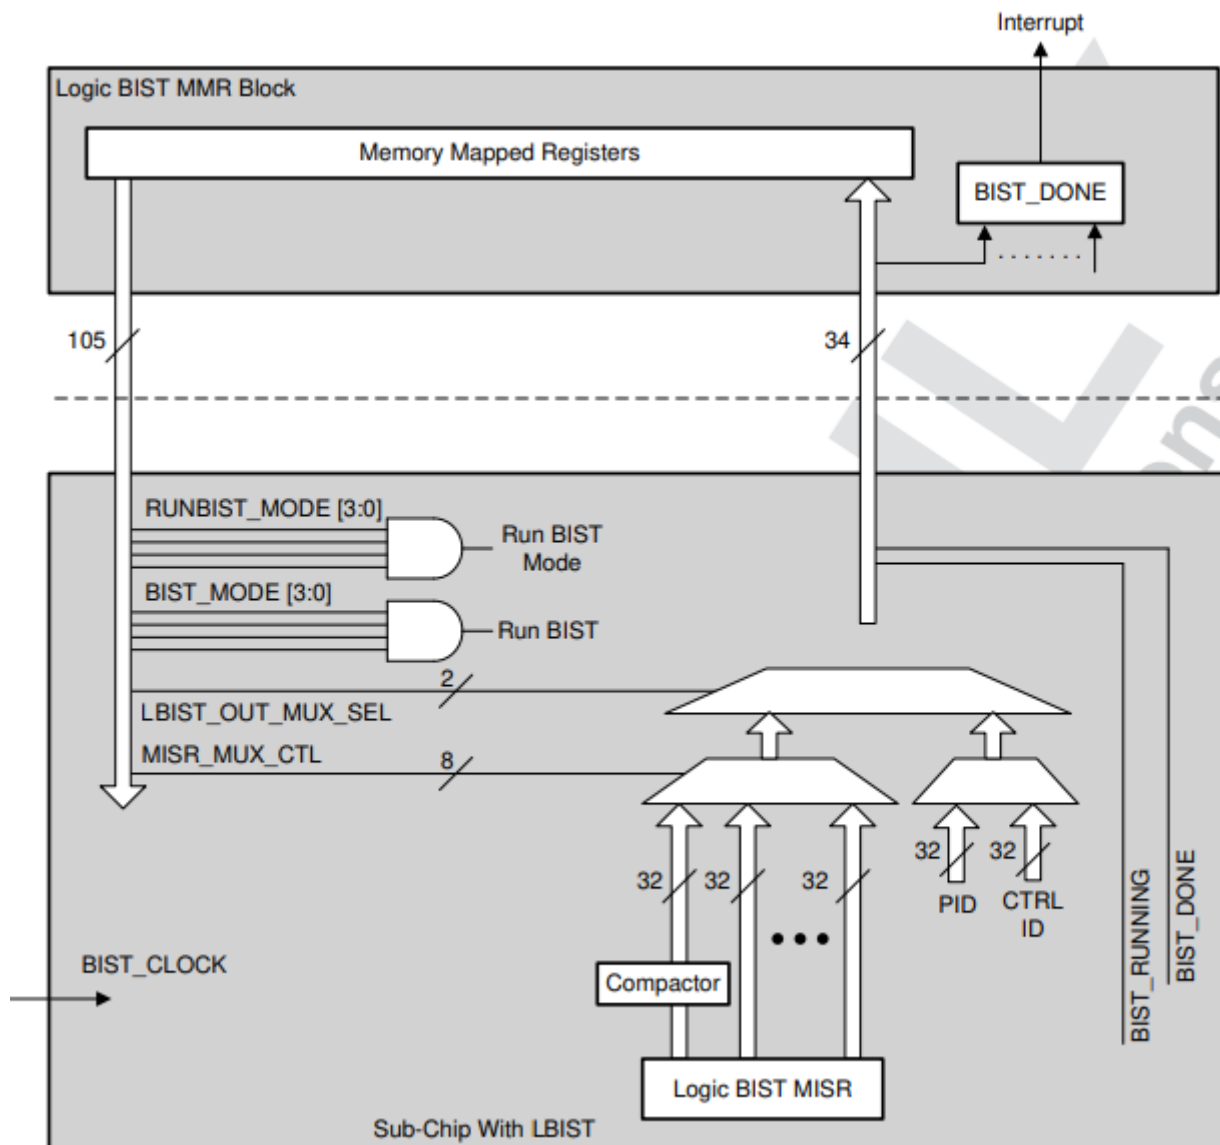

Figure 12-555. LBIST Submodules

12.10.4.2.1 Sub-Chip Isolation

During LBIST run-time execution, the block under test by LBIST must be isolated from the remainder of the design so as not to negatively impact the operation of other areas of the SoC. This is accomplished by logically isolating the block under test. LBIST requires that the block inputs be isolated for LBIST macro operation (i.e. the inputs need to be in a deterministic state to obtain coverage). The block outputs need to be isolated so that the LBIST operation does not corrupt other logic in the SoC dependent on the outputs of the block being LBISTed.

12.10.4.2.2 HW Power-On Self-Test (POST)

HW Power-On Self-Test (POST) tests are hardware tests performed every time the device is powered up, and are executed by hardware prior to ROM code being run. Software can check the HW POST MISR status in CTRL_MMR_WKUP registers. See *Device Configuration -> Module Integration -> LBIST* for details on modules which are tested by HW POST, and location of status results. Reference *Initialization Overview* for further details on device boot flow.

12.10.4.2.3 Software Initiated Self-Test

The self-test operation for each IP can only be performed during periods where the IP is idle, as such recommendation is to run these tests at during device startup. Run time logic BIST will corrupt the state of every flip-flop in the IP, but it will not corrupt the state of the RAMs. The software that runs the self-test is responsible for:

- Informing the system that the IP is temporarily offline
- Saving the state of any critical registers in the IP before starting the self-test
- Triggering the self-test
- Restoring critical register values and/or reinitializing the IP after the self-test has completed

12.10.4.2.4 Programming Sequence Software Initiated Self-Test

Execution of the LBIST tests requires preparation of the IPs under test by bringing them to a certain power and reset state before executing the test. It will be required that the application bring the cores/IPs to the proper state before executing the LBIST. Additionally, there is an "exit sequence" that is required to bring the cores/IPs back to the system control after the LBIST test is executed.

- For IP cores that are paired (ie A72, R5 etc), the entry sequence and exit sequence steps should be followed for both of cores, when either of the cores is the IP under test. Paired Cores are noted in *Device Configuration -> Module Integration -> LBIST*.
- For IP cores that have auxiliary cores defined, the entry sequence exist sequence steps should be followed for these auxiliary cores as well.

12.10.4.2.4.1 Entry Sequence

1. Software decides to execute Self-Test.
2. Software must take appropriate steps to bring the target IP off-line.
 - a. This may include disabling interfaces, disabling interrupts, and storing any state information for re-start after Self-Test execution, but the required actions are to be determined by software.
3. Software places target IP in PSC_SOFTWARE_RESET_DISABLE State.
4. Program Self-Test MMRs to enable to:
 - a. Switch clocks and override resets to the IP.

12.10.4.2.4.2 LBIST Execution

To initiate the Logic Self-Test Operation (LBIST), follow below sequence, using values available in *Device Configuration -> Module Integration -> LBIST*.

1. Program MMRs to configure LBIST, using values available in *Device Configuration -> Module Integration->LBIST*.
 - a. Set LBIST_CTRL register, divide_ratio, dc_def, values appropriate for block under test
 - b. Clear and set LBIST_CTRL[7] load_div.
 - c. Set LBIST_PATCOUNT scan_pc_def, reset_pc_def, set_pc_def and static_pc_def to desired value
 - d. Set LBIST_SEEDn, prpg_def value
2. Enable self-test isolation of the IP
 - a. Set LBIST_SPARE[0] to 1.
3. Program MMRs to run LBIST.
 - a. Set LBIST_CTRL[31] bist_reset to 1'b0
 - b. Set LBIST_CTRL[15:12] runbist_mode to 1'b1111
 - c. Set LBIST_CTRL[31] bist_reset to 1'b1
 - d. Set LBIST_CTRL[27:24] bist_run to 4'b1111
4. Optional check status by reading LBIST_STAT[15] bist_running.
5. Wait for LBIST_STAT[31] bist_done interrupt
6. Check the MISR signature and compare to expected value.
 - a. Set LBIST_STAT[9:8] lbist_out_mux_ctrl to 2'b1x
 - b. Set LBIST_STAT[7:0] lbist_misr_mux_ctrl to 32'd0 (selects compact MISR signature)
 - c. Read LBIST_STAT[31:0] to trigger updating of LBIST_MISR
 - d. Read LBIST_MISR[31:0]

12.10.4.2.4.3 Exit Sequence

There are two options after Self-Test operation has completed. If the IP module is not needed by the system, the software may leave the IP in the PSC disable state with no further action. If software desires to begin using the IP after Self-Test, the following operations must be performed: Software must restore system control of the block by:

1. Programming Self-Test MMRs to switch back clock and reset control to the system
 - a. Set LBIST_CTRL[27:24] bist_run to 0
 - b. Set LBIST_CTRL[31] bist_reset to 0
2. Power off the LBISTed IP
3. Remove the BIST isolation set in the Self-Test Entry Sequence, by setting LBIST_SPARE[0] to 1.
4. Power-on the LBISTed IP (software reset disable state)
5. Power-off and on the LBISTed IP

12.10.5 Programmable Built-In Self Test (PBIST)

12.10.5.1 PBIST Overview

The PBIST (Programmable Built-In Self Test) architecture provides a memory BIST engine for varying levels of coverage across many embedded memory instances.

Built-in Self-test (BIST) is a feature that allows self testing of the memory areas and logic circuitry in an Integrated Circuit (IC) without any external test equipment. In an embedded system, these tests are typically used during boot time or shutdown of the system to check the health of an SoC. PBIST is used to test the memory regions in the SoC and provides detection for permanent faults. The primary use case for PBIST is when it is invoked at start-up providing valuable information on any stuck-at bits in the memory.

There can be multiple instances of PBIST in the SoC, and each has a number of memory regions associated with it. For further details on PBIST instances see *Device Configuration -> Module Integration -> PBIST*.

PBIST is expected to be run at power-up, but can be run at anytime between power-up and power-down of the device with following conditions:

- PBIST must be run from a different core than is being tested. This is because the PBIST test will impact any S/W which is running on core, upon which the PBIST test is being run.
- When PBIST test is being run, the memories under test must be isolated from the rest of the system, as any memory accesses to the H/W module memory during the PBIST test could cause it to fail.

12.10.5.2 PBIST Functional Description

The PBIST architecture consists of a small CPU with an instruction set targeted specifically towards testing memories. This CPU includes both the control and the instruction registers necessary to execute the individual memory algorithms. Once an algorithm is loaded into the instruction registers, it can be run on multiple memories of different sizes or types by changing the control register. The following figure shows the basic block diagram for PBIST.

Figure 12-556. PBIST Block Diagram

12.10.5.3 PBIST Configuration Registers

PBIST uses internal configuration registers. All the configuration registers are memory mapped for access through the CPU or another programmable interface.

Details on the configuration registers are available in the register description spreadsheet.

12.10.5.4 PBIST Status Registers

Fail Status Data Registers

The FSRDL0[31:0], FSRDL1[31:0], FSRDU0[31:0] and FSRDU1[31:0] are read only internal registers that capture the failure data in case of failures.

- FSRDL0 corresponds to Port 0
- FSRDL1 corresponds to Port 1
- FSRDU0 and FSRDU1 registers are not used

Note

PBIST MISR is currently supported by H/W only for PBIST test of ROM.

Fail Status Address Register

Not used in TDA4VH device

Fail Status Count Register

Not used in TDA4VH device

Fail Status Fail Register

The FSRF0[31:0] and FSRF1[31:0] read only registers indicate whether a failure occurred or not.

- FSRF0 indicates Port 0 failures and FSRF1 indicates Port 1 failures.
- Register value is zero filled on read

12.10.5.5 Programming Sequence

12.10.5.5.1 PBIST Entry Sequence

1. Ensure IPs modules under test are isolated such that the rest of the device does not send transactions to the IPs under test
2. Put IPs modules under test in enable state and reset state

3. Assert reset for the IP modules if available
4. Assert PBIST_EN MMRs for the IPs if available
5. Put IP modules under test in enable state, but not reset state

12.10.5.5.2 PBIST Programming

12.10.5.5.2.1 PBIST Positive Test

To initiate the PBIST test of the H/W IP modules, follow the below programming sequence.

1. PBIST_PACT – Set PACT[1:0] to turn on internal PBIST clocks. While this bit is 0, any access to PBIST will not go through.
2. PBIST_CMS – PBIST Clock Mux Select Register, program to select between clock inputs.
 - Set PBIST_CMS[1:0] to 1 to enable internal PBIST controller clock. When this bit is 0, any access to PBIST will not go through.
3. PBIST_MARGIN_MODE - Safety enable and algorithm subset select register. This register is repurposed on the TDA4VH device.
 - PBIST_MARGIN_MODE [2:0] are safety enable bits, set all bits 1.
 - PBIST_MARGIN_MODE [3] selects algorithm subset #0 or #1
 - MARGIN_MODE[3] should be programmed to 0 for software based PBIST.
4. PBIST_L0 - Variable loop count register
 - Initialize to 0.
5. PBIST_ALGO - Algorithm mask register
 - The default value of this register is all 1s.
 - To meet the safety coverage requirements, TI will run a subset of all of the available algorithms.
 - Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> Positive Test Data to program this register.
6. PBIST_RINFOL - RAM info mask register (lower)
 - The default value of this register is all 1s.
 - To meet the safety coverage requirements, TI will run a subset of all of the available algorithms.
 - Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> Positive Test Data to program this register.
7. PBIST_RINFOU - Ram info mask register (upper)
 - See PBIST_RINFOL above.
8. PBIST_OVER - Override register
 - PBIST_OVERRIDE [3] is the PBIST_ALGO override bit.
 - To meet the safety coverage requirements, TI will run a subset of all available algorithms. To run this subset, set this bit to 0.
 - PBIST_OVERRIDE[0] is PBIST_RINFO override bit
 - To meet the safety coverage requirements, TI will run a subset of all available algorithms. To run this subset, set this bit to 0.
9. PBIST_SCR0 - Address scrambling register (lower)
 - The PBIST_SCR0 programmed value is not used on TDA4VH device.
10. PBIST_SCR4 - Address scrambling register (upper)
 - Upper bits for address scrambling programmability.
 - The PBIST_SCR4 programmed value is not used on TDA4VH device.
11. PBIST_DLR - Datalogger register
 - Put PBIST controller into the appropriate modes and start the test.
 - Use rom-based config mode: set bit [2], DLR0_ROM to 1 for PBIST test for ROM mode and set bit [4], DLR_CAM0 to 1 for config mode.
12. Wait for PBIST Module StatusWait for PBIST controller interrupt.
 - Upon completion of the test, an interrupt will be generated and the system interrupt handler will read the pbist_fail register to confirm pass/fail status of the test.
13. If the NUM_TEST_VECTORS entry, in *Device Configuration->Module Integration 0 -> PBIST Positive Test Data* is greater than one, run the test again, with the next set of PBIST_AGLO and PBIST_INFO values.

12.10.5.5.2.2 PBIST Negative Test

To initiate a negative PBIST test of the H/W IP modules, follow the below programming sequence.

1. PBIST_PACT – Set PACT[1:0] While this bit is 0, any access to PBIST will not go through.
 - Set to 1 to turn on internal PBIST clocks.
2. PBIST_MARGIN_MODE - Safety enable and algorithm subset select register. This register is repurposed on the TDA4VH device.
 - PBIST_MARGIN_MODE[2:0] are safety bits, set all bits 1.
 - PBIST_MARGIN_MODE [3] selects algorithm subset #0 or #1
 - ROM0 is for system-test and basic production test.
 - MARGIN_MODE[3] is not used in PBIST Negative test.
3. PBIST_L0 - Variable loop count register
 - Initialize to 0.
4. PBIST_DLR - Datalogger register
 - Put PBIST controller into the appropriate modes and start the test.
 - Set bit [4] for config mode by programming 0x10
5. Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> Negative Test Data, to program the following registers.
 - PBIST_RF0L, PBIST_RF0U
 - PBIST_RF1L, PBIST_RF1U
 - PBIST_RF2L, PBIST_RF2U
 - PBIST_RF3L, PBIST_RF3U
 - PBIST_RF4L, PBIST_RF4U
 - PBIST_D
 - PBIST_E
6. Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> Negative Test Data, to program below registers.
 - PBIST_DLR
 - PBIST_CA2
 - PBIST_CL0
 - PBIST_CA3
 - PBIST_IO0
 - PBIST_CL1
 - PBIST_I3
 - PBIST_I2
 - PBIST_CL2
 - PBIST_CA1
 - PBIST_CA0
 - PBIST_CL3
 - PBIST_I1
 - PBIST_RAMT
 - PBIST_CSR
 - PBIST_CMS
7. Set PBIST_STR to 0x1, to start.
8. Wait for PBIST controller interrupt. Upon completion of the test, an interrupt will be generated and the system interrupt handler will read the pbist_fail registers below to confirm pass/fail status of the test.
 - Read registers FSRF0,1 for port0,1 pbist fail.
 - Expected value for both: 0x1
 - Read registers FSRA0,1
 - Expected value for both: 0x0
 - Read registers FSRDL0,1
 - Expected value for both: 0xFFFFFFFF

12.10.5.5.2.3 PBIST Tests for ROM

1. PBIST_PACT – Set PACT[1:0] to 0x1, to turn on internal PBIST clocks. While this bit is 0, any access to PBIST will not go through.
2. PBIST_MARGIN_MODE - Safety enable and algorithm subset select register. This register is repurposed on the TDA4VH device.
 - PBIST_MARGIN_MODE[2:0] are safety enable bits, set all bits 1.
 - PBIST_MARGIN_MODE[3] select algorithm subset, set to 0
 - PBIST_MARGIN_MODE[3] is not used in the PBIST tests for ROM
3. PBIST_L0 - Variable loop count register
 - Initialize to 0.
4. PBIST_DLR - Datalogger register
 - Put PBIST controller into the appropriate modes and start the test.
 - Set bit [4] for config mode, bit [8] for MISR mode, and bit [9] for go-nogo test. Expected MISR value is programmed into PBIST_D and PBIST_E.
5. Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST -> ROM Test Data, to program below registers.
 - PBIST_RF0L, PBIST_RF0U
 - PBIST_RF1L, PBIST_RF1U
 - PBIST_RF2L, PBIST_RF2U
 - PBIST_RF3L, PBIST_RF3U
 - PBIST_RF4L, PBIST_RF4U
 - PBIST_RF5L, PBIST_RF5U
 - PBIST_RF6L, PBIST_RF6U
 - PBIST_RF7L, PBIST_RF7U
 - PBIST_RF8L, PBIST_RF8U
 - PBIST_RF9L, PBIST_RF9U
 - PBIST_RF10L, PBIST_RF10U
 - PBIST_D
 - PBIST_E
6. Use TI recommended values from Section 5. Device Configuration -> Module Integration -> PBIST-> ROM Test Data, to program below registers.
 - PBIST_CA2
 - PBIST_CL0
 - PBIST_CA3
 - PBIST_IO0
 - PBIST_CL1
 - PBIST_I3
 - PBIST_I2
 - PBIST_CL2
 - PBIST_CA1
 - PBIST_CA0
 - PBIST_CL3
 - PBIST_I1
 - PBIST_RAMT
 - PBIST_CSR
 - PBIST_CMS
7. Set PBIST_STR[0] to 0x1 to start
8. Wait for PBIST Module StatusWait for PBIST controller interrupt.
 - Upon completion of the test, an interrupt will be generated and the system interrupt handler will read the pbist fail register to confirm pass/fail status of the test.
 - Optionally the MISR value, in FSRDL0 can be read back and compared to the value entered into registers PBIST_D / PBIST_E in Step 5. If values are equal, this is indicative of a pass, if values are different, this indicates a fail. This MISR comparison has been done by H/W in the preceding sub bullet.
9. For modules in *Device Configuration -> Module Integration -> PBIST -> PBIST tests for ROM Data*, that have more than one vector, run the test again for each vector. The Exit Sequence Reset should be followed before running next test.

12.10.5.5.3 PBIST Exit Sequence Reset

PBIST soft reset (bring PBIST back to the state for next PBIST execution)

1. Set register, PBIST_PACT = 0x1
2. Set register, PBIST_L0 = 0
3. Set register, PBIST_PID = 0
4. Set register, PBIST_OVER = 0xF
5. Set register, PBIST_DLR = 0
6. Set register, PBIST_CMS = 0

Bring PBIST back to default state (state for when PBIST is not being used)

1. Set register PBIST_MARGIN_MODE = 0
2. Set register PBIST_RAMT = 0
3. Set register PBIST_PACT = 0

12.10.6 ECC Aggregator

This section describes the common ECC aggregator functionality.

12.10.6.1 ECC Aggregator Overview

To increase functional and system reliability the memories (for example, FIFOs, queues, SRAMs and others) in many device modules and subsystems are protected by error correcting code (ECC). This is accomplished through an ECC aggregator and ECC wrapper. The ECC aggregator is connected to these memories (hereinafter ECC RAMs) and involved in the ECC process. Each memory is surrounded by an ECC wrapper which performs the ECC detection and correction. The wrapper communicates via serial interface with the aggregator which has memory mapped configuration interface.

The ECC aggregator is also connected to interconnect ECC components that protect the command, address and data buses of the system interconnect. ECC is calculated for the data bus and parity and redundancy for the command and address buses. Each interconnect ECC component has the same serial interface for communication with the aggregator as the ECC wrapper. An ECC aggregator may be connected to both endpoints - the ECC wrapper and interconnect ECC component.

The ECC aggregator, ECC wrapper and interconnect ECC component are considered as single entity and are hereinafter referred to as ECC aggregator unless otherwise explicitly specified.

Table 12-515 lists the device modules and subsystems which have ECC aggregator.

12.10.6.1.1 ECC Aggregator Features

The ECC aggregator has the following features:

- Reduces memory software errors via single error correction (SEC) and double error detection (DED)
- Provides a mechanism to control and monitor the ECC protected memories in a module or subsystem
- SEC and DED over the system interconnect data bus and parity and redundancy for the system interconnect command and address buses
- Generates an interrupt for correctable error
- Generates an interrupt for non-correctable error
- Supports inject only mode for diagnostic purposes
- Supports software readable status for single and double-bit ECC errors and associated information such as row address where error has occurred and data bits that have been flipped
- Supports up to 256 ECC endpoints. An ECC endpoint can be either ECC RAM or interconnect ECC component.
- Detects single bit error via parity checking on:
 - Memory mapped configuration interface FIFO
 - Serial interface FIFO
 - Serial interface transaction
- Single bit error detection via parity checking results in a non-correctable error interrupt
- Supports timeout mechanism on transactions over the ECC serial interface. Timeout occurrence results in a non-correctable error interrupt.
- Certain control bits have redundancy and if a bit flips an interrupt is generated

12.10.6.1.2 ECC Aggregator Ports

12.10.6.2 ECC Aggregator Functional Description

This section describes the architecture and functional details of the ECC aggregator.

Note

See Appendix Spreadsheet for ECC Aggregators Interconnect details.

12.10.6.2.1 ECC Aggregator Block Diagram

Figure 12-557 shows the ECC aggregator block diagram.

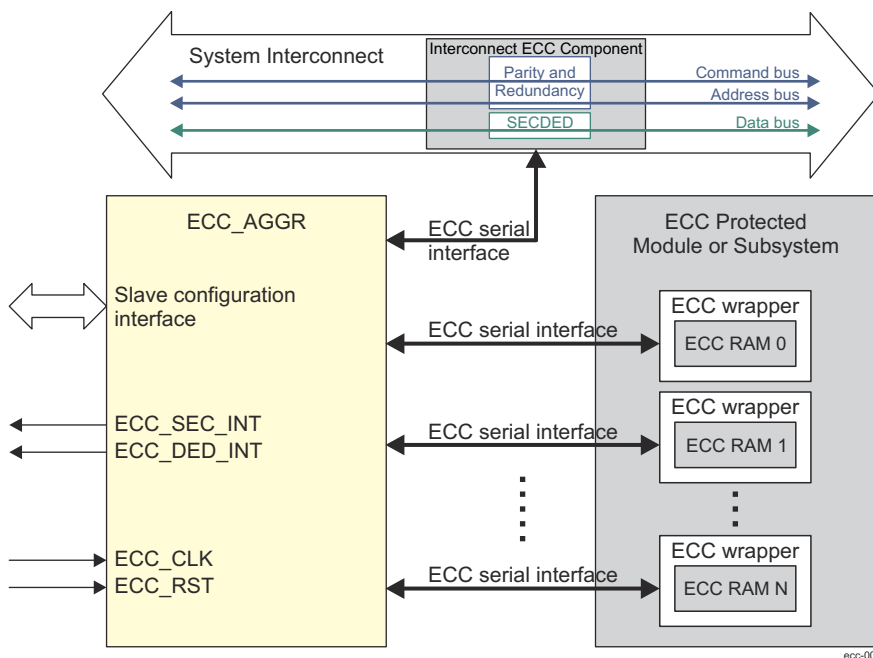

Figure 12-557. ECC Aggregator Block Diagram

The ECC aggregator is connected to one or more ECC endpoints each of which has assigned a unique ID used when the endpoint is accessed for status information or configuration. The ECC aggregator provides software access to all ECC related registers through its memory mapped slave configuration interface while the serial interface is used to communicate with the ECC endpoints. Upon detection of single or double-bit error the corresponding interrupt line is asserted.

12.10.6.2.2 ECC Aggregator Register Groups

The ECC aggregator has ECC control, status and interrupt registers for each ECC endpoint in a module or subsystem. These registers are memory mapped and occupy 1 KB address space although part of it may contain reserved locations. The registers are split in the following types:

- **Global registers.** They are common to all ECC endpoints associated with the ECC aggregator and include the ECC_VECTOR and ECC_REV registers. Each ECC endpoint has assigned a unique ID. When this ID is written to the ECC_VECTOR[10-0] ECC_VECTOR field the corresponding endpoint is selected either for control or for status reading.
- **ECC control and status registers.** These registers are specific to each ECC endpoint and reside in the range from address offset 0x10 to 0x28, if the endpoint is ECC RAM or from 0x10 to 0x24, if the endpoint is interconnect ECC component. They are memory mapped but are accessed through the ECC serial interface. They are also selected by the ECC endpoint ID written to the ECC_VECTOR[10-0] ECC_VECTOR field. Because of latency on the serial interface the ECC control and status registers are read by performing special sequence as described in Section 12.10.6.2.3. These registers have also different functionality for both types of endpoints - ECC RAM and interconnect ECC component.
- **Interrupt registers.** They include interrupt status, interrupt enable, interrupt disable, and EOI registers. For more information, see *Interrupts*.

12.10.6.2.3 Read Access to the ECC Control and Status Registers

Read accesses to the ECC control and status registers for each ECC endpoint represent read operations over the ECC serial interface and are triggered by performing the following sequence:

1. Software writes the following in the ECC_VECTOR register:
 - The ECC endpoint ID in the ECC_VECTOR[10-0] ECC_VECTOR field to select particular ECC endpoint.
 - The register read address in the ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field to select which register has to be read through the ECC serial interface.
 - A value of 0x1 in the ECC_VECTOR[15] RD_SVBUS bit to trigger read operation through the ECC serial interface.
2. Software polls the ECC_VECTOR[24] RD_SVBUS_DONE bit to check if it is 0x1. This indicates that the read operation on the ECC serial interface has completed.
3. Software reads the data from the register previously selected by the ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field.

The following is an example for serial read operation:

1. Write 0x0010 8005 to the ECC_VECTOR register. This sends read request to the ECC_WRAP_REV or ECC_CBASS_REV register (address = 0x10) associated with ECC endpoint with ID = 5.
2. Poll the ECC_VECTOR[24] RD_SVBUS_DONE bit until value of 0x1 is read.
3. Read the ECC_WRAP_REV or ECC_CBASS_REV register to get its value.

12.10.6.2.4 Serial Write Operation

Write operations over the ECC serial interface are performed as follows:

1. Software specifies the ECC endpoint ID in the ECC_VECTOR[10-0] ECC_VECTOR field. The ECC_VECTOR[23-16] RD_SVBUS_ADDRESS field is a don't care but the ECC_VECTOR[15] RD_SVBUS bit must be set to 0x0.
2. Software performs regular write operation to the desired address. If the ECC endpoint ID has already been specified, step 1 can be skipped. Unlike serial read operations it is not necessary to always specify the endpoint ID before performing serial write operation.

The following is an example for serial write operation:

1. Write 0x0000 0008 to the ECC_VECTOR register.
2. Write 0x0000 000F to the ECC_CTRL register. This sends write request with data 0x0000 000F to the ECC_CTRL register associated with ECC RAM with ID = 8.

12.10.6.2.5 Interrupts

The ECC aggregator generates the following interrupts:

- Correctable interrupt (ECC_SEC_INT) where hardware can correct the error but notifies the system in case of SEC.
- Non-correctable interrupt (ECC_DED_INT) where hardware cannot correct the error in cases of DED, parity check, redundancy check or timeout occurrence.

The following is the sequence for servicing interrupts:

- Software enables the interrupts for an ECC endpoint by writing 0x1 to the corresponding bit of the following interrupt enable registers:
 - ECC_SEC_ENABLE_SET_REG0 through ECC_SEC_ENABLE_SET_REG7 for the correctable interrupt
 - ECC_DED_ENABLE_SET_REG0 through ECC_DED_ENABLE_SET_REG7 for the non-correctable interrupt
- On receiving an interrupt, software checks which ECC endpoint has caused the error by reading the following interrupt status registers:
 - ECC_SEC_STATUS_REG0 through ECC_SEC_STATUS_REG7 for the correctable interrupt
 - ECC_DED_STATUS_REG0 through ECC_DED_STATUS_REG7 for the non-correctable interrupt
- Software performs serial read operations as described in [Section 12.10.6.2.3](#) to read the following status registers that contain details about the error:
 - If the endpoint is ECC RAM:

- ECC_ERR_STAT1
- ECC_ERR_STAT2
- ECC_ERR_STAT3
- If the endpoint is interconnect ECC component:
 - ECC_CBASS_ERR_STAT1
 - ECC_CBASS_ERR_STAT2
- After the interrupt has been serviced, depending on the error type, software should clear the corresponding status bits in the ECC_ERR_STAT1 and ECC_ERR_STAT3 registers or in the ECC_CBASS_ERR_STAT1 register. Software has to poll these registers to guarantee that status bits are cleared as there is no other indication for write completion over the ECC serial interface.
The value of the *_PEND_CLR fields in the ECC_CBASS_ERR_STAT1 register must be read and then written back to decrement the count of each field back to 0x0. A further error capture into the ECC_CBASS_ERR_STAT1 register does not occur unless all its fields are 0x0. The decrement value should not be larger than the read value. If a field in the ECC_CBASS_ERR_STAT1 register should not be modified, write a value of 0x0 to that field.
- Software writes 0x1 to the corresponding end of interrupt register to clear the interrupt:
 - ECC_SEC_EOI_REG for the correctable interrupt
 - ECC_DED_EOI_REG for the non-correctable interrupt

12.10.6.2.6 Inject Only Mode

There are modules that already perform the ECC generation and checking as part of their data path. In this case, the ECC wrapper may be configured in inject only mode, if needed. In this mode the ECC wrapper does not perform ECC detection and correction. The inject only mode allows users to inject single or double-bit errors so that the module logic can be tested for diagnostic purposes.

Note

There is no software control to enable inject only mode. It is configured via tie-off value. Inject only and ECC modes are mutually exclusive.

The interconnect ECC component also supports error injection mode. There is error injection logic for testing of the error checking logic (checkers). The injection logic can be configured to inject either single or double bit error and what data pattern to be used for injection (ECC_CBASS_CTRL[11-8] ECC_PATTERN). The ECC_CBASS_ERR_CTRL1 and ECC_CBASS_ERR_CTRL2 registers should be written first to setup the injection. Then, either the ECC_CBASS_CTRL[3] FORCE_SE or the ECC_CBASS_CTRL[4] FORCE_DE bit must be set to 0x1 to start the injection. Both bits must not be set at the same time. If the injection should continue in incrementing mode, then the ECC_CBASS_CTRL[5] FORCE_N_BIT bit should be set to 0x1. Once the FORCE_N_BIT is set, then each successive injection can simply write the ECC_CBASS_CTRL register to set the FORCE_SE or FORCE_DE again. Reading 0x0 from either the FORCE_SE or the FORCE_DE bit indicates that the injection has completed, as these bits automatically clear when the checker indicates that it has performed the injection. The time for an injection to complete is not guaranteed, so some delay is needed between successive injections.

12.10.6.2.7 ECC Error Injection Sequence

The ECC aggregator is a critical component for enhancing system reliability by protecting memories in various device modules and subsystems. The ECC Aggregator is connected to these memory and interconnect components which have the ECC, to provide access to control and monitor the ECC protected memories in a module or subsystem.

The ECC aggregator supports error injection to aid in diagnostic purposes and to evaluate robustness. The Error Injection feature supported by the ECC aggregator allows users to deliberately introduce errors into their system to test the resilience and effectiveness of error correction mechanisms. This feature helps in evaluating the robustness of the ECC aggregator by simulating real-world error scenarios, enabling users to identify potential vulnerabilities and improve their error handling strategies.

This feature includes configurable parameters such as ECC aggregator type, subtype, error type, and injection location, allowing users to customize their testing scenarios based on their specific requirements.

12.10.6.2.7.1 Types of Error Injection

ECC is a mechanism for providing increased protection against soft errors by allowing single bit errors to be detected and corrected and double bit errors to be detected. The ECC Control Register can be used to inject single bit or double bit errors. For more information on this register, refer to [Section 12.10.6.2.2](#). These errors are then reported through the Error Signal Module (ESM).

- **Single Error Correction (SEC):** In the event of single bit errors, the ECC aggregator has the ability to both detect and correct these errors, ensuring the integrity of the data. Single bit error injection is supported for all endpoints and checkers. Single bit error correction is not supported for parity and redundancy type of checkers.
- **Double Error Detection (DED):** For double bit errors, the ECC aggregator can detect these errors. However, it does not have the capability to correct them. Instead, it signals the presence of these errors to the Central Processing Unit (CPU) via ESM interrupts. This is supported for all RAM wrapper types and interconnect EDC checker type of endpoints. Parity and Redundant checker types do not support double bit ECC error injection.

The ECC aggregator plays a crucial role in maintaining data accuracy by correcting single bit errors and detecting double bit errors, although it cannot correct the latter. This process helps in enhancing the overall system reliability. Each ECC aggregator connects to two kinds of ESM events – Correctable error events (for SEC events) and Un-correctable error events (for DED events and parity and redundancy checker types). ESM is used for notification of events from endpoints which are not Inject-Only. Inject-Only endpoints notify errors through IP-specific mechanisms. Sometimes a separate ESM event (not via ECC aggregator) is available. Please refer to the individual IP sections for more details on the ESM events generated.

The ECC aggregator provides support for injecting single and double bit errors. In the case of RAM wrapper type endpoints, errors can be injected to a specific row or can be requested to be injected on the next row access (`n_row`). Errors can be requested to be injected once or on repeated reads. For Interconnect endpoint types, single and double bit errors (depending on the checker type) can be injected.

12.10.6.2.7.1.1 ECC Wrapper Type Endpoints

Each memory is surrounded by an ECC wrapper which performs the ECC detection and correction. The wrapper communicates via serial interface with the aggregator which has memory a mapped configuration interface. For RAM wrapper types, after injecting the error, the RAM location where the error was injected needs to be accessed in order to trigger the error interrupt. If the “force_n_row” option is selected during error injection, then any RAM access will trigger the interrupt and the specific row is not needed.

12.10.6.2.7.1.2 EDC Interconnect Type Endpoints

The ECC aggregator is also connected to interconnect ECC components that protect the command, address and data buses of the system interconnect. ECC is calculated for the data bus and parity and redundancy for the command and address buses. For the interconnect types, the type of checker must be verified to determine if they are parity or redundant types.

12.10.6.2.7.1.3 Inject Only ECC Endpoints

Some modules may already do the generation of and checking of ECC as part of their data path. In this case, the ECC wrapper does not have to perform ECC detection and correction and is configured in inject only mode. The wrapper will not add extra bits to the ram, generate, nor check ECC. It will, however, allow the user to inject single or double-bit errors so that the IP's logic can be tested for diagnostic purposes. Detection and correction occurs in the IP itself. In some cases, the error may also be routed to ESM, but not to the same ESM event as the ECC aggregator. For more information on these memories, refer to [Section 12.10.6.2.6](#).

12.10.6.2.7.1.4 Full Functionality Error Capture ECC Endpoints

These ECC aggregators possess the ability to perform Error Injection alongside Error Capture. The wrapper can be utilized to introduce either single or double-bit errors, while also having the capability to detect and correct errors.

For more information regarding the ECC endpoint types, refer to the Appendix spreadsheet.

12.10.6.2.7.2 Types of ECC Checkers

There are various checkers for bus signals, MMRs, or internal registers in the interconnect.

12.10.6.2.7.2.1 Parity Type Checkers

The most common checker type is parity. The parity type refers to checkers where a parity bit is added to cover the entire signal. The parity bit is the \sim^{\wedge} signal, where the signal width can be any number of bits.

12.10.6.2.7.2.2 Redundant Type Checkers

The redundant type refers to checkers for critical signals (like request). The redundant signal is the opposite of the signal it is protecting.

12.10.6.2.7.2.3 Error Detect and Correct (EDC) Type Checkers

The EDC type refers to SECDED error-correcting code that can correct single bit error, and detect a two bit error. For more information regarding the ECC checker type for each aggregator, refer to the Appendix spreadsheet.

12.10.6.2.7.3 Recommendations for Testing Error Injection

The following are the general recommendations on when the error injection on ECC aggregators must be performed:

- The ECC error injection and monitoring of the error response should be run at 'startup' where possible.
- An alternative recommended approach is to run ECC error injection at 'shutdown'.

When running of ECC error injection during 'runtime', the system integrator must be aware of the below:

For interconnect endpoints:

- The ECC SEC error injection runs during idle cycles, so can be run during 'runtime' for checkers of all types.
 - Parity and redundant bit error injections are non-destructive and can be done at runtime.
- The ECC DED error injection runs during idle cycles, so can be run during 'runtime'.
 - Only single bit error injections are to be done on parity/redundant checker types. This is because these protect odd number of injections. A 2 bit injection on parity will not cause a failure.

For RAM memories:

- ECC self-test for SEC on RAM memories, can be run at runtime:
 - The ECC self-test for SEC injects a single-bit error that is corrected in-line.
- ECC DED error injection during 'runtime' for RAM memories, should only be done for memories with direct read access
 - Two examples of direct read access memories are MSMC SRAM and MCU SRAM
 - Double-bit error injection on all other embedded SRAMS could possibly result in the downstream IP reading bad data if run during 'runtime'
- CC error injection on inject-only memories, should be run at 'startup', they are not recommended to be run during 'runtime'. For more information on these memories, refer to [Section 12.10.6.2.6](#).

12.10.6.2.7.4 Error Injection Programming Sequence

12.10.6.2.7.4.1 ESM Initialization

The ESM instance must be initialized with the following sequence. This initialization will allow the application to specify for each event whether the interrupt is enabled or disabled, the priority of the event, and whether the nErrorPin assertion is enabled or disabled for the event. This needs to be done only once. All the required ESM events can be initialized at the same time.

For more information on the ESM, refer to [Section 12.10.2](#).

To initialize the ESM module for a specified instance:

1. Clear all raw status and enable bits by setting ESM_SFT_RST Register bits [3:0] to 0Fh, to reset the ESM
2. Write 0x1 to the appropriate bits in the ESM_ERR_STS register. This step will clear the configuration interrupt raw status

- Write 0x1 to the appropriate bits in the ESM_ERR_EN_SET register, to enable the configuration error interrupt as described in [Section 12.10.2.3.1.1](#).
- Write 0x1 to the appropriate bits in the error group j of the ESM_STS_j register. This step will clear the level interrupt raw status.
- Write 0x1 to the appropriate bits in the error group j of the ESM_INTR_EN_SET_j register, to enable the level error interrupt.
- Write 0x1 to the appropriate bits in the error group j of the ESM_INT_PRIO_j register, to indicate which interrupt the corresponding event influences (if enabled) for event group j.
- If required, write 0x1 to the appropriate bits in the error group j of the ESM_PIN_EN_SET_j register, to set error output corresponding to the desired events.
- Enable the global interrupts by setting ESM_EN Register bits [3:0] to 0Fh

12.10.6.2.7.4.2 ECC Initialization

- Setting the timeout bit is required to enable notification for ECC serial interface timeout errors. The parity bit must be set to enable notification for parity errors. To enable the timeout (bit 1) and parity (bit 0) bits, write 0x1 to the ECC_AGGR_ENABLE_SET register.
- Write 0x1 to the ECC_SEC_ENABLE_SET_REGx (to enable correctable SEC error interrupts) and ECC_DED_ENABLE_SET_REGx (to enable uncorrectable DED error interrupts) registers for required endpoints.

The following register configurations are per endpoint and done through the SVBUS programming interface. Refer to [Section 12.10.6.2.4](#) for more information.

- Write 0x1 to the ECC_CHECK field of the ECC_CBASS_CTRL register to enable ECC check for interconnect endpoints.
- Write 0x1 to the ENABLE_RMW, ECC_CHECK and ECC_ENABLE bit fields of the ECC_CTRL register to enable ECC check for wrapper type endpoints.

12.10.6.2.7.4.3 Error Injection

For ECC Wrapper Type Endpoints:

- Write to the ECC_ERR_CTRL1 Register to set the row address where FORCE_SEC or FORCE_DED needs to be applied. This is ignored if FORCE_N_ROW is set.
- Configure the ECC_RAM_CTRL bits[6:3] register based on the type of error injection.
- Perform a read back of the ECC_RAM_CTRL register to confirm error injection. The read value may not be same as what is written as some fields in the register are not writable or can self-clear.
- For RAM wrapper types, after injecting the error, the RAM needs to be accessed in the row where the error was injected (if FORCE_N_ROW is used, any row can be accessed) in order to trigger the error interrupt.
- For Inject-only Wrapper endpoints, only error injection is possible via the ECC aggregator, the detection and correction is be done by the IP itself.

Field	Name	Type	Reset	Description
0	ecc_enable	r/w	1	Enable ECC generation. Reset to 1 with inject only configuration, but any write to this register byte clears this bit to 0. Resets to 1 in all other configurations.
1	ecc_check	r/w	1/0	Enable ECC check. ECC is completely bypassed if both ecc_enable and ecc_check are '0'. Reset to 0 with inject only configuration, and not writable. Reset to 1 in all other configurations.
2	enable_rmw	r/w	1/0	Enable read-modify-write on partial word writes. If disabled ecc detection and correction will no longer work and if re-enabled the ram contents must all be rewritten to correct ecc codes. Reset to 0 with inject only configuration, and not writable. Reset to 1 in all other configurations.

Field	Name	Type	Reset	Description
3	force_sec	r/w	0	Force single-bit error. Cleared the cycle following the error if error_once is asserted. for write through mode this applies to writes as well as reads.
4	force_ded	r/w	0	Force double-bit error. Cleared the cycle following the error if error_once is asserted. for write through mode this applies to writes as well as reads.
5	force_n_row	r/w	0	Force single/double-bit error on the next RAM access. for write through mode this applies to writes as well as reads.
6	error_once	r/w	0	If this bit is set, the force_sec/force_ded will inject an error to the specified row only once. The force_sec bit will be cleared the cycle after the error is generated. For double-bit errors, the force_ded bit will be cleared the cycle following the double-bit error. In either case force_n_row will be cleared as well. Any subsequent reads will not force an error.
7	check_parity	r/w	1	Enables parity checking on internal data
8	Check svbus timeout	r/w	1	Enable svbus timeout mechanism
9-31	Reserved			

For ECC Interconnect Type Endpoints:

1. Clear any pending error injection by writing 0x0 to the bit fields of the ECC_CBASS_CTRL register
2. Configure the ECC_CBASS_ERR_CTRL1 and ECC_CBASS_ERR_CTRL2 registers based on the error group and type of error injection.
3. Write to the ECC_CBASS_CTRL register to inject the error.
4. For interconnect types, the error injection happens on idle cycles, so no additional access of the memory is required.

12.10.6.2.7.4.4 Error Handling

1. When an error event occurs, the user can query and collect the information about the endpoint and offset information for the location relative to the start of the associated RAM.
2. To clear the ECC error event, clear the pending status of the ECC error events by configuring the ECC_RAM_ERR_STAT1 (for Wrapper type endpoints) and SDL_EDC_CTL_ERR_STATUS1(for Interconnect type endpoints) register.
3. The ECC_SEC_EOI_REG register is used to re-trigger the pulse interrupt signal to ensure that any nested interrupt events are serviced. The software interrupt handler must write to the ECC_SEC_EOI_REG register at the end of the current interrupt processing routine, so that new events can re-trigger the pulse interrupt signal again. For level interrupt signals the ECC_SEC_EOI_REG register is not functional and must not be used.
4. Clear the ESM error interrupt using the ESM registers.

12.10.6.3 ECC Aggregator Registers

Table 12-518 lists the memory-mapped registers for an ECC Aggregator (ECC_AGGR).

Table 12-523. ECC_ERR_STAT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	ECC_BIT1	R	0h	Indicates the bit position in the RAM data that is in error. For example, a value of 1h indicates that bit [1] in the RAM data is in error. This is valid only for single-bit errors. Note NOTE: Not used in inject only mode. Always read as 0h.
15	CLR_CTRL_REG_ERR	R/W1C	0h	Clear the CTR_REG_ERR bit. A write of 1h clears this bit and the CTR_REG_ERR bit, but if the redundancy protected bits in the ECC_CTRL register have not been written to a known state to correct the error, this flag is immediately set again.
14-13	CLR_PARITY_ERR	R/W	0h	A write of a non-zero value to this field decrements the CLR_ECC_DED and ECC_DED fields by that value. If the value written is less than the current one, the non-correctable interrupt (ECC_DED_INT) stays asserted. If the value to decrement is more than the current value, the result is 0. 0h - No parity errors have occurred 1h - 1 parity error has occurred 2h - 2 parity errors have occurred 3h - 3 or more parity errors have occurred
12	CLR_ECC_OTHER	R/W1C	0h	Clear other error status. 1h indicates a successive single-bit error. Writing 1h clears the status bit.

Table 12-523. ECC_ERR_STAT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11-10	CLR_ECC_DED	R/W	0h	<p>A write of a non-zero value to this field decrements it and the ECC_DED field by that value. If the value written is less than the current one, the non-correctable interrupt (ECC_DED_INT) stays asserted. If the value to decrement is more than the current value, the result is 0.</p> <p>0h - No double-bit errors have occurred 1h - 1 double-bit has error occurred 2h - 2 double-bit have errors occurred 3h - 3 or more double-bit errors have occurred</p> <hr/> <p style="text-align: center;">Note</p> <p>NOTE: Not used in inject only mode. Always read as 0h.</p> <hr/>
9-8	CLR_ECC_SEC	R/W	0h	<p>A write of a non-zero value to this field decrements it and the ECC_SEC field by that value. If the value written is less than the current one, the correctable interrupt (ECC_SEC_INT) stays asserted. If the value to decrement is more than the current value, the result is 0.</p> <p>0h - No single-bit errors have occurred 1h - 1 single-bit has occurred 2h - 2 single-bit have occurred 3h - 3 or more single-bit have occurred</p> <hr/> <p style="text-align: center;">Note</p> <p>NOTE: Not used in inject only mode. Always read as 0h.</p> <hr/>
7	CTR_REG_ERR	R/W1S	0h	<p>Indicates that a redundancy protected bit in the ECC_CTRL register has been flipped. This means that the redundancy logic have detected a state where not all values are the same and has defaulted to the reset state. Software needs to re-write these registers to a known state. A write of 1h sets this bit.</p> <p>0h - Bit not flipped 1h - Bit flipped</p>
6-5	PARITY_ERR	R/W1S	0h	<p>2-bit saturating counter for the number of parity errors that have occurred since last cleared. This is also a status set register and a non-zero value sets the level interrupt. Software can also write a value to the CLR_PARITY_ERR field to decrement this counter.</p> <p>0h - No parity errors have occurred 1h - 1 parity error has occurred 2h - 2 parity errors have occurred 3h - 3 or more parity errors have occurred</p>
4	ECC_OTHER	R/W1S	0h	<p>1h - Indicates that successive single-bit errors have occurred while a write-back is still pending. Software can also write 1h to set the pending status and write 1h to the corresponding clear bit to clear the status.</p> <hr/> <p style="text-align: center;">Note</p> <p>NOTE: Not used in inject only mode. Always read as 0h.</p> <hr/>

Table 12-523. ECC_ERR_STAT1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	ECC_DED	R/W	0h	<p>2-bit saturating counter for the number of double-bit errors that have occurred since last cleared. This is also a status set register and a non-zero value sets the level interrupt. Software can also write a value to the CLR_ECC_SEC field to decrement this counter.</p> <p>0h - No double-bit errors have occurred 1h - 1 double-bit has error occurred 2h - 2 double-bit have errors occurred 3h - 3 or more double-bit errors have occurred</p> <hr/> <p style="text-align: center;">Note</p> <p>NOTE: Not used in inject only mode. Always read as 0h.</p> <hr/>
1-0	ECC_SEC	R/W	0h	<p>2-bit saturating counter for the number of single-bit errors that have occurred since last cleared. This is also a status set register and a non-zero value sets the level interrupt. Software can also write a value to the CLR_ECC_SEC field to decrement this counter.</p> <p>0h - No single-bit errors have occurred 1h - 1 single-bit has occurred 2h - 2 single-bit have occurred 3h - 3 or more single-bit have occurred</p> <hr/> <p style="text-align: center;">Note</p> <p>NOTE: Not used in inject only mode. Always read as 0h.</p> <hr/>

12.10.6.3.6 ECC_ERR_STAT2 Register (Offset = 24h) [reset = X]

13.6 Debug Memory Map.....	2241
13.7 Application Support.....	2242

13.1 Introduction to SoC Debug Framework

The SoC debug capabilities are centered around the Debug Subsystem (DEBUGSS). The DEBUGSS works in conjunction with the debug capabilities integrated in the various processing units (such as CPUs and hardware accelerators) to provide a comprehensive hardware platform for a rich debug and development experience.

The SoC debug framework provides support for the following features:

- Top-level debug support
 - IEEE 1149.1 (JTAG + boundary scan) and IEEE 1149.6 (boundary scan extensions)
 - Centralized debug access gateway (DEBUGSS) that provides support for debug access and trace in multiple CPU core subsystems
 - JTAG can access all debug and system resources
 - Other system masters can also access all debug resources (self-hosted debug)
 - Direct debug master to system memory that bypasses any CPU datapath used for debug
 - Global execution and system level debug triggering (simultaneous run/halt)
 - Arm CoreSight cross trigger architecture
 - Channel Interface (CI)
 - Cross Trigger Interface (CTI), Cross Trigger Matrix (CTM)
 - Arm/TI trigger merge at the DEBUGSS level
 - Trace architecture that includes various trace sources, sinks and supporting modules
 - Discrete event trace
 - Counter, Timer, and System Event Trace (CTSET) module
 - CBA4 compliant bus probing
 - CPTracer2 (CPT2) aggregators and probes
 - Three levels of bus probing (SoC, MCU domain, MSMC)
 - Software message trace
 - CoreSight STM-500 module
 - Universal debug time distribution for correlating various trace sources
 - Wide Timestamp Interface (WTI)
 - Trace distribution via Arm Advanced Trace Bus (ATB) network
 - Trace storing into dedicated on-chip Trace Buffer Router (TBR) modules
 - Trace streaming off-chip
 - Export via CoreSight Trace Port Interface Unit (TPIU)
 - Export via high-speed functional interfaces (Ethernet, PCIe)
 - Requires software assistance
 - Advanced debug power, clock and reset management
 - Ownership aware peripheral debug events (suspend mapping)
 - Authenticating a debug connection on device configured for high-security (HS) operations
- Compute Cluster debug support
 - A72SS
 - Invasive debug (halt mode, monitor mode)
 - Non-invasive debug (processor trace, performance monitoring)
 - CoreSight Embedded Trace Macrocell (ETM)
 - Cross triggering via CoreSight CTI and CTM
 - C71SS
 - Core debug
 - Advanced Event Triggering (AET)
 - Real-time trace
 - Physical address watchpoints
 - Event analysis
 - MSMC
 - Bus probing
 - Discrete event trace
 - Cross triggering via CoreSight CTI and CTM
- R5FSS debug support

- Invasive debug (halt mode, monitor mode)
- Non-invasive debug (processor trace, performance monitoring)
- CoreSight ETM-R5
- Cross triggering via CoreSight CTI and CTM
- DMPAC debug support
 - HWA basic debug (system visibility, run control)
 - Cross triggering
 - Discrete event trace
- VPAC debug support
 - HWA basic debug (system visibility, run control)
 - Cross triggering
 - Discrete event trace

Figure 13-1 shows a high-level overview of the SoC debug framework.

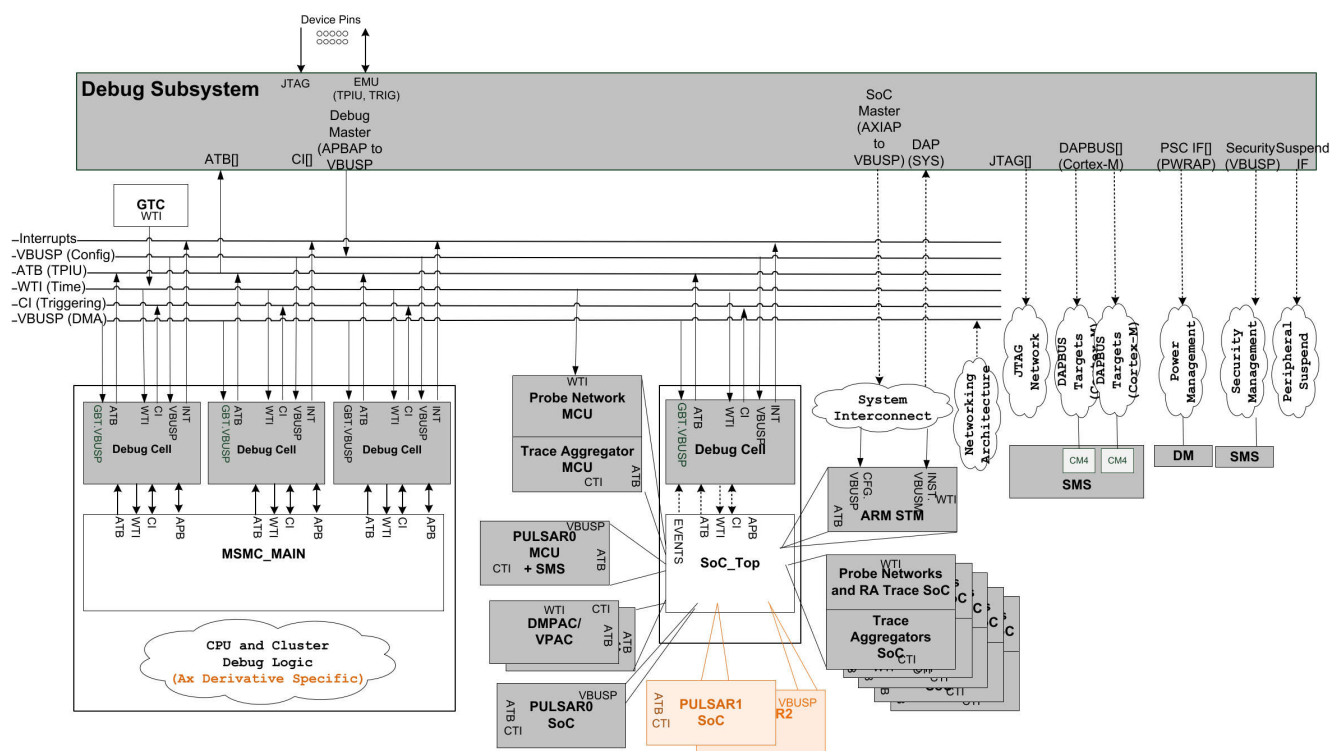

Figure 13-1. SoC Debug Framework Overview

13.2 Debug Interfaces

13.2.1 JTAG Interface

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals: TRSTn, TCK, TMS, TDI, and TDO
- Two EMU[1:0] TI extensions

Table 13-1 describes the JTAG interface signals.

Table 13-1. JTAG Interface Signals

Signal Name	I/O Type ⁽¹⁾	Description
TRSTn	I	<i>Test Reset</i> . Initializes and disables the test interface.
TCK	I	<i>Test Clock</i> . Controls the timing of the test interface independently from any system clocks. TCK is pulsed by the equipment controlling the test and not by the tested device.
TMS	I	<i>Test Mode Select</i> . Controls the transitions of the test interface state machine.
TDI	I	<i>Test Data Input</i> . Supplies the data to the JTAG registers.
TDO	O/Z	<i>Test Data Output</i> . Used to serially output the data from the JTAG registers to the equipment controlling the test.
EMU0	I/O	TI legacy channel 0 trigger or boot mode select
EMU1	I/O	TI legacy channel 1 trigger or boot mode select

(1) I = Input; I/O = Input or output; O/Z = Output or three-state

Note

For information about JTAG internal pullup/pulldown resistors and electrical data and timing parameters, see the device Data Manual.

Note

The JTAG ID code for the device is .

13.2.2 Trace Port

Trace data can be exported off-chip to an external equipment through the device trace port, associated with the TPIU module. In this device, the TPIU provides support for up to data pins plus a dedicated export clock and a control signal. Table 13-2 describes the trace port signals.

Table 13-2. Trace Port Signals

Pin Name	TPIU Signal Name	I/O Type ⁽¹⁾	Description
TRC_CLK	TRACECLK	O	Trace Clock
TRC_CTL	TRACECTL	O	Trace Control

(1) O = Output

Note

Although the TPIU is internally configured for a maximum port size of 32 bits (this is reflected in the TPIU Supported Port Size Register), the actual TPIU supported port size is maximum bits. This is defined by the number of device pins available for trace.

Note

Trace port pins are shared with other functional (application) pins on the device boundary. To use the trace port, the user must program the device pin manager (CTRL_MMR) properly. Pin multiplexing is provided in section *Pin Multiplexing* in device Data Manual, and associated pad configuration registers are described in the *Control Module (CTRL_MMR)* TRM chapter.

13.2.3 Trace Connector and Board Layout Considerations

Texas Instruments supports a variety of eXtended Development System (XDS) JTAG controllers with various debug capabilities beyond only JTAG support. The following document is a good reference for guidelines: *Emulation and Trace Headers* (literature number SPRU655). More information can also be found here: [XDS Target Connection Guide](#).

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

13.3 SoC Level Debug

13.3.1 Debug Subsystem

The Debug Subsystem (DEBUGSS) is the core of the SoC debug framework. It provides support for the following key features:

- Dedicated debug datapath to memory mapped debug in processing subsystems
- Dedicated debug master on SoC top-level
- Trace merge and export via Arm CoreSight Funnel and TPIU
- Debug trigger merging/bridging
- Advanced power aware debug status and run control
 - Non-intrusive debug through power state changes
- Global run control
- Processor access to all debug features (including JTAG scan) for full "self-hosted" debug
- Application access to AP agents (APB-AP, AXI-AP, JTAG-AP)
- Support remote debug agents access to Cortex-M and scan based processors

13.3.2 Debug Cells

Another key module in the SoC debug framework is the DEBUGCELL. The following DEBUGCELL instances are supported in the device:

13.3.2.1 Debug Cell Features

13.3.2.1.1 MCU_DEBUGCELL Features

The MCU_DEBUGCELL provides the following features:

- Event analysis
 - Supports hardware event trace and profiling via CT-SET
- Trace capture and draining
 - Embedded 16KB CT-TBR
 - Can operate in either circular buffer mode or system bridge mode
 - Supports real-time draining of CT-TBR via a high-performance VBUSM interface
 - Interrupt support for acquisition complete
 - DMA event support for data available
- Trace distribution
 - Supports the following trace sources: MCU Island, SoC Aggregator AC, SoC Aggregator HC
 - Supports replication of trace to enable on-chip capture via CT-TBR and off-chip export via TPIU
- Cross triggering
 - 64 trigger inputs
 - 64 trigger outputs

13.3.2.1.2 SOC_DEBUGCELL Features

The SOC_DEBUGCELL supports the following features:

- Event analysis
 - Supports hardware event trace and profiling via CT-SET
- Trace capture and draining
 - Embedded CT-TBR
 - Can operate in either circular buffer mode or system bridge mode
 - Supports real-time draining of CT-TBR via a high-performance VBUSM interface
 - Interrupt support for acquisition complete
 - DMA event support for data available
- Trace distribution
 - Supports replication of trace to enable on-chip capture via CT-TBR and off-chip export via TPIU
- Cross triggering
 - 64 trigger inputs
 - 64 trigger outputs

13.3.2.1.3 CC_DEBUGCELL Features

The CC_DEBUGCELL supports the following features:

- Trace capture and draining
 - Embedded 64KB CT-TBR
 - Supports real-time draining of CT-TBR via a high-performance VBUSM interface
 - Interrupt support for acquisition complete
 - DMA event support for data available
- Trace distribution
 - Supports trace from Compute Cluster only
 - Supports replication of trace to enable on-chip capture via CT-TBR and off-chip export via TPIU

Note

The CC_DEBUGCELL does not provide support for event analysis and cross triggering. These features are handled inside the Compute Cluster.

13.3.3 Trace Infrastructure

13.3.3.1 Trace Data Flow

The SoC debug framework supports an architecture for moving trace data from various trace sources in the system to various trace sinks. This data path uses standard Arm CoreSight ATB components, such as trace funnels and replicators. [Figure 13-2](#) shows a high-level summary of the trace data flow.

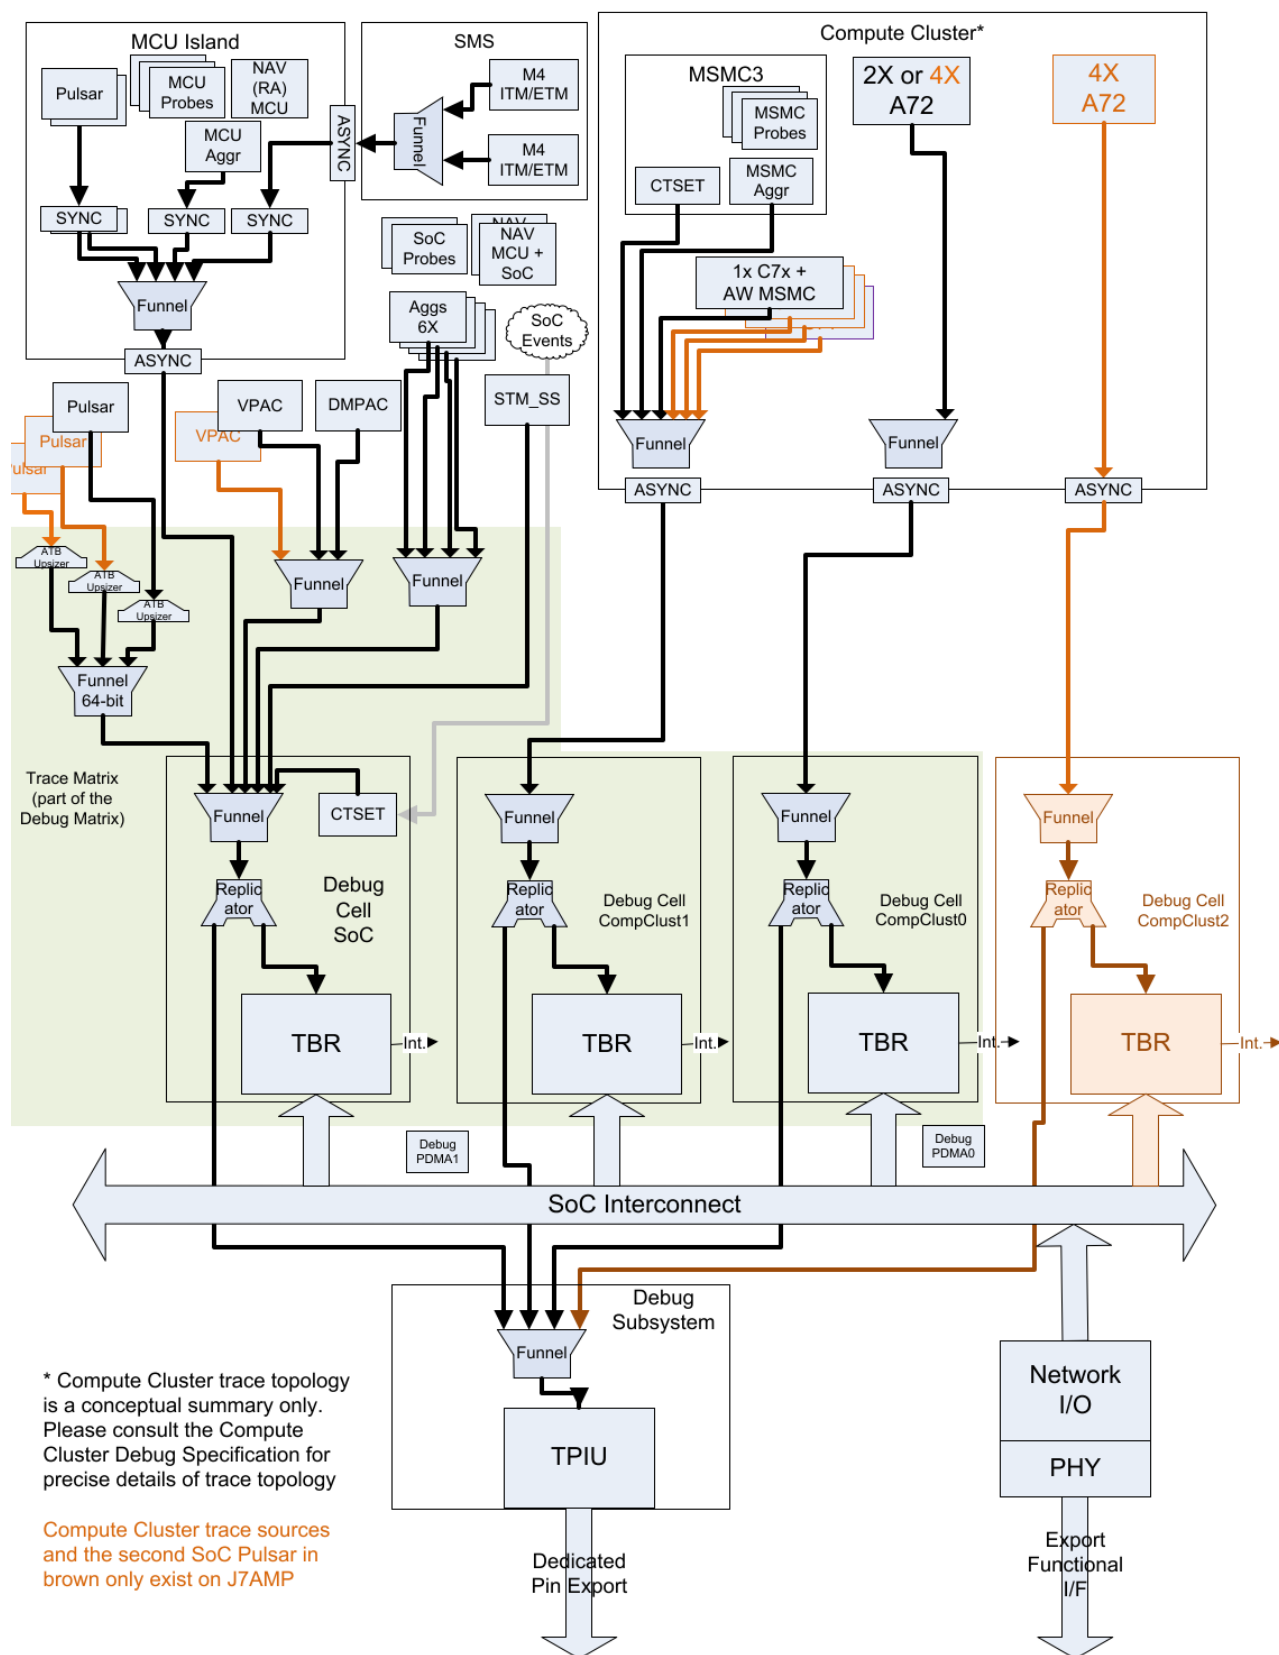

Figure 13-2. SoC Trace Data Flow

13.3.3.2 Trace Export Paths

The TPIU export path via dedicated pins requires no additional support from SoC functional layers with the exception of any pin multiplexing of application functions and trace at the pins themselves.

Export via the TBRs will intrude on the application domain. For export over all high performance functional interfaces other than USB (such as Ethernet or PCIe), the standard data available event from the TBR / DEBUGCELL can be used by system and/or packet DMA to signal that a buffer of trace data is ready to be transferred. Two dedicated PDMA modules are deployed to allow trace data to be drained from the TBRs in each DEBUGCELL and eventually exported via high speed various functional interfaces. These PDMA's have dedicated channels for streaming data from the burst capable slaves on the DEBUGCELL. This data is streamed via PSIL through the UDMA and then to any slave interface in the system. The mapping of DEBUGCELL signals to PDMA channels is defined in the *Peripheral DMA (PDMA) TRM* chapter.

13.3.3.3 ATB Slave Port Mapping

The debug cells and DEBUGSS have multiple ATB slave interfaces. The funnels used in both are non-programmable, but there is a priority scheme that gives the lowest order ports the highest priority. For this reason, port mapping has some importance for maximizing critical trace throughput and the ordering is defined below.

13.3.3.3.1 DEBUGSS ATB Mapping

13.3.3.3.2 CC_DEBUGCELL ATB Mapping

13.3.3.3.3 SOC_DEBUGCELL ATB Mapping

shows the mapping of device ATB masters to SOC_DEBUGCELL ATB port.

13.3.3.3.4 MCU_DEBUGCELL ATB Mapping

[Table 13-3](#) shows the mapping of device ATB masters to MCU_DEBUGCELL ATB port.

Table 13-3. MCU_DEBUGCELL ATB Mapping

Debug Cell ATB Port Index	ATB Master
0	Debug Cell SoC
1	Debug Cell 0 Compute Cluster
2	Debug Cell 1 Compute Cluster
3	Debug Cell 2 Compute Cluster
4-6	Reserved

13.3.4 Debug and Interconnect Visibility

The SoC debug framework provides support for monitoring transactions on the various interconnects in the system via CPTracer2 probes and probe/trace aggregators. The probes provide the following high-level functions:

- Statistical profiling of access latency at an interconnect master node
- Statistical profiling of data throughput at an interconnect node
- Transaction trace at a probed node

The trace aggregators are responsible for merging trace from multiple probes and forwarding it to local buffers in debug cells and/or to TPIU for pin export.

13.3.4.1 SoC Level Probes

Each probe supports the following features:

- Main functionality:
 - Latency statistics collection: Statistics on the timeliness of responses to slave requests are collected over a sampling window and then read by a profiling entity (for example, an application thread) or forwarded on the system trace path

- Throughput statistics collection: Statistics on the amount of data moving across a master of slave interface are collected over a sampling window and then read by a profiling entity (for example, an application thread) or forwarded on the system trace path
- Transaction trace: Information about specific transactions occurring at a slave or master interface is captured and forwarded on the system trace path
- Supports CBA 4.0 (VBUSM, VBUSM.C)
- Address range and bus qualifier filtering
- Serial configuration I/F to minimize route overhead
- Bus specific probe interface for monitoring bus transactions
- Trace export to aggregator via write-only VBUSP interface
- Uses TI High-Level Trace Message (HLTM) format
- All trace messages tagged with universal debug time
 - Probe gets only the 16 LSBs of the 48-bit gray coded universal debug time
- A CTI compliant trigger input/output interface
 - Two input triggers are used for starting and stopping the configured functionality (statistics or trace)
 - Trace capable probes also support an output trigger that is used to signal a transaction match to external logic (a data watchpoint trigger)

13.3.4.1.1 Latency Statistics Collection

Characterizing latency involves analyzing how long masters must wait for their transaction requests to complete. Collecting latency statistics at the probe interface involves counting several different conditions associated with bus transactions:

- The number of transactions that match the configured filter criteria is collected in a match counter
- The number of transactions that matched the filter criteria and were also collected in a tracked counter
- The total time the initiator waited for tracked transactions to complete is collected in a total wait counter
 - The total wait time in this counter can be divided by the number of tracked transactions in the tracked counter to obtain the average latency
- A watermark counter for individual latency is maintained in a max wait watermark
 - Each transactions latency is compared against the previous max wait value and the greater of the two values is retained
- The total time an initiator was waiting for transaction credits is also collected in a credit wait counter
 - This count is only needed for bus architectures that require the receipt of credit(s) before a transaction request can be presented
 - The credit wait time cannot be associated with any particular bus transaction since they wait occurs before the transaction is presented to the filter
 - The credit wait counter is a VBUSM.C feature only

If configured for trace export, a latency statistics trace packet is constructed and forwarded to the trace aggregator each time the statistics window expires.

13.3.4.1.2 Throughput Statistics Collection

Characterizing throughput involves analyzing the amount of data that is transferred across an interface. Collecting throughput statistics at the probe interface involves counting several different conditions associated with bus transactions:

- The total number of bytes transferred across the interface is collected in a total bytes counter
- The total number of transactions that were used to calculate the byte total is collected in a total matched counter
- Total bytes / total matched will provide the average transaction length

If configured for trace export, a throughput statistics trace packet is constructed and forwarded to the trace aggregator each time the statistics window expires.

13.3.4.1.3 Transaction Trace Capture

Transaction trace supports the capability to provide a snapshot of a bus transaction. A filter functionality is used to designate which transaction(s) should be traced. If a transaction seen on the probe interface matches the

filter criteria, all of the pertinent information pertaining to the transaction is captured and forwarded in a trace message to the trace aggregator. The following applies:

- Transaction trace support monitoring transaction commands only. The data associated with a transaction is not captured
- The data portion of the trace message contains the bus values captured when the trace event was triggered by a filter match
- A trace event can result in a trigger event (see [Section 13.3.4.1.4](#))

13.3.4.1.4 Probe Filtering

Each probe implements filter logic at the bus interfaces that allows the probe to operate on a subset of all the transactions snooped at the probe interface to the bus. Probe filtering is comprised of two functions:

- Address range filtering
 - Probes can filter a transaction by an inclusive address range that is defined by a Lower address boundary and an Upper address boundary
 - Depending on register configuration, a match will assert true if:
 - Any of the destination addresses of the transaction fall inside the designated range
 - Any of the destination addresses of the transaction fall outside the designated range
 - If the low bound is greater than or equal to the high bound the behavior of the address filter is undefined
- Transaction qualifier filtering
 - Bus qualifier filtering is done via a mask and compare scheme
 - Bus qualifiers are connected to one or more filter registers in the probe
 - Each filter register has an associated mask register
 - Filter register is configured with the required values for the filtering scenario and the mask register is used to designate bits to be excluded from the comparison
 - A bus qualifier comparison is considered true when value of the filter qualifier registers AND-ed with the filter mask registers is equal to the value of the qualifier inputs AND-ed with the filter qualifier registers
 - Bus qualification filtering is applied when a valid transaction is detected at the probe interface. For transactions with multiple data phases, bus qualifiers that might change during these multiple data phases should not be used for filtering (for example, byte enables)

Note that both address range filtering and transaction qualifier filtering must assert as true for an access to meet the filtering criteria.

13.3.4.1.5 Probe Cross Trigger Support

The probe supports two CTI compatible input trigger interfaces:

- ProbeEnable: If CTI start monitoring is enabled, all probe functionality is suppressed until the start trigger is received. Once received:
 - Statistics collection and export resumes
 - Trace messaging resumes
 - Output triggering is enabled
- ProbeDisable: If CTI stop monitoring is enabled, all probe functionality is suppressed after this trigger is received. Once received:
 - No statistics are exported
 - No trace messages are generated
 - No output triggers are generated

In the case of simultaneous triggers, ProbeDisable has priority. When trigger controls are enabled, it is possible for the probe to toggle between enabled and disabled states based upon activity seen on the trigger inputs.

The probe also supports a CTI compatible output trigger that is dedicated to transaction trace monitoring.

13.3.4.1.6 Probe Ownership

A CPTracer2 probe implements an ownership mechanism to manage whether a debugger or an application entity has exclusive control over its memory mapped resources. The identity of the requesting entity is determined by how the access was generated. A CPU-initiated access is always considered to be initiated by an

application entity. The initiating entity for the debug tools is identified via an in-band bus qualifier whose state is typically first set by the master that originated the request. Probe ownership mechanism can be accessed via a dedicated ownership control and status register.

13.3.4.2 Trace Aggregators

Each trace aggregator supports the following features:

- Collects trace data from up to 32 trace sources
- Timestamp reconstruction (using universal debug time)
- HLTMs encoded into MIPI STP 2.0 compliant stream
- ATB interface for merging aggregator trace with all other trace in the SoC
- Implements bridging that allows the aggregator configuration interface to host the configuration interfaces of all 32 connected trace sources
- Continuous read mode minimizes latency for reads of remote trace source config interfaces

13.3.4.2.1 Trace Input Bus Interface

The trace aggregator has a 32-bit input bus interface for collecting data from various trace sources. The arbitration scheme is such that trace sources behave in a cooperative manner to ensure that their data is received within the timing boundaries allocated for any HLTMs. It is required that:

- All HLTMs must be less than 32 data words
- The HLTMs must be transferred on consecutive bus clock cycles (no master stalls)

Note that the trace aggregator has no HW protection to prevent trace sources from violating these rules. If one or more trace sources attached to the aggregator violates these rules, the data from all sources may be corrupt.

13.3.4.2.2 Message Management

Trace sources forward their data to the trace aggregator as HLTMs and the arbitration layer sends one HLTMs at a time to the encoding and export layers where the message is encoded into STP format and forwarded via the SoC level ATB network. The HLTMs is comprised of a header and up to 31 x 32-bit data words.

13.3.4.2.2.1 HLTMs Format

The first 32-bit word of a HLTMs message contains the header and the remainder of the HLTMs is the function specific trace data from the source. The end of the HLTMs is defined when the source asserts the last data payload word on the VBUSP slave. The maximum number of 32-bit data payload words allowed in a HLTMs is 31.

Figure 13-3 shows the HLTMs format.

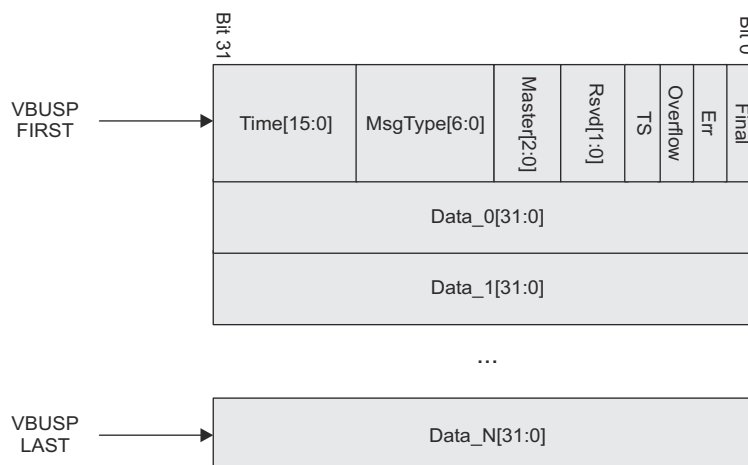

Figure 13-3. HLTMs Format

The HLTMs header is defined by the following fields:

- [31-16] Time

- Corresponds to the 16 LSBs of the global debug time, captured by the trace source when the HLTM was created
- These LSBs are combined with the current global debug time that aggregator has sampled
- If a time-stamp is requested (via TS field), the resultant 48-bit time is presented to the STP format and export logic when the last data of the HLTM is transferred
- This field is valid for any HLTM, even HLTMs with Err or Overflow
- [15-9] MsgType
 - The trace source uses this field to designate which type of HLTM is being transferred
 - The mapping is specific to the type of trace source and up to 128 different message types can be supported
 - The value in this field is presented to the STP format and export logic for every transfer cycle associated with this HLTM
 - This field is valid for any HLTM, even HLTMs with Err or Overflow asserted
- [8-6] Master
 - The trace source uses this field to designate a hierarchical master space
 - This field is only useful when the trace source sits behind a second level of trace source merge
 - The value in this field is combined with the port number in to create an 8-bit master identifier. The resultant master value is presented to the STP format and export logic for every transfer cycle associated with this HLTM
 - This field is valid for any HLTM, even HLTMs with Err or Overflow asserted.
- [5-4] Rsvd: Reserved
- [3] TS
 - The trace source sets this bit if it wants to associate a global debug time with the encoded HLTM
 - If set, a 48-bit time will be constructed (see Time field). This value is presented to the message interface on the STP format and export logic. The time-stamped data request is made when the last data of the HLTM is passed to the STP format and export logic
 - If TS is 0, then no TS reconstruction is required
 - This field is valid for any HLTM, even HLTMs with Err or Overflow asserted.
- [2] Overflow
 - The trace source sets this bit to indicate that some data loss has occurred in the source, but the error is recoverable
 - Any data associated with this HLTM is discarded and a MERR message is stimulated from the STP format and export logic
 - The trace source may send subsequent data after an HLTM with Overflow set. These will be processed normally, and the decode SW in the tooling should consider messages received after the MERR to be valid
 - Err and Overflow shall never be asserted in the same HLTM. Behavior is undefined in this scenario
- [1] Err
 - The trace source sets this bit to indicate that a fatal error has occurred in the trace source
 - Any data associated with this HLTM is discarded before forwarding to STP format and export logic and a FLAG or FLAG_TS message is stimulated from the STP format and export logic
 - The trace source may send subsequent data after an HLTM with Err set. These will be processed normally, but the decode SW in the tooling may choose to ignore them since a fatal error has been flagged
 - Err and Overflow shall never be asserted in the same HLTM. Behavior is undefined in this scenario
- [0] Final
 - The trace source sets this to indicate that this HLTM is the final data associated with an outstanding flush request
 - The STP glue logic will then assert a flush request to the message interface of the STP format and export logic when the final data word of the last pre-flush HLTM (from all sources) is transferred across this interface
 - Final is valid for any HLTM, even HLTMs with Err or Overflow asserted

13.3.4.2.2.2 Data Payload

The data payload of the HLTM are transferred to the STP format and export logic as 32-bit values. This will result in the generation of STP D32 messages for each 32-bit value in the payload.

13.3.4.2.2.3 Time Reconstruction

In order to minimize route congestion, only the 16 LSBs of the global debug time are routed to each of the probes attached to the trace aggregator. As such, the probes can only sample these 16-bit when they need to assign a time to a trace event. The full 48-bit time is reconstructed in the trace aggregator.

13.3.4.2.3 Trace Aggregator Ownership

A trace aggregator implements an ownership mechanism to manage whether a debugger or an application entity has exclusive control over its memory mapped resources. The identity of the requesting entity is determined by how the access was generated. A CPU-initiated access is always considered to be initiated by an application entity. The initiating entity for the debug tools is identified via an in-band bus qualifier whose state is typically first set by the master that originated the request. Trace aggregator ownership mechanism can be accessed via a dedicated ownership control and status register.

13.3.4.3 Trace Source Mapping to Trace Aggregator Inputs

13.3.5 Software Message Trace

Software message trace is supported by the STM subsystem (STM_SS).

13.3.5.1 STM Features

The STM_SS is a simple subsystem that is based on the Arm System Trace Macrocell v500 (STM500). It provides the following major features:

- A memory mapped interface for generating STP messages
 - Instrumented SW can post high-level messages to the STM interface
 - Messages are encoded as MIPI STP with unique IDs based on *RouteID* of the initiating master
- A debug time input interface for providing timestamp information to the STP stream
 - Universal debug time is used to tag the message
- An ATB master for exporting the STP stream to the SoC trace infrastructure
 - SOC_DEBUGCELL for on-chip capture or transfer to functional domain for export (PCIE, Ethernet, etc)
 - DEBUGSS for dedicated pin export
- CTI triggers for controlling trace flow

The Arm STM500 is a module that allows system level masters to generate STP messages via memory-mapped access to a stimulus port. The addresses used for these accesses control the following:

- Type and size of the STP data messages message generated
- Whether a debug timestamp is required
- Trace source (that is, STP master and channel)
- Behavior of the stimulus port (blocking/non-blocking)

Note

For more details on STM500 functionality, see *ARM CoreSight STM-500 System Trace Macrocell Technical Reference Manual*.

The STM_SS additionally provides the following functionality:

- Protocol bridging for the STM stimulus port (VBUSM-to-AXI on the STM)
- Address lookups to convert VBUSM *RouteID* values to extended AXI address bits for delineating STP masters on the STM AXI stimulus port
- Configuration port mapping and protocol conversion (VBUSP-to-APB for STM and CTI)
- Conversion of gray encoded global debug time to binary time
- Local trigger conversion to CS compatible trigger channels interface

13.3.5.2 STM Master ID Mapping

The stimulus port on the STM supports 64 independent master interfaces that are each 24-bits wide:

- [23:8] define the channel ID
- [7:0] define the particulars of the STP message generated

In order to minimize the address footprint of the STM and also to ease SW development, the source of the transaction request is used to select the master space. As such, the upper bits of the STM stimulus port [29:24] are derived from the bus ID of the message source.

13.3.6 Hardware Event Trace and Profiling

Hardware event trace and profiling is supported by the Counter, Timer and System Event Trace (CTSET) module.

13.3.6.1 CTSET Features

The CTSET is a trace module used for monitoring key system events and functions as a centralized profiling module for an entire subsystem. It supports the following features:

- Monitor hardware events
 - Each event is qualified by an Event-ID
- Enable/disable event detection
- Start/stop event monitoring upon external trigger
- Global/local timestamping
- Generate hardware message upon system event or every sampling window boundary
 - System messages generated are STPv2.0 based
- Generate counter configuration message (CCM) or counter state message (CSM) when configured
- Interleave hardware messages and CCM/CSM messages
- Generate interrupt/debug events
- Enable/disable counter/timer; ability to chain two 32-bit counters
- Program CTSET from debugger/application

13.3.6.2 CTSET Message Protocol

The STM export logic supports two message formats:

- A Counter Configuration Message (CCM) used to broadcast the configuration of all active counters in the system
 - The main function of the CCM is to provide the trace processing system with information about the configuration of the CTSET
- A Counter State Message (CSM) used to broadcast the current state of each active counter in the system

13.3.6.2.1 Counter Configuration Message

A CCM is constructed using the following STP message primitives:

- A header word (32-bit STP data word)
- One or two counter valid words (32-bit STP data word) that indicate which counters are active and included in the message frame
- One or more counter configuration words (32-bit STP data word) that contain the counter configuration settings for every counter designated for export
 - The final write has a timestamp to mark the end of the message frame. The final data is still D32
 - On ATB interface this message will be bounded by a global timestamp and the timestamp value, and will be based on STP 2.0

Figure 13-4 shows the CCM message format.

DM32 HDR	D32 VALID_0	D32 VALID_1	D32 CONFIG_0	...	D32 CONFIG_N-1	D32TS CONFIG_N
-------------	----------------	----------------	-----------------	-----	-------------------	-------------------

Figure 13-4. CCM Message Format

13.3.6.2.2 Counter State Message

A CSM is constructed using the following STP message primitives:

- A header word (32-bit STP data word)
- One or two counter valid words (32-bit STP data word) that indicate which counters are active and included in the message frame

- One or two counter overflow words (32-bit STP data word) that indicate which of the counters have wrapped since the last message frame
 - Overflow export is an optional feature
- One or more counter value words (32-bit STP data word) that contain the counter values for every counter designated for export
 - The final write has a timestamp to mark the end of the message frame. The final data is still D32
 - On ATB interface this message will be bounded by a global timestamp and the timestamp value, and will be based on STP 2.0

Figure 13-5 shows the CSM message format.

DM32 HDR	D32 VALID_0	D32 VALID_1	D32 OVER_0	D32 OVER_1	D32 VALUE_0	...	D32 VALUE_N-1	D32TS VALUE_N
-------------	----------------	----------------	---------------	---------------	----------------	-----	------------------	------------------

Figure 13-5. CSM Message Format

13.3.6.3 SoC Level Event Profiling and Event Trace Mapping

A set of debug signals from the MCAN modules in the MAIN and MCU domains are routed to the hardware event (HWEVENT) inputs of SOC_DEBUGCELL, allowing these signals to be profiled or traced via the CTSET in that debug cell.

13.3.7 Debug and Device Management

13.3.7.1 Power-AP Overview

The SoC debug framework implements the Power-AP module to provide:

- A method for the debug tooling to query the power, reset and/or clock status of the system and any independent subdomains within the system. This allows the tooling to understand if the current state of a system or subdomain will support an active debug connection
- A method for the debug tooling to request changes in system functionality that might override the current functional states of power/reset/clock (for example, preventing power/clock down while actively debugging a target in a dynamically powered domain)
- Capability to hold the entire device or a subsystem within the device in reset until the debug tools can attach. This provides developers a method for debugging subsystems as they transition out of reset (wait-in-reset operation)
- Control for synchronously requesting execution state changes for cores in multiple subdomains. This allows the debug tooling to synchronously halt, step and run a set of cores in a multiple core system. In addition, an interface is provided that reflects the execution state of those cores without requiring an active debug connection to that core. Using this, the debug tooling can remotely monitor and control a subdomain while it transitions through all the normal power/clock/reset functional modes

The Power-AP interfaces with various modules in the system that include:

- Chip-level power/clock/reset control logic
- Debug logic in CPU cores in the managed subdomains
- Chip-level triggering architecture

Ports on the Power-AP and DEBUGSS exist for each debug target in the system. Status and control signals from these ports are integrated with the debug target (usually an individual CPU) and the PSC/LPSC that is managing the subdomain with that CPU. These are generally logical subdomains as LPSC/PSC can manage power for multiple cores.

13.3.7.2 Subdomain Level Status and Control

13.3.7.2.1 Subdomain Power Status and Control

The Power-AP provides facilities for allowing the debug tooling to determine the power state of the associated managed subdomain. It can also override the power state of that subdomain.

13.3.7.2.1.1 Subdomain Power Status

The Power-AP supports five debug directives for subdomain power status:

- **POWER:** Indicates the current power state of the functional logic in the managed subdomain
- **DEBUGPOWER:** Indicates the current power state of the debug logic in the managed subdomain
- **POWERLOSS:** Indicates that the domain has entered a powered off state at least once since the last time the bit was cleared
- **RETENTION:** Indicates that the domain has entered a non-functional retention state at least once since the last time the bit was cleared
- **POWERDOWNDESIRED:** Indicates that debug power controls are artificially preventing the domain from entering a powered down state

13.3.7.2.1.2 Subdomain Power Control

The Power-AP supports two debug directives for subdomain power control:

- **FORCEACTIVE:** Used to request power and clocks be restored to the managed subdomain
- **INHIBITSLEEP:** Used to request that the current power/clock state of the subdomain be maintained, so a debug connection can be supported

In general, INHIBITSLEEP is more useful for debugging a system that might enter functional states that would prevent debugging. Set this directive when the subdomain is in a state where debug is possible (that is, halted with clocks and power active). When execution resumes, power transitions that might impact the debug connection will be prevented.

13.3.7.2.2 Subdomain Clock Status and Control

The Power-AP provides facilities for allowing the debug tooling to determine the clock state of the associated managed subdomain. It can also override the clock state of that subdomain.

13.3.7.2.2.1 Subdomain Clock Status

The Power-AP supports two debug directives for subdomain clock status:

- **CLOCK:** Indicates the current clock state of the functional logic in the managed subdomain
- **CLOCKDOWNDESIRED:** Indicates that debug clock controls are artificially preventing the domain from entering a clock off state

13.3.7.2.2.2 Subdomain Clock Control

The debug clock control of the managed subdomain is closely coupled to the power controls defined in [Section 13.3.7.2.1.2](#).

13.3.7.2.3 Subdomain Reset Status and Control

The Power-AP provides facilities for allowing the debug tooling to determine the reset state of the associated managed subdomain. It can also override the clock state of that subdomain.

13.3.7.2.3.1 Subdomain Reset Status

The Power-AP supports three debug directives for subdomain reset status:

- **RESETOCCURRED:** Indicates that the subdomain functional reset has been asserted at least once since the last time the status was cleared. It is used by the tools to signal the user that system state may have changed significantly because there has been a functional reset
- **INRESET:** Indicates the current reset status of the managed subdomain
- **UNATURALRESET:** Indicates that the natural reset state of the managed subdomain is being overridden by debug reset requests

13.3.7.2.3.2 Subdomain Reset Control

The debug tooling can request an override of the reset state of the managed domain via the RESETCONTROL directive. The possible overrides are defined in [Table 13-4](#). When a debug reset override request is preventing the subdomain from entering the normal (by application flow) reset state, the UNATURALRESET directive is set.

Table 13-4. RESETCONTROL Details

Value	Command	Description
000	Normal operation	Reset operates under the normal control of the application or device controls.

Table 13-4. RESETCONTROL Details (continued)

Value	Command	Description
001	Wait-in-reset (extend reset)	The module(s) controlled by this secondary TAP will remain in the reset state once the reset has been asserted. This bit alone does not reset the processor.
010	Block reset	Warm-reset to the module is blocked. At this point, only emulation reset controls will work.
011	Block & assert reset	Assert and hold the reset to the module.
100	Halt-on-reset	If halt-on-reset=1, a debug request shall be made if warm reset is asserted to the debug TAP. If halt-on-reset=0, no debug request shall be generated.
101	Cancel	Cancels reset command lockout
110	Halt-on-reset + block reset	Enable functionality of '100' and '010'
111	Halt-on-reset + block & assert reset	Enable functionality of '100' and '011'

The Power-AP module provides the capability to control local reset of processor subsystems.

13.3.7.2.3.3 Subdomain Wait-in-Reset

When the RESETCONTROL directive is requesting wait-in-reset mode, no action is taken until the subdomain enters the reset state by natural application/system flow. At this point, the reset to the domain is automatically extended until debug releases it via the RELEASEWIR directive. Note that after a debug extended reset is released, the wait-in-reset request may still be asserted, and the next functional reset seen will also be extended.

13.3.7.2.4 Subdomain Execution Control and Status

The Power-AP also provides facilities for controlling core execution and obtaining core execution state. These features enable a basic level of execution control that can be realized with a direct debug connection to a CPU core. As such, the power/clock states of the subdomain can be allowed to transition to any functional state required by the application.

13.3.7.2.4.1 Subdomain Debug Connection

The Power-AP has a DEBUGENABLE directive that is used to drive a "debug active" signal to the associated cores in the managed domain. When the tools set this directive, the debug logic in a CPU or other debugable module is automatically activated. This is particularly valuable when the subdomain is completely powered down, but there is a desire for debug capability (breakpoints) immediately after it is repowered.

13.3.7.2.4.2 Subdomain Debug Status

The Power-AP has a DEBUGATTENTION directive that is used to indicate the execution state of a CPU or other debugable module in the managed domain, without having to establish a direct debug connection to that CPU. When the associated CPU is halted by debug, this directive is asserted. Tools can read that in the Power-AP. Since halted cores generally prevent power transitions in their domains, the tools can be assured that they can safely connect to the debug logic in the CPU.

13.3.7.2.4.3 Subdomain Debug Execution Control

Many CPUs can be restarted (from a debug halt state) by asserting a signal on their module boundary. The EXECUTEACTION directive is associated to this signal. When the associated CPU is configured for this type of execution (this is a core specific function), setting this directive will cause the CPU to resume execution. Since this resume function can be accomplished without an active debug connection to the CPU, the managed domain can immediately move to its natural power state without impacting debug.

The GLOBALEXEMASK system directive can be used to mask multiple EXECUTEACTION subdomain directives. This mask can be removed with a single tools write, which will assert the "restart" signal to a set of CPUs simultaneously, thus providing pseudo-synchronous restart capabilities across multiple CPUs in multiple managed domains.

The debug tools can also request that CPU(s) in the managed domain halt immediately after reset. The RESETCONTROL directive supports modes for halt-on-reset. When in these modes, a debug halt request to the CPU(s) in the managed domain is asserted and maintained whenever a functional reset request is detected.

This results in a CPU halt as soon as the reset is released and the CPU enters a state where debug halts are excepted. This halts the CPU at the first "debugable" instruction in the boot sequence.

13.3.7.3 System Level Status and Control

In addition to subdomain status and control, the Power-AP provides system level status and debug control.

13.3.7.3.1 System Level Generic Data

The Power-AP provides two device-specific statuses:

- DEVICETYPE: Used to convey to the tools some information about the particulars of the device debug debugged
- SYSTEMSTAT: Indicates some dynamic system status

13.3.7.3.2 System Level Reset Control and Status

The Power-AP provides facilities for allowing the debug tooling to determine the reset state of the associated managed subdomain. It can also override the reset state of that subdomain.

13.3.7.3.3 System Level Connect Control

The Power-AP provides the ability to mimic a debugger connect status (for memory mapped debug agents or debug agents accessing SoC through a non-JTAG interface) through writing to the DBGCON directive with the WE directive set. A value of 0x9 must be written to achieve connected status. Any value other than 0x9 may be written to disconnect from connected status with the WE directive set.

13.3.7.3.3.1 System Level Reset Status

The Power-AP supports three debug directives for system level reset status:

- RESETOCCURED: A sticky status that indicates that the system level functional reset has been asserted at least once since the last time the status was cleared. It is used by the tools to signal the user that system state may have changed significantly because there has been a functional reset
- INRESET: Indicates the current reset status of the system
- UNATURALRESET: Indicates that the natural reset state of the system is being overridden by debug reset requests

13.3.7.3.3.2 System Level Reset Control

The Power-AP supports three debug directives for system level reset control:

- SYSTEMRESET: Used to request a system level warm reset be asserted and deasserted
- BLOCKRESET: Used to request the deassertion of a system level warm reset
- WIRREQ: Used request a system level wait-in-reset

13.3.7.3.3.3 System Level Wait-in-Reset

When the WIRREQ directive is requesting wait-in-reset mode, no action is taken until the system enters the reset state by natural application/system flow. At this point, the reset to the system is automatically extended until debug releases it via the GLOBALRELEASEWIR directive. Note that after a debug extended reset is released, the wait-in-reset request may still be asserted, and the next functional reset seen will also be extended.

13.3.7.3.4 System Level Execution Control

The Power-AP also supports global execution control. As defined in [Section 13.3.7.2.4.3](#), the GLOBALEXEMASK system directive can be utilized to synchronously send debug restart requests to multiple cores in managed subdomains. In addition, the CLEAREXEFLAGS system directive is used to globally clear all the EXECUTEACTION subdomain directives.

13.3.8 Debug Cross Trigger Network

The SoC debug framework supports a cross trigger network which provides a way to propagate debug events across the device:

- A debug module can be programmed to generate a debug event

- Another debug module can be programmed to be sensitive to that debug event and to generate an action upon trigger detection

Examples of debug events: processor entering debug state, CPTracer2 probe match, ETM trigger, etc.

Examples of debug actions: debug request generation, interrupt request generation, start/stop trace, etc.

The SoC supports two types of debug trigger integration. Debug cells are used to integrate discrete CTI compliant triggers (fully asynchronous) from modules such as CPTracer2 bus probes. These triggers are merged internal to the debug cells and are presented on consolidated trigger channel interfaces. Other modules also merge multiple discrete trigger internally and provide trigger channel interfaces on their boundaries. Figure 13-6 shows a high level view of this topology.

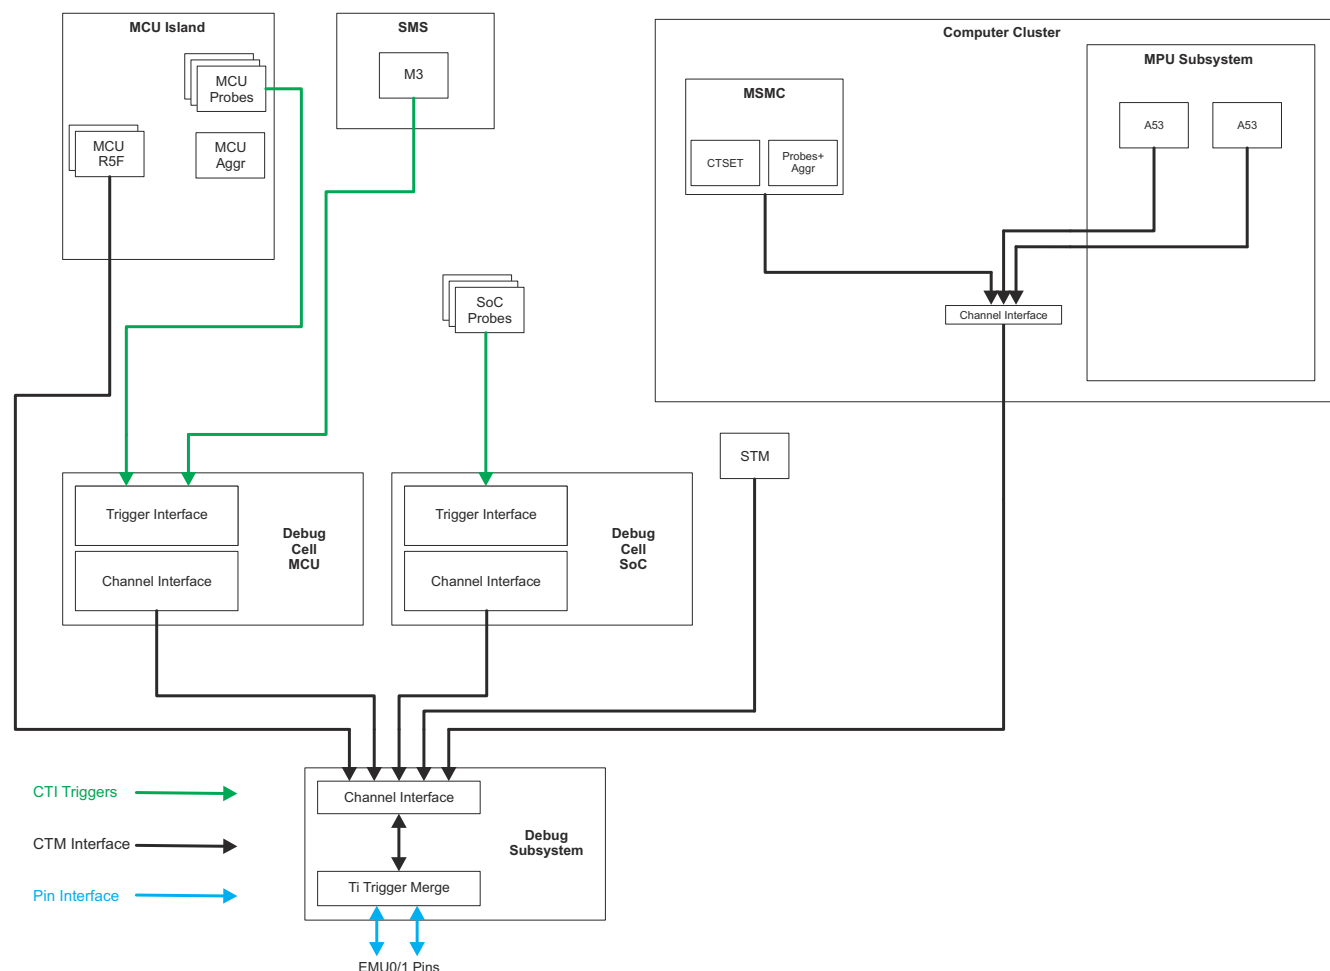

Figure 13-6. Debug Trigger Topology

13.3.8.1 Debug Cell CTI Trigger Mapping

Table 13-5 shows the mapping of MCU and SoC AC/HC level probes to the MCU_DEBUGCELL CTI ports.

Table 13-5. MCU_DEBUGCELL Trigger Mapping

13.3.9 Debug Suspend

Normal debug actions should not corrupt the correctness of the application and should keep the intrusion to the application to a minimum. This requires that all peripherals that are sensitive to debug events should be debug aware. Specifically:

- A peripheral that is sensitive to a debug event (CPU halt) should behave properly during processor suspension. This is communicated to the peripheral from the CPU through a debug suspend event
- A peripheral that is sensitive to debug access should distinguish accesses initiated from a debugger versus from an application. This is communicated from the debugging master to the peripheral as debug requests
- Errors triggered by debug access should not cause any undesired interrupt or exception to the normal execution of a processor

The SoC supports a suspend mechanism which provides a means to stop a closely-coupled hardware process running on a device peripheral when the host processor enters debug state. The suspend mechanism is important for debug to ensure that peripherals operate in a lock-step manner with a host processor. To facilitate the operation of such peripherals, each of the following processors in the SoC outputs a group of signals indicating their execution state:

Accordingly, an entry is provided for each peripheral that needs to take into account the suspend signals from these processors. Typically, one or two bits (FREE and/or SOFT) are implemented in the peripheral register dedicated to debug suspend control. The SOFT bit should be programmed based on whether or not an immediate pause of the peripheral function is required or if the peripheral suspend should occur only after a particular completion point is reached in the normal peripheral operation. The FREE bit should be programmed to enable or disable the debug suspend functionality.

The SoC debug framework provides a configurable debug suspend to peripheral mapping that allows shared peripherals to be configured to honor the halt signal from any debug target in the system. This is accomplished via a debug suspend router (DBG_SUSP_RTR) which represents an array of muxes and a set of associated control registers. CPU suspend outputs are mapped to DBG_SUSP_RTR inputs and peripheral suspend inputs are mapped to DBG_SUSP_RTR outputs.

summarize the suspend sources (device CPUs) and suspend sinks (device peripherals) mapping, respectively.

13.3.10 Debug Time Distribution

The SoC debug framework supports a universal debug time distribution architecture that provides a common time value bus to the following trace sources in the SoC:

- DEBUGSS
- Compute Cluster
- Debug cells

- STM subsystem
- Probe aggregators and their associated probes
- DMPAC
- VPAC

The following trace sources are *not* aligned to the universal debug time:

- All R5F (uses an older Arm trace technology)

Timestamping in trace streams allows accurate correlation of traces from across the SoC. The source for debug timestamp is the Global Timebase Counter (GTC) module which outputs a 48-bit graycode value. It is then converted to binary locally in each trace module.

Note

All CPTracer2 bus probes receive only the 16 LSBs of the distributed time value. The full time is reconstructed in the parent aggregator.

For more details on the GTC, see the *Global Timebase Counter* TRM chapter.

13.3.11 Debug Wakeup

In this SoC, the DEBUGSS resides in the VD_CORE voltage domain and is powered down in many power modes. In order to be able to reliably connect the debug tooling (via JTAG port), there is a requirement to support debug connection only when VD_WAKE is powered on. To accomplish this, an ICEMelter module is instantiated in VD_WAKE, and the EMU0/1, TCK and nTRST JTAG signals are mapped to I/O pins in VD_WAKE. The ICEMelter monitors these I/O signals and upon detecting an active debug connection, it signals the to force a wakeup of VD_CORE and associated DEBUGSS power domain (PD_DEBUG). DEBUGSS and associated logic remain powered, clocked and out of reset for as long as ICEMelter is detecting an active debug connection.

In addition, the boot modes selected by EMU0/1 at device POR are detected and held until the DEBUGSS is powered. These modes can be used to put the device in wait-in-reset (WIR) mode, where all subdomains other than the are held in reset awaiting a debug connection. The supports an operating sequence that detects WIR assertion during the boot process. For a GP device, the ROM spins near the beginning of the boot sequence, allowing the debug tools to connect before the majority of the ROM code executes. Once connected, the debug tool can be used to move the PC past the spin and the ROM code can be executed under debug control.

As referenced above, the ICEMelter module interacts with and DEBUGSS and can manage debug behavior of the device right from POR by sampling the EMU0/1 pin interface. The details are defined in [Table 13-6](#).

Table 13-6. Debug Boot Modes

Boot Mode	EMU1	EMU0	Actions
Normal	1	1	Device boots nomally. Debug can connect at any time, but the context will be post boot.
Wait-in-Reset (WIR)	1	0	<ol style="list-style-type: none"> 1. ICEMelter asserts WIR active signal to and DEBUGSS. 2. samples the WIR active input at boot to determine behavior for boot. 3. DEBUGSS asserts WIR request for all subdomains managed via Power-AP. 4. Device remains essentially quiescent until debug can connect and release WIR for debug of boot sequences.
Reserved	0	1	Behavior is undefined.
Reserved	0	0	Behavior is undefined.

13.3.12 Debug and Safety

Functional safety is an important aspect of the device. In general, the intrusive nature of debug operations is in conflict with many of the requirements associated with the safety function (for example: error detection, graceful recovery to known states, etc). As such, the SoC debug framework relies on the assumption that debug logic

will be disabled during operation of a safety function. See system assumption SA_23 in device Safety Manual for reference.

The SoC debug modules will not be powered by default in fielded systems. The isolation signals on the boundaries of these components will be configured such that debug intrusion on system functionality is not possible. These modules will be powered during an active debug connection, but at this point, safety requirements are secondary as the user has consciously decided to interact with the system. Even then, it is possible for the device security manager to provide an operating mode that only supports non-invasive debug.

Application threads can also obtain control of the DEBUGSS and the debug components in the system but functional firewalls should only allow this from trusted/secure threads.

13.4 Compute Cluster Debug

13.4.1 Debug at the Compute Cluster Level

The debug capabilities that are deployed within the Compute Cluster are mostly deployed at lower levels of hierarchy, that is within the processor subsystems and the MSMC. Some of these features require special handling at the Compute Cluster level. This includes:

- Debug ROM table
 - Facilitates tooling software's identification of debug resources embedded within the Compute Cluster and underlying processor subsystems
- Debug configuration
 - Supported via CBA VBUSP interface
 - Provides a dedicated configuration path for debug components within the Compute Cluster
 - Remote and embedded debuggers, debug libraries, and application code use this interface to configure and use debug features embedded at different levels of hierarchy within the Compute Cluster
 - Compute Cluster address map is 64MB
- Cross triggering
 - Supported via Arm Coresight Channel Interface (CI)
 - Provides support for management of triggering resources within the Compute Cluster and across the SoC
 - Arm CoreSight Cross Trigger Matrix (CTM) supports the management of multiple CoreSight Channel Interface (CI) interfaces
- Trace data path
 - Supported via AMBA ATB v1.1 interface
 - Provides support for merging of one or more trace streams into a common trace data path through the use of a CoreSight ATB Trace Funnel
 - ATB interface includes some key trace specific functions including in-band flushing and synchronization requests
- Debug time distribution
 - Supported via Arm Coresight Wide Timestamp Interface (WTI)
 - Facilitates the distribution of the 48-bit global debug time to the various trace sources that exist inside the Compute Cluster hierarchy

13.4.2 Debug at the A72SS Level

13.4.2.1 A72SS Debug Features

The A72 processor supports the following native features:

- Halt mode and monitor mode debug
- Six hardware breakpoints and four watchpoints
- Asynchronous aborts
- Processor trace
- Performance monitoring
- Cross triggering

13.4.2.2 A72SS Debug Modes

The A72 CPU supports invasive and non-invasive debug modes. The invasive debug mode is intended primarily for run-control debugging. Invasive debug mode provides support for:

- Monitor mode: In monitor mode, a debug event causes a debug exception to occur. A debug exception that relates to instruction execution generates a prefetch abort exception. A debug exception that relates to a data access generates a data abort exception. A software handler can then take control to examine or alter the processor state. Monitor debug mode is essential in real-time systems where the processor cannot be halted to collect debug information.
- Halt mode: In halt mode, a debug event causes the processor to enter debug state. In debug state, the processor stops executing instructions from the location indicated by the program counter, but is instead controlled through the external debug interface, in particular using the Instruction Transfer Register (DBGITR)

Non-invasive debug includes all debug features that permit data and program flow to be observed, but that do not permit modification of the main processor state. Non-invasive debug mode support includes processor instruction trace, sample-based profiling, and performance monitoring.

13.4.2.3 A72SS Processor Trace

The A72 cluster integrates a CoreSight Embedded Trace Macrocell (ETM), which performs real-time instruction/data flow tracing based on the ETMv4 architecture. It generates information that can be used by trace receiver to reconstruct the execution of all or part of a program.

The A72 processor trace has the following characteristics:

- Program and data trace
- Two exclusive trace sinks:
 - TPIU: Trace exported to an external trace receiver
 - CC_DEBUGCELL: Trace stored to embedded TBR for draining through high-speed serial interfaces
 - CC0_DEBUGCELL supports A72SS0
 - CC2_DEBUGCELL supports A72SS1
- Trace can be optionally cycle accurate (useful for profiling sections of code)
- Timestamped via global debug time

13.4.2.4 A72SS Performance Monitoring

The A72 processor includes a Performance Monitoring Unit (PMU) that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU gathers statistics about the operation of the processor and memory system.

The A72 PMU events are listed in the *ARM Cortex-A72 MPCore Processor Technical Reference Manual*.

13.4.2.5 A72SS Cross Triggering

The A72 cluster provides cross triggering support by implementing CoreSight Cross Trigger Interface (CTI) and Cross Trigger Matrix (CTM) modules.

[Table 13-7](#) and [Table 13-8](#) show the A72 CTI mapping. Note that it is the same for all A72 cores in the Compute Cluster.

Table 13-7. A72 CTI - CTITRIGIN Assignment

CTITRIGIN	Function	Description
0	DBGTRIGGER	Pulsed on entry to debug state
1	PMUIRQ	PMU generated interrupt
2	Reserved	Reserved
3	Reserved	Reserved
4	EXTOUT[0]	ETM external output 0
5	EXTOUT[1]	ETM external output 1
6	EXTOUT[2]	ETM external output 2
7	EXTOUT[3]	ETM external output 3

Table 13-8. A72 CTI - CTITRIGOUT Assignment

CTITRIGIN	Function	Description
0	EDBGRQ	Causes the processor to enter debug state
1	PMUIRQ	Causes the processor to exit debug state
2	CTIIRQ	CTI Interrupt
3	Reserved	Reserved
4	EXTIN[0]	ETM external input 0
5	EXTIN[[1]	ETM external input 1
6	EXTIN[[2]	ETM external input 2
7	EXTIN[[3]	ETM external input 3

13.4.3 Debug at the C71SS Level

The C71 debug architecture provides three basic visibility and control mechanisms:

- Core debug controller
 - Defines a means of supporting fundamental debug requirements such as:
 - System visibility: access to application visible resources, and certain private resources
 - Debug events: breakpoints, triggers, and other requests to halt
 - Run control: run, single-step, halt
 - Cross-triggering: input and output triggers that can be used to alter or convey execution state
 - Provides support for the core debug modes:
 - Halt/Stop mode
 - Real-time mode
 - Monitor/Embedded mode
- Trace subsystem
 - Collects and exports trace data over an ATB bus interface without intrusiveness to the behavior of application code running on the CPU (real-time trace)
 - Real-time trace allows the observation of:
 - Program flow (with or without the associated stall cycles)
 - Global timestamp associated with occurrence of trace events that can be correlated across multiple cores
 - Memory reference info: any combination of PC of the instruction packet generating memory reference, the memory reference address, the memory reference size (8, 16, 32, 64, 128, 256, 512) and type (R/W), the memory reference read or write data value (up to 64-bits only)
 - Auxiliary events
 - Streaming buffer parameters
 - Trace can be stored on-chip or exported off-chip (supported by a dedicated debug cell)
- Triggering (AET): Facilitates the debugging of complex issues by enabling features such as:
 - Context sensitive breakpoints (thread aware)
 - Data watchpoints
 - Chained breakpoints
 - Profiling counters with watermark support
 - Visibility into events generated from within the CPU, across the C71SS, and external to the C71SS
 - Trace stream filtering

13.4.4 Debug at the MSMC Level

The MSMC supports high-bandwidth resource access between the Compute Cluster CPU subsystems and the rest of the SoC. As the primary resource in the SoC that manages processor traffic, MSMC is an ideal location to characterize the traffic flowing to/from the Compute Cluster CPU subsystems and the rest of the SoC. In addition to understanding traffic patterns, a developer would be interested in learning about how those patterns might be influenced by other events and activities going on. To support the debug needs of MSMC, event trace (CTSET) and bus probe (CPTracer2) components are used.

13.4.4.1 MSMC Probes

MSMC includes two instances of CPTracer2. MSMC supports probing the following:

- Coherent slave interfaces: The full duplex implementation (initiator and target-side) requires two bus probes
- Two internal DRU interfaces: One initiator (write) bus probe, one target (read) bus probe
- Two external memory initiator interfaces: Requires two bus probes (one bus probe each interface)

13.4.4.2 MSMC CTSET Events

MSMC core logic exports CTSET events for various debugging and profiling activities. The MSMC CTSET event map includes:

VBUSM.C supports DVM across the Compute Cluster to help synchronize virtualization hardware features such as translation lookaside buffers (TLB and uTLB).

13.4.4.3 MSMC Cross Triggering

13.5 R5FSS Debug

13.5.1 R5FSS Debug Features

The R5F processor supports the following native features:

- Halt mode and monitor mode debug
- Eight hardware breakpoints and six watchpoints
- Asynchronous aborts
- Processor trace
- Performance monitoring
- Cross triggering

13.5.2 R5FSS Processor Trace

The R5FSS integrates a CoreSight Embedded Trace Macrocell (ETM-R5), which provides real-time instruction trace and data trace for the Cortex-R5F microprocessor. The ETM-R5 macrocell generates information that trace software tools use to reconstruct the execution of all or part of a program.

For full reconstruction of program execution, the ETM-R5 macrocell is able to trace:

- All instructions, including condition code pass/fail and dual issue information
- Load/store address and data values
- Data values used in coprocessor register transfers
- Values of context-ID changes
- Target addresses of taken direct and indirect branch operations
- Exceptions
- Changes in processor instruction set state
- Entry to and return from debug state when halt debug mode is enabled
- Cycle counts between executed instructions

The ETM-R5 macrocell contains logic that enables the user to control tracing by specifying the exact set of triggering and filtering conditions required for a particular application.

Note

The R5FSS processor trace does not support the universal debug time.

13.5.3 R5FSS Performance Monitoring

The R5F processor includes a Performance Monitoring Unit (PMU) that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU gathers statistics about the operation of the processor and memory system.

The R5F PMU events are listed in the *ARM Cortex-R5F Technical Reference Manual*.

13.5.4 R5FSS Cross Triggering

The R5FSS cluster provides cross triggering support by implementing CoreSight CTI and CTM modules. These cross triggering modules provide support for useful cases, such as cross triggering between ETM and TBR in MCU_DEBUGCELL:

- ETM can generate a trigger that can be used to stop TBR data capture
- TBR can send *buffer full* or *acquisition complete* events to the ETM

13.6 Debug Memory Map

The on-chip debug resources can be accessed through a JTAG accessible DAP or through the system address space. The DAPBUS AP space is mapped as described in [Section 13.6.1](#). The System address mapping of debug components can be found in the TRM Memory Map chapter.

13.6.1 Debug and Boundary Scan Access and Control

On-Chip debug resources are made available through three mechanisms:

- JTAG access via DAP and related APs
- JTAG access via Boundary Scan TAP
- Embedded access to debug resources via SoC address space

DAP

Off-chip debug tools are able to access On-Chip debug resources via the JTAG interface when not in Boundary Scan mode (see below). A CoreSight™ Compliant DAP architecture provides access via a DP and a collection of APs:

- SWJ-DP: Arm® CoreSight™ compliant SWJ Debug Port provides support for a JTAG interface with a 4-bit IR

Note

Even though an SWJ-DP is implemented on-chip, only JTAG is supported. This device does not support SWD.

- APB-AP: Arm® CoreSight™ APB Access Port provides access to the Debug-APB address space which is the primary configuration space for On-Chip Debug resources.
- AXI-AP: Arm® CoreSight™ AXI Access Port provides access to the SoC address space, allowing visibility and control over system resources.
- Config-AP: TI Configuration AP supports access to SoC debug management registers
- Power-AP: TI Configuration AP supports advanced power, reset, and clock management. (See *Power, Reset, Clock Management*)

[Table 13-25](#) describes the APSEL assignment for this device.

Table 13-25. DAP APSEL Assignment

APSEL	AP	Description
0	Config-AP	TI AP - Reserved
1	APB-AP	Provides access to Debug Config Plane
2	AXI-AP	Provides access to SoC Address Space
3	Power-AP	TI AP - Extended Power/Reset/Clock Control
4-5	Reserved	Reserved for future use
6	SEC-AP	TI AP - Authentication Interface
10-31	Reserved	Reserved for future use

Boundary Scan

This device supports boundary scan using an IEEE 1149.1 compliant JTAG TAP that is made visible through the use of a compliance-enable mode (see *Debug Boot Modes and Boundary Scan Compliance*). IEEE 1149.1 and 1149.6 Boundary Scan support are defined in device-specific BSDL files that can be found in the respective device's product folder on ti.com.

SoC Address Space

The device architecture provides access to On-Chip debug resources through the SoC Address Space. This includes access to all DAP Access Ports (APs) as well as the Debug-APB address space.

13.7 Application Support

TI includes a set of system level debug facilities in the Debug Subsystem of devices known as Chip Tools (CTools). For easy integration of processor trace and system trace into applications, a set of libraries commonly referred to as CToolsLib are provided. CToolsLib is a collection of embedded target APIs/libraries focused on enabling easy access to the CTools. For more information about these libraries, downloadable files, and other useful links, please visit the CToolsLib Wiki site:

<http://processors.wiki.ti.com/index.php/CToolsLib>

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

• Updated PI Functional Description section.....	794
• Removed RAT Availability section.....	800
• Updated Interrupt Architecture section.....	801
• Updated INTRTR Overview section.....	813
• Moved Interrupt tables to Appendix spreadsheet.....	813
• Updated DMA Hardware/Software Interface section.....	823
• Updated Descriptors section.....	823
• Added Note.....	825
• Added Note.....	829
• Added Note.....	831
• Updated Transfer Request Descriptor section.....	834
• Updated Overview section.....	837
• Updated Transfer Request Formats section.....	839
• Updated FLAGS Field Descriptions table.....	840
• Updated Transfer Request Minimum Size Type 15 Four Dimensional Block Copy with Repacking and Indirection Support table.....	842
• Updated Configuration Specific Flags table.....	844
• Updated ADDR Field Format table.....	845
• Updated DADDR Field Format table.....	846
• Updated Transfer Response Record section.....	855
• Added Note.....	855
• Updated Submission Error STATUS_INFO Encodings table.....	856
• Updated Transfer Exception STATUS_INFO Encodings table.....	857
• Added Channels section.....	857
• Added BCDMA Queues section.....	859
• Added BCDMA - Ring Operation section.....	879
• Added BCDMA - Output Event Generation section.....	880
• Added BCDMA - Split Transmit Channel Setup section.....	881
• Added BCDMA - Split Transmit Operation Pause section.....	882
• Added BCDMA - Split Transmit Channel Teardown section.....	882
• Added BCDMA - Split Transmit Error / Exception Handling section.....	883
• Added BCDMA - Split Receive Channel Setup section.....	884
• Added BCDMA - Split Receive Channel Pause section.....	884
• Added BCDMA - Split Receive Channel Teardown section.....	884
• Added BCDMA - Split Receive Operation (TR Packet) section.....	885
• Added BCDMA - Split Receive Error / Exception Handling section.....	886
• Updated NAVSS Interrupt Configuration section.....	892
• Updated NAVSS Interrupts Description section.....	892
• Updated Application Example section.....	893
• Added UDMA Overview diagram.....	898
• Updated Tx Channel Allocation section.....	905
• Updated Rx Channel Allocation section.....	906
• Updated Inbound Event Map table.....	907
• Added RINGACC Not Supported Features section.....	913
• Updated RINGACC Configuration Parameters table.....	913
• Updated Proxy Configuration Parameters table.....	922
• Added Proxy Not Supported Features section.....	923
• Updated Secure Proxy Configuration Parameters table.....	926
• Added Secure Proxy Not Supported Features section.....	926

• Updated Interrupt Aggregators Parameters table.....	931
• Added PSIL Subsystem (PSILSS) section.....	940
• Replaced "UDMA" with "DMA".....	950
• Added PDMA Registers section.....	971
• Clarify configuration of GPIO interrupt generation.....	1062
• [UART Interrupts] added additional register bit information for 001100 row in UART Mode Interrupts table.....	1147
• [Wake-Up Interrupt] modified topic to include conditions for wake-up interrupt.....	1148
• [Transmit FIFO Trigger] changed register naming to align with RA. Updated note to correct register bits...	1150
• [Receive FIFO Trigger] changed register naming to align with RA. Updated note to correct register bits....	1151
• [FIFO DMA Mode Operation] Updated register naming to match RA.....	1153
• [Multi-drop Parity Mode with Address Match] added line at end of topic detailing supported and unsupported modes.....	1175
• [Time-guard] added details related to other modes.....	1176
• Updated PCIe Subsystem I/O Signals table.....	1382
• Updated USB3SS0 Input/Output Description table and removed USB3SS1 Input/Output Description table.....	1415
• Changed OTFA references to OTFE.....	1432
• Added FSS Memory Regions table.....	1433
• Removed GPMC Memory Regions section.....	1471
• Added eMMC PHY BIST section.....	1573
• Updated DSS Environment section.....	1876
• Added DISPC Environment section.....	1877
• Added DSI Environment section.....	1878
• Added EDP Environment section.....	1878
• Updated DCC Functional Description section.....	2143
• Updated ESM Configuration Error Interrupt section.....	2150
• Updated ESM Low Priority Error Level Event section.....	2152
• Updated ESM Low Priority Error Pulse Event section.....	2152
• Updated ESM High Priority Error Level Event section.....	2153
• [PSA Signature Register] added CRC polynomial equations for all supported CRC polynomials.....	2162
• Added Logical Built-In Self-Test (LBIST) chapter.....	2173
• Added Programmable Built-In Self Test (PBIST) section.....	2176
• Moved ECC Aggregators Interconnect tables to Appendix spreadsheet.....	2185
• Added ECC Error Injection Sequence section.....	2187
• Added ECC Aggregator Registers section.....	2192
• Updated Debug Memory Map section.....	2241
